The table below describes the significant fields shown in the display.

Table 93: show diag subslot Field Descriptions for Cisco 3845 Series Routers

Field	Description
Hardware Revision	Revision number (signifying a minor revision) of the SPA hardware.
Top Assy. Part Number	Part number of the SPA.
Product Identifier (PID)	Product number of the SPA.
Board Revision	Revision number of the circuit board in the module.
Deviation Number	Deviation number of the module.
Fab Version	Fabrication version of the module.

Field	Description
PCB Serial Number	Serial number of the printed circuit board.
Top Assy. Revision	Revision number (signifying a minor revision) of the SPA.
RMA Test History	History of RMA testing.
RMA Number	RMA number of the module.
RMA History	History of RMA on this module.
Version Identifier	Nonapplicable to this module.
CLEI Code	Common Language Equipment Identification number. (nonapplicable on this module)
Product (FRU) Number	Product identification number.
EEPROM Format Version	Version of EEPROM format.
EEPROM Contents	Contents of EEPROM output.

Cisco uBR10012 and uBR7200 Series Broadband Routers

The following is a sample output from the **show diag** command displaying diagnostic information for the cable clock card:

```
router# show diag

Clockcard:
 National clock card with T1 controller
 EEPROM contents at hardware discovery:
 Hardware Revision        :1.1
 Part Number              :800-05867-02
 Board Revision           :11
 Deviation Number         :0-0
 Fab Version              :02
 PCB Serial Number        :CAB04046NXV
 RMA Test History         :00
 RMA Number               :0-0-0-0
 RMA History              :00
 EEPROM format version 4
 EEPROM contents (hex):
   0x00:04 FF 40 01 AC 41 01 01 C0 46 03 20 00 16 EB 02
   0x10:42 31 31 80 00 00 00 00 02 02 C1 8B 43 41 42 30
   0x20:34 30 34 36 4E 58 56 03 00 81 00 00 00 00 04 00
```

The table below describes the fields displayed by the **show diag** command.

Table 94: show diag Field Descriptions for Cisco uBR10012 and uBR7200 Series Routers

Field	Description
National clock card with T1 controller	The system has identified the cable clock card.

Field	Description
EEPROM contents at hardware discovery	EEPROM programmed data present when the system identified the clock card.
Hardware Revision	Version number of the card.
Part Number	Part number of the card.
Board Revision	Revision number (signifying a minor revision) of the card.
Deviation Number	Revision number (signifying a minor deviation) of the card.
Fab Version	Manufacturing fabrication version number.
PCB Serial Number	Serial number of the printed circuit board.
RMA Test History	Counter indicating how many times diagnostics have been performed on this card.
RMA Number	Return material authorization number, which is an administrative number assigned if the card needs to be returned for repair.
RMA History	Counter indicating how many times the card has been returned and repaired.
EEPROM format version	Version number of the EEPROM format.
EEPROM contents (hex)	Dumps of EEPROM programmed data.

The following is a sample output from the **show diag** command displaying revision-level information for the cable line card (slot 6):

```
Router# show diag

Slot 6:
        MC11 port adapter, 1 port

```

The table below describes the fields displayed by the **show diag** command for the cable line card (slot 6).

Table 95: show diag Field Descriptions for Cable Line Card

Field	Description
MC11 port adapter	Line card type.
Port adapter is analyzed	The system has identified the Cisco CMTS port adapter.
Port adapter insertion time	Elapsed time since insertion.
Hardware Revision	Version number of the Cisco CMTS port adapter.
Part Number	In the Cisco CMTS, the part number of the port adapter.
Board Revision	Revision number (signifying a minor revision) of the Cisco CMTS port adapter.
Deviation Number	Revision number (signifying a minor deviation) of the Cisco CMTS port adapter.
Fab Version	Manufacturing fabrication version number.
PCB Serial Number	Serial number of the printed circuit board.
RMA Test History	Counter indicating how many times diagnostics have been performed on this port adapter.
RMA Number	Return material authorization number, which is an administrative number assigned if port adapter needs to be returned for repair.
RMA History	Counter indicating how many times the port adapter has been returned and repaired.
Calibration Data	Input power calibration range.
Calibration values	Upstream port gain calibration constant.
Unknown Field (type)	Unrecognized EEPROM fields.
EEPROM format version	Version number of the EEPROM format.
EEPROM contents (hex)	Dumps of EEPROM programmed data.

Tip In Cisco IOS Release 12.1(12)EC, Release 12.2(8)BC1, and later releases, you can add a timestamp to **show** commands using the **exec prompt timestamp** command in line configuration mode.

The following is a sample output displaying information on the Cisco Ethernet SPA:

The table below describes the significant fields shown in the display.

Table 96: show diag Field Descriptions for Cable Line Card

Field	Description
Hardware Revision	Version number of the card.
Top Assy. Part Number	Part number of the port adapter.
Board Revision	Revision number (signifying a minor revision) of the Cisco CMTS port adapter.
CLEI Code	Common language equipment identifier codes that are used by Telcordia licenses to uniquely identify the telecommunication equipment in their network.
Deviation Number	Revision number (signifying a minor deviation) of the Cisco CMTS port adapter.
Fab Version	Manufacturing fabrication version number.
PCB Serial Number	Serial number of the printed circuit board.
RMA Test History	Counter indicating how many times diagnostics have been performed on this port adapter.
RMA Number	Return material authorization number, which is an administrative number assigned if port adapter needs to be returned for repair.

Field	Description
RMA History	Counter indicating how many times the port adapter has been returned and repaired.

Cisco uBR7225VXR and Cisco uBR7246VXR Universal Broadband Routers: Example

The following is a sample output from the **show diag** command for a Cisco uBR-MC88V cable interface line card, on a Cisco uBR7246VXR universal broadband router. The output shows that the diagnostic mode on the line card is enabled.

Router# show diag5

```

The table below describes significant fields shown in the display.

Table 97: show diag Field Descriptions for Cisco uBR7225VXR and Cisco uBR7246VXR Series Routers

Field	Description
Controller Type	Line card type.
PCB Serial Number	Serial number of the printed circuit board.
Hardware Revision	Version number of the port adapter.
Top Assy. Part Number	Part number of the port adapter.
Top Assy. Revision	Revision number (signifying a minor revision) of the port adapter.
Product Identifier (PID)	Cisco product ID.
Version Identifier (VID)	Used to track the version of the customer orderable PID.
CLEI Code	Common language equipment identifier codes that are used by Telcordia licenses to uniquely identify the telecommunication equipment in their network.
Deviation Number	Revision number (signifying a minor deviation) of the port adapter.
Fab Version	Version number (signifying a major version) of the port adapter.
RMA Test History	Counter indicating the number of times the port adapter has been returned and repaired.
RMA Number	Return material authorization number. An administrative number assigned when the port adapter is returned for repair.
RMA History	Counter indicating the number of times the port adapter has been returned and repaired.
Licensing Transaction ID	License transaction identifier.
EEPROM contents (hex)	Dumps of EEPROM programmed data.
License	License type.
Calibration Data	Calibration data of upstream VGA chips.
Number of US points	Number of physical upstream channels supported by the port adapter.
Number of freqs	Number of upstream frequencies used in the upstream calibration process (5, 30, and 65 MHz).

The table below describes significant fields shown in the display.

Table 98: show diag Field Descriptions for Cisco ASR 1000 Series Routers

Field	Description
Asset ID	Power or fan module identifier.
CLEI Code	Common language equipment identifier codes that are used by licensees to uniquely identify the telecommunication equipment in their network.
Hardware Revision	Version number of the port adapter.
PCB Serial Number	Serial number of the printed circuit board.
Product Identifier (PID)	Cisco product ID.
Top Assy. Part Number	Part number of the port adapter.
Top Assy. Revision	Revision number (signifying a minor revision) of the port adapter.
Version Identifier (VID)	Used to track the version of the customer orderable PID.

Related Commands

Command	Description
dsl operating-mode (ADSL)	Modifies the operating mode of the digital subscriber line for an ATM interface.
show c7300	Displays the types of hardware (processors, line cards, jacket cards, and so on) installed in the Cisco 7304 router slots, including the bundled Flash, and current FPGA versions.
show c7300 errorlog	Displays error information on a Cisco 7304 router.
show dsl interface atm	Shows all ADSL-specific information for a specified ATM interface.
showcontrollers fastethernet	Displays Fast Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show controllers integrated-service-engine	Displays controller information for integrated-service-engine network modules.
showinterfaces integrated-service-engine	Displays basic interface configuration information for integrated-service-engine network modules.

show diagnostic bootup level

To display the coverage level for the configured bootup diagnostics, use the **showdiagnosticbootuplevel**command in user EXEC or privileged EXEC mode.

show diagnostic bootup level

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command displays the bootup diagnostic level configured on the switch. The bootup diagnostic level determines which diagnostic tests will be performed when the device boots. The following bootup diagnostic levels can be displayed in the output of this command:

Level	Explanation
Bypass	The device performs no bootup diagnostic tests.
Complete	The device performs all diagnostic tests marked with attribute M (Minimal) or C (Complete) in the output of the **showdiagnosticcontentmodule** command.
Minimal	The device performs all diagnostic tests marked with attribute M (Minimal) in the output of the **showdiagnosticcontentmodule** command.

Examples

This example shows how to display the configured bootup diagnostic level:

```
Router# show diagnostic bootup level
Current Bootup Diagnostic Level = Complete
```

Related Commands

Command	Description
diagnostic bootup level	Sets the bootup diagnostic level.
show diagnostic content module	Displays the available diagnostic tests.

show diagnostic content module

To display information about available tests, including test ID, test attributes, and supported coverage test levels for each test and for all modules, use the **showdiagnosticcontentmodule**command in user EXEC or privileged EXEC mode.

show diagnostic content module {**all***listslot* | *slot/subslot*}

Syntax Description

all	Displays information about available tests for all modules.
list	List of modules in the following format: • Entries are separated by a comma, for example, 1,4,6-10. • Ranges are specified with a hyphen, for example, 1-4,6-10.
slot	Single module by slot number.
slot / *subslot*	Single submodule by slot number and subslot or bay within the module.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI4	This command was integrated into Cisco IOS Release 12.2(33)SXI4. A health-monitoring (HM) test, TestAclFpgaMonitor, was introduced for ABA cards.

Usage Guidelines

For each available diagnostic test, a set of attributes is displayed as a series of characters in the Attributes field of the command output. An asterisk (*) in the character location indicates that the attribute is not applicable to the test. The following set of attributes is displayed:

Character	Attribute	Description
1	M	The test runs when the bootup diagnostic level is set to either Minimal or Complete.
	C	The test runs when the bootup diagnostic level is set to Complete.
2	B	The test runs when the **diagnosticstart***platform***testbasic** command is entered.
3	P	The test runs on a port, not the entire device (per-port test).
	V	The test runs on the entire device (per-device test).

Character	Attribute	Description
4	D	The test disrupts the network traffic (disruptive test).
	N	The test can be run when the system is online without disrupting the network traffic (nondisruptive test).
5	S	If the card under test is a standby card, only the standby card runs the test. The test does not run from the active card. If the card under test is an active card, the active card runs the test on itself.
6	X	The test is not an HM test.
7	F	The monitoring interval of the test cannot be modified by the user (fixed monitoring test).
8	E	The user cannot disable the test (always enabled test).
9	A	Monitoring is active for this test.
	I	Monitoring is inactive for this test.
10	R	The test cycles power to the line cards and reloads the supervisor engine.
11	K	The test resets the line card after completion.
12	T	The test shuts down all ports and reloads the supervisor engine.

If a test is configured to run periodically, the interval will be displayed in the Test Interval field of the command output in the format ddd hh:mm:ss.ms, indicating days, hours, minutes, seconds, and milliseconds. For example, the test interval of a test that will run every 15 minutes will be displayed as 000 00:15:00.00. The test interval of a test that will run every 14 days will be displayed as 014 00:00:00.00.

If a test failure is determined by multiple errors rather than a single error, the error threshold will be displayed in the Threshold field of the command output.

You can use the **showdiagnosticdescriptionmodule**command to see a detailed description of a diagnostic test.

Examples

The following example shows how to display the test suite, the monitoring interval, and test attributes for module 5:

```
Router# show diagnostic content module 5
Module 5: Supervisor Engine 2T 10GE w/ CTS (Active)
Diagnostics test suite attributes:
    M/C/* - Minimal bootup level test / Complete bootup level test / NA
      B/* - Basic ondemand test / NA
    P/V/* - Per port test / Per device test / NA
    D/N/* - Disruptive test / Non-disruptive test / NA
      S/* - Only applicable to standby unit / NA
      X/* - Not a health monitoring test / NA
      F/* - Fixed monitoring interval test / NA
      E/* - Always enabled monitoring test / NA
      A/I - Monitoring is active / Monitoring is inactive
      R/* - Power-down line cards and need reload supervisor / NA
      K/* - Require resetting the line card after the test has completed / NA
```

```
     T/* - Shut down all ports and need reload supervisor / NA
                                                     Test Interval   Thre-
ID   Test Name                            Attributes      day hh:mm:ss.ms shold

40) TestNVRAMBatteryMonitor ---------> ***N**F*A***    000 01:00:00.00 72
```

Note The HM test, TestAclFpgaMonitor, is applicable only for Aphrodite, Berytos, and Anteros (ABA) cards. This test is run to monitor the access control list (ACL) ternary content addressable memory (TCAM) reply status.

Note The HM test TestNVRAMBatteryMonitor monitors the NVRAM battery status and is applicable only to the Supervisor Engine 2T.

The table below describes the significant fields shown in the display.

Table 99: show diagnostic content module Field Descriptions

Field	Description
ID	Unique identifier of the diagnostic test.
Test Name	Name of the diagnostic test.
Attributes	Health state of the diagnostic.
Test Interval	Periodic interval at which the test is run.
Threshold	Maximum number of consecutive test failures required by the diagnostic test to take recovery action.

Related Commands

Command	Description
diagnostic bootup level	Sets the bootup diagnostic level.
diagnostic monitor	Configures the HM diagnostic testing.
diagnostic ondemand	Configures the on-demand diagnostics.
diagnostic schedule test	Sets the scheduling of test-based diagnostic testing for a specific module or schedules a supervisor engine switchover.
show diagnostic description module	Describes the diagnostic tests.

show diagnostic cns

To display the information about the CNS subject, use the **show diagnostic cns** command in user EXEC or privileged EXEC mode.

show diagnostic cns {**publish** | **subscribe**}

Syntax Description

publish	Displays the subject with which the diagnostic results is published.
subscribe	Displays the subscribed subjects.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The CNS subsystem communicates with remote network applications through the CNS-event agent and follows the publish and subscribe model. An application sets itself up to receive events by subscribing to the approprate event subject name.

Examples

This example shows how to display the subject with which the diagnostic results is published:

```
Router# show diagnostic cns publish
Subject: cisco.cns.device.diag_results
```

This example shows how to display the subscribed subject:

```
Router# show diagnostic cns subscribe
Subject: cisco.cns.device.diag_get_results
```

Related Commands

Command	Description
diagnostic cns	Configures the CNS diagnostics.

show diagnostic description module

To display a detailed description of a diagnostic test available on a module, use the **showdiagnosticdescriptionmodule**command in user EXEC or privileged EXEC mode.

show diagnostic description module {**slot** | **slot**/**subslot**} **test** {**all** | **test-id** | **test-name**}

Syntax Description

slot	Specifies a module by slot number.
slot/subslot	Specifies a submodule by slot number and subslot or bay within the module.
all	Displays descriptions of all available tests.
test-id	Test identification number. See the Usage Guidelines for a list of tests.
test-name	Test name. See the Usage Guidelines for a list of tests.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can display detailed descriptions of diagnostic tests by specifying the test ID, the test name, or the **all**keyword in this command. The test ID and test name for available diagnostic tests are displayed in the output of the **showdiagnosticcontentmodule**command.

Examples

This example shows how to display the description of TestIPv6FibShortcut on module 1:

```
Router# show diagnostic description module 1 test TestIPv6FibShortcut
TestIPv6FibShortcut :
        This test verifies the IPv6 FIB forwarding of the layer 3 forwarding
        engine. One diagnostic IPv6 FIB and an adjacency entry are installed
        and a diagnostic IPv6 packet is sent to make sure it is forwarded
        accordingly based on rewritten MAC and VLAN information.
```

This example shows how to display the description of test number 15 on module 1:

```
Router# show diagnostic description module 1 test 15
TestIPv6FibShortcut :
        This test verifies the IPv6 FIB forwarding of the layer 3 forwarding
        engine. One diagnostic IPv6 FIB and an adjacency entry are installed
        and a diagnostic IPv6 packet is sent to make sure it is forwarded
        accordingly based on rewritten MAC and VLAN information.
```

Related Commands

Command	Description
show diagnostic content module	Displays the available diagnostic tests.

show diagnostic events

To display the diagnostic event log, use the **showdiagnosticevents**command in user EXEC or privileged EXEC mode.

show diagnostic events [{**event-type** *event-type* | **module** {**all***slotslot/subslot*}}]

Cisco ASR 1000 Series Aggregation Services Routers
show diagnostic events [{**event-type** *event-type* | **slot** {*number* | **all**}}]

Syntax Description

event-type *event-type*	(Optional) Displays events of a specified type, where *event-type* values are **error**, **info**, and **warning**.
module	(Optional) Displays the event log for a module, where: • **all** --Displays the event log for all modules. • *slot* --Chassis slot location of the module. • *slot* / *subslot* --Subslot or bay location of the submodule.
slot {*number* | **all**}	(Optional--Cisco ASR 1000 Series Routers) Displays the event log for the specified hardware slots, where: • *number* --Chassis slot location of the hardware, such as **R0** for route processor 0. • **all** --Displays the event log for hardware in all supported slots.

Command Default

When no optional keywords are specified, the **showdiagnosticevents** command displays all events for all hardware module or slot locations.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 2.6	This command was integrated into Cisco IOS XE Release 2.6.

Usage Guidelines

If you do not enter a **module** keyword and argument for the **showdiagnosticevents** command, the event log for all modules is displayed.

On the Cisco ASR 1000 Series Aggregation Services Routers, if no optional keywords are entered, the event log for all supported slots is displayed.

The following fields are displayed in the command output:

Field	Description
Time Stamp	Date and time of the diagnostic event, in the format MM:DD hh:mm:ss.mss.
ET	Type of event (I=Info, W=Warning, E=Error).
Card	Module associated with the event.
Event Message	Event description.

Examples

The following example shows how to display the diagnostic event log for events of type Info:

```
Router# show diagnostic events event-type info
Diagnostic events (storage for 500 events, 14 events recorded)
Number of events matching above criteria = 10
Event Type (ET):I - Info, W - Warning, E - Error
Time Stamp         ET [Card] Event Message
------------------ --  -------------------------------------------------------
08/26 15:51:04.335 I  [1] TestIndexLearn Passed
08/26 15:51:04.335 I  [1] Diagnostics Passed
08/26 15:51:15.511 I  [8] TestLoopback Passed
08/26 15:51:15.511 I  [8] Diagnostics Passed
08/26 16:15:02.247 I  [1] TestDontLearn Passed
08/26 16:15:02.247 I  [1] Diagnostics Passed
08/26 16:15:12.683 I  [8] TestNetflowInlineRewrite Passed
08/26 16:15:12.683 I  [8] Diagnostics Passed
08/26 16:15:42.207 I  [2] TestActiveToStandbyLoopback Passed
08/26 16:15:42.207 I  [2] Diagnostics Passed
```

The following example shows the results of all events for the predefined TestErrorCounterMonitor test on route processor 0 on a Cisco ASR 1000 Aggregation Services Router:

```
Router# show diagnostic events slot R0

Diagnostic events (storage for 10 events, 10 events recorded)
Number of events matching above criteria = 10
Event Type (ET): I - Info, W - Warning, E - Error
Time Stamp         ET [Card] Event Message
------------------ -- ------ -------------------------------------------------
10/13 04:29:00.384 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:05.501 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:10.607 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:15.730 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:20.835 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:25.939 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:31.044 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:36.149 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:41.252 E  [R0]    TestErrorCounterMonitor Failed
10/13 04:29:46.356 E  [R0]    TestErrorCounterMonitor Failed
```

Related Commands

Command	Description
diagnostic event-log size	Modifies the diagnostic event log size dynamically.
diagnostic monitor	Configures the health-monitoring diagnostic testing.

Command	Description
diagnostic ondemand	Configures the on-demand diagnostics.
diagnostic schedule test	Sets the scheduling of test-based diagnostic testing for a specific module or schedule a supervisor engine switchover.
diagnostic start	Runs the specified diagnostic test.
diagnostic stop	Stops the testing process.

show diagnostic result slot

To display diagnostic test results for supported hardware slot locations, use the **showdiagnosticresultslot** command in privileged EXEC configuration mode.

show diagnostic result slot [{*number* [{**detail** | **failure** [**detail**] | **test** *testid* [**detail**] | **xml**}] | **all** [{**detail** | **failure** [**detail**]}]}]

Syntax Description

number	(Optional) Slot location of the hardware for which you want diagnostic test results, such as **R0** for route processor slot 0.
detail	(Optional) Displays additional detailed information for the specified diagnostic test.
failure	(Optional) Displays only failed diagnostic test results.
test *test-id*	(Optional) Displays diagnostic test results for one or more specific tests, where *test-id* is one of the following: • Name of a diagnostic test. • Number of a diagnostic test. • Range of diagnostic test numbers (startrange-endrange). • List of diagnostic test numbers or range of numbers, separated by commas. • **all** --Keyword specifying all diagnostic tests.
xml	(Optional) Displays diagnostic text results in Extensible Markup Language (XML) format.
all	(Optional) Displays diagnostic test results for all supported hardware locations.

Command Default

If you do not specify any options, the command displays diagnostic test results for all supported hardware slot locations.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.6	This command was introduced.

Usage Guidelines

If a test does not exist for the hardware, "*Diagnostic is not available* " is shown.

In the command output, the possible testing results are as follows:

- Passed (.)
- Failed (F)
- Unknown (U)

Examples

The following example shows a passed diagnostic test (indicated by a ".") called TestErrorCounterMonitor on route processor slot 0, and no supported diagnostic tests on slot F0 and slot 0:

```
Router# show diagnostic result slot all
Current bootup diagnostic level: minimal
slot R0: ASR1000-RP1           SerialNo : JAE1218GSMR
  Overall Diagnostic Result for slot R0 : PASS
  Diagnostic level at card bootup: minimal
  Test results: (. = Pass, F = Fail, U = Untested)
    1) TestErrorCounterMonitor ---------> .
Diagnostic[slot F0]: Diagnostic is not available.
Diagnostic[slot 0]: Diagnostic is not available.
```

The following example shows detailed information about the diagnostic test on the hardware in slot R0:

```
Router# show diagnostic result slot R0 detail

Current bootup diagnostic level: minimal
slot R0: ASR1000-RP1           SerialNo : JAE1224L2QP
  Overall Diagnostic Result for slot R0 : PASS
  Diagnostic level at card bootup: minimal
  Test results: (. = Pass, F = Fail, U = Untested)
  ___________________________________________________________________________
    1) TestErrorCounterMonitor ---------> .
          Error code ------------------> 0 (DIAG_SUCCESS)
          Total run count -------------> 871
          Last test testing type ------> Health Monitoring
          Last test execution time ----> Oct 13 2009 03:15:47
          First test failure time -----> Oct 13 2009 02:02:32
          Last test failure time ------> Oct 13 2009 03:10:09
          Last test pass time ---------> Oct 13 2009 03:15:47
          Total failure count ---------> 10
          Consecutive failure count ---> 0
  ___________________________________________________________________________
```

show diagnostic simulation failure

To display a list of simulated test failures installed by the user for a module, use the **showdiagnosticsimulationfailure** command in user EXEC or privileged EXEC mode.

show diagnostic simulation failure [{**all** | **module** {**all***list slot* | *slot*/*subslot*}}]

Syntax Description

all	(Optional) Displays the diagnostic simulation failure for all modules.
module	(Optional) Specifies the module number.
list	A list of modules in the following format: • Entries are separated by a comma, for example, 1,4,6-10. • Ranges are specified with a hyphen, for example, 1-4,6-10.
slot	Specifies a single module by slot number.
slot / *subslot*	Specifies a single submodule by slot number and subslot or bay within the module.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you do not enter a **module** keyword and argument for this command, information for all modules is displayed.

A diagnostic test configured for failure simulation is identified in the output of this command by its test ID number. You can use the **showdiagnosticdescriptionmodule**command to see the name and detailed description of a diagnostic test.

Examples

The following example shows how to display the simulated test failures installed by the user on module 1:

```
Router# show diagnostic simulation failure module 1
Module 1:
    Test #17: Simulation = Always Fail
```

Related Commands

Command	Description
show diagnostic description module	Describes the diagnostic tests.
test diagnostic simulation	Configures simulated diagnostic test conditions.

show diagnostic health

To display the output for the health checks performed, use the **showdiagnostichealth**command in user EXEC or privileged EXEC mode.

show diagnostic health

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SXI	This command was introduced.

Usage Guidelines

The command output displays the following system health check information:

- CPU and memory utilization
  - Displays warning if the CPU utilization in the last five minutes is greater than 70%
  - Displays total, free, and reserved memory statistics
- EARL recovery patch occurrences, shown as a log
- Nonzero ASIC error registers on all modules using the output listing of TestErrorCounterMonitor
- Nonzero port level error counters for all ports

Examples

This example shows how to display the output for the health checks performed:

```
Router# show diagnostic health
CPU utilization for the past 5 mins is greater than 70%
five minutes: 81%
EARL reset history:
Module 1 : WS-SUP32-GE-3B EARL patch log -
Num. of times patch applied   : 0
Num. of times patch requested : 0
Non-zero port counters for 1/8 -
13.                       linkChange = 338702
Non-zero port counters for 1/9 -
 0.                  rxCRCAlignErrors = 2
 3.                    rxFragmentPkts = 9
 6.                        ifInErrors = 30
13.                        linkChange = 1
Current bootup diagnostic level: minimal
Test results: (. = Pass, F = Fail, U = Untested)
36) TestErrorCounterMonitor ---------> F
Error code ------------------> 1 (DIAG_FAILURE)
Total run count -------------> 29
Last test execution time ----> Mar 16 2008 19:04:02
First test failure time -----> Mar 16 2008 19:03:21
Last test failure time ------> Mar 16 2008 19:04:02
```

```
Last test pass time ---------> Mar 16 2008 19:03:19

```

Related Commands

Command	Description
diagnostic monitor	Configures the health-monitoring diagnostic testing.

show diagnostic ondemand settings

To display the settings for the on-demand diagnostics, use the **showdiagnosticondemandsettings**command in user EXEC or privileged EXEC mode.

show diagnostic ondemand settings

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The command output shows the number of test iterations to be performed and the action to be taken on a test failure. Possible actions are:

- continue--Continue the ondemand tests until the test failure limit is reached.
- stop--Stop the ondemand tests immediately if a test fails.

Examples

This example shows how to display the settings for the on-demand diagnostics:

```
Router# show diagnostic ondemand settings
Test iterations = 1
Action on test failure = continue
```

Related Commands

Command	Description
diagnostic ondemand	Configures the on-demand diagnostics.

show diagnostic result module

To display the diagnostic test results for a module, use the **showdiagnosticresult**command in user EXEC or privileged EXEC mode.

show diagnostic result module {**all***listslot* | *slot* / *subslot*} [{**detail** | **failure** [**detail**] | **test** *test-id* [**detail**] | **xml**}]

Syntax Description

all	Displays diagnostic test results for all modules.
list	A list of modules in the following format: • Entries are separated by a comma, for example, 1,4,6-10. • Ranges are specified with a hyphen, for example, 1-4,6-10.
slot	Specifies a single module by slot number.
slot/subslot	Specifies a single submodule by slot number and subslot or bay within the module.
detail	(Optional) Displays the detailed test results.
failure	(Optional) Displays the failed test results.
test *test-id*	(Optional) Displays the test results only for the specified test. See the Usage Guidelines for a list of tests.
xml	(Optional) Displays the test results in XML form.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for theSupervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

In the command output, the possible testing results are as follows:

- Passed (.)
- Failed (F)
- Unknown (U)

To display only the results of failed diagnostic tests, use the **failure**keyword.

To display the results of a specific diagnostic test, specify the *test-id* number using the **test***test-id*keyword and argument. The *test-id* numbers for available diagnostic tests are displayed in the output of the **showdiagnosticcontentmodule**command.

You can use the **showdiagnosticdescriptionmodule**command to see a detailed description of a diagnostic test.

Examples

This example shows how to display a summary of all diagnostic test results for the module in slot 3:

```
Router# show diagnostic result module 3
Current bootup diagnostic level:complete
Module 3:
  Overall Diagnostic Result for Module 8 :PASS
  Diagnostic level at card bootup:complete
  Test results:(. = Pass, F = Fail, U = Untested)
   1) TestLoopback :
      Port  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24
      ----------------------------------------------------------------------------

Related Commands

Command	Description
show diagnostic content module	Displays the available diagnostic tests.
show diagnostic description module	Describes the diagnostic tests.

show diagnostic sanity

To display sanity check results, use the **show diagnostic sanity** command in privileged EXEC mode.

show diagnostic sanity

Syntax Description

This command has no arguments or keywords.

Command Default

Displays information for all the Gigabit Ethernet WAN interfaces in the Cisco 7600 series router.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The sanity check runs a set of predetermined checks on the configuration with a possible combination of certain system states to compile a list of warning conditions. The checks are designed to look for anything that seems out of place and are intended to serve as an aid to maintaining the system sanity.

The following is a list of the checks that are run and the action taken when the condition is found:

- Checks whether the default gateways are reachable. If so, the system stops pinging.
- If a port auto-negotiates to half duplex, the system flags it.

Trunking Checks

- If a trunk port has the mode set to “on,” the system flags it.
- If a port is trunking and mode is auto, the system flags it.
- If a trunk port is not trunking and the mode is desirable, the system flags it.
- If a trunk port negotiates to half duplex, the system flags it.

Channeling Checks

- If a port has channeling mode set to on, the system flags it.
- If a port is not channeling and the mode is set to desirable, the system flags it.
- If a VLAN has a Spanning-Tree root of 32K (root is not set), the system flags it.

Spanning-Tree VLAN Checks

- If a VLAN has a max age on the Spanning-Tree root that is different than the default, the system flags it.
- If a VLAN has a fwd delay on the Spanning-Tree root that is different than the default, the system flags it.
- If a VLAN has a fwd delay on the bridge that is different than the default, the system flags it.

- If a VLAN has a fwd delay on the bridge that is different than the default, the system flags it.
- If a VLAN has a hello time on the bridge that is different than the default, the system flags it.

Spanning-Tree Port Checks

- If a port has a port cost that is different than the default, the system flags it.
- If a port has a port priority that is different than the default, the system flags it.

UDLD Checks

- If a port has UDLD disabled, the system flags it.
- If a port had UDLD shut down, the system flags it.
- If a port had a UDLD undetermined state, the system flags it.

Assorted Port Checks

- If a port had receive flow control disabled, the system flags it.
- If a trunk port had PortFast enabled, the system flags it.
- If a inline power port has any of the following states:
    - denied
    - faulty
    - other
    - off

The system flags it.

- If a port has a native VLAN mismatch, the system flags it.
- If a port has a duplex mismatch, the system flags it.

Bootstring and Config Register Checks

- The config register on the primary supervisor engine (and on the secondary supervisor engine if present) must be one of the following values: 0x2 , 0x102, or 0x2102.
- The system verifies the bootstring on the primary supervisor engine (and on the secondary supervisor engine if present). The system displays a message if the bootstring is empty.
- The system verifies that every file is specified in the bootstring. The system displays a message if the file is absent or shows up with a wrong checksum.

If only *device* **:** is specified as a filename, then the system verifies that the first file is on the device.

Assorted Checks

- The system displays a message if IGMP snooping is disabled.
- The system displays a message if any of the values of the snmp community access strings {RO,RW,RW-ALL} is the same as the default.
- The system displays a message if any of the modules are in states other than “Ok.”

- The system displays a message that lists all the tests that failed (displayed as an “F”) in the **show test all** command.
- The system displays a message if *fast is not configured on the switch anywhere.
- The system displays a message if there is enough room for the crashinfo file on the bootflash:.
- The system displays a message if multicast routing is enabled globally but is not applied to all interfaces.
- The system displays a message if IGMP snooping is disabled and RGMP is enabled.

Examples

This example displays samples of the messages that could be displayed with the **show diagnostic sanity** command:

```
Router# show diagnostic sanity
Pinging default gateway 10.6.141.1 ....
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.6.141.1, timeout is 2 seconds:
..!!.
Success rate is 0 percent (0/5)
IGMP snooping disabled please enable it for optimum config.
IGMP snooping disabled but RGMP enabled on the following interfaces,
please enable IGMP for proper config :
Vlan1, Vlan2, GigabitEthernet1/1
Multicast routing is enabled globally but not enabled on the following
interfaces:
GigabitEthernet1/1, GigabitEthernet1/2
A programming algorithm mismatch was found on the device bootflash:
Formatting the device is recommended.
The bootflash: does not have enough free space to accomodate the crashinfo file.
Please check your confreg value : 0x0.
Please check your confreg value on standby: 0x0.
The boot string is empty. Please enter a valid boot string .
Could not verify boot image "disk0:" specified in the boot string on the
slave.
Invalid boot image "bootflash:asdasd" specified in the boot string on the
slave.
Please check your boot string on the slave.
UDLD has been disabled globally - port-level UDLD sanity checks are
being bypassed.
OR
[
The following ports have UDLD disabled. Please enable UDLD for optimum
config:
Fa9/45
The following ports have an unknown UDLD link state. Please enable UDLD
on both sides of the link:
Fa9/45
]
The following ports have portfast enabled:
Fa9/35, Fa9/45
The following ports have trunk mode set to on:
Fa4/1, Fa4/13
The following trunks have mode set to auto:
Fa4/2, Fa4/3
The following ports with mode set to desirable are not trunking:
Fa4/3, Fa4/4
The following trunk ports have negotiated to half-duplex:
Fa4/3, Fa4/4
The following ports are configured for channel mode on:
Fa4/1, Fa4/2, Fa4/3, Fa4/4
```

```
The following ports, not channeling are configured for channel mode
desirable:
Fa4/14
The following vlan(s) have a spanning tree root of 32768:
1
The following vlan(s) have max age on the spanning tree root different from
the default:
1-2
The following vlan(s) have forward delay on the spanning tree root different
from the default:
1-2
The following vlan(s) have hello time on the spanning tree root different
from the default:
1-2
The following vlan(s) have max age on the bridge different from the
default:
1-2
The following vlan(s) have fwd delay on the bridge different from the
default:
1-2
The following vlan(s) have hello time on the bridge different from the
default:
1-2
The following vlan(s) have a different port priority than the default
on the port FastEthernet4/1
1-2
The following ports have recieve flow control disabled:
Fa9/35, Fa9/45
The following inline power ports have power-deny/faulty status:
Gi7/1, Gi7/2
The following ports have negotiated to half-duplex:
Fa9/45
The following vlans have a duplex mismatch:
Fas 9/45

The following interafaces have a native vlan mismatch:
interface (native vlan - neighbor vlan)
 Fas 9/45 (1 - 64)
The value for Community-Access on read-only operations for SNMP is the same
as default. Please verify that this is the best value from a security point
of view.
The value for Community-Access on write-only operations for SNMP is the same
as default. Please verify that this is the best value from a security point
of view.
The value for Community-Access on read-write operations for SNMP is the same
as default. Please verify that this is the best value from a security point
of view.
Please check the status of the following modules:
8,9
Module 2 had a MINOR_ERROR.
The Module 2 failed the following tests:
TestIngressSpan
The following ports from Module2 failed test1:
1,2,4,48
```

show diagnostic schedule module

To display the current scheduled diagnostic tasks, use the **showdiagnosticschedulemodule**command in user EXEC or privileged EXEC mode.

show diagnostic schedule module {**all***listslot* | *slot* / *subslot*}

Syntax Description

all	Displays the current scheduled diagnostic tasks for all modules.
list	A list of modules in the following format: • Entries are separated by a comma, for example, 1,4,6-10. • Ranges are specified with a hyphen, for example, 1-4,6-10.
slot	Specifies a single module by slot number.
slot/subslot	Specifies a single submodule by slot number and subslot or bay within the module.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

A scheduled diagnostic test is identified in the output of this command by its test ID number. With the test ID number, you can see the name and detailed description of the diagnostic test by using the **showdiagnosticdescriptionmodule**command.

Examples

This example shows how to display the current scheduled diagnostic tasks for the module in slot 1:

```
Router# show diagnostic schedule module 1
Current Time = 07:55:30 UTC Fri August 2 2002
Diagnostic for Module 1:
Schedule #1:
        To be run on January 3 2003 23:32
        Test ID(s) to be executed:1.
Schedule #2:
        To be run daily 14:45
        Test ID(s) to be executed:2.
Schedule #3:
        To be run weekly Monday 3:33
        Test ID(s) to be executed:all.
```

Related Commands

Command	Description
diagnostic schedule test	Sets the scheduling of test-based diagnostic testing for a specific module or schedule a supervisor engine switchover.
show diagnostic description module	Describes the diagnostic tests.

show diagnostic status

To display the currently running diagnostics tests, use the **showdiagnosticstatus**command in user EXEC or privileged EXEC mode.

show diagnostic status

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	This command was introduced for the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

For each installed module, the following fields are displayed in the command output:

Field	Description
Card	The slot number of the module associated with the event
Description	A description of the module
Current Running Test	The diagnostic test running on the module
Run by	The diagnostic test category that initiated the running test. The categories are: • BU--This test is running as a part of the bootup diagnostics • HM--This test is running as a part of the health monitoring diagnostics • OD--This was initiated as an ondemand diagnostic test • SCH--This test is running as a scheduled diagnostic test

Examples

This example shows how to display the currently running diagnostics tests:

```
Router# show diagnostic status
<BU> - Bootup Diagnostics, <HM> - Health Monitoring Diagnostics, <OD> - OnDemand Diagnostics,
 <SCH> - Scheduled Diagnostics
====== ================================= =============================== ======
Card   Description                       Current Running Test            Run by
------ --------------------------------- ------------------------------- ------
3      CEF720 48 port 10/100/1000mb Ethe TestLoopback                    <OD>
5      Supervisor Engine 720 (Hot)       TestScratchRegister             <HM>
6      Supervisor Engine 720 (Active)    N/A                             N/A
```

```
8      CEF720 8 port 10GE with DFC       N/A                              N/A
====== ================================= ================================ ======
```

Related Commands

Command	Description
diagnostic start	Runs the specified diagnostic test.
diagnostic stop	Stops the testing process.
show diagnostic content module	Displays the available diagnostic tests.
show diagnostic description module	Describes the diagnostic tests.

show dsc clock

To display information about the dial shelf controller clock, use the **showdscclock**command in privileged EXEC mode with the line card execute (**execute-on**) command.

execute-on {**slot** *slot-number* | **all**} **show dsc clock**

Syntax Description

execute-on	Executes commands remotely on a line card.
slot *slot-number*	Displays information for a specific slot. Slot number (12 or 13) must be occupied by a DSC card.
all	Executes the command on all line cards.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You must use the **showdscclock** command from the router using the **execute-on** command.

Examples

The following is sample output from the **showdscclock** command:

```
Router# execute-on slot 12
 show dsc clock
Router#
Primary Clock:
--------------
Slot: 3, Port 1, Line 0, Priority = 3 up since 00:37:56
Time elapsed since last failure of the primary = 00:38:59

Backup clocks:
Source  Slot    Port    Line    Priority    Status      State
--------------------------------------------------------------
Trunk   1       2       0       10          Good        Configured

All feature boards present are getting good clock from DSC
```

The table below describes the significant fields shown in the display.

Table 100: show dcs clock Field Descriptions

Field	Description
Primary clock	The clock designated as the master timing clock.

Field	Description
Priority	The order in which a clock is designated to back up the primary clock or the next higher priority clock in case of its failure.
Backup Source	The clock signal source, such as a trunk, internal clock, or external generator.
Feature board	An application-specific card in the dial shelf, such as a line card.
Trunk	The trunk line connected to the ISP or central office.
Status	Whether the clock source is capable of providing a synch source signal.
State	Whether the clock source is connected and assigned a priority.

Related Commands

Command	Description
execute-on	Executes commands remotely on a line card.

show dsi

To display information about the dial shelf interconnect (DSI) port adapter parameters, use the **showdsi** command in privileged EXEC mode with the line card execute (**execute-on**) command.

execute-on {**slot** *slot-number* | **all**} **show dsi**

Syntax Description

execute-on	Executes commands remotely on a line card.
slot *slot-number*	Displays information for a specific slot. Slot number (12 or 13) must be occupied by a DSC card.
all	Executes the command on all line cards.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The dial shelf interconnect (DSI) port adapter connects the Cisco 5814 dial shelf to the Cisco 7206 router shelf. The DSI port adapter allows data transfers between the dial shelf and the router shelf. Data is converted into packets by the feature cards, transmitted to a hub on the dial shelf controller card, and from there sent to the router shelf. Conversely, packets from the router shelf are sent to the dial shelf controller card, where they are transmitted over the backplane to the modem and trunk cards. The show dsi command is used to show information about the dial shelf interconnect hardware, interface, physical link, PCI registers, and address filters.

Examples

The following is sample output from the **showdsi**command:

```
Router# execute-on slot 1 show dsi
DSI-Tx-FastEthernet0 is up, line protocol is up
  Hardware is DEC21140A, address is 0008.26b7.b008 (bia 0008.26b7.b008)
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  Half-duplex, 100Mb/s, 100BaseTX/FX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 01:17:09, output 00:00:00, output hang never

The table below describes the significant fields shown in the display.

Table 101: show dsi Field Descriptions

Field	Description
FastEthernet0 ... is up ... is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type (for example, MCI Ethernet, SCI,[2] CBus[3] Ethernet) and address.

Field	Description
Internet address	Internet address followed by subnet mask.
MTU	Maximum Transmission Unit of the interface.
BW	Bandwidth of the interface in kilobits per second.
DLY	Delay of the interface in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100% reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
ARP type:	Type of Address Resolution Protocol assigned.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface. Useful for knowing when a dead interface failed.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231ms (and less than 232ms) ago.
Output queue, input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped due to a full queue.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.

Field	Description
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received ... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the medium's minimum packet size. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the medium's maximum packet size. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Number of packets whose receipt was aborted.
watchdog	Number of times watchdog receive timer expired. It happens when receiving a packet with length greater than 2048.
multicast	Number of multicast packets received.

Field	Description
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted due to an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times a Type 2 Ethernet controller was restarted because of errors.
babbles	The transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble.
deferred	Deferred indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
output buffer failures	Number of failed buffers and number of buffers swapped out.

[2] SCI = Single Cell Input
[3] CBus = Command Bus

Command	Description
execute-on	Executes commands on a line card.
show dsip	Displays all information about the DSIP.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dsip

To display all information about the Distributed System Interconnect Protocol (DSIP) on a Cisco AS5800, use the **showdsip**command in EXEC mode.

show dsip

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Your Cisco AS5800 universal access server uses a protocol used by the Cisco 7206 router shelf to communicate back and forth with the Cisco 5814 dial shelf controller card(s) and feature cards. Although dial shelf interconnect (DSI) configuration is transparent to the user, there are several show commands to help you view your setup, and debug commands to help you troubleshoot your system.

To display a subset of this information, use the**showdsipclients**, **showdsipnodes**, **showdsipports**, **showdsipqueue**,**showdsiptracing**, **showdsiptransport**, and **showdsipversion** commands.

Examples

The following is sample output from the **showdsip**command. For a description of the fields shown in the sample output, refer to the individual **showdsip**commands listed in the “Usage Guidelines” section.

```
Router# show dsip

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the processors running the DSIP.
show dsip ports	Displays information about local and remote ports.
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dsip clients

To display information about Distributed System Interconnect Protocol (DSIP) clients, use the **showdsipclients**command in EXEC mode.

show dsip clients

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to see whether a client is actually registered with DSIP and using its services.

Consider the following example: a client “Trunk” seems to be defunct on a particular node with absolutely no input/output activity. The command show dsip ports does not show any Trunk port among its local ports though all other client ports show up. The problem might be that the Trunk client did not even register with DSIP. To confirm this, use the show dsip clients command.

Examples

The following is sample output from the **showdsipclients**command. This command lists the clients.

```
Router# show dsip clients
ID    Name
0   Console
1   Clock
2   Modem
3   Logger
4   Trunk
5   Async data
6   TDM
7   Dial shelf manager
8   Environment Mon
9   DSIP Test
```

Related Commands

Command	Description
show dsip nodes	Displays information about the processors running the DSIP.
show dsip ports	Displays information about local and remote ports
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.

Command	Description
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.

show dsip nodes

To display information about the processors running the Distributed System Interconnect Protocol (DSIP), use the **showdsipnodes**command in EXEC mode.

show dsip nodes

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use show dsip nodes to see the nodes (slots) connected by DSIP and the node specific sequence numbers. The former information is also available from show dsip transport. The sequence numbers are useful for support engineers while debugging a problem.

Examples

The following is sample output from the **showdsipnodes** command:

```
Router# show dsip nodes

DSIP ipc nodes:
---------------
There are 9 nodes in this IPC realm.

```

The table below describes the significant fields shown in the display.

Table 102: show dsip nodes Field Descriptions

Field	Description
ID	DSIP uses Cisco’s IPC (Inter Process Communication) module for nondata related (client control messages etc.) traffic. A seat or node is a computational element, such as a processor, that can be communicated with using IPC services. A seat is where entities and IPC ports reside. The IPC maintains a seat table which contains the seatids of all the seats in the system. Normally this seatid is a function of the slot number.
Type	Local: Local node. DSIP: Remote DSIP node.
Name	Each seat (node) has a name to easily identify it. There is only one primary node and rest are subordinate nodes. The master node name is “IPC Master” and the slave node name is “Seat:Slave X”, where “X” is the slot number of the node.
Last Sent/Last Heard	Each node maintains two sequence numbers for the last sent and last heard.
Last Sent	Whenever a message is sent out, the “last sent” counter is updated.
Last Heard	Whenever a message is received from a remote node, “last heard” is updated.

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip ports	Displays information about local and remote ports
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.

show dsip ports

To display information about local and remote ports, use the **showdsipports**command in EXEC mode.

show dsip ports [{**local** | **remote** [**slot**]}]

Syntax Description

local	(Optional) Displays information for local ports. The local port is the port created at a seat's local end.
remote	(Optional) Displays information for remote ports. The remote port is the port residing on a remote seat to which DSIP IPC based connection is open.
slot	(Optional) Specifies a slot number to display information for a specific card on the dial shelf.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The DSIP communication going through the IPC stack uses ports. The creation of a port returns a 32-bit port ID which is the endpoint for communication between two IPC clients.

The show dsip ports command is used to check clients that are up and running:

- To see the local ports that are created and the activity on them.
- To see the remote ports which are connected and to see the activity on them.

If no options are specified, information is displayed for both local and remote ports.

Examples

The following is sample output from the **showdsipports** command:

```
Router# show dsip ports

Dsip Local Ports:
----------------
Client:Portname             Portid    In-Msgs   Bytes     Last-i/p
Console:Master              10004     0         0         never
Clock:Master                10005     16        1800      00:00:05
Modem:Master                10006     90        70162     00:10:08
Logger:Master               10007     0         0         never
Trunk:Master                10008     792       62640     00:00:03
Async data:Master           10009     0         0         never
TDM:Master                  1000A     7         112       00:10:44
Dial shelf manager:Master   1000B     15        2256      00:00:27
DSIP Test:Master            1000C     1294      1294      00:00:00
```

```
Dsip Remote Ports:
-----------------
Client:Portname             Portid    Out-Msgs  Bytes     Last-o/p  Last-act
Clock:Slave1                101005F   1         24        00:10:46  00:10:46
Trunk:Slave1                1010061   12        1776      00:10:46  00:10:46
Modem:Slave5                1050050   96        2148      00:10:21  00:10:44
Modem:Slave6                1060050   105       2040      00:10:25  00:10:48

Modem:Slave11               10B0050   107       2192      00:10:39  00:11:02
Clock:Slave12               10C000D   1         24        00:11:07  00:11:07
Dial shelf manager:Slave12  10C000E   15        2256      00:00:45  00:11:05
DSIP Test:Slave12           10C000F   0         0         never     00:11:05
```

The table below describes the significant fields shown in the display.

Table 103: show dsip ports Field Descriptions

Field	Description
Client:Portname	Client name and port name. Port Name. The port names can be determined because they are based on a uniform naming convention that includes the following elements: • Client name • Master/slave status • Slot number Any client can derive the port name of the other client it wants to talk to once it knows its physical location, using the following formula: Master/Slave Status Port Name Syntax Master *Client-Name***:Master,**for example, **Console:Master** Slave *Client-Name***:Slave***Slot*, for example, **Clock:Slave1**
Portid	Port ID. The Port ID is a 32-bit identifier comprised of **seatid** and the **port-number**. The IPC maintains a seat table which contains the seatids of all the seats in the system. A seat is where clients and ports reside. The seat ID is a function of the slot number. Port number is the sequential number of the port that is being created on a particular seat, for example: 0,1, 2, etc.
In-Msgs/	The total number of input messages that were received on a particular port.
Out-Msgs	The total number of output messages that were sent to a particular remote port.
Bytes(in/out)	The total number of bytes that were received on a particular port or sent to a remote port. The number of bytes on this port up to the time of the execution of the **show** command.
Last-i/p	Elapsed time since the last input was received on a local port.
Last-o/p	Elapsed time since the last message was sent to a particular remote port.
Last-act	Elapsed time since the connection to a remote port was opened.

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the nodes (slots) connected by DSIP on a system.
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dsip queue

To display the number of IPC messages in the transmission queue waiting for acknowledgment, use the **showdsipqueue**command in EXEC mode.

show dsip queue

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

IPC is inter-process communication. Processes communicate by exchanging messages held in queue buffers. Use the show dsip queue to display the status of these queue buffers.

Examples

The following is sample output from the **showdsipqueue**command when the system is operating correctly:

```
Router# show dsip queue

DSIP ipc queue:
---------------
There are 0 IPC messages waiting for acknowledgment in the transmit queue.
There are 0 messages currently in use by the system.
```

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the nodes (slots) connected by DSIP on a system.
show dsip ports	Displays information about local and remote ports.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dsip tracing

To display Distributed System Interconnect Protocol (DSIP) tracing buffer information, use the **showdsiptracing**command in EXEC mode.

show dsip tracing [{**control** | **data** | **ipc**}] [{*slot* | **entries** *entry-number* [*slot*]}]

Syntax Description

control	(Optional) Displays the control tracing buffer.
data	(Optional) Displays the data tracing buffer.
ipc	(Optional) Displays the inter-process communication tracing buffer.
slot	(Optional) Specifies a specific slot number on the dial shelf. Slot number can range from 0 to 14.
entries *entry-number*	(Optional) Specifies the number of entries to trace. Entries can be 1 to 500.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This feature allows logging of DSIP media header information. Use the **showdsiptracing**command to obtain important information of the various classes of DSIP packets (Control/Data/IPC) coming in. You must first use the **debugdsiptracing** command then use the **showdsiptracing**command to display the logged contents. To clear the information, use the **cleardsiptracing** command.

Examples

The following is sample output from the **showdsiptracing**command:

```
Router# debug dsip tracing
DSIP tracing debugging is on
Router#
Router# show dsip tracing
Dsip Control Packet Trace:
----------------------------------------------------------------------------
Dest:00e0.b093.2238 Src:0007.5387.4808 Type:200B SrcShelf:1 SrcSlot:1 MsgType:0 MsgLen:82
Timestamp: 00:00:03
----------------------------------------------------------------------------

```

```
 Timestamp: 00:00:03
----------------------------------------------------------------------------
Dest:00e0.b093.2238 Src:0007.5387.4848 Type:200B SrcShelf:1 SrcSlot:9 MsgType:0 MsgLen:82
Timestamp: 00:00:03
```

The table below describes the significant fields shown in the display.

Table 104: show dsip tracing Field Descriptions

Field	Description
Dest	The destination MAC address in the DSIP packet.
Src	The source MAC address in the DSIP packet.
Type	There are three types of DSIP packets: • Control--0x200B • IPC--0x200C • Data--0x200D
SrcShelf	The source shelf ID of the DSIP packet.
SrcSlot	The source slot of the DSIP packet.
MsgType	Used to further demultiplex Data packets. Not used for Control and IPC type packets.
MsgLen	Length of the message excluding the DSIP header.
Timestamp	Time elapsed since the packet was received.

Related Commands

Command	Description
clear dsip tracing	Clears DSIP tracing logs.
debug dsip tracing	Enables DSIP trace logging for use with the show dsip tracing commands.
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the nodes (slots) connected by DSIP on a system.
show dsip ports	Displays information about local and remote ports.
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show dsip version	Displays DSIP version information.

show dsip transport

To display information about the Distributed System Interconnect Protocol (DSIP) transport statistics for the control/data and IPC packets and registered addresses, use the **showdsiptransport**command in EXEC mode.

show dsip transport

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showdsiptransport**command:

```
Router# show dsip transport
DSIP Transport Statistics:
 IPC : input msgs=4105, bytes=375628; output msgs=4105, bytes=248324
        total consumed ipc msgs=669;  total freed ipc msgs = 669
        transmit contexts in use = 11, free = 245, zombie = 0, invalid = 0
        ipc getmsg failures = 0, ipc timeouts=0
        core getbuffer failures=0, api getbuffer failures=0
dsip test msgs rcvd = 1200, sent = 0
 CNTL: input msgs=488, bytes=40104; output msgs=68, bytes=4080
        getbuffer failures=0
 DATA: input msgs=0, bytes=0; output msgs=426, bytes=5112

 Shelf1 : Slot12: 0007.4b67.8260, Status=remote
Router#
```

The table below describes the significant fields shown in the display:

Table 105: show dsip transport Field Descriptions

Field	Description
DSIP Transport Statistics:	There are basically three kinds of communication channels between the DSIP modules running on two processors: 1. IPC: DSIP IPC-based reliable/best-effort channel. 2. CNTL: Control packet channel for DSIP modules to communicate between themselves. For example, keepalive messages and initial handshake messages between two DSIP modules are exchanged over this channel. 3. DATA: DSIP fast data packet channel.
input msgs/output msgs	The number of input/output packets on a particular channel.
bytes	The number of input bytes received or sent on a particular channel.
total consumed ipc msgs	The total number of IPC messages consumed so far from the IPC buffer pool.
total freed ipc msgs	The total number of IPC messages returned to the IPC buffer pool so far.
transmit contexts in use	DSIP for each active reliable connection to a remote port keeps a transmit context. This context holds all the important information pertaining to the remote connection, such as, destination portid, port name, number of message and bytes sent to that port etc. This is created when first time a connection is opened to a remote port and is reused for all subsequent communication to that port.
free	Free transmit context is available.
zombie	When DSIP tears down a connection to a remote slot, all the transmit contexts to that slot should return to the free pool. But instead of immediately returning to the free pool, all such contexts first end up on a zombie queue, spend their last few seconds here and then eventually return to the free queue.
invalid	Each transmit context has a magic number. While returning contexts to the free queue, if any transmit context is found to be corrupted, it is marked as invalid and is not returned to the free queue.
ipc getmsg failures	Number of times we failed to get an ipc message.
ipc timeouts	The retry timeouts of the reliable DSIP transport stack.
core getbuffer failures	The number of times DSIP transport layer has failed to allocate buffers for the IPC transport.
aip getbuffer failures	The number of times DSIP transport has failed to allocate buffers while preparing to transmit data received from the clients.
dsip test msgs received/sent	The DSIP test messages received and sent by invoking received/sent the “DSIP Test” client.

Field	Description
DSIP Private Buffer Pool Hits	DSIP by default gets all its buffers from the public buffer pools. If for some reason, it runs out of those buffers, it falls back on a DSIP private pool. This number indicates the number of times DSIP has used this fallback pool.
DSIP Registered Addresses	The MAC addresses of nodes (slots) participating in DSIP communication including the local node. The master sees N slaves whereas slave sees only master (excluding themselves). The information is presented in the following form: Shelf*X*: Master | Slot*Y* : *MACAddress* : Status= local | remote

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the nodes (slots) connected by DSIP on a system.
show dsip ports	Displays information about local and remote DSIP ports.
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip version	Displays DSIP version information.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dsip version

To display Distributed System Interconnect Protocol (DSIP) version information, use the **showdsipversion**command in EXEC mode.

show dsip version

Syntax Description

This command has no arguments or keywords.

Command Modes

EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showdsipversion**command:

```
Router# show dsip version

DSIP version information:
------------------------
Local DSIP major version = 5,    minor version = 2

All feature boards are running DSIP versions compatible with router shelf

Local Clients Registered Versions:
------------------------------------
Client Name      Major Version   Minor Version
Console          52
Clock            1               1
Modem            0               0
Logger           No version      No version
Trunk            No version      No version
Async data       No version      No version
TDM              No version      No version
DSIP Test        No version      No version

Mismatched  Remote Client Versions:
-----------------------------------
```

DSIP is version-controlled software that should be identified and kept current.

Related Commands

Command	Description
show dsip clients	Lists the clients registered with DSIP on a system.
show dsip nodes	Displays information about the nodes (slots) connected by DSIP on a system.

Command	Description
show dsip ports	Displays information about local and remote DSIP ports.
show dsip queue	Displays the number of messages in the retransmit queue waiting for acknowledgment.
show dsip tracing	Displays DSIP tracing buffer information.
show dsip transport	Displays information about the DSIP transport statistics for the control/data and IPC packets and registered addresses.
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show dtp interface

To display the desktop publishing (DTP) interface details, use the**showdtpinterface**command in user EXEC or privileged EXEC mode.

show dtp interface [*type number*]

Syntax Description

type	Interface type. For more information, use the question mark (**?**) online help function.
number	Interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (**?**) online help function.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.4(22)T	This command was introduced in a release earlier than Cisco IOS Release 12.4(22)T.

Examples

The following is sample output from the **showdtpinterface** command:

```
Router# show dtp interface gigabitEthernet 0/0
DTP Interface Information:
  TOS/TAS/TNS:                              ACCESS/UNKNOWN/ACCESS
  TOT/TAT/TNT:                              UNKNOWN/UNKNOWN/UNKNOWN
  Neighbor address 1:                       000000000000
  Neighbor address 2:                       000000000000
  Hello timer expiration ms/state:          0/STOPPED
  Access timer expiration ms/state:         0/STOPPED
  Negotiation timer expiration ms/state:    0/STOPPED
  Multidrop timer expiration ms/state:      0/STOPPED
  FSM state:                                S1:OFF
  # times multi & trunk:                    0
  Enabled:                                  0
  In STP:                                   0
```

The following is sample output from the **showdtpinterface** command on a Catalyst 3000 series router:

```
Router# show dtp interface
DTP information for GigabitEthernet0/1:
  TOS/TAS/TNS:                                 ACCESS/AUTO/ACCESS
  TOT/TAT/TNT:                                 NATIVE/NEGOTIATE/NATIVE
  Neighbor address 1:                          000000000000
  Neighbor address 2:                          000000000000
  Hello timer expiration (sec/state):          3/RUNNING
  Access timer expiration (sec/state):         never/STOPPED
  Negotiation timer expiration (sec/state):    never/STOPPED
  Multidrop timer expiration (sec/state):      never/STOPPED
  FSM state:                                   S2:ACCESS
  # times multi & trunk                        0
  Enabled:                                     yes

```

The table below describes the significant fields shown in the display.

Table 106: show dtp interface Field Descriptions

Field	Description
TOS	Indicates the Operational Trunk state of the port, except when the port is in the Negotiation phase. In the Negotiation phase, the status is either Trunk or Access.
TAS	Indicates the Trunk Admin state of the port, which is one of the following: ON/OFF/AUTO/DESIRABLE.
TNS	Indicates the Trunk Admin state to be sent in DTP packets when the port is in S3 or S5 DTP negotiation state.
TAT	Indicates the Trunk Admin (Encapsulation) Type of the port which is one of the following: Negotiation/Native/ISL/DOT1Q
TOT	Indicates the Trunk Operation Type or current Operational Encapsulation Type of the port, which is one of the following: Native/ISL/DOT1Q.
TNT	Indicates the Trunk Operational Type to be sent in DTP packets when the port is in either S3 or S5 DTP negotiation state.
Neighbor address 1/2	Indicates the MAC address of the neighbor connected or the Neighbor Port MAC Address 1/2 in case of multi-neighbors on the same port.
Hello timer	Indicates that a DTP advertisement is sent after the timer expires. The timer keeps running as long as DTP is enabled and the port is capable of negotiating. The time interval during negotiation is 1 second, and 30 seconds when the port is in spanning tree protocol (STP) or has reached a final DTP state.
Access timer	This timer is started when the port is in Trunk state, participates in STP (state S6), and the mode is AUTO/DESIRABLE. When the timer expires, the port is set to Access state. The interval for this timer is “10 * Hello Timer.” The interval gets reset/restarted whenever the port (which is in S6 state) receives a DTP packet and confirms its present state.
Negotiation timer	This timer is started when the port enters into an S3 or S5 DTP negotiation state. When the timer expires, the DTP state of the port moves into either Trunk/Non-Trunk. The time interval is 3 seconds and the timer is restarted if the received DTP packet changes the Trunk state or type.

Field	Description
Multidrop timer	This timer is started when the port (which is in Trunk/AUTO/DESIRABLE mode) detects multiple neighbors. The port is then configured as Access port or S4 state. When the timer expires the port moves to negotiation or S2 state. After 3 seconds, port stays in S4 state and manual intervention is needed to move it to Trunk state. The interval for this timer is "10 * Hello Timer" and it gets reset or restarted whenever the port receives a DTP packet from multiple neighbors.
FSM state	Indicates the Finite State Machine State or DTP port state. There are 5 FSM states as follows: • S1: OFF: Physical port is not in the operational state. There is no data packet transmission or receipt. • S2: ACCESS: Port state is non-Trunk and is added to the STP. • S3: NT-DTP: Port state is in negotiation phase. The port is not added to the STP and there is no data packet transmission or receipt. • S4: ACCESS-M: Port state is non-Trunk and is added to the STP. Port receives the DTP packets from multiple neighbors. • S5: T-DTP: Port is in ISL/.1Q Trunk mode. Port is not added to the STP and there is no data packet transmission or receipt. • S6: TRUNK: Port state is ISL/.1Q Trunk mode and is added to the STP. **Note** In DTP, once the final state is negotiated, the port added to the STP is either in Trunk or Access state.
# times multi & trunk	Indicates the presence of multi-neighbors and their count.
Enabled/Disabled	Indicates if DTP is enabled or disabled
In STP	Indicates if the port is added to the STP or not.

Related Commands

Command	Description
show interfaces trunk	Displays interface trunking information.

show eobc

To display the information about the Ethernet out-of-band channel (EOBC) interface, use the **showeobc** command in user EXEC or privileged EXEC mode.

show eobc

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the information about the EOBC interface:

```
Router>
show eobc
EOBC0/0 is up, line protocol is up
  Hardware is DEC21143, address is 0000.2100.0000 (bia 0000.2100.0000)
  MTU 0 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not set
  Unknown duplex, Unknown Speed, MII
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:00, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 25/2147483647, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     172196 packets input, 11912131 bytes
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     172144 packets output, 11363476 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out

Related Commands

Command	Description
show environment alarm	Displays the information about the environmental alarm.
show environment status	Displays the information about the operational FRU status.

show errdisable detect

To display the error-disable detection status, use the **show errdisable detect** command in user EXEC or privileged EXEC mode.

show errdisable detect

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17b)SXA	This command was changed to include packet-buffer error status information.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the error-disable detection status:

```
Router>
show errdisable detect
ErrDisable Reason    Detection status
-----------------    ----------------
udld                 Enabled
bpduguard            Enabled
rootguard            Enabled
packet-buffer-err    Enabled
pagp-flap            Enabled
dtp-flap             Enabled
link-flap            Enabled
Router#
```

Related Commands

Command	Description
errdisable detect cause	Enables the error-disable detection.

show errdisable recovery

To display the information about the error-disable recovery timer, use the **show errdisable recovery** command in EXEC mode.

show errdisable recovery

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the information about the error-disable recovery timer:

```
Router#
show errdisable recovery
ErrDisable Reason    Timer Status
-----------------    --------------
udld                 Enabled
bpduguard            Enabled
rootguard            Enabled
pagp-flap            Enabled
dtp-flap             Enabled
link-flap            Enabled
Timer interval:300 seconds
Interfaces that will be enabled at the next timeout:
Interface    Errdisable reason    Time left(sec)
---------    -----------------    --------------
Fa9/4           link-flap             279
```

Related Commands

Command	Description
errdisable recovery	Configures the recovery mechanism variables.
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.

show esmc

To display the Ethernet synchronization message channel (ESMC) processes on a device, use the **show esmc** command in privileged EXEC mode.

show esmc [{**detail** | **interface** *type number*}]

Syntax Description

detail	(Optional) Provides a detailed display of ESMC processes.
interface *type number*	(Optional) Specifies the interface type and interface number. For more information, use the question mark (?) online help function.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2) SNI	This command was introduced into Cisco ASR 901 Aggregation Services Router.
Cisco IOS XE Release 3.8S	This command was integrated into Cisco IOS XE Release 3.8S.

Examples

The following example shows the ESMC processes enabled on a device:

```
Device# show esmc detail

Interface: GigabitEthernet0/0/0
Administrative configurations:
  Mode: Synchronous
  ESMC TX: Enable
  ESMC RX : Enable
  QL RX configured : NA
  QL TX configured : NA
Operational status:
  Port status: UP
  QL Receive: QL-SSU-B
  ESMC Information rate : 1 packet/second
  ESMC Expiry: 5 second
```

The table below describes the significant fields shown in the display.

Table 107: show esmc Field Descriptions

Field	Description
Mode	Synchronous or asynchronous mode of packet transmission.
ESMC TX	Option for transmitting ESMC data.
ESMC RX	Option for receiving ESMC data.

Field	Description
QL RX configured	Quality level receive configuration.
QL TX configured	Quality level transmit configuration.
ESMC Information rate	Rate at which ESMC information Protocol Data Unit (PDU) is transmitted in packet per second.
ESMC Expiry	Duration in which the ESMC receipt is expired.

Related Commands

Command	Description
esmc mode ql-disabled	Disables the ESMC on an interface.
esmc process	Enables the ESMC process in a device.
show interfaces accounting	Displays the number of packets of each protocol type that have been sent through all configured interfaces.

show etherchannel

To display EtherChannel information for a channel, use the **showetherchannel** command in privileged EXEC mode.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers
show etherchannel [*channel-group*] {**port-channel** | **brief** | **detail** | **summary** | **port** | **load-balance**}

Cisco Catalyst Switches
show etherchannel [*channel-group*] {**port-channel** | **brief** | **detail** | **summary** | **port** | **load-balance** | **protocol**} [*expression*]

Syntax Description

channel -group	(Optional) Number of the channel group. If you do not specify a value for the *channel -group* argument, all channel groups are displayed.
port -channel	Displays port channel information.
brief	Displays a summary of EtherChannel information.
detail	Displays detailed EtherChannel information.
summary	Displays a one-line summary per channel group.
port	Displays EtherChannel port information.
load -balance	Displays load-balance information.
protocol	Displays the enabled protocol.
expression	(Optional) Expression in the output to use as a reference point.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(7)XE	This command was introduced on Cisco Catalyst 6000 family switches.
12.1(3a)E3	This command was modified. The number of valid values for the *channel -group* argument were changed.
12.1(5c)EX	This command was modified. The number of valid values for the *channel-group* argument were changed.
12.2(2)XT	This command was modified to support switchport creation on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(14)SX	This command was implemented on the Supervisor Engine 720.
12.2(17a)SX1	This command was modified. The output of the **showetherchannelload-balance** command was changed to include IPv6 information. The display was changed to include Multiprotocol Label Switching (MPLS) information.

Release	Modification
12.2(17d)SXB	This command was modified to support the Supervisor Engine 2.
12.2(8)T	This command was modified to support switchport creation.
12.2(33)SXH	This command was modified. The output of the **showetherchannelport-channel** and the **showetherchanneldetail**commands was changed to include Link Aggregation Control Protocol (LACP) fast switchover status. The number of valid values for the *channel -group* argument was changed.
12.2(33)SRC	This command was modified. The output of the **showetherchannelport-channel** and the **showetherchanneldetail**commands was changed to show the status of the LACP Single Fault Direct Load Balance Swap feature, to show the last applied hash distribution algorithm, and to include LACP fast switchover status.
12.2(33)SXI3	This command was modified. The output of the **showetherchannelsummary**, **showetherchannelport-channel**, and **showetherchanneldetail** commands was changed to show the standalone disable option.

Usage Guidelines

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

The *channel-group* argument supports six EtherChannels and eight ports in each channel.

If you do not specify a value for the *channel-group* argument, all channel groups are displayed.

Cisco Catalyst Switches

The number of valid values for the *channel-group* argument depends on the software release. For software releases prior to Cisco IOS Release 12.1(3a)E3, valid values are from 1 to 256; for Cisco IOS Release 12.1(3a)E3, 12.1(3a)E4, and 12.1(4)E1, valid values are from 1 to 64. Cisco IOS Release 12.1(5c)EX and later support a maximum of 64 values ranging from 1 to 256. Cisco IOS Release 12.2(33)SXH supports a maximum of 64 values ranging fro m 1 to 282.

If you do not specify a value for the *channel-group* argument, all channel groups are displayed.

In the output, the Passive port list field is displayed for Layer 3 port channels only. This field means that the physical interface, which is still not up, is configured to be in the channel group (and indirectly in the only port channel in the channel group).

The *channel-group*values from 257 to 282 are supported on the Catalyst 6500 series Cisco Services Module (CSM) and the Catalyst 6500 series Firewall Services Module (FWSM) only.

In the output, the Passive port list field is displayed for Layer 3 port channels only. This field means that the physical interface, which is still not up, is configured to be in the channel group (and indirectly is the only port channel in the channel group).

If the interface is configured as part of the channel in ON mode, the**showetherchannelprotocol** command displays Protocol: - (Mode ON).

In the output of the **showetherchannelsummary** command, the following conventions apply:

- In the column that displays the protocol that is used for the channel, if the channel mode is ON, a hyphen (-) is displayed.
- For LACP, multiple aggregators are supported. For example, if two different bundles are created, Po1 indicates the primary aggregator, and Po1A and Po1B indicates the secondary aggregators.

In the output of the **showetherchannelload-balance** command, the following conventions apply:

- For EtherChannel load balancing of IPv6 traffic, if the traffic is bridged onto an EtherChannel (for example, it is a Layer 2 channel and traffic in the same VLAN is bridged across it), the traffic is always load balanced by the IPv6 addresses or src, dest, or src-dest, depending on the configuration. For this reason, the switch ignores the MAC/IP/ports for bridged IPv6 traffic. If you configure src-dst-mac, the src-dst-ip(v6) address is displayed. If you configure src-mac, the src-ip(v6) address is displayed.
- IPv6 traffic that is routed over a Layer 2 or a Layer 3 channel is load balanced based on MAC addresses or IPv6 addresses, depending on the configuration. The MAC/IP and the src/dst/src-dst are supported, but load balancing that is based on Layer 4 ports is not supported. If you use the **port** keyword, the IPv6 addresses or either src, dst, or src-dst, is displayed.

Examples

Protocol Information

The following example shows how to display the enabled protocol:

```
Router# show etherchannel protocol
Channel-group listing:
                ----------------------- 
Group: 12
----------
Protocol:  PAgP
Group: 24
----------
Protocol:   -  (Mode ON)
Router#
```

Port Channel Information for a Specific Group

The following example shows how to display port channel information for a specific group:

```
Router# show etherchannel 12 port-channel
Group: 12
----------
                Port-channels in the group:
                ----------------------
Port-channel: Po1
------------
Age of the Port-channel   = 143h:01m:12s
Logical slot/port   = 14/1           Number of ports = 2
GC                  = -              HotStandBy port = null
Port state          = Port-channel Ag-Inuse
Protocol            = LACP
Fast-switchover     = enabled
Ports in the Port-channel:
Index   Load   Port    EC state
------+------+------+------------
  0     55     Fa4/1   active
  1     AA     Fa4/2   active
Time since last port bundled:    16h:28m:58s    Fa4/1
Time since last port Un-bundled: 16h:29m:00s    Fa4/4
```

The following example shows that direct load swapping is enabled.

```
Router# show etherchannel 15 port-channel
                Port-channels in the group:
Port-channel: Po15    (Primary Aggregator)
Age of the Port-channel   = 0d:18h:16m:49s
Logical slot/port   = 14/7          Number of ports = 1
HotStandBy port = null
Port state              = Port-channel Ag-Inuse
Protocol                =   LACP
! The following line of output is added with support
of the LACP Single Fault Direct Load Swapping feature. !
Direct Load Swap = enabled
Ports in the Port-channel:

```

Load Balancing

The following examples show how to display load-balancing information:

```
Router#
 show etherchannel load-balance
Source XOR Destination mac address
Router#
 show etherchannel load-balance
EtherChannel Load-Balancing Configuration:
        dst-mac
        mpls label-ip
EtherChannel Load-Balancing Addresses Used Per-Protocol:
Non-IP: Destination MAC address
  IPv4: Destination MAC address
  IPv6: Destination MAC address (routed packets)
        Destination IP address (bridged packets)
  MPLS: Label or IP
```

Summary Information for a Specific Group

The following example shows how to display a summary of information for a specific group:

```
Router#
show etherchannel 1 brief
Group state = L3
Ports: 2   Maxports = 8
port-channels: 1 Max port-channels = 1
Partner's information:
```

The following example shows the hash distribution algorithm that was last applied:

```
Router# show etherchannel
 10 summary
Flags:  D - down        P - bundled in port-channel
        I - stand-alone s - suspended
        H - Hot-standby (LACP only)
        R - Layer3      S - Layer2
        U - in use      N - not in use, no aggregation
        f - failed to allocate aggregator
```

```

Related Commands

Command	Description
channel-group	Assigns and configures an EtherChannel interface to an EtherChannel group.
channel-protocol	Sets the protocol that is used on an interface to manage channeling.
interface port-channel	Accesses or creates the IDB port channel.

show etherchannel load-balancing

To display the load-balancing method applied to Gigabit EtherChannel (GEC) interfaces, use the **showetherchannelload-balancing** command in user EXEC or privileged EXEC mode.

show etherchannel load-balancing

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.
Cisco IOS XE Release 2.5	This command was modified. Information about the port-channel configuration and flow-based load balancing was added to the output.

Usage Guidelines

The **showetherchannelload-balancing** command shows which load-balancing method is applied to the port channels of a GEC interface, both at the global level and for each port channel.

There are two methods of load balancing on a GEC interface:

- VLAN-manual--All packets forwarded over the same VLAN subinterface are considered part of the same flow and are mapped to the member link specified in the configuration.
- Flow-based--Traffic flows are mapped to different member links based on the packet header.

Examples

The following example shows output from this command for a port channel configured with VLAN-manual load balancing:

```
Router# show etherchannel load-balancing

EtherChannel Load-Balancing Method:
Global LB Method: vlan-manual

  Port-Channel:                       LB Method
    Port-channel1                   :  vlan-manual
```

The table below describes the significant fields shown in the display.

Table 108: show etherchannel load-balancing Field Descriptions

Field	Description
Global LB Method	Load balancing method set globally for all port channels with the **port-channelload-balancingvlan-manual** command.
Port Channel LB Method	Load balancing method set for the specific port channels with the **load-balancing**command. This configuration takes precedence over the global configuration.

Related Commands

Command	Description
load-balancing	Applies a load-balancing method to a GEC interface.
port-channel load-balancing vlan-manual	Applies the VLAN-manual load-balancing method globally to all GEC interfaces.
show interfaces port-channel etherchannel	Displays the load-balancing bucket distribution currently in use for a GEC interface.

show fabric

To display the information about the crossbar fabric, use the **showfabric** command in EXEC mode.

show fabric [**active**]
show fabric {**channel-counters** | **errors** | **status**} [{*slot* | **all**}]
show fabric switching-mode [**module** {*slot* | **all**}]
show fabric utilization [{*slot* | **all**}]

Syntax Description

active	(Optional) Displays the redundancy status for the Switch Fabric Module.
channel-counters	Displays the fabric channel-counter information.
errors	Displays the errors that are associated with the crossbar fabric; see the "Usage Guidelines" section for additional information.
status	Displays the current status of the fabric channel.
slot	(Optional) Number of the slot.
all	(Optional) Displays the information for all modules using the crossbar fabric.
switching-mode	Displays the module switching mode; see the "Usage Guidelines" section for additional information.
module *slot*	(Optional) Displays the switching mode for the specified slot.
module all	(Optional) Displays the switching mode for all installed modules.
utilization	Displays the percentage utilization for each fabric channel.

Command Default

This command has no default settings.

Command Modes

EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

If you specify *slot*, the information is displayed for the specified slot. If you specify **all**, the information for all slots using the crossbar fabric is displayed. If you do not specify *slot* or **all**, the display is the same as if you entered **all**.

To display all the related crossbar fabric information, enter the **showfabric** command without keywords.

A fabric channel is each connection between a module and the crossbar fabric module. Each module can have zero, one, or two fabric channels. The more fabric channels that a module has, the more overall bandwidth is available to the module.

The following errors are associated with the crossbar fabrics:

- Synchronization errors--General errors are the most common types of errors.
- Heartbeat errors--The supervisor engine sends out periodic heartbeat packets to each module using the crossbar fabric. If any of these modules or the crossbar fabric fail to detect heartbeat packets for a period of time, this error is reported.
- CRC errors--All packets crossing the crossbar fabric are CRC protected. If any of the ASICs between a module and the crossbar fabric module detect a CRC error, this error is reported.

The three types of fabric switching modes are as follows:

- Bus--Packets that travel across the traditional backplane and that are shared by all modules to be switched by the supervisor engine. Modules without the crossbar fabric connectors are restricted to this mode. The 48-port 10/100TX RJ-45 module is an example of this module type.
- Crossbar--Packets with headers only that travel across the traditional backplane to be switched by the supervisor engine and that travel across the crossbar fabric. The 16-port Gigabit Ethernet GBIC switching module is an example of this module type.
- dCEF--Packets that are switched by the module and that travel across the crossbar fabric. The 16-port Gigabit Ethernet GBIC switching module and the 16-port Gigabit Ethernet module are examples of this module type. The 16-port Gigabit Ethernet GBIC switching module can be in any of these three modes, but the 16-port Gigabit Ethernet module can only be in dCEF mode.

The threshold information is shown only when you enter the **nofabricswitching-modeallowtruncated** command.

In the **showfabricswitching-mode** command output, the possible global switching modes are as follows:

- Flow-through (Bus)--Mode that the switch uses for traffic between nonfabric-enabled modules and for traffic between a nonfabric-enabled module and a fabric-enabled module. In this mode, all traffic passes between the local bus and the supervisor engine bus.
- Truncated--Mode that the switch uses for traffic between fabric-enabled modules when both fabric-enabled and nonfabric-enabled modules are installed. In this mode, the switch sends a truncated version of the traffic (the first 64 bytes of the frame) over the switch fabric channel.
- Compact--Mode that the switch uses for all traffic when only fabric-enabled modules are installed. In this mode, a compact version of the DBus header is forwarded over the switch fabric channel, which provides the best possible performance.

In the **showfabricswitching-mode** command output , depending on the supervisor engine installed, the following messages appear:

- With a Supervisor Engine 2, this message is included in the output:

```
An enabled Switch Fabric is not required for the system to operate
```

- With a Supervisor Engine 720, this message is included in the output:

```
Fabric module is not required for system to operate
```

Examples

This example shows how to display the redundancy status of the Switch Fabric Module:

```
Router# show fabric active
Active fabric card in slot 5
No backup fabric card in the system
Router#
```

This example shows how to display the channel-counter information:

```
Router# show fabric channel-counters
slot channel   rxErrors   txErrors  txDropped
    1       0          0          0          0
Router#
```

This example shows how to display the errors that are associated with the crossbar fabric:

```
Router# show fabric errors
Module errors:
slot     channel        crc      hbeat       sync      DDR sync
   1           0          0          0          0             0
   8           0          0          0          0             0
   8           0          0          0          0             0
   9           0          0          0          0             0
Fabric errors:
slot     channel       sync     buffer    timeout
   1           0          0          0          0
   8           0          0          0          0

   9           0          0          0          0
Router#
```

This example shows how to display the module switching mode:

```
Router# show fabric switching-mode
Global switching mode is Truncated
An enabled Switch Fabric is not required for the system to operate
Modules are allowed to operate in bus mode
Truncated mode is not allowed unless threshold is met
Threshold for truncated mode operation is 2 SFM-capable cards
 Module Slot     Switching Mode
     1           Bus
     2           Crossbar
     3           Crossbar
     4           Bus
     5           No Interfaces
     7           DCEF
     9           DCEF
Router#
```

This example shows how to display the fabric-channel status:

```
Router# show fabric status
slot    channel      speed           module           fabric
                                      status            status
    1          0         8G              OK                OK
    5          0         8G              OK      Up- Timeout
    6          0        20G              OK     Up- BufError
```

```
    8          0          8G              OK               OK
    8          1          8G              OK               OK
    9          0          8G    Down- DDRsync              OK
Router#
```

This example shows how to display the percentage utilizations for all fabric-enabled channels:

```
Router# show fabric utilization all
slot    channel  Ingress %   Egress %
    1          0          0          0
crc       hbeat       sync       sync
    1          0          0          0          0          0
Router#
```

show fm features

To display the information about the feature manager, use the **showfmfeatures** command in user EXEC or privileged EXEC mode.

show fm features

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the information about the feature manager:

```
Router>
show fm features
Designated MSFC:1 Non-designated MSFC:1
Redundancy Status:designated
Interface:FastEthernet2/10 IP is enabled
  hw[EGRESS] = 1, hw[INGRESS] = 1
  hw_force_default[EGRESS] = 0, hw_force_default[INGRESS] = 0

          feature #:1
          feature id:FM_IP_ACCESS
          ACL:101
Router>
```

This example shows how to display the lines of feature manager information starting with the line that begins with Redundancy:

```
Router>
show fm features | begin Redundancy
Redundancy Status: designated
Router>
```

Related Commands

Command	Description
show fm summary	Displays a summary of FM Information.

show fm inband-counters

To display the number of inband packets that are sent by the Multilayer Switching Feature Card (MSFC) for server load balancing (SLB) and Web Cache Coprocessor Protocol (WCCP), use the **showfminband-counters** command in privileged EXEC mode.

show fm inband-counters

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The output display for the **showfminband-counters** command includes the number of SLB inband packets that are sent by the MSFC and the number of WCCP inband packets that are sent by the MSFC.

If CBAC is configured, the command output displays the number of packets that are sent for CBAC by the MSFC.

Examples

This example shows how to display the number of SLB and WCCP inband packets that are sent by the MSFC:

```
Router# show fm inband-counters
Inband Packets Sent
 Slot  WCCP          SLB
 1     0             0
 2     0             0
 3     0             0
 4     0             0
 5     0             0
 6     0             0
 7     0             0
 8     0             0
 9     0             0
 10    0             0
 11    0             0
 12    0             0
 13    0             0
Router#
```

show gnss

To display the output of the GNSS configuration, use the **show gnss** command in privileged EXEC mode.

show gnss [{**location** | **satellite** | **status** | **time** | **device**}]

Syntax Description

location	(Optional) Displays the location of the GNSS module.
satellite	(Optional) Displays the satellites configured or detected by the GNSS module.
status	(Optional) Displays the status of the GNSS module.
time	(Optional) Displays the time on the GNSS module.
device	(Optional) Displays the hardware information of the active GNSS module.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.17	This command was introduced.

Usage Guidelines

Use this command to verify the GNSS configuration.

Examples

The following examples show the output generated by this command:

```
Router# show gnss

Current GNSS Location:

LOC: 12:56.183600 N 77:41.768000 E 819.10 m

Router# show gnss satellite all

All Satellites Info:

----------------------------------------------------------------------------------
21          0                1          1                 0           47
14          1                1          1                 0           48
18          2                1          1                 0           49
22          3                1          1                 0           46
27          4                1          1                 0           44
24          5                1          1                 0           44
31          6                1          1                 0           47

Router# show gnss status

GNSS status:

GNSS device: detected
Lock status: Power-up
Receiver Status: Auto
Clock Progress: Phase Locking
```

```
Survey progress: 100
Satellite count: 7
Holdover Duration: 0
PDOP: 1.01 TDOP: 1.00
HDOP: 0.71 VDOP: 0.72
Minor Alarm: ANTENNA_OPEN NOT_DISCIPLINING_OSC
Major Alarm: None

Router# show gnss time

Current GNSS Time:

Time: 2015/11/30 10:20:33 UTC Offset: 17

Router# show gnss device
GNSS device:

  Serial number: FOC2130ND5X
  Firmware version: 1.4
  Firmware update progress: NA
  Authentication: Passed
```

In the **show gnss device** command output, serial number and authentication information is shown only for pluggable GNSS module like Cisco ASR 903. It is not shown for Cisco ASR 920.

show gtp

To display information related to Enhanced Wireless Access Gateway (EWAG) General Packet Radio Service (GPRS) Tunneling Protocol (GTP), use the **show gtp** command in privileged EXEC mode.

show gtp {**apn** [**statistics**] {*apn-index* | **all**} | **mcsa statistics** | **parameters** | **path** {**all** | [{**statistics**}] **remote-address** *path-address* [{**vrf** *vrf-name*}]} | **pdp-context** {**all** | **apn** *apn-index* | **imsi** *imsi-value* [{**detail**}] | **ms-address** *end-user-address* [{**vrf** *vrf-name*}] [{**detail**}] | **msisdn** *msisdn-value* [{**detail**}] | **teid-u** *user-teid* [{**detail**}]} | **statistics** | **tunnel** *interface type*}

Syntax Description

apn	Displays Access Point Name (APN) information.
apn-index	Index of the APN.
all	Displays information about all APNs.
statistics	(Optional) Displays information about APN counters.
mcsa statistics	Displays statistical information about Mobile Client Service Abstraction (MCSA) counters.
parameters	Displays information about GTP parameters.
path	Displays information about GTP path.
all	Displays information about all GTP paths.
statistics	Displays statistics related to a path.
remote-address *path-address*	Displays GTP path for a specified path address.
vrf *vrf-name*	Specifies the virtual routing and forwarding (VRF) containing the IP address.
pdp-context	Displays information about GTP Packet Data Protocol (PDP) data structures.
all	Displays information about all PDPs.
apn *apn_index*	Displays information about PDPs for the specified APN.

imsi *imsi_value*	Displays information about PDPs for the specified International Mobile Subscriber Identity (IMSI) value.
detail	Displays information about PDPs for the specified IMSI value in detail.
ms-address *end-user-address*	Displays information about PDPs for a specified end-user IPv4 address.
teid-u *user-teid*	Displays information about PDPs for a specified Tunnel Endpoint Identifier (TEID) user.
statistics	Displays information about GTP counters.
tunnel *interface type*	Displays information about GTP tunnels.

Command Default

This command has no defaults.

Command Modes

Previliged EXEC (#)

Command History

Release	Modification
Cisco IOS Release XE 3.8S	This command was introduced.

Usage Guidelines

Examples

The following is sample output of **show gtp apn** command:

```
Device# show gtp apn 1

apn_index   : 1            apn_name = starent.com
GGSN Addr   : 10.1.2.1
Primary DNS : 10.1.2.1
DHCP Addr   : 10.10.197.1     DHCP Lease: 6000
Tunnel MTU  : 1500
Number of active PDPs in this APN : 0

Default GW      Prefix Length Name              MAC Address     PDP Count
```

The table below describes the significant fields shown in the display.

Table 109: show gtp apn Field Descriptions

Field	Description
apn_index	Index of the APN.
apn_name	Name of the APN.
GGSN Addr	Gateway GPRS Support Node (GGSN) IP address of the APN.
Primary DNS	Primary Domain Name System (DNS) Address of the APN.
DHCP Addr	DHCP Address of the APN
Tunnel MTU	Maximum Transmission unit of a tunnel.
DHCP Lease	DHCP lease time in seconds.
Number of active PDPs in this APN	Number of active PDPs in the APN.

Related Commands

Command	Description
debug gtp	Debugs EWAG GTP.
gtp	Enables EWAG GTP.

show hspw-aps-icrm

To view information about hot standby pseudowires (HSPW), use the **showhspw-aps-icrm** command in privileged EXEC mode.

show hspw-aps-icrm {**group** *group-id* | **all**}

Syntax Description

group	Specifies the HSPW Automatic Protection Switching (APS) group.
group-id	HSPW APS group identifier.
all	Displays all the HSPW APS and inter chassis redundancy manager (ICRM) groups.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS 15.2(1)S	This command was introduced.
Cisco IOS XE 3.11S	This command was integrated into Cisco IOS XE Release 3.11S.

Usage Guidelines

Use this command to display information about a particular HSPW APS group or all HSPW APS and ICRM groups.

The following is sample output from the **show hspw-aps-icrm** command when **group** *group-id* is used to display information about a particular HSPW APS group:

```
Router# show hspw-aps-icrm group 100

ICRM group id 100, Flags : My core isolated No,Peer core isolated No,
State Connect
APS Group id 1 hw_if_index 33 APS valid:Yes
Total aps grp attached to ICRM group 100 is 1
```

Displaying Information About All HSPW APS and ICRM Groups

The following is sample output from the **show hspw-aps-icrm** command when **all** is used to display information about all the HSPW APS and ICRM groups:

```
Router# show hspw-aps-icrm all

ICRM group id 100, Flags : My core isolated No,Peer core isolated No,
State Connect
APS Group id 1 hw_if_index 33 APS valid:Yes
Total aps grp attached to ICRM group 100 is 1 ICRM group count
attached to MR-APS HSPW feature is 1
```

Related Commands

Command	Description
show aps	Displays information about the current APS feature on the router.

show hub

To display information about the hub (repeater) on an Ethernet interface of a Cisco 2505 or Cisco 2507 router, use the **showhub** command in user EXEC or privileged EXEC mode.

show hub commandshow hub [**ethernet** *number* [*port* [*end-port*]]]

Syntax Description

ethernet	(Optional) Indicates that this is an Ethernet hub.
number	(Optional) Hub number, starting with 0. Because there is currently only one hub, this number is 0.
port	(Optional) Port number on the hub. On the Cisco 2505 router, port numbers range from 1 to 8. On the Cisco 2507 router, port numbers range from 1 to 16. If a second port number follows, this port number indicates the beginning of a port range.
end-port	(Optional) Ending port number of a range.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not specify a port or port range for the **showhub** command, the command displays all ports (for example, ports 1 through 16 on a Cisco 2507 router) by default. Therefore, the **showhub**, **showhubethernet0**, and **showhubethernet0116** commands produce the same result.

If no ports are specified, the command displays some additional data about the internal port. The internal port is the hub's connection to Ethernet interface 0 inside the box. Ethernet interface 0 still exists; physical access to the interface is via the hub.

Examples

Information for a Specific Port

The following is sample output from the **showhub** command for hub 0, port 2 only:

```
Router# show hub ethernet 0 2
Port 2 of 16 is administratively down, link state is down
  0 packets input, 0 bytes
  0 errors with 0 collisions
     (0 FCS, 0 alignment, 0 too long,
      0 short, 0 runts, 0 late,
      0 very long, 0 rate mismatches)
  0 auto partitions, last source address (none)
  Last clearing of "show hub" counters never
```

```
Repeater information (Connected to Ethernet0)
  2792429 bytes seen with 18 collisions, 1 hub resets
  Version/device ID 0/1 (0/1)
  Last clearing of "show hub" counters never
```

Information for All Ports

The following is sample output from the **showhub** command for hub 0, all ports:

```
Router# show hub ethernet 0
Port 1 of 16 is administratively down, link state is up
  2458 packets input, 181443 bytes
  3 errors with 18 collisions
     (0 FCS, 0 alignment, 0 too long,
      0 short, 3 runts, 0 late,
      0 very long, 0 rate mismatches)
  0 auto partitions, last source address was 0000.0cff.e257
  Last clearing of "show hub" counters never
.
.
.
Port 16 of 16 is down, link state is down
  0 packets input, 0 bytes
  0 errors with 0 collisions
     (0 FCS, 0 alignment, 0 too long,
      0 short, 0 runts, 0 late,
      0 very long, 0 rate mismatches)
  0 auto partitions, last source address (none)
  Last clearing of "show hub" counters never

Repeater information (Connected to Ethernet0)
  2792429 bytes seen with 18 collisions, 1 hub resets
  Version/device ID 0/1 (0/1)
  Last clearing of "show hub" counters never

Internal Port (Connected to Ethernet0)
  36792 packets input, 4349525 bytes
  0 errors with 14 collisions
     (0 FCS, 0 alignment, 0 too long,
      0 short, 0 runts, 0 late,
      0 very long, 0 rate mismatches)
  0 auto partitions, last source address (none)
  Last clearing of "show hub" counters never
```

The table below describes significant fields shown in the display.

*Table 110: **show hub** Field Descriptions*

Field	Description
Port ... of ... is administratively down	Port number out of total ports; indicates whether the interface hardware is currently active or down because of the following: • The link-state test failed. • The MAC address mismatched when source address configured. • It has been taken down by an administrator.

Field	Description
link state is up	Indicates whether port has been disabled by the link-test function. If the link-test function is disabled by the user, nothing will be shown here.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
errors	Sum of FCS, alignment, too long, short, runts, very long, and rate mismatches.
collisions	Number of messages retransmitted due to Ethernet collisions.
FCS	Counter for the number of frames detected on the port with an invalid frame check sequence.
alignment	Counter for the number of frames of valid length (64 to 1518 bytes) that have been detected on the port with an FCS error and a framing error.
too long	Counter for the number of frames that exceed the maximum valid packet length of 1518 bytes.
short	Counter for the number of instances when activity is detected with duration less than 74 to 82 bit times.
runts	Number of packets that are discarded because they are smaller than the medium's minimum packet size. For example, any Ethernet packet that is less than 64 bytes is considered a runt.
late	Counter for the number of instances when a collision is detected after 480 to 565 bit times in the frame.
very longs	Counter for the number of times the transmitter is active in excess of 4 to 7.5 milliseconds.
rate mismatches	Counter for the number of occurrences when the frequency, or data rate of incoming signal is noticeably different from the local transmit frequency.
auto partitions	Counter for the number of instances where the repeater has partitioned the port from the network.
last source address	Source address of last packet received by this port. Indicates "none" if no packets have been received since power on or a hub reset.
Last clearing of "show hub" counters	Elapsed time since the **clearhubcounters** command was entered. Indicates "never" if counters have never been cleared.
Repeater information (Connected to Ethernet0)	Indicates that the following information is about the hub connected to the Ethernet interface shown.
... bytes seen with ... collisions, ... hub resets	Hub resets is the number of times the hub has been reset by network management software or by the **clearhub** command.

Field	Description
Version/device ID 0/1 (0/1)	Hub hardware version. IMR+ version device of daughter board.
Internal Port (Connected to Ethernet0)	Set of counters for the internal AUI port connected to the Ethernet interface.

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

show hw-module all fpd

To display the current versions of all field-programmable devices (FPDs) for all of the supported card types on a router, enter the **showhw-moduleallfpd** command in privileged EXEC mode.

show hw-module all fpd

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.

12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.4(15)T	Added an example for the PA-MC-T3-EC port adapter.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco 4400 Series ISRs in Cisco IOS XE Release 3.9S

Usage Guidelines

Other than the FPD version information, the output for this command can also contain useful FPD-related notes.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

In Cisco IOS Release 12.2(33)SCB, the FPD image upgrade is supported only for the SPAs inserted in the SIP-600 jacket card on a Cisco uBR10012 router.

Examples

Cisco 7200 VXR

The following example shows an FPD image file version that requires an upgrade (indicated by the asterisk) for the NPE-G2 network processing engine in the Cisco 7200 VXR router:

```
Router# show hw-module all fpd
==== ====================== ====== =============================================
                             H/W    Field Programmable   Current   Min. Required
```

```
Slot Card Type              Ver.  Device: ID-Name    Version      Version
==== ====================== ====== ================== =========== ==============
 npe NPE-G2                 1.5   1-NPEG2 I/O FPGA       0.18         0.20 *
---- ---------------------- ------ ------------------ ----------- --------------
   0 VSA                    0.0   1-VSA                  0.10         0.10
==== ====================== ====== ==============================================
NOTES:
       - FPD images that are required to be upgraded are indicated with a '*'
         character in the Minimal Required Version field.
       - The following FPD image package file is required for the upgrade:
         c7200-fpd-pkg.124-4.XD.pkg
```

The following example shows that all FPDs for the port adapter have the minimum required version. For the NPE-400, the "###" characters in the ID-Name, Current Version, and Min, Required Version fields indicate that FPD does not apply to the NPE-400.

```
Router# show hw-module all fpd
==== ====================== ====== ==============================================
                            H/W   Field Programmable   Current   Min. Required
Slot Card Type              Ver.  Device: ''ID-Name''  Version      Version
==== ====================== ====== ================== =========== ==============
 npe NPE-400                1.1   ############           #.#         #.#
---- ---------------------- ------ ------------------ ----------- --------------
   1 PA-MC-1T3-EC           1.0   1-ToySurprise FPGA     1.2         1.1
                                  2-Subrate FPGA         1.4         1.4
                                  3-Rommon/IPL           2.0         2.0
==== ====================== ====== ==============================================
```

Cisco 7600 Series

The following example shows FPD image file versions for all SIPs and SPAs in the Cisco 7600 series router:

```
Router# show hw-module all fpd
==== ====================== ====== ==============================================
                            H/W   Field Programmable   Current   Min. Required
Slot Card Type              Ver.  Device: ID-Name    Version      Version
==== ====================== ====== ================== =========== ==============
   4 7600-SIP-200           0.132 1-I/O FPGA             0.19        0.18
                                  2-EOS FPGA             0.22        0.22
                                  3-PEGASUS TX FPGA      0.121       0.121
                                  4-PEGASUS RX FPGA      0.13        0.13
                                  5-ROMMON               1.1         1.1
---- ---------------------- ------ ------------------ ----------- --------------
 4/0 SPA-4XOC3-ATM          1.0   1-I/O FPGA             0.121       0.121
---- ---------------------- ------ ------------------ ----------- --------------
 4/1 SPA-8XCHT1/E1          0.117 1-ROMMON               2.12        2.12
                                  2-I/O FPGA             0.22        0.22
---- ---------------------- ------ ------------------ ----------- --------------
 4/3 SPA-4XCT3/DS0          0.253 1-ROMMON               2.12        2.12
                                  2-I/O FPGA             0.21        0.21
                                  3-T3 SUBRATE FPGA      0.15        0.15
==== ====================== ====== ==============================================
```

The following example shows FPD image file versions that require an upgrade (indicated by the asterisk) for two SIPs in the Cisco 7600 series router. The SIPs are disabled due to the version mismatch.

```
Router# show hw-module all fpd
```

```
==== ====================== ====== =============================================

will be added later

Related Commands

Command	Description
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.

show hw-module slot (6500)

To display information for a SPA interface processor (SIP) or a module, use the **showhw-moduleslot** command in privileged EXEC configuration mode.

show hw-module slot *slot* {**clear-block** | **oversubscription** | **port-group-mapping**}

Syntax Description

slot	Specifies the chassis slot number. See the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
clear-block	Displays the clearing of the head-of-line blocking status.
oversubscription	Displays the oversubscription mode of each port-group.
port-group-mapping	Displays the port group mapping.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXF5	Support for this command was introduced (Catalyst 6500 series switch).
12.(33)SXH1	This command was changed to add the **oversubscription** and the **port-group-mapping** keywords (Catalyst 6500 series switch).
12.2(33)SXH2	This command was changed to support the following modules: • WS-X6716-10G-3C • WS-X6716-10G-3CXL

Usage Guidelines

This command is supported on the following modules:

- WS-X6708-10G-3C--The port-group**mapping** and the clear-block keywords are not supported.
- WS-X6708-10G-3CXL--The port-group *num* and the clear-block keywords and argument are not supported.
- WS-X6716-10G-3C
- WS-X6716-10G-3CXL

The port-group mappings for the WS-X6716-10G-3C and the WS-X6716-10G-3CXL modules are as follows:

- Group 1--Ports 1 to 4. Port 1 is enabled in transparent mode.
- Group 2--Ports 5 to 8. Port 5 is enabled in transparent mode.
- Group 3--Ports 9 to 12. Port 9 is enabled in transparent mode.

- Group 4--Ports 13 to 16. Port 13 is enabled in transparent mode.

For the WS-X6716-10G-3C and the WS-X6716-10G-3CXL modules in transparent mode, ports 2, 3, 4, 6, 7, 8, 10, 11, 12, 14, 15, 16 are disabled.

Examples

This example shows how to display the current configuration status for the four port-groups:

```
Router# show hw-module slot 2 clear-block
Port-group Clear-block
1          Enabled
2          Disabled
3          Disabled
4          Enabled
Router#
```

This example shows how to display the port group mapping of each port group:

```
Router# show hw-module slot 2 port-group-mapping
Port-group Ports
1          1, 2, 3, 4
2          5, 6, 7, 8
3          9, 10, 11, 12
4          13, 14, 15, 16
```

This example shows how to display the oversubscription mode of each port group:

```
Router# show hw-module slot 3 oversubscription
Port-group oversubscription mode
1          Enabled
2          Disabled
3          Enabled
4          Disabled
Router#
```

Related Commands

Command	Description
hw-module oversubscription	Administratively enables or disables the oversubscribed ports on a module.

show hw-module slot align

To display alignment data for a SPA interface processor (SIP) or other module, use the **showhw-moduleslotalign** command in privileged EXEC configuration mode.

show hw-module slot *slot* **align** [**cpu** {**0** | **1**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
cpu 0 |**1**	(Optional) Number of the CPU (0 or 1) for which you want to display data.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The number of CPUs available varies by the type of SIP. Although the Cisco 7600 SIP-200 has two CPUs, you can display alignment data for the first CPU (CPU 0) only.

Examples

The following example shows that there has not been any alignment data for the SIP installed in slot 2 of the router:

```
Router# show hw-module slot 2 align
No alignment data has been recorded.
No spurious memory references have been recorded.
```

show hw-module slot fpd

To display the current versions of all field-programmable devices (FPDs) for a SIP in the specified slot location and for all of the SPAs installed in that SIP, or to display the current versions of any FPD-capable cards, enter the **showhw-moduleslotfpd** command in privileged EXEC mode.

Cisco 7200 VXR
show hw-module slot {*slot* | **npe**} **fpd**

Cisco 7304, Cisco 7600 Series, Cisco 12000 Series
show hw-module slot *slot* **fpd**

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide. For slot numbering in the Cisco 7200 VXR router, refer to the Cisco 7200 VXR Installation and Configuration Guide .
npe	NPE-G2 network processing engine in the Cisco 7200 VXR router.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD	This command was integrated into Cisco IOS Release 12.4(4)XD, and the npe keyword was added.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.

Usage Guidelines

Use the **showhw-moduleslotfpd** command to show the FPD image version information for a particular SIP and all of its installed SPAs, or to display the current versions of FPD-capable cards in the Cisco 7200 VXR router. To display FPD information for all of the supported card types on a router, use the **showhw-moduleallfpd** command.

Other than the FPD version information, the output for this command can also contain useful FPD-related notes.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

Cisco 7200 VXR

The following example shows that the FPD version on the NPE-G2 meets the minimum FPD version requirements:

```
Router# show hw-module slot npe fpd
==== =================== ====== =============================================
                             H/W   Field Programmable   Current   Min. Required
Slot Card Type               Ver.  Device: "ID-Name"    Version      Version
==== =================== ====== ================== =========== ==============
 npe NPE-G2                  1.3   1-NPEG2 I/O FPGA       0.19        0.1
==== =================== ====== =============================================
```

The following example shows FPD information for the VPN Services Adapter (VSA) in slot 0:

```
Router# show hw-module slot 0 fpd
==== =================== ====== =============================================
                             H/W   Field Programmable   Current   Min. Required
Slot Card Type               Ver.  Device: "ID-Name"    Version      Version
==== =================== ====== ================== =========== ==============
   0 VSA                     0.0   1-VSA                  0.9         0.8
==== =================== ====== =============================================
```

Cisco 7600 Series

The following example shows that the FPD versions on the SIP installed in chassis slot 4, and each of its installed SPAs, meet the minimum FPD version requirements:

```
Router# show hw-module slot 4 fpd
==== ====================== ====== =============================================
                                H/W   Field Programmable   Current   Min. Required
Slot Card Type                  Ver.  Device: "ID-Name"    Version      Version
==== ====================== ====== ================== =========== ==============
   4 7600-SIP-200               0.550 1-I/O FPGA             1.1         1.1
                                      2-EOS FPGA             1.211       1.211
                                      3-PEGASUS TX FPGA      1.129       1.129
                                      4-PEGASUS RX FPGA      1.3         1.3
                                      5-ROMMON               1.2         1.2

==== ====================== ====== =============================================
```

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.

Command	Description
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.

show hw-module slot logging

To display logging information for a SPA interface processor (SIP) or other module, use the **showhw-moduleslotlogging** command in privileged EXEC configuration mode.

show hw-module slot *slot* **logging** [**cpu** {**0** | **1**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
cpu 0 |**1**	(Optional) Number of the CPU (0 or 1) for which you want to display data.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The number of CPUs available varies by the type of SIP. Although the Cisco 7600 SIP-200 has two CPUs, you can display alignment data for the first CPU (CPU 0) only.

Examples

The following example shows logging information and messages for the SIP installed in slot 2 of the router:

```
Router# show hw-module slot 2 logging
Syslog logging: enabled (0 messages dropped, 2 messages rate-limited, 0 flushes,
 0 overruns)
    Console logging: level debugging, 90 messages logged
    Monitor logging: level debugging, 0 messages logged
    Buffer logging: level debugging, 92 messages logged
    Exception Logging: size (4096 bytes)
    Count and timestamp logging messages: disabled
Log Buffer (8192 bytes):
00:00:01:  hyp_dev_attach
00:00:01:  hyp_dev_init
00:00:01:  hyp_init

show hw-module slot proc cpu

To display CPU utilization for each process on a SPA interface processor (SIP) or other module, use the **showhw-moduleslotproccpu**command in privileged EXEC configuration mode.

show hw-module slot *slot* **proc cpu** [**cpu** {**0** | **1**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
cpu 0 |1	(Optional) Number of the CPU (0 or 1) for which you want to display data.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The number of CPUs available varies by the type of SIP. Although the Cisco 7600 SIP-200 has two CPUs, you can display alignment data for the first CPU (CPU 0) only.

Examples

The following example shows CPU utilization per process for the SIP installed in slot 2 of the router:

```
Router# show hw-module slot 2 proc cpu
CPU utilization for five seconds: 0%/0%; one minute: 0%; five minutes: 0%
 PID Runtime(ms)   Invoked      uSecs   5Sec   1Min   5Min TTY Process

show hw-module slot tech-support through show interfaces vg-anylan

show hw-module slot tech-support

To display system information for a SPA interface processor (SIP) or other module to troubleshoot a problem, use the **showhw-moduleslottech-support**command in privileged EXEC configuration mode.

show hw-module slot *slot* **tech-support** [**cpu** {**0** | **1**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
cpu 0 |1	(Optional) Number of the CPU (0 or 1) for which you want to display data.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **showhw-moduleslottech-support** command to gather information about the SIP or other module to troubleshoot a problem. Certain error messages request that you gather this information and have it available when reporting a problem to Cisco Systems technical support personnel.

The **showhw-moduleslottech-support**command runs a collection of different **show** commands to gather information about your system environment and configuration.

The number of CPUs available varies by the type of SIP. Although the Cisco 7600 SIP-200 has two CPUs, you can display alignment data for the first CPU (CPU 0) only.

Examples

The following example shows system information for the SIP installed in slot 5 of the router:

show hw-module subslot

To display diagnostic information about internal hardware devices for a SPA, use the **show hw-module subslot** command in privileged EXEC configuration mode.

To display diagnostic information about modules and interfaces on a Cisco 4400 Series ISR, use the **show hw-module subslot** command in privileged EXEC mode.

show hw-module subslot [*slot*/*subslot*] {**brief** | **config** | **counters** | **errors** | **registers** | **status**} **device** *port*

Cisco 4400 Series Integrated Services Router (ISR)

show hw-module subslot [*slot*/*subslot*]
all | **attribute** | **entity** | **fpd** | **oir** | **sensors** | **subblock**

Syntax Description

slot	(Optional) Chassis slot number or module interface slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. For more information on slots for the Cisco 4400 Series ISR, refer to hardware installation guide.
/subslot	(Optional) Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information. For more information on subslots for the Cisco 4400 Series ISR, refer to hardware installation guide.
all*subslot*	Selects all supported modules and displays diagnostic and register information related to the modules including: • **attribute**--Detailed module attribute information • **entity**--MIB details of an entity[1]. • **fpd**--Field programmable devices (fpd) information • **oir**--Online insertion and removal (oir) summary • **sensors**--Environmental sensor summary • **subblock**--Internal data structure related to the supported module[1] • **tech-support**--Subslot information for technical support

brief config | **counters errors** | **registers status**	Specifies the display of diagnostic and register information related to the following areas: • **brief**--Reserved for future. • **config**--Displays information related to configuration of the specified internal hardware device. • **counters**--Displays statistics related to the processing by the specified internal hardware device. • **errors**--Reserved for future. • **registers**--Displays register information for the specified internal hardware device. • **status**--Displays status information for the specified internal hardware device.
device	Specifies the internal hardware device or path on the SPA for which you want to display diagnostic information, including the field programmable gate array (FPGA) device, MAC device, PHY device, or System Packet Interface Level 4 (SPI4) path from the MSC to the FPGA device.
port	(Optional) Port or interface number. Refer to the appropriate hardware manual for port information. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco 4400 Series ISR and integrated into Cisco IOS XE Release 3.9 S.

Usage Guidelines

Use the **show hw-module subslot** command to obtain diagnostic information about an interface on the SPA.

The **counters** keyword displays a subset of the statistics that are also provided by the **show controllers fastethernet** command for the specified SPA device.

Use the **show hw-module subslot** command in Cisco 4400 Series ISRs to obtain diagnostic information related to all supported Cisco services modules and network interface modules(NIM). You can use the **show hw-module subslot all oir** command to verify the operation and proper activation of a module after an online insertion or removal.

Show hw-module subslot all oir Example

The following sample output from the **show hw-module subslot all oir** command verifies activation and proper operation of all supported modules on the router:

```
Router#show hw-module subslot all oir

 Module          Model               Operational Status

-------------- ------------------ -------------------------

subslot 0/1    NIM-8MFT-T1/E1       ok
subslot 1/0    SM-X T1/E1           ok
```

Examples

The following examples provide sample output for several versions of the **show hw-module subslot** command for a SPA located in the top subslot (0) of the MSC that is installed in slot 4 on a Cisco 7304 router.

show hw-module subslot config fpga Example

The following shows sample output from the **show hw-module subslot config** command for the FPGA device on the first interface (port 0):

```
Router# show hw-module subslot 4/0 config fpga 0
FPGA RX Config
  RX FIFO parity select is even
  RX CRC check is  enabled
  RX SHIM header insertion is  disabled
  RX Flow control is enabled
  RX CRC strip is  enabled
  RX TCAM LKUP is enabled
FPGA TX Config
  TX FIFO parity select is even
  TX CRC generation is enabled
  TX Padding is enabled
```

show hw-module subslot config phy Example

The following shows sample output from the **show hw-module subslot config** command for the PHY device on the first interface (port 0):

```
Router# show hw-module subslot 4/0 config phy 0
  PHY version: identifier1 = 0x141, identifier2 = 0xCD2
  PHY Configuration:
  control (reg 0) = 0x3100
    PHY state: not in reset, not powered down, not isoloated
    speed: 100 Mbps, duplex: full
    auto-negotiation enabled, loopback disabled, collision test disabled
  phy specific control (reg 16) = 0x78
    force link good: no
    MDI cross-over mode: automatic crossover
    Tx FIFO depth: +/- 16 bits, Rx FIFO depth: +/- 16 bits
    never assert CRS on transmit, energy detect: off
```

```
    enable extended distance: no, 125 clock: low
    MAC interface power: always up, SQE test: disabled
    polarity reversal: enabled, jabber function: enabled
  extended phy specific control (reg 20) = 0xCE2
    line loopback: disabled, detect lost lock: no, enabled RCLK
    master downshift counter: 4, slave downshift counter: 0
    default MAC interface speed: 1000 Mbps
    fiber auto-negotiation disabled
    add delay to RX_CLK for RXD outputs: yes
    add delay to GTX_CLK for TXD latching: yes
  auto-negotiation advertisement for 10/100 (reg 4) = 0xDE1
    10Base-Tx half-duplex: yes, full-duplex: yes
    100Base-Tx half-duplex: yes, full-duplex: yes
    pause frame support: yes, asymmetric pause: yes
    set remote fault bit: no, advertise next page: no
```

show hw-module subslot counters fpga Example

The following shows sample output from the **show hw-module subslot counters** command for the FPGA device on the first interface (port 0):

Note This information is also available using the **show controllers fastethernet** command.

```
Router# show hw-module subslot 4/0 counters fpga 0
Input: Total (good & bad) packets: 5734
         TCAM drops: 4908
         Satisfy (host-backpressure) drops: 0
         CRC drops: 0
         PL3 RERRs: 0
  Output: EOP (SPI4) errors: 0
```

show hw-module subslot status mac Example

The following shows sample output from the **show hw-module subslot** command for MAC device status on the first interface (port 0):

```
Router# show hw-module subslot 4/0 status mac 0
  Status registers:
    speed = 100 Mbps, duplex = full, interface mode = copper
    spi3 side loopback is disabled, line side loopback is disabled
    padding is disabled, crc add is disabled
    force duplex is enabled
  Rx FIFO status:
    Read pointer = 0xCDE, Write pointer = 0xCDE
    Occupancy of FIFO in 8 byte locations = 0
    Reset is not set
    Overflow event did not occur
  Tx FIFO status:
    Read pointer = 0x498, Write pointer = 0x498
    Occupancy of FIFO in 8 byte locations = 0
    Overflow event did not occur
    Underflow event did not occur
    Out of sequence event did not occur
```

show hw-module subslot status phy Example

The following shows sample output from the **show hw-module subslot** command for PHY device status on the first interface (port 0):

```
Router# show hw-module subslot 4/0 status phy 0
  PHY Status:
  status (reg 1) = 0x7949
    link is down, auto-negotiation is not complete
    remote fault not detected, jabber not detected
  phy specific status (reg 17) = 0x4100
    link is down (real-time), speed/duplex not resolved
    speed: 100 Mbps, duplex: half
    page not received, cable length is 80 - 110m
    MDI cross-over status: MDI, downshift status: no
    energy detect status: active
    transmit pause: disabled, receive pause: disabled
    polarity: normal, jabber: no
  phy specific extended status (reg 27) = 0x848B
    Fiber/ copper auto selection disabled, copper link
    Serial interface auto-negotiation bypass disabled
    Serial interface auto-negotiation bypass status:
      Link came up because regular fiber autoneg completed
    Interrupt polarity is active low
  receive error count: 0x0
```

Related Commands

Command	Description
hw-module subslot service-engine session	Opens a session on the Cisco WebEx Node SPA console.
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.

show hw-module subslot fpd

To display the current versions of all field-programmable devices (FPDs) for a particular SPA or all of the active SPAs on a router, use the **showhw-modulesubslotfpd** command in privileged EXEC mode.

Cisco 7304 Router
show hw-module subslot [*slot*/*subslot*] **fpd**

Cisco 7600 Series Routers, Catalyst 6500 Series Switches, Cisco 12000 Series Routers, and Cisco uBR10012 Universal Broadband Router
show hw-module subslot {*slot*/*subslot* | **all**} **fpd**

Syntax Description

slot	Chassis slot number. Refer to the platform-specific SPA hardware installation guide and the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
all	Specifies display of FPD information for all SPAs in the system. **Note** The **all** keyword is not supported for SPAs on the Cisco 7304 router.

Command Default

For the Cisco 7304 router, if no location is specified, the output for this command will show information for all supported card types on the router.

For the Cisco 7600 series routers, Catalyst 6500 series switches, and Cisco 12000 series routers, there is no default behavior or values.

For more information about FPD upgrades on shared port adapters (SPAs), refer to the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S2	This command was introduced.
12.2(18)SXE	The **all** keyword was added in Cisco IOS Release 12.2(18)SXE on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S and introduced on Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

Other than the FPD version information, the output for this command may also contain useful FPD-related notes.

Cisco 7304 Router

The **all** keyword is not supported on the Cisco 7304 router. The *slot/subslot* arguments are optional, and if you do not specify them, the command displays FPD information for all supported card types on the router.

Cisco 7600 Series Routers, Catalyst 6500 Series Switches, 12000 Series Routers, and Cisco uBR10012 Universal Broadband Router

If you do not use the **all** keyword, then you must specify the *slot/subslot* arguments to select the location of a particular card. There is no default behavior for this command on the Cisco 7600 series routers.

Examples

Displaying FPD Information for a Particular SPA Example

This example shows the output when using the *slot/subslot* arguments to identify a particular SPA. This SPA meets the minimum FPD requirements with that particular Cisco IOS release.

```
Router#
show hw-module subslot 4/0 fpd
==== ====================== ====== =============================================
                             H/W   Field Programmable   Current   Min. Required
Slot Card Description        Ver.  Device: "ID-Name"    Version      Version
==== ====================== ====== ================== =========== ==============
4/0 SPA-4XOC3-ATM           1.0   1-I/O FPGA            0.121       0.121
==== ====================== ====== =============================================
```

Cisco uBR10012 Universal Broadband Router

The following example shows the output when using the *slot/subslot* arguments to identify a particular SPA on a Cisco uBR10012 router:

```
Router#
show hw-module subslot 3/1 fpd
==== ====================== ====== =============================================
                             H/W   Field Programmable   Current   Min. Required
Slot Card Type               Ver.  Device: "ID-Name"    Version      Version
==== ====================== ====== ================== =========== ==============
3/1 SPA-24XDS-SFP           1.0   1-Modena BLAZE FPG  1285.1444   1285.1444
==== ====================== ====== =============================================
```

Displaying FPD Information for all SPAs in the System Example

This example shows FPD image file versions for all SPAs in the system:

```
Router# show hw-module subslot all fpd
==== ====================== ====== =============================================
                             H/W   Field Programmable   Current   Min. Required

Displaying Information for all SPAs in the System Example (Cisco 7304 only)

The **all** keyword is not supported on the Cisco 7304 router.

To display all FPD image file versions for all SPAs on a Cisco 7304 router, enter the **showhw-modulesubslotfpd** command without specifying a slot and subslot. The following example shows all FPD image file versions on a Cisco 7304 router:

```
Router# show hw-module subslot fpd
==== ====================== ====== =============================================
                            H/W    Field Programmable   Current   Min. Required
Slot Card Description       Ver.   Device:"ID-Name"     Version      Version
==== ====================== ====== ================== =========== ==============
 2/0 SPA-4FE-7304           0.32

```

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location on a router, and for all of the SPAs installed in that SIP.

show hw-module subslot oir

To display the operational status of a shared port adapter (SPA), use the **showhw-modulesubslotoir** command in privileged EXEC configuration mode.

show hw-module subslot {*slot* / *subslot* | **all**} **oir** [**internal**]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
all	Displays OIR status for all supported card types in the system.
internal	(Optional) Displays detailed diagnostic information. This option is intended for internal diagnostic use with Cisco Systems technical support personnel.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(25)S3	This command was introduced.
12.2(18)SXE	Thiscommand was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **showhw-modulesubslotoir** command to obtain operational status information about one or all SPAs. To display information for a specific SPA, specify the slot number of the SIP and the subslot number of the SPA about which you want information.

To display information for all SPAs in the router, do not specify the *slot*/*subslot* arguments and use the **all** keyword. If no location is specified, the output for this command will show information for all SPAs in the router.

The optional **internal** keyword displays detailed diagnostic information that is recommended only for use with Cisco Systems technical support personnel.

Examples

The following example shows the operational status of all of the SPAs installed in a router where two of the SPAs are in an out-of-service condition:

```
Router# show hw-module subslot all oir
Module         Model              Operational Status
-------------- ------------------ -------------------------
subslot 4/0    SPA-4XOC3-POS      booting
subslot 4/1    SPA-4XOC3-ATM      out of service(FPD upgrade failed)
subslot 4/2    SPA-4XOC3-POS      ok
subslot 4/3    SPA-1XTENGE-XFP    out of service(SPA unrecognized)
```

The table below describes the possible values for the Operational Status field in the output.

Note The following status descriptions are not applicable to every SPA and can be platform-specific.

Table 111: Operational Status Field Descriptions

Operational Status	Description
admin down	SPA is administratively disabled by the **hw-modulesubslotshutdown** global configuration command.
booting	SPA is initializing.
missing	SPA is not present in the SIP subslot.
ok	SPA is operational.
out of service (*reason*)	The SPA is out of service for one of the following reasons: **Note** The following reasons are not applicable to every SPA and can be platform-specific. • Analyze failed--Failed to create a SPA data structure, most likely due to a memory allocation problem. • Authentication failed--A SPA has failed hardware validation. • Data structure create error--Failed to create a SPA data structure, most likely due to a memory allocation problem. • Event corrupt--A SPA online insertion and removal (OIR) event has been corrupted. This could be caused by a corrupted message between the SIP and the Route Processor (RP) or some other software or hardware problem. • Event sequence error--A SPA OIR event was received out of sequence. This could be caused by a corrupted message between the SIP and the Route Processor (RP) or some other software or hardware problem. • Fail code not set--Failure code could not be read from a SPA OIR event message. This could be caused by a corrupted message between the SIP and the RP or some other software or hardware problem. • Failed too many times--A SPA is disabled because it has failed more than the allowable limit on the platform.

Operational Status	Description
	• FPD upgrade failed--A field-programmable device, such as the Field-Programmable Gate Array (FPGA), failed to automatically upgrade. • H/W signal deasserted--The SPA_OK or PWR_OK hardware signal indicating that the SPA is accessible is no longer asserted. • Heartbeat failed--Occurs when intelligent SPAs encounter heartbeat failures. • Incompatible FPD--An FPGA version mismatch with the Cisco IOS software has been detected for the SPA. • Init timeout--Time limit has been reached during initialization of a SPA. • Read SPA type failed--A read from the hardware for the SPA type failed. • Reload request--A SPA reload is in progress from the **hw-modulesubslotreload** command. • SPA h/w error--The SPA software driver has detected a hardware error. • SPA ready timeout--A timeout ocurred on the RP while waiting for the SPA to become operational. • SPA type mismatch--Occurs when you have preconfigured a SPA of one type, but have inserted a SPA of a different type. **Note** This reason code only applies to those platforms that support pre-configuration. This is not applicable to a Cisco 7600 series router or Catalyst 6500 series switch. • SPA unrecognized--SPA is not supported by the Cisco IOS software release. • Start failed--Failed to start interfaces on SPA. • Unexpected inserted event--The SPA OIR software has received a SPA insertion event when the OIR software considered the SPA already present. • Wait h/w ok timeout--A timeout occurred while waiting for the SPA_OK and PWR_OK hardware signals to be asserted. • Wait start timeout--A timeout occurred on the SIP while waiting for permission from the RP to bring up the SPA.
stopped	SPA has been gracefully deactivated using the **hw-modulesubslotstop** privileged EXEC command on the Cisco 7304 router.

The following example shows the operational status of all of the SPAs installed in a router where all SPAs are running successfully:

```
Router# show hw-module subslot all oir

Module        Model                Operational Status
------------- -------------------- ------------------------
```

```
subslot 1/1   SPA-2XOC3-ATM        ok
subslot 4/0   SPA-2XT3/E3          ok
subslot 4/1   SPA-4XOC3-POS        ok
subslot 4/2   SPA-8XCHT1/E1        ok
```

The following example shows sample output when using the optional **internal** keyword:

```
Router# show hw-module subslot 4/0 oir internal

Related Commands

Command	Description
hw-module subslot reload	Restarts a SPA and its interfaces.
hw-module subslot shutdown	Shuts down a SPA with or without power.

show hw-module subslot service-engine status

To display the Cisco WebEx Node SPA application status on a Cisco ASR 1000 Series Router, use the **showhw-modulesubslotservice-enginestatus**command in privileged EXEC mode.

show **hw-module** **subslot** *slot*/*subslot* **service-engine** **status**

Syntax Description

slot	Specifies the chassis slot number for the Cisco ASR 1000 Series Router SIP.
/ *subslot*	Specifies the secondary subslot number on a Cisco ASR 1000 Series Router SIP where a SPA is installed.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
IOS XE Release 2.4	Thiscommand was introduced.

Usage Guidelines

Use the **showhw-modulesubslotservice-enginestatus**command to obtain information about the Cisco WebEx Node SPA application status. This includes configuration information sent from the Route Processor (RP) and the operation status of the application.

Examples

The following example provides sample output for the **showhw-modulesubslotservice-enginestatus**command for a Cisco WebEX Node SPA located in the top subslot (0) of the SIP that is installed in slot 0 on a Cisco ASR 1000 Series Router:

Related Commands

Command	Description
hw-module subslot service-engine session	Opens a session on the Cisco WebEx Node SPA console.
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and that are used for authentication on a Cisco WebEx Node SPA.

Command	Description
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.

show hw-module subslot transceiver

To display the information about an optical transceiver installed in a shared port adapter (SPA), use the **showhw-modulesubslottransceiver** command in privileged EXEC configuration mode.

show hw-module subslot slot/**subslot transceiver port** {**idprom** [{**brief** | **detail** | **dump**}] | **status**}

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
port	Port or interface number. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
idprom	Displays detailed hardware information for the specified transceiver.
brief	(Optional) Displays summary hardware information for the specified transceiver.
detail	(Optional) Displays detailed hardware information for the specified transceiver.
dump	(Optional) Displays register information for the specified transceiver.
status	Displays operational status for the specified transceiver.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **showhw-modulesubslottransceiver** command to obtain hardware information or operational status for optical devices installed in a SPA.

Cisco Systems qualifies the small form-factor pluggable (SFP) optics modules that can be used with SPAs.

> **Note** The SPAs will only accept the SFP modules listed as supported in this document. An SFP check is run every time an SFP module is inserted into a SPA and only SFP modules that pass this check will be usable.

If a transceiver has not been qualified by Cisco Systems for use with a SPA, the **showhw-modulesubslottransceiverstatus** command reports the following message:

```
The transceiver in slot 4 subslot 0 port 2
  is not a Cisco supplied component. In the current configuration
  third party transceivers are not serviced.
```

If a transceiver has not been qualified by Cisco Systems for use with a SPA, the**showhw-modulesubslottransceiveridprom** command reports the following message:

```
Transceiver is not a Cisco supplied part: the system cannot read the IDPROM
```

Examples

Example of the show hw-module subslot transceiver idprom Command for an OC-3 Transceiver

The following example shows hardware IDPROM information for an OC-3, short reach, multimode transceiver installed in the first interface port (0) of the SPA located in subslot 2 of the SIP installed in chassis slot 7:

```
Router# show hw-module subslot 7/2 transceiver 0 idprom

IDPROM for transceiver POS7/2/0:
  Description                               = SFP optics (type 3)
  Transceiver Type:                         = OC3 SR-1/STM1 MM (1)
  Product Indentifier (PID)                 = TRP-03BCS
  Vendor Revision                           =
  Serial Number (SN)                        = 2169298
  Vendor Name                               = OCP
  Vendor OUI (IEEE company ID)              = 00.00.00 (0)
  Device State                              = Enabled.
  CLEI code                                 = ^@^@^Cc#}0^Ll5
  Cisco part number                         = hc?z^B<@^E^R^@

Example of the show hw-module subslot transceiver status Command

The following example shows the operational status of the transceiver installed in the third interface port (2) of the SPA located in subslot 0 of the SIP installed in chassis slot 4:

```
Router# show hw-module subslot 4/0 transceiver 2 status
The Transceiver in slot 4 subslot 0 port 2 is enabled.
  Module temperature                = +41.617 C
  Transceiver Tx supply voltage     = 3292.0 uVolts
  Transceiver Tx bias current       = 4840 uAmps
  Transceiver Tx power              = 349.2 uWatts
  Transceiver Rx optical power      = 0.5 uWatts
```

show hw-programmable

To display the current Complex Programmable Logic Device (CPLD) or Field-Programmable Gate Array (FPGA) version in a particular line card on a Cisco ASR 1000 Series Router, use the **showhw-programmable** command in Privileged EXEC configuration mode.

show hw-programmable {**all** | **R0** | **R1** | **F0** | **F1** | **0 . . 5**}

Syntax Description

all	This selects all line card types in a Cisco ASR 1000 Series Router.
R0	RP slot 0. In the Cisco ASR 1006 Routers and Cisco ASR 1013 Routers, it is the lower RP slot. In Cisco ASR 1002 and Cisco ASR 1004, it is the only slot.
R1	RP slot 1. This is only in the Cisco ASR 1006 and Cisco ASR 1013 Routers. It is the higher RP slot.
F0	This is the embedded services processor (ESP) slot 0. In the Cisco ASR 1006 Routers and Cisco ASR 1013 Routers, it is the lower ESP slot. In Cisco ASR 1002 and Cisco ASR 1004, it is the only slot.
F1	This is the embedded services processor (ESP) slot 2. This is only in the Cisco ASR 1006 and Cisco ASR 1013 Routers. It is the higher ESP slot.
0..5	This is one of the SIP carrier card slots. Select a slot number zero (0) through five (5). **Note** A CPLD upgrade cannot be performed in slot 5 in the ASR100-SIP10. Move the CPLD card to another slot.

Command Default

None

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
3.1S	This command was introduced in Cisco IOS XE Release 3.1S.

Usage Guidelines

This command displays the current CPLD and FPGA versions in a particular card by examining the contents of the hw-programmable package file.

For procedures on performing a CPLD upgrade, see the Upgrading Field Programmable Hardware Devices for Cisco ASR 1000 Series Routers document.

Examples

The following example displays the current CPLD and FPGA versions in slot R0 of the router:

```
Router# show hw-programmable r0
Hw-programmable versions

Slot                CPLD version               FPGA version
-----------------------------------------------------------
R0                  10021901                   08112501
```

The following example displays all CPLD and FPGA versions, including RP, ESP, and SIP carrier card:

```
Router# show hw-programmable all
Hw-programmable versions

Slot              CPLD version              FPGA version
-----------------------------------------------------------
R0                10021901                  08112501
R1                N/A                       N/A
F0                1001270D                  09081902
F1                1003190E                  10040702
1                 07091401                  N/A
2                 07091401                  N/A
3                 07091401                  N/A
4                 07091401                  N/A
5                 07091401                  N/A
```

Related Commands

Command	Description
upgrade hw-programmable	Performs a Complex Programmable Logic Device (CPLD) or Field-Programmable Gate Array (FPGA) upgrade on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable progress	Displays the progress of the line card-field upgradeable device (LC-FPD) on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable	Displays the names and versions of individual files in the hw_programmable package file.

show icc

To display the information about the interface controller card (ICC) counter and status, use the **showicc** command in user EXEC or privileged EXEC mode.

show icc {**counters** | **flowcontrol** | **mcast** | **status**}

Syntax Description

counters	Displays the counter information.
flowcontrol	Displays the flow control information.
mcast	Displays the multicast information.
status	Displays the status information.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the information about the ICC counter:

```
Router>
show icc counters
total tx RPC packets to slot 1 LCP = 0
  detail by request id: (<request-id>=<number-of-packets>)
   2 =0            7 =0            8 =0            10=0
   11=0            12=0            14=0            17=0
   18=0            19=0            20=0
total rx RPC packets from slot 1 LCP = 0
  detail by request id: (<request-id>=<number-of-packets>)
   2 =5            7 =7            8 =11           10=4
   11=1            12=2            14=1            17=67
   18=7            19=159          20=29
total tx MCAST-SP packets to slot 1 LCP = 0
  detail by request id: (<request-id>=<number-of-packets>)
   6 =0            7 =0            8 =0            9 =0
   12=0            14=0
total rx MCAST-SP packets from slot 1 LCP = 0
  detail by request id: (<request-id>=<number-of-packets>)
   6 =1            7 =1            8 =1            9 =1
   12=41           14=67
total tx L3-MGR packets to slot 1 LCP = 0
  detail by request id: (<request-id>=<number-of-packets>)
   1 =0            2 =0            3 =0
total rx L3-MGR packets from slot 1 LCP = 0
```

```
  detail by request id: (<request-id>=<number-of-packets>)
   1 =1            2 =2            3 =1
Router#
```

This example shows how to display the information about the ICC status:

```
Router>
show icc status
Class Name             Msgs Pending  Max Pending  Total Sent
----- ---------------- ------------  -----------  ----------
    2 RPC                         0            3         403
    3 MSC                         0            1           1
    5 L3-MGR                      0            4        4173
   13 TCAM-API                    0           10          26
Router#
```

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.

show interfaces cem

T o display the statistics of the cem group, use the **showinterfacescem**commandin privilege exec mode.

show interfaces cem *slot/subslot/port*

Syntax Description

slot	Slot number where the SIP is installed.
subslot	Subslot number of the SIP where CEOPS SPA has been installed and circuit emulation has been configured.
port	Port number of the interface on the CEOPS SPA where circuit emulation has been configured.

Command Default

No default behavior or values

Command Modes

Privilege Exec Mode (Exec)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced.

Usage Guidelines

The **showinterfacescem**command has been introduced on Cisco ASR 1000 Series Router in Cisco IOS XE Release 3.3.0S. The command output provides details regarding the various CEM groups configured and the various time slots to which the groups are attached.

Examples

The following example shows the command output of the show interfaces cem command:

```
Router# show interfaces cem 0/1/0
CEM0/1/0 is up, line protocol is up
  Hardware is Circuit Emulation Interface
  MTU 1500 bytes, BW 155520 Kbit/sec, DLY 0 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation CEM, loopback not set
  Keepalive not supported
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/0 (size/max)
  5 minute input rate 64000 bits/sec, 250 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     1779066 packets input, 56930112 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 unknown protocol drops
     0 output buffer failures, 0 output buffers swapped out
```

Related Commands

Command	Description
clear interface cem	Clears the cem channel.

show interface history

To display histograms of interface utilization, use the **showinterfacehistory** command in privileged EXEC mode.

show interface [*type number*] **history** [{**all** | **60sec** | **60min** | **72hour**}] [{**both** | **input** | **output**}]

Syntax Description

type	(Optional) Interface type.
number	(Optional) Port number of the interface.
all	(Optional) Specifies the histograms representing the last 60 seconds, the last 60 minutes, and the last 72 hours of interface utilization.
60sec	(Optional) Specifies the histograms representing the last 60 seconds of interface utilization.
60min	(Optional) Specifies the histograms representing the last 60 minutes of interface utilization.
72hour	(Optional) Specifies the histograms representing the last 72 hours of interface utilization.
both	(Optional) Specifies both the input histograms and the output histograms.
input	(Optional) Specifies the input histograms.
output	(Optional) Specifies the output histograms.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)XNE	This command was introduced.

Usage Guidelines

The **showinterfacehistory** command displays histograms of interface utilization. The y-axis represents the input or output rate in packets per second, kilobits per second, or megabits per second. Kilobits per second is used when the bandwidth of the interface is less than one gigabit per second. Megabits per second is used for more than one gigabit per second.

The x-axis represents time in units of seconds, minutes or hours with the most current time at the left side of the histogram. There are three histograms available: the last 60 seconds, the last 60 minutes, and the last 72 hours.

The interface counters specified in the **history(interface)** command are displayed under the x-axis of each histogram. Each counter has a five-character identification as listed in the command. The identification is displayed at the beginning of each counter line. The number in the column indicates that the counter incremented by that amount during the specified interval. When the counter exceeds a single digit, the values are displayed vertically.

Examples

The following example shows the histogram output of interface history:

```
Router# show interface gigabitethernet 0/1 history 60min
```

```

                  0    5    0    5    0    5    0    5    0    5    0
   Unkno 000000000000000000000000000000000000000000000000000000000000
   oDrop 000000000000000000000000000000000000000000000000000000000000
         GigabitEthernet0/1 output rate(mbits/sec)  (last 60 minutes)
                 * = maximum   # = average
```

The input rate histogram shows that the input rate peaked at 9 Mbps and 4 minutes prior to the command execution. During that one-minute interval, there were 35 input multicast packets and 247 input drops. The counter values in the histogram should be read vertically.

The output rate histogram shows that the output rate reached 8 Mbps twice; once 7 minutes prior and the second time 26 minutes prior to the command execution. There were no unknown protocol drops and no output drops during the last 60 minutes.

The table below describes the significant fields shown in the display.

Table 112: show interface history Field Descriptions

Field	Description
Mlcst	Ethernet input multicast.
iDrop	Input drops.
Unkno	Unknown protocol drops.
oDrop	Output drops.

Related Commands

Command	Description
history (interface)	Enables an interface to maintain utilization history.

show interface sdcc

To display configuration information and statistics for a sections data communications channel (SDCC) interface, use the **showinterfacesdcc** command in privileged EXEC mode.

show interface sdcc *slot/subslot/port*

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
/ *port*	(Optional) Port or interface number. Refer to the appropriate hardware manual for port information. For SPAs, refer to the corresponding “Specifying the Interface Address on a SPA” topics in the platform-specific SPA software configuration guide.

Command History

Release	Modification
12.2(11)BC3	This command was introduced.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support POS SPAs on the Cisco 7304 router.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support POS SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support POS SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

Cisco 7600 Series Router and Catalyst 6500 Series Switch Example

The following command displays configuration information and statistics for SDCC interface 7/0/0:

```
Router# show interface sdcc 7/0/0
SDCC7/0/0 is up, line protocol is up
```

```
  Hardware is SDCC
  Internet address is 10.11.11.10/8
  MTU 1500 bytes, BW 192 Kbit, DLY 20000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation HDLC, crc 16, loopback not set
  Keepalive not set
  Last input 00:00:38, output 00:00:38, output hang never
  Last clearing of "show interface" counters 00:00:48
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo
  Output queue:0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     5 packets input, 520 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicast)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     5 packets output, 520 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

Cisco 12000 Series Router Example

The following is sample output from the **showinterfacesdcc**command on a Cisco 12000 series router for POS interface 1/1/0 (which is the interface for port 0 of the SPA in subslot 1 of the SIP in chassis slot 1):

```
Router# show interface sdcc 1/1/0

SDCC1/1/0 is administratively down, line protocol is down
  Hardware is SDCC
  MTU 1500 bytes, BW 192 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, crc 32, loopback not set
  Keepalive set (10 sec)
  Last input never, output never, output hang never
  Last clearing of "show interface" counters 00:01:55
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

The table below describes the significant fields shown in these displays.

*Table 113: **show interface sdcc** Field Descriptions*

Field	Description
SDCCx/y/z is up, line protocol is up	Indicates whether the interface hardware is currently active and can transmit and receive or whether it has been taken down by an administrator.

Field	Description
Hardware is. . .	Hardware type: • SDCC-- Section Data Communications Channel
Internet address is	Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to interface.
crc	Cyclic redundancy check size (16 or 32 bits).
Loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 2231 ms (and less than 232 ms) ago.
Queueing strategy	First-in, first-out (FIFO) queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).

Field	Description
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
throttles	Not supported for POS interfaces.
parity	Report of the parity errors on the interface.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.

Field	Description
abort	Illegal sequence of one bits on the interface.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router’s receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Not supported for POS interfaces.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
output buffer failures	Not supported for POS interfaces.
output buffers swapped out	Not supported for POS interfaces.
carrier transitions	Number of times the carrier detect signal of the interface has changed state.

show interfaces

To display statistics for all interfaces configured on the router or access server, use the **show interfaces** command in privileged EXEC mode.

Cisco 2500 Series, Cisco 2600 Series, Cisco 4700 Series, and Cisco 7000 Series
show interfaces [*type number*] [*first*] [*last*] [**accounting**]

Catalyst 6500 Series, Cisco 7200 Series and Cisco 7500 Series with a Packet over SONET Interface Processor
show interfaces [**type slot/port**] [{**accounting** | **counters protocol status** | **crb** | **dampening** | **description** | **dot1ad** | **etherchannel** [**module number**] | **fair-queue** | **irb** | **mac-accounting** | **mpls-exp** | **precedence** | **random-detect** | **rate-limit** | **stats** | **summary** | **switching** | **utilization** {*type number*}}]

Cisco 7500 Series with Ports on VIPs
show interfaces [*type slot/port-adapter/port*]

Cisco 7600 Series
show interfaces [{*type number* | **null** *interface-number* | **vlan** *vlan-id*}]

Channelized T3 Shared Port Adapters
show interfaces serial [*slot/subslot/port/t1-num* **:** *channel-group*]

Shared Port Adapters
show interfaces type [*slot/subslot/port* [*/sub-int*]]

Syntax Description

type	(Optional) Interface type. Allowed values for *type* can be **atm**, **async**, **auto-template**, **bvi**, **bri0**, **ctunnel**, **container**, **dialer**, **e1**, **esconPhy**, **ethernet**, **fastethernet**, **fcpa**, **fddi**, **filter**, **filtergroup**, **gigabitethernet**, **ge-wan**, **hssi**, **longreachethernet**, **loopback**, **mfr**, **multilink**, **module**,**null**, **posport-channel**, , **port-group**, **pos-channel**, **sbc**, **sdcc**, **serial**, **sysclock**, **t1**, **tengigabitethernet**, **token**, **tokenring**, **tunnel**, **vif**, **vmi**, **virtual-access**, **virtual-ppp**, **virtual-template**, **virtual-tokenring**. **voaBypassIn**, **voaBypassOut**, **voaFilterIn**, **voaFilterOut**, **voaIn**, **voaOut**. **Note** The type of interfaces available is based on the type of router used.
number	(Optional) Port number on the selected interface.
first last	(Optional) For Cisco 2500 series routers, ISDN Basic Rate Interfae (BRI) only. The *first* argument can be either 1 or 2. The *last* argument can only be 2, indicating B channels 1 and 2. D-channel information is obtained by using the command without the optional arguments.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.

counters protocol status	(Optional) Displays the current status of the protocol counters enabled.
crb	(Optional) Displays interface routing or bridging information.
dampening	(Optional) Displays interface dampening information.
description	(Optional) Displays the interface description.
etherchannel [**module***number*]	(Optional) Displays interface Ether Channel information. • **module** --The **module** keyword limits the display to interfaces available on the module.
fair-queue	(Optional) Displays interface Weighted Fair Queueing (WFQ) information.
irb	(Optional) Displays interface routing or bridging information.
mac-accounting	(Optional) Displays interface MAC accounting information.
mpls-exp	(Optional) Displays interface Multiprotocol Label Switching (MPLS) experimental accounting information.
precedence	(Optional) Displays interface precedence accounting information.
random-detect	(Optional) Displays interface Weighted Random Early Detection (WRED) information.
rate-limit	(Optional) Displays interface rate-limit information.
stats	(Optional) Displays interface packets and octets, in and out, by using switching path.
summary	(Optional) Displays an interface summary.
switching	(Optional) Displays interface switching.
null *interface-number*	(Optional) Specifies the null interface, that is **0**.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot information.
/ *port*	(Optional) Port number. Refer to the appropriate hardware manual for port information.
/ *port-adapter*	(Optional) Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

slot / *subslot* / *port* / *t1-num* **:** *channel-group*	(Optional) Channelized T3 Shared Port Adapters Number of the chassis slot that contains the channelized T3 Shared Port Adapters (SPA) (for example, 5/0/0:23), where: • *slot* --(Optional) Chassis slot number. For SPA interface processors (SIPs), refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. • / *subslot*-- (Optional) Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information. • / *port* --(Optional) Port or interface number. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide. • / *t1-num*-- (Optional) T1 time slot in the T3 line. The value can be from 1 to 28. • **:** *channel-group*-- (Optional) Number 0-23 of the DS0 link on the T1 channel.
[*slot*/*subslot*/*port*/*sub-int*]]	(Optional) Shared Port Adapters Number of the chassis slot that contains the SPA interface (for example, 4/3/0), where: • *slot* --(Optional) Chassis slot number. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. • / *subslot*-- (Optional)Secondary slot number on a SIP where a SAP is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information. • / *port* --(Optional) Port or interface number. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide. • / *sub-int* -- (Optional) Subinterface number (for those SPAs that support subinterface configuration).
vlan *vlan-id*	(Optional) Specifies the VLAN ID; valid values are from 1 to 4094.

Command Modes

User EXEC (>)

Privileged EXEC (#)

Command History

Release	Modification
10.0	This command was introduced.
12.0(3)T	This command was modified to include support for flow-based WRED .
12.0(4)T	This command was modified to include enhanced display information for dialer bound interfaces.
12.0(7)T	This command was modified to include **dialer** as an interface type and to reflect the default behavior.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(20)S2	This command was integrated into Cisco IOS Release 12.2(20)S2 and introduced a new address format and output for SPA interfaces on the Cisco 7304 router. The *subslot* argument was introduced.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3.
12.2(14)SX	This command was modified. Support for this command was added for the Supervisor Engine 720.
12.2(17d)SXB	This command was modified. Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2SX. The uplink dual-mode port information was updated.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
2.2(33)SXJ01	This command was integrated into Cisco IOS Release 12.2(33)SXJ01.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers, and the **tengigabitethernet** interface type was added. 10-Gigabit Ethernet interfaces were introduced with the release of the 1-Port 10-Gigabit Ethernet SPA.
12.2(18)SXF	This command was integrated into Cisco IOS Release 12.2(18)SXF.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRB1	This command was updated to display operational status for Gigabit Ethernet interfaces that are configured as primary and backup interfaces (Cisco 7600 series routers).
12.2(31)SB	This command was integrated in Cisco IOS Release 12.2(31)SB.
12.2(33)SB	This command was modified. The default value of the command was modified on the Cisco 10000 series router for the PRE3 and PRE4.

Release	Modification
Cisco IOS XE Release 2.5	This command was implemented on Cisco ASR 1000 Series Aggregation Services Routers.
12.2(50)SY	This command was integrated in Cisco IOS Release 12.2(50)SY and the dot1ad keyword was added.
15.1(01)SY	This command was integrated in Cisco IOS Release 15.1(50)SY.

Usage Guidelines

Display Interpretation

The **show interfaces** command displays statistics for the network interfaces. The resulting output varies, depending on the network for which an interface has been configured. The resulting display on the Cisco 7200 series routers shows the interface processors in slot order. If you add interface processors after booting the system, they will appear at the end of the list, in the order in which they were inserted.

Information About Specific Interfaces

The *number* argument designates the module and port number. If you use the **show interfaces** command on the Cisco 7200 series routers without the *slot/port* arguments, information for all interface types will be shown. For example, if you type **show interfaces** you will receive information for all Ethernet, serial, Token Ring, and FDDI interfaces. Only by adding the type *slot/port* argument you can specify a particular interface.

Cisco 7600 Series Routers

Valid values for the *number* argument depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

The port channels from 257 to 282 are internally allocated and are supported on the Content Switching Module (CSM) and the Firewall Services Module (FWSM) only.

Statistics are collected on a per-VLAN basis for Layer 2-switched packets and Layer 3-switched packets. Statistics are available for both unicast and multicast traffic. The Layer 3-switched packet counts are available for both ingress and egress directions. The per-VLAN statistics are updated every 5 seconds.

In some cases, you might see a difference in the duplex mode that is displayed between the **show interfaces** command and the **show running-config**commands. In this case, the duplex mode that is displayed in the **show interfaces** command is the actual duplex mode that the interface is running. The **show interfaces** command shows the operating mode for an interface, and the **show running-config** command shows the configured mode for an interface.

If you do not enter any keywords, all counters for all modules are displayed.

Command Variations

You will use the **show interfaces** command frequently while configuring and monitoring devices. The various forms of the **show interfaces** commands are described in detail in the sections that follow.

Dialer Interfaces Configured for Binding

If you use the **show interfaces** command on dialer interfaces configured for binding, the display will report statistics on each physical interface bound to the dialer interface; see the following examples for more information.

Removed Interfaces

If you enter a **show interfaces** command for an interface type that has been removed from the router or access server, interface statistics will be displayed accompanied by the following text: "Hardware has been removed."

Weighted Fair Queueing Information

If you use the **show interfaces** command on a router or access server for which interfaces are configured to use weighted fair queueing through the **fair-queue** interface command, additional information is displayed. This information consists of the current and high-water mark number of flows.

Cisco 10000 Series Router

In Cisco IOS Release 12.2(33)SB, when a multilink PPP (MLP) interface is down/down, its default bandwidth rate is the sum of the serial interface bandwidths associated with the MLP interface.

In Cisco IOS Release 12.2(31)SB, the default bandwidth rate is 64 Kbps.

Examples

The following is sample output from the **show interfaces** command. Because your display will depend on the type and number of interface cards in your router or access server, only a portion of the display is shown.

Note If an asterisk (*) appears after the throttles counter value, it means that the interface was throttled at the time the command was run.

```
Router# show interfaces
Ethernet 0 is up, line protocol is up
  Hardware is MCI Ethernet, address is 0000.0c00.750c (bia 0000.0c00.750c)
  Internet address is 10.108.28.8, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 10000 Kbit, DLY 100000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 4:00:00
  Last input 0:00:00, output 0:00:00, output hang never
  Last clearing of "show interface" counters 0:00:00
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 2000 bits/sec, 4 packets/sec
     1127576 packets input, 447251251 bytes, 0 no buffer
     Received 354125 broadcasts, 0 runts, 0 giants, 57186* throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     5332142 packets output, 496316039 bytes, 0 underruns
     0 output errors, 432 collisions, 0 interface resets, 0 restarts
.
.
.
```

Example with Custom Output Queueing

The following example shows partial sample output when custom output queueing is enabled:

```
Router# show interfaces
Last clearing of "show interface" counters 0:00:06
Input queue: 0/75/0 (size/max/drops); Total output drops: 21
Output queues: (queue #: size/max/drops)
     0: 14/20/14  1: 0/20/6  2: 0/20/0 3: 0/20/0 4: 0/20/0 5: 0/20/0
     6: 0/20/0 7: 0/20/0  8: 0/20/0  9: 0/20/0  10: 0/20/0
.
```

.
.

When custom queueing is enabled, the drops accounted for in the output queues result from bandwidth limitation for the associated traffic and lead to queue length overflow. Total output drops include drops on all custom queues and the system queue. Fields are described with the weighted fair queueing output in the table below.

Example Including Weighted-Fair-Queueing Output

For each interface on the router or access server configured to use weighted fair queueing, the **show interfaces** command displays the information beginning with *Inputqueue***:** in the following display:

```
Router# show interfaces
Ethernet 0 is up, line protocol is up
  Hardware is MCI Ethernet, address is 0000.0c00.750c (bia 0000.0c00.750c)
  Internet address is 10.108.28.8, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 10000 Kbit, DLY 100000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 4:00:00
  Last input 0:00:00, output 0:00:00, output hang never
  Last clearing of "show interface" counters 0:00:00
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 2000 bits/sec, 4 packets/sec
     1127576 packets input, 447251251 bytes, 0 no buffer
     Received 354125 broadcasts, 0 runts, 0 giants, 57186* throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     5332142 packets output, 496316039 bytes, 0 underruns
     0 output errors, 432 collisions, 0 interface resets, 0 restarts
Input queue: 0/75/0 (size/max/drops); Total output drops: 0
Output queue: 7/64/0 (size/threshold/drops)
         Conversations 2/9 (active/max active)
```

The table below describes the input queue and output queue fields shown in the preceding two displays.

Table 114: Weighted-Fair-Queueing Output Field Descriptions

Field	Description
Input Queue	
size	Current size of the input queue.
max	Maximum size of the queue.
drops	Number of messages discarded in this interval.
Total output drops	Total number of messages discarded in this session.
Output Queue	
size	Current size of the output queue.
threshold	Congestive-discard threshold. Number of messages in the queue after which new messages for high-bandwidth conversations are dropped.

Field	Description
drops	Number of dropped messages.
Conversations: active	Number of currently active conversations.
Conversations: max active	Maximum number of concurrent conversations allowed.

Example with Accounting Option

To display the number of packets of each protocol type that have been sent through all configured interfaces, use the **show interfaces accounting** command. When you use the **accounting** option, only the accounting statistics are displayed.

Note Except for protocols that are encapsulated inside other protocols, such as IP over X.25, the accounting option also shows the total bytes sent and received, including the MAC header. For example, it totals the size of the Ethernet packet or the size of a packet that includes High-Level Data Link Control (HDLC) encapsulation.

Per-packet accounting information is kept for the following protocols:

- AppleTalk
- Address Resolution Protocol (ARP) (for IP, Frame Relay, Switched Multimegabit Data Service (SMDS))
- Connectionless Network Service (CLNS)
- Digital Equipment Corporation (DEC) Maintenance Operations Protocol (MOP)

The routers use MOP packets to advertise their existence to Digital Equipment Corporation machines that use the MOP. A router periodically broadcasts MOP packets to identify itself as a MOP host. This results in MOP packets being counted, even when DECnet is not being actively used.

- DECnet
- HP Probe
- IP
- LAN Manager (LAN Network Manager and IBM Network Manager)
- Novell
- Serial Tunnel Synchronous Data Link Control (SDLC)
- Spanning Tree
- SR Bridge
- Transparent Bridge

Example with DWRED

The following is sample output from the **show interfaces** command when distributed WRED (DWRED) is enabled on an interface. Notice that the packet drop strategy is listed as “VIP-based weighted RED.”

```
Router# show interfaces hssi 0/0/0
Hssi0/0/0 is up, line protocol is up
  Hardware is cyBus HSSI
  Description: 45Mbps to R1
Internet address is 10.200.14.250/30
MTU 4470 bytes, BW 45045 Kbit, DLY 200 usec, rely 255/255, load 1/255
Encapsulation HDLC, loopback not set, keepalive set (10 sec)
Last input 00:00:02, output 00:00:03, output hang never
Last clearing of "show interface" counters never
Queueing strategy: fifo
Packet Drop strategy: VIP-based weighted RED
Output queue 0/40, 0 drops; input queue 0/75, 0 drops
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
1976 packets input, 131263 bytes, 0 no buffer
Received 1577 broadcasts, 0 runts, 0 giants
0 parity
4 input errors, 4 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
1939 packets output, 130910 bytes, 0 underruns
0 output errors, 0 applique, 3 interface resets
0 output buffers copied, 0 interrupts, 0 failures
```

Example with ALC

The following is sample output from the **show interfaces** command for serial interface 2 when Airline Control (ALC) Protocol is enabled:

```
Router# show interfaces serial 2
Serial2 is up, line protocol is up
Hardware is CD2430
MTU 1500 bytes, BW 115 Kbit, DLY 20000 usec, rely 255/255, load 1/255
Encapsulation ALC, loopback not set
Full-duplex enabled.
     ascus in UP state: 42, 46
     ascus in DOWN state:
     ascus DISABLED:
Last input never, output never, output hang never
Last clearing of “show interface” counters never
Queueing strategy: fifo
Output queue 0/40, 0 drops; input queue 0/75, 0 drops
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 3 interface resets
0 output buffer failures, 0 output buffers swapped out
DCD=down  DSR=down  DTR=down  RTS=down  CTS=down
```

Example with SDLC

The following is sample output from the **show interfaces** command for an SDLC primary interface supporting the SDLC function:

```
Router# show interfaces
Serial 0 is up, line protocol is up
 Hardware is MCI Serial
 MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
 Encapsulation SDLC-PRIMARY, loopback not set
      Timers (msec): poll pause 100 fair poll 500. Poll limit 1
      [T1 3000, N1 12016, N2 20, K 7] timer: 56608 Last polled device: none
      SDLLC [ma: 0000.0C01.14--, ring: 7 bridge: 1, target ring: 10
             largest token ring frame 2052]
SDLC addr C1 state is CONNECT
       VS 6, VR 3, RCNT 0, Remote VR 6, Current retransmit count 0
       Hold queue: 0/12 IFRAMEs 77/22 RNRs 0/0 SNRMs 1/0 DISCs 0/0
       Poll: clear, Poll count: 0, chain: p: C1 n: C1
       SDLLC [largest SDLC frame: 265, XID: disabled]
  Last input 00:00:02, output 00:00:01, output hang never
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 517 bits/sec, 30 packets/sec
  Five minute output rate 672 bits/sec, 20 packets/sec
       357 packets input, 28382 bytes, 0 no buffer
       Received 0 broadcasts, 0 runts, 0 giants
       0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
       926 packets output, 77274 bytes, 0 underruns
       0 output errors, 0 collisions, 0 interface resets, 0 restarts
       2 carrier transitions
```

The table below shows the fields relevant to all SDLC connections.

*Table 115: **show interfaces** Field Descriptions When SDLC Is Enabled*

Field	Description
Timers (msec)	List of timers in milliseconds.
poll pause, fair poll, Poll limit	Current values of these timers.
T1, N1, N2, K	Current values for these variables.

The table below shows other data given for each SDLC secondary interface configured to be attached to this interface.

Table 116: SDLC Field Descriptions

Field	Description
addr	Address of this secondary interface.

Field	Description
State	Current state of this connection. The possible values follow: • BOTHBUSY--Both sides have told each other that they are temporarily unable to receive any more information frames. • CONNECT--A normal connect state exists between this router and this secondary. • DISCONNECT--No communication is being attempted to this secondary. • DISCSENT--This router has sent a disconnect request to this secondary and is awaiting its response. • ERROR--This router has detected an error, and is waiting for a response from the secondary acknowledging this. • SNRMSENT--This router has sent a connect request (SNRM) to this secondary and is awaiting its response. • THEMBUSY--This secondary has told this router that it is temporarily unable to receive any more information frames. • USBUSY--This router has told this secondary that it is temporarily unable to receive any more information frames.
VS	Sequence number of the next information frame this station sends.
VR	Sequence number of the next information frame from this secondary that this station expects to receive.
RCNT	Number of correctly sequenced I-frames received when the Cisco IOS software was in a state in which it is acceptable to receive I-frames.
Remote VR	Last frame transmitted by this station that has been acknowledged by the other station.
Current retransmit count	Number of times the current I-frame or sequence of I-frames has been retransmitted.
Hold queue	Number of frames in hold queue/Maximum size of hold queue.
IFRAMEs, RNRs, SNRMs, DISCs	Sent and received count for these frames.
Poll	“Set” if this router has a poll outstanding to the secondary; “clear” if it does not.
Poll count	Number of polls, in a row, given to this secondary at this time.
chain	Shows the previous (p) and next (n) secondary address on this interface in the round-robin loop of polled devices.

Sample show interfaces accounting Display

The following is sample output from the **show interfaces accounting** command:

```
Router# show interfaces accounting
Interface TokenRing0 is disabled
Ethernet0
                Protocol    Pkts In   Chars In   Pkts Out  Chars Out
                      IP     873171  735923409      34624    9644258
                  Novell     163849   12361626      57143    4272468
                 DEC MOP          0          0          1         77
                     ARP      69618    4177080       1529      91740
Interface Serial0 is disabled
Ethernet1
                Protocol    Pkts In   Chars In   Pkts Out  Chars Out
                      IP          0          0         37      11845
                  Novell          0          0       4591     275460
                 DEC MOP          0          0          1         77
                     ARP          0          0          7        420
Interface Serial1 is disabled
Interface Ethernet2 is disabled
Interface Serial2 is disabled
Interface Ethernet3 is disabled
Interface Serial3 is disabled
Interface Ethernet4 is disabled
Interface Ethernet5 is disabled
Interface Ethernet6 is disabled
Interface Ethernet7 is disabled
Interface Ethernet8 is disabled
Interface Ethernet9 is disabled
Fddi0
                Protocol    Pkts In   Chars In   Pkts Out  Chars Out
                  Novell          0          0        183      11163
                     ARP          1         49          0          0
```

When the output indicates that an interface is “ disabled,” the router has received excessive errors (over 5000 in a keepalive period).

Example with Flow-Based WRED

The following is sample output from the **show interfaces** command issued for the serial interface 1 for which flow-based WRED is enabled. The output shows that there are 8 active flow-based WRED flows, that the maximum number of flows active at any time is 9, and that the maximum number of possible flows configured for the interface is 16:

```
Router# show interfaces serial 1
Serial1 is up, line protocol is up
  Hardware is HD64570
  Internet address is 10.1.2.1/24
  MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec,
Reliability 255/255, txload 237/255, rxload 1/255
  Encapsulation HDLC, loopback not set
  Keepalive not set
  Last input 00:00:22, output 00:00:00, output hang never
  Last clearing of "show interface" counters 00:17:58
  Input queue: 0/75/0 (size/max/drops); Total output drops: 2479
Queueing strategy: random early detection(RED)
    flows (active/max active/max): 8/9/16
```

```
    mean queue depth: 27
    drops: class  random   tail     min-th   max-th   mark-prob
           0      946      0        20       40       1/10
           1      488      0        22       40       1/10
           2      429      0        24       40       1/10
           3      341      0        26       40       1/10
           4      235      0        28       40       1/10
           5      40       0        31       40       1/10
           6      0        0        33       40       1/10
           7      0        0        35       40       1/10
           rsvp   0        0        37       40       1/10
  30 second input rate 1000 bits/sec, 2 packets/sec
  30 second output rate 119000 bits/sec, 126 packets/sec
     1346 packets input, 83808 bytes, 0 no buffer
     Received 12 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     84543 packets output, 9977642 bytes, 0 underruns
     0 output errors, 0 collisions, 6 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
     DCD=up  DSR=up  DTR=up  RTS=up  CTS=up
```

Example with DWFQ

The following is sample output from the **show interfaces** command when distributed weighted fair queueing (DWFQ) is enabled on an interface. Notice that the queueing strategy is listed as “VIP-based fair queueing.”

```
Router# show interfaces fastethernet 1/1/0
Fast Ethernet 1/1/0 is up, line protocol is up
  Hardware is cyBus Fast Ethernet Interface, address is 0007.f618.4448 (bia 00e0)
  Description: pkt input i/f for WRL tests (to pagent)
  Internet address is 10.0.2.70/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive not set, fdx, 100BaseTX/FX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output 01:11:01, output hang never
  Last clearing of "show interface" counters 01:12:31
  Queueing strategy: VIP-based fair queueing
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     1 packets output, 60 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffers copied, 0 interrupts, 0 failures
```

Example with DNIS Binding

When the **show interfaces** command is issued on an unbound dialer interface, the output looks as follows:

```
Router# show interfaces dialer 0
Dialer0 is up (spoofing), line protocol is up (spoofing)
  Hardware is Unknown
  Internet address is 10.1.1.2/8
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec, rely 255/255, load 3/255
  Encapsulation PPP, loopback not set
  DTR is pulsed for 1 seconds on reset
  Last input 00:00:34, output never, output hang never
  Last clearing of "show interface" counters 00:05:09
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 1000 bits/sec, 0 packets/sec
     18 packets input, 2579 bytes
     14 packets output, 5328 bytes
```

But when the **show interfaces** command is issued on a bound dialer interface, you will get an additional report that indicates the binding relationship. The output is shown here:

```
Router# show interfaces dialer 0
Dialer0 is up, line protocol is up
  Hardware is Unknown
  Internet address is 10.1.1.2/8
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation PPP, loopback not set
  DTR is pulsed for 1 seconds on reset
  Interface is bound to BRI0:1
  Last input 00:00:38, output never, output hang never
  Last clearing of "show interface" counters 00:05:36
Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     38 packets input, 4659 bytes
     34 packets output, 9952 bytes
Bound to:
BRI0:1 is up, line protocol is up
  Hardware is BRI
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation PPP, loopback not set, keepalive not set
  Interface is bound to Dialer0 (Encapsulation PPP)
  LCP Open, multilink Open
  Last input 00:00:39, output 00:00:11, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     78 packets input, 9317 bytes, 0 no buffer
     Received 65 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     93 packets output, 9864 bytes, 0 underruns
     0 output errors, 0 collisions, 7 interface resets
     0 output buffer failures, 0 output buffers swapped out
     4 carrier transitions
```

At the end of the Dialer0 output, the **show interfaces** command is executed on each physical interface bound to it.

The following is sample output from the **show interfaces dialer stats** command:

```
Router# show interfaces dialer 0 stats
```

```
Dialer0
  Switching path    Pkts In   Chars In   Pkts Out  Chars Out
       Processor          0          0          6       1694
       Route cache  2522229  610372530     720458  174343542
             Total  2522229  610372530     720464  174345236
```

Example with BRI

In this example, the physical interface is the B1 channel of the BRI0 link. This example also illustrates that the output under the B channel keeps all hardware counts that are not displayed under any logical or virtual access interface. The line in the report that states "Interface is bound to Dialer0 (Encapsulation LAPB)" indicates that the B interface is bound to Dialer0 and the encapsulation running over this connection is Link Access Procedure, Balanced (LAPB), not PPP, which is the encapsulation configured on the D interface and inherited by the B channel.

```
Router# show interfaces bri0:1
BRI0:1 is up, line protocol is up
  Hardware is BRI
  MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation PPP, loopback not set, keepalive not set

Interface is bound to Dialer0 (Encapsulation LAPB)
  LCP Open, multilink Open
  Last input 00:00:31, output 00:00:03, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 1 packets/sec
  5 minute output rate 0 bits/sec, 1 packets/sec
     110 packets input, 13994 bytes, 0 no buffer
     Received 91 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     135 packets output, 14175 bytes, 0 underruns
     0 output errors, 0 collisions, 12 interface resets
     0 output buffer failures, 0 output buffers swapped out
     8 carrier transitions
```

Any protocol configuration and states should be displayed from the Dialer0 interface.

Example with a Fast Ethernet SPA on a Cisco 7304 Router

The following is sample output from the **show interfaces fastethernet** command for the second interface (port 1) in a 4-Port 10/100 Fast Ethernet SPA located in the bottom subslot (1) of the Modular Service Cards (MSC) that is installed in slot 2 on a Cisco 7304 router:

```
Router# show interfaces fastethernet 2/1/1
FastEthernet2/1/1 is up, line protocol is up
  Hardware is SPA-4FE-7304, address is 00b0.64ff.5d80 (bia 00b0.64ff.5d80)
  Internet address is 192.168.50.1/24
  MTU 9216 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, 100BaseTX/FX
ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:22, output 00:00:02, output hang never
  Last clearing of "show interface" counters never
```

```
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     5 packets input, 320 bytes
     Received 1 broadcasts (0 IP multicast)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog
     0 input packets with dribble condition detected
     8 packets output, 529 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets
     0 babbles, 0 late collision, 0 deferred
     2 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

Example for an Interface with an Asymmetric Receiver and Transmitter Rates

```
Router# show interfaces e4/0
Ethernet4/0 is up, line protocol is up
  Hardware is AmdP2, address is 000b.bf30.f470 (bia 000b.bf30.f470)
  Internet address is 10.1.1.9/24
  MTU 1500 bytes, BW 10000 Kbit, RxBW 5000 Kbit, DLY 1000 usec,
     reliability 255/255, txload 1/255, rxload 254/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:00, output 00:00:01, output hang never
  Last clearing of "show interface" counters 00:03:36
  Input queue: 34/75/0/819 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  30 second input rate 7138000 bits/sec, 14870 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
     3109298 packets input, 186557880 bytes, 0 no buffer
     Received 217 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     22 packets output, 1320 bytes, 0 underruns
     11 output errors, 26 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 117: show interfaces fastethernet Field Descriptions--Fast Ethernet SPA

Field	Description
Fast Ethernet...is up ...is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type (for example, SPA-4FE-7304) and MAC address.

Field	Description
Description	Alphanumeric string identifying the interface. This appears only if the **description** interface configuration command has been configured on the interface.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface. The default is 1500 bytes for the 4-Port 10/100 Fast Ethernet SPA.
BW	Bandwidth of the interface in kilobits per second.
RxBW	Receiver bandwidth of the interface, in kilobits per second. This value is displayed only when an interface has asymmetric receiver and transmitter rates.
DLY	Delay of the interface in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload, rxload	Load on the interface (in the transmit "tx" and receive "rx" directions) as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set, and the time interval.
Half-duplex, Full-duplex	Indicates the duplex mode for the interface.
100Mb/s, 10Mb/s	Speed of the interface in megabits per second.
100BaseTX/FX	Media protocol standard.
ARP type:	Type of ARP assigned and the timeout period.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This field is not updated by fast-switched traffic.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is displayed. If that field overflows, asterisks are printed. **Note** This field does not apply to SPA interfaces.

Field	Description
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. A series of asterisks (***) indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Input queue (size/max/drops/flushes)	Packet statistics on the input queue reported as: • Size--Number of packets in the input queue. • Max--Maximum size of the queue. • Drops--Number of packets dropped because of a full input queue. • Flushes--Number of packets dropped as part of selective packet discard (SPD). SPD implements a selective packet drop policy on the router's IP process queue. Therefore, it applies only to process-switched traffic.
Total output drops	Total number of packets dropped because of a full output queue.
Queueing strategy	Type of Layer 3 queueing active on this interface. The default is first-in, first-out (FIFO).
Output queue (size/max)	Number of packets in the output queue (size), and the maximum size of the queue (max).
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
Received...broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is smaller than 64 bytes is considered a runt.

Field	Description
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is larger than 1536 bytes is considered a giant. **Note** For the 4-Port 10/100 Fast Ethernet SPA, the default is that a giant is any packet greater than 1536 bytes. However, if you modify the maximum transmission unit (MTU) for the interface, this counter increments when you exceed the specified MTU for the interface.
throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.
input errors	Includes runts, giants, no buffer, cyclic redundancy check (CRC), frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy check generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
watchdog	Number of times the watchdog receive timer expired. Expiration happens when receiving a packet with a length greater than 2048 bytes.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented for informational purposes only; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle.

Field	Description
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. Interface resets can occur when an interface is looped back or shut down.
babbles	Transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble.
deferred	Number of times that the interface had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission. **Note** This field does not apply to SPA interfaces.
output buffer failures, output buffers swapped out	These counters are not used by the 4-Port 10/100 Fast Ethernet SPA on the Cisco 7304 router.

Example with a Gigabit Ethernet SPA on a Cisco 7304 Router

The following is sample output from the **show interfaces gigabitethernet** command for the first interface (port 0) in a 2-Port 10/100/1000 Gigabit Ethernet SPA located in the top subslot (0) of the MSC that is installed in slot 4 on a Cisco 7304 router:

```
Router# show interfaces gigabitethernet 4/0/0

GigabitEthernet4/0/0 is up, line protocol is down
  Hardware is SPA-2GE-7304, address is 00b0.64ff.5a80 (bia 00b0.64ff.5a80)
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Half-duplex, 1000Mb/s, link type is auto, media type is RJ45
  output flow-control is unsupported, input flow-control is unsupported
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:09, output hang never
  Last clearing of "show interface" counters never
```

```
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicast)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     109 packets output, 6540 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets
     0 babbles, 0 late collision, 0 deferred
     1 lost carrier, 0 no carrier, 0 PAUSE output
     0 output buffer failures, 0 output buffers swapped out
```

Example with Gigabit Ethernet SPAs Configured as Primary and Backup Interfaces on a Cisco 7600 Router

The following examples show the additional lines included in the display when the command is issued on two Gigabit Ethernet interfaces that are configured as a primary interface (gi3/0/0) and as a backup interface (gi3/0/11) for the primary:

```
Router# show interfaces gigabitEthernet 3/0/0

GigabitEthernet3/0/0 is up, line protocol is up (connected)
  Hardware is GigEther SPA, address is 0005.dc57.8800 (bia 0005.dc57.8800)
  Backup interface GigabitEthernet3/0/11, failure delay 0 sec, secondary disable delay 0
sec,
  .
  .
  .
Router# show interfaces gigabitEthernet 3/0/11

GigabitEthernet3/0/11 is standby mode, line protocol is down (disabled)
  .
  .
  .
```

The table below describes the fields shown in the display for Gigabit Ethernet SPA interfaces.

Table 118: show interfaces gigabitethernet Field Descriptions--Gigabit Ethernet SPA

Field	Description
GigabitEthernet...is up ...is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type (for example, SPA-2GE-7304) and MAC address.
Backup interface	Identifies the backup interface that exists for this, the primary interface.

Field	Description
Failure and secondary delay	The period of time (in seconds) to delay bringing up the backup interface when the primary goes down, and bringing down the backup after the primary becomes active again. On the Cisco 7600 router, the delay must be 0 (the default) to ensure that there is no delay between when the primary goes down and the backup comes up, and vice versa.
Standby mode	Indicates that this is a backup interface and that it is currently operating in standby mode.
Description	Alphanumeric string identifying the interface. This appears only if the **description** interface configuration command has been configured on the interface.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface. The default is 1500 bytes for the 2-Port 10/100/1000 Gigabit Ethernet SPA.
BW	Bandwidth of the interface in kilobits per second.
DLY	Delay of the interface in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload, rxload	Load on the interface (in the transmit “tx” and receive “rx” directions) as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set, and the time interval.
Half-duplex, Full-duplex	Indicates the duplex mode for the interface.
1000Mb/s, 100Mb/s, 10Mb/s	Speed of the interface in megabits per second.
link type	Specifies whether autonegotiation is being used on the link.
media type	Interface port media type: RJ45, SX, LX, or ZX.
100BaseTX/FX	Media protocol standard.
ARP type:	Type of ARP assigned and the timeout period.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This field is not updated by fast-switched traffic.

Field	Description
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is displayed. If that field overflows, asterisks are printed. **Note** This field does not apply to SPA interfaces.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. A series of asterisks (***) indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Input queue (size/max/drops/flushes)	Packet statistics on the input queue reported as: • Size--Number of packets in the input queue. • Max--Maximum size of the queue. • Drops--Number of packets dropped because of a full input queue. • Flushes--Number of packets dropped as part of SPD. SPD implements a selective packet drop policy on the router's IP process queue. Therefore, it applies only to process-switched traffic.
Total output drops	Total number of packets dropped because of a full output queue.
Queueing strategy	Type of Layer 3 queueing active on this interface. The default is FIFO.
Output queue (size/max)	Number of packets in the output queue (size), and the maximum size of the queue (max).
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.

Field	Description
Received...broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is smaller than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is larger than 1536 bytes is considered a giant. **Note** For the 2-Port 10/100/1000 Gigabit Ethernet SPA, the default is that a giant is any packet greater than 1536 bytes. However, if you modify the MTU for the interface, this counter increments when you exceed the specified MTU for the interface.
throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy check generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
watchdog	Number of times the watchdog receive timer expired. Expiration happens when receiving a packet with a length greater than 2048 bytes.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented for informational purposes only; the router accepts the frame.
packets output	Total number of messages transmitted by the system.

Field	Description
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. Interface resets can occur when an interface is looped back or shut down.
babbles	Transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble.
deferred	Number of times that the interface had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission. **Note** This field does not apply to SPA interfaces.
output buffer failures, output buffers swapped out	These counters are not used by the 2-Port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router.

Example with a Packet over SONET/SDH (POS) SPA on a Cisco 7600 Series Router and Catalyst 6500 Series Switch

The following is sample output from the **show interfaces pos** command on a Cisco 7600 series router or Catalyst 6500 series switch for POS interface 4/3/0 (which is the interface for port 0 of the SPA in subslot 3 of the SIP in chassis slot 4):

```
Router# show interfaces pos 4/3/0

POS4/3/0 is up, line protocol is up  (APS working - active)
  Hardware is Packet over SONET
  Internet address is 10.0.0.1/8
```

```
MTU 4470 bytes, BW 622000 Kbit, DLY 100 usec, rely 255/255, load 1/255
Encapsulation HDLC, crc 16, loopback not set
Keepalive not set
Scramble disabled
Last input 00:00:34, output 04:09:06, output hang never
Last clearing of "show interface" counters never
Queueing strategy:fifo
Output queue 0/40, 0 drops; input queue 0/75, 0 drops
      Available Bandwidth 622000 kilobits/sec
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
   782 packets input, 226563 bytes, 0 no buffer
   Received 0 broadcasts, 1 runts, 0 giants, 0 throttles
            0 parity
   1 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
   271 packets output, 28140 bytes, 0 underruns
   0 output errors, 0 applique, 2 interface resets
   0 output buffer failures, 0 output buffers swapped out
   2 carrier transitions
```

The table below describes the significant fields shown in this display.

*Table 119: **show interfaces pos** Field Descriptions--POS SPA*

Field	Description
POS4/3/0 is up, line protocol is up	Indicates whether the interface hardware is currently active and can transmit and receive or whether it has been taken down by an administrator.
Hardware is. . .	Hardware type: • For POSIP--cyBus Packet over SONET • For POS SPAs--Packet over SONET
Internet address is	Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to the interface.
Loopback	Indicates whether loopbacks are set.
Keepalive	Indicates whether keepalives are set.

Field	Description
Scramble	Indicates whether SONET payload scrambling is enabled. SONET scrambling is disabled by default. For the POS SPAs on the Cisco 12000 series routers, scrambling is enabled by default.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 2231 ms (and less than 232 ms) ago.
Queueing strategy	FIFO queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with number of packets ignored. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.

Field	Description
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
throttles	Not supported for POS interfaces.
parity	Report of the parity errors on the interface.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits, or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.
abort	Illegal sequence of one bits on the interface.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, because some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
applique	Indicates an unrecoverable error has occurred on the POSIP applique. The system then invokes an interface reset.

Field	Description
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
output buffer failures	Not supported for POS interfaces.
output buffers swapped out	Not supported for POS interfaces.
carrier transitions	Number of times the carrier detect signal of the interface has changed state.

Example with a POS SPA on a Cisco 12000 Series Router

The following is sample output from the **show interfaces pos** command on a Cisco 12000 series router for POS interface 1/1/0 (which is the interface for port 0 of the SPA in subslot 1 of the SIP in chassis slot 1):

```
Router# show interfaces pos 1/1/0

POS1/1/0 is up, line protocol is up
  Hardware is Packet over SONET
  Internet address is 10.41.41.2/24
  MTU 4470 bytes, BW 9952000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation HDLC, crc 32, loopback not set
  Keepalive not set
  Scramble enabled
  Last input 00:00:59, output 00:00:11, output hang never
  Last clearing of "show interface" counters 00:00:14
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
        Available Bandwidth 9582482 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
              0 parity
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     1 packets output, 314 bytes, 0 underruns
     0 output errors, 0 applique, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

Example of Displaying Traffic for a Specific Interface on a Cisco CSR 1000v Series Cloud Services Router

For each interface on the router, the **show interfaces** command displays information about the link. In the following example, for the line starting with `Full Duplex`, the interface port media type is: `Virtual`, not a physical media type such as `RJ45`. This shows that the interface belongs to a cloud services router (Cisco CSR 1000v Series Cloud Services Router (CSR 1000v) or Cisco Integrated Services Router (ISRv)).

```
Router# show interfaces GigabitEthernet1

GigabitEthernet1 is up, line protocol is up
  Hardware is CSR vNIC, address is 000d.3a16.20f1 (bia 000d.3a16.20f1)
  Internet address is 12.0.0.4/24
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full Duplex, 1000Mbps, link type is auto, media type is Virtual
```

Example with a POS SPA SDCC Interface on a Cisco 12000 Series Router

The following is sample output from the **show interfaces sdcc**command on a Cisco 12000 series router for POS interface 1/1/0 (which is the interface for port 0 of the SPA in subslot 1 of the SIP in chassis slot 1):

```
Router# show interfaces sdcc 1/1/0

SDCC1/1/0 is administratively down, line protocol is down
  Hardware is SDCC
  MTU 1500 bytes, BW 192 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, crc 32, loopback not set
  Keepalive set (10 sec)
  Last input never, output never, output hang never
  Last clearing of "show interface" counters 00:01:55
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

The table below describes the significant fields shown in the display.

*Table 120: **show interfaces sdcc** Field Descriptions--POS SPA*

Field	Description
SDCC1/1/0 is administratively down, line protocol is down	Indicates whether the interface hardware is currently active and can transmit and receive or whether it has been taken down by an administrator.
Hardware is. . .	Hardware type is SDCC--Section Data Communications Channel.
Internet address is	Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.

Field	Description
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to the interface.
crc	Cyclic redundancy check size (16 or 32 bits).
Loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 2231 ms (and less than 232 ms) ago.
Queueing strategy	FIFO queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.

Field	Description
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with number of packets ignored. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
throttles	Not supported for POS interfaces.
parity	Report of the parity errors on the interface.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits, or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.
abort	Illegal sequence of one bits on the interface.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.

Field	Description
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, because some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Not supported for POS interfaces.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
output buffer failures	Not supported for POS interfaces.
output buffers swapped out	Not supported for POS interfaces.
carrier transitions	Number of times the carrier detect signal of the interface has changed state.

Example with a T3/E3 Shared Port Adapter

The following example shows the interface serial statistics on the first port of a T3/E3 SPA installed in subslot 0 of the SIP located in chassis slot 5:

```
Router# show interfaces serial 5/0/0
Serial5/0/0 is up, line protocol is up
  Hardware is SPA-4T3E3
  Internet address is 10.1.1.2/24
  MTU 4470 bytes, BW 44210 Kbit, DLY 200 usec,
     reliability 255/255, txload 234/255, rxload 234/255
  Encapsulation HDLC, crc 16, loopback not set
  Keepalive set (10 sec)
  Last input 00:00:05, output 00:00:00, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 40685000 bits/sec, 115624 packets/sec
  5 minute output rate 40685000 bits/sec, 115627 packets/sec
     4653081241 packets input, 204735493724 bytes, 0 no buffer
     Received 4044 broadcasts (0 IP multicast)
     0 runts, 0 giants, 0 throttles
              0 parity
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     4652915555 packets output, 204728203520 bytes, 0 underruns
     0 output errors, 0 applique, 4 interface resets
     0 output buffer failures, 0 output buffers swapped out
 2 carrier transitions
```

The table below describes the fields shown in the **show interfaces serial** output for a T3/E3 SPA.

Note The fields appearing in the ouput will vary depending on card type, interface configuration, and the status of the interface.

Table 121: show interfaces serial Field Descriptions--T3/E3 SPA

Field	Description
Serial	Name of the serial interface.
line protocol is	If the line protocol is up, the local router has received keepalive packets from the remote router. If the line protocol is down, the local router has not received keepalive packets form the remote router.
Hardware is	Designates the specific hardware type of the interface.
Internet address is	The IP address of the interface.
MTU	The maximum packet size set for the interface.
BW	Bandwidth in kilobits per second.
DLY	Interface delay in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload	Transmit load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
rxload	Receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method.
crc	CRC size in bits.
loopback	Indicates whether loopback is set.
keepalive	Indicates whether keepalives are set.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.

Field	Description
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing of show interface counters	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 milliseconds (and less than 232 ms) ago.
Input queue	Packet statistics on the input queue reported as: • Size--Current size of the input queue. • Max--Maximum size of the input queue. • Drops--Packets dropped because the queue was full. • Flushes--Number of times that data on queue has been discarded.
Total output drops	Total number of dropped packets.
Queueing strategy	FIFO queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue	Number of packets in the output queue (size), and the maximum size of the queue (max).
5-minute input rate	Average number of bits and packets received per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
5-minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.

Example with a 1-Port 10-Gigabit Ethernet SPA on a Cisco 12000 Series Router

The following is sample output from the **show interfaces tengigabitethernet** command for the only interface (port 0) in a 1-Port 10 Gigabit Ethernet SPA located in the top subslot (0) of the carrier card that is installed in slot 7 on a Cisco 12000 series router:

```
Router# show interfaces tengigabitethernet 7/0/0
TenGigabitEthernet7/0/0 is up, line protocol is up (connected)
  Hardware is TenGigEther SPA, address is 0000.0c00.0102 (bia 000f.342f.c340)
  Internet address is 10.1.1.2/24
  MTU 1500 bytes, BW 10000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not supported
  Full-duplex, 10Gb/s
  input flow-control is on, output flow-control is on
ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:10, output hang never
  Last clearing of "show interface" counters 20:24:30
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
  L2 Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes
  L3 in Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes mcast
  L3 out Switched: ucast: 0 pkt, 0 bytes mcast: 0 pkt, 0 bytes
     237450882 packets input, 15340005588 bytes, 0 no buffer
     Received 25 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     0 input packets with dribble condition detected
     1676 packets output, 198290 bytes, 0 underruns
     0 output errors, 0 collisions, 4 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 PAUSE output
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 122: show interfaces tengigabitethernet Field Descriptions--10-Gigabit Ethernet SPA

Field	Description
TenGigabitEthernet...is up ...is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type and MAC address.
Description	Alphanumeric string identifying the interface. This appears only if the **description** interface configuration command has been configured on the interface.
Internet address	Internet address followed by subnet mask.

Field	Description
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface in kilobits per second.
DLY	Delay of the interface in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload, rxload	Load on the interface (in the transmit "tx" and receive "rx" directions) as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set, and the time interval.
Half-duplex, Full-duplex	Indicates the duplex mode for the interface.
10Gb/s	Speed of the interface in Gigabits per second.
input flow control ...	Specifies if input flow control is on or off.
ARP type:	Type of ARP assigned and the timeout period.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This field is not updated by fast-switched traffic.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is displayed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. A series of asterisks (***) indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.

Field	Description
Input queue (size/max/drops/flushes)	Packet statistics on the input queue reported as: • Size--Number of packets in the input queue. • Max--Maximum size of the queue. • Drops--Number of packets dropped because of a full input queue. • Flushes--Number of packets dropped as part of SPD. SPD implements a selective packet drop policy on the router's IP process queue. Therefore, it applies only to process-switched traffic.
Total output drops	Total number of packets dropped because of a full output queue.
Queueing strategy	Type of Layer 3 queueing active on this interface. The default is FIFO.
Output queue (size/max)	Number of packets in the output queue (size), and the maximum size of the queue (max).
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
L2 Switched	Provides statistics about Layer 2 switched traffic, including unicast and multicast traffic.
L3 in Switched	Provides statistics about received Layer 3 traffic.
L3 out Switched	Provides statistics about sent Layer 3 traffic.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
Received...broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.

Field	Description
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy check generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
watchdog	Number of times the watchdog receive timer expired.
multicast	Number of multicast packets.
pause input	Number of pause packets received.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented for informational purposes only; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.

Field	Description
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. Interface resets can occur when an interface is looped back or shut down.
babbles	Transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble.
deferred	Number of times that the interface had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
pause output	Number of pause packets transmitted.
output buffer failures, output buffers swapped out	Number of output butters failures and output buffers swapped out.

Displaying Traffic for a Specific Interface Example

This example shows how to display traffic for a specific interface:

```
Router# show interfaces GigabitEthernet1/1

GigabitEthernet0/1 is up, line protocol is up
  Hardware is BCM1125 Internal MAC, address is 0016.9de5.d9d1 (bia 0016.9de5.d9d1)
  Internet address is 172.16.165.40/27
  MTU 1500 bytes, BW 100000 Kbit/sec, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, media type is RJ45
  output flow-control is XON, input flow-control is XON
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:11, output 00:00:08, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     10 packets input, 2537 bytes, 0 no buffer
     Received 10 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 46 multicast, 0 pause input
     0 input packets with dribble condition detected
     18 packets output, 3412 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     7 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     2 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

Note The unknown protocol drops field displayed in the above example refers to the total number of packets dropped due to unknown or unsupported types of protocol. This field occurs on several platforms such as the Cisco 3725, 3745, 3825, and 7507 series routers.

This example shows how to display traffic for a FlexWAN module:

```
Router# show interfaces pos 6/1/0.1

POS6/1/0.1 is up, line protocol is up
  Hardware is Packet over Sonet
  Internet address is 10.1.2.2/24
  MTU 4470 bytes, BW 155000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation FRAME-RELAY <<<+++ no packets info after this line
Arches#sh mod 6
Mod Ports Card Type                              Model              Serial No.
--- ----- -------------------------------------- ------------------ -----------
  6    0  2 port adapter FlexWAN                 WS-X6182-2PA       SAD04340JY3
Mod MAC addresses                       Hw    Fw           Sw           Status
--- ---------------------------------- ------ ------------ ------------ -------
  6  0001.6412.a234 to 0001.6412.a273   1.3   12.2(2004022 12.2(2004022 Ok
Mod Online Diag Status
--- -------------------
  6 Pass
Router#
```

Related Commands

Command	Description
fair-queue	Enables WFQ.
interface	Configures an interface type and enters interface configuration mode.
show controllers fastethernet	Displays Fast Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show controllers pos	Displays information about the POS controllers.
show controllers serial	Displays controller statistics.

show interfaces accounting

To display the number of packets of each protocol type that have been sent through all configured interfaces, use the **showinterfacesaccounting** command in user EXEC or privileged EXEC mode.

show interfaces [{*interface type number* | **null** *interface-number* | **vlan** *vlan-id*}] **accounting**

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, and **port-channel**, **atm**, and **ge-wan**.
type number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
null *interface-number*	(Optional) Specifies the null interface; the valid value is **0**.
vlan *vlan-id*	(Optional) Specifies the VLAN ID; valid values are from 1 to 4094.

Command Modes

User EXEC

Privileged EXEC (#)

Command History

Release	Modification
12.2(17a)SX1	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRC	Support for IPv6 was added.
12.2(33)SB	This command was integrated into Cisco IOS Release 12.2(33)SB.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.
15.4(2)S	This command was integrated into Cisco IOS Release 15.4(2)S.

Usage Guidelines

Note The Pkts Out and Chars Out fields display IPv6 packet counts only. The Pkts In and Chars In fields display both IPv4 and IPv6 packet counts, except for tunnel interfaces. For tunnel interfaces, the IPv6 input packets are counted as IPv6 packets only.

Due to hardware limitations on the ASIC, PFC IPv4 and IPv6 packets cannot be differentiated in the Pkts In and Chars In fields for IP count the IPv6 and IPv4 packets that are hardware forwarded. The Pkts In and Chars In fields for IPv6 only count software-forwarded packets. The IP Pkts Out and Chars Out fields show IPv4 packets, and the IPv6 Pkts Out and Chars Out fields show IPv6 packets.

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

The port channels from 257 to 282 are internally allocated and are supported on the CSM and the FWSM only.

If you do not enter any keywords, all counters for all modules are displayed.

Examples

This example shows how to display the number of packets of each protocol type that have been sent through all configured interfaces:

```
Device# show interfaces gigabitethernet 5/2 accounting

GigabitEthernet5/2
Protocol Pkts In Chars In Pkts Out Chars Out
IP       50521   50521000 0        0
DEC MOP  0       0        1        129
CDP      0       0        1        592
IPv6     11      834      96       131658
```

The table below describes the significant fields shown in the display.

Table 123: show interfaces accounting Command Output Fields

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	For IP it is the number of IPv4 software switched, IPv4 and IPv6 hardware switched packets received for the specified protocol. For IPv6 it is the number of IPv6 software switched packets received for the specified protocol.
Chars In	For IP it is the number of IPv4 software switched, IPv4 and IPv6 hardware switched characters received for the specified protocol. For IPv6 it is the number of IPv6 software switched characters received for the specified protocol.
Pkts Out	For IP it is the number of IPv4 sofware and hardware switched packets transmitted for the specified protocol. For IPv6 it is the number of IPv6 sofware and hardware switched packets transmitted for the specified protocol.
Chars Out	For IP it is the number of IPv4 software and hardware switched characters transmitted for the specified protocol. For IPv6 it is the number of IPv6 software and hardware switched characters transmitted for the specified protocol.

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.

show interfaces analysis-module

To display status, traffic data, and configuration information about the analysis module interface, use the **showinterfacesanalysis-module** command in user EXEC or privileged EXEC mode.

show interfaces analysis-module *slot/unit*

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network analysis module (NAM). For NAM, always use 0.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

The analysis module interface is a Fast Ethernet interface on the router that connects to the internal interface on the Network Analysis Module (NM-NAM).

Examples

The command in the following example displays status, traffic data, and configuration information about the analysis module interface when the NM-NAM is installed in slot 2 of a Cisco 3745.

```
Router# show interfaces analysis-module 2/0

Network-Analyzer2/0 is up, line protocol is up
  Hardware is I82559FE, address is 0001.a535.0920 (bia 0001.a535.0920)
  Internet address is 10.1.1.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:26, output 00:00:00, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 4682
  Queueing strategy: fifo
  Output queue: 0/60 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 36000 bits/sec, 22 packets/sec
     905 packets input, 38190 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     671863 packets output, 96101624 bytes, 0 underruns
```

```
0 output errors, 0 collisions, 1 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 124: show interfaces analysis-module Field Descriptions

Field	Description
Network-Analyzer	Indicates whether the analysis module interface hardware is currently active. The analysis module interface is the router-side interface for the internal Ethernet segment between the router and the NAM network module. If the analysis module interface hardware is operational, the output states that the “Network-Analyzer 1/0 is up.” If the interface has been taken down by an administrator, the output states that the “Network-Analyzer 1/0 is administratively down.”
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or whether the line has been taken down by an administrator.
Hardware is...address is	Hardware type and address.
MTU	Maximum transmission unit (MTU) of the analysis module interface.
BW	Bandwidth of the interface, in kbps.
DLY	Delay of the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload	Transmit load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
rxload	Receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether or not loopback is set.
Keepalive	Indicates whether or not keepalives are set and the interval between keepalives if they have been set.
ARP type...ARP Timeout	Type of Address Resolution Protocol (ARP) assigned and length of timeout.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by the interface and processed locally on the router. This field is useful for detecting when a dead interface failed. **Note** This field is not updated by fast-switched traffic.

Field	Description
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. This field is useful for detecting when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because a transmission took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. Asterisks (***) indicate that the elapsed time is too large to be displayed.
Input queue	Number of packets in the input queue. Each number is followed by a slash, the maximum size of the queue, the number of packets dropped because of a full queue, and the number of times that queued packets have been discarded.
Total output drops	Number of packets in the output queue that have been dropped because of a full queue.
Queueing strategy	Queueing strategy applied to the interface, which is configurable under the interface. The default is FIFO (first-in, first-out).
Output queue	Number of packets in the output queue, and the maximum size of the queue. Each number is followed by a slash.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic that it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within 2 percent of the instantaneous rate of a uniform stream of traffic over that period. **Note** The 5-minute period referenced in this output is a load interval that is configurable under the interface. The default value is 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received...broadcasts	Number of broadcasts received.

Field	Description
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
throttles	Number of times that the interface requested another interface within the router to slow down.
input errors	Errors that include runts, giants, no buffer, cyclic redundancy checksum (CRC), frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Errors created when the CRC generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station that is transmitting bad data.
frame	Number of packets received incorrectly that have a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times that the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets that were ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from system buffer space described. Broadcast storms and bursts of noise can cause the ignored count to increase.
input packets with dribble condition detected	Number of packets with dribble condition. Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages that have been transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, that have been transmitted by the system.
underruns	Number of times that the transmitter has run faster than the router could handle. This may never be reported on some interfaces.

Field	Description
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface that is being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages that have been retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets that were queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles	Count of frames greater than 1518 bytes that have been transmitted, indicating that the transmitter has been on the interface longer than the time necessary to transmit the largest frame.
late collision	Number of late collisions. A collision becomes a late collision when it occurs after the preamble has been transmitted.
deferred	Deferred indicates that the chip, while ready to transmit a frame, had to defer because the carrier was asserted.
lost carrier	Number of times that the carrier was lost during transmission.
no carrier	Number of times that the carrier was not present during the transmission.
output buffer failures, output buffers swapped out	Number of failed buffers and number of buffers swapped out.

Related Commands

Command	Description
show controllers analysis-module	Displays controller information for the analysis module interface.

show interfaces bdi

To display statistics for bridge domain interfaces (BDI) configured on the router, use the **show interfaces** command in privileged EXEC mode.

show interfaces [*type number*]

Syntax Description

number	(Optional) Port number on the selected interface.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
controller	(Optional) Displays the interface status, configuration and controller status.
counters	(Optional) Displays the current status of the protocol counters enabled.
crb	(Optional) Displays interface routing or bridging information.
dampening	(Optional) Displays interface dampening information.
description	(Optional) Displays the interface description.
etherchannel	(Optional) Displays interface Ether Channel information.
history	(Optional) Displays the interface history.
irb	(Optional) Displays interface routing or bridging information.
mac-accounting	(Optional) Displays interface MAC accounting information.
mpls-exp	(Optional) Displays interface Multiprotocol Label Switching (MPLS) experimental accounting information.
precedence	(Optional) Displays interface precedence accounting information.
random-detect	(Optional) Displays interface Weighted Random Early Detection (WRED) information.
rate-limit	(Optional) Displays interface rate-limit information.
stats	(Optional) Displays interface packets and octets, in and out, by using switching path.
summary	(Optional) Displays an interface summary.

Command Default

This command has no default settings.

Command Modes

User EXEC (>)
Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.2S	This command was introduced on Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows BDI configuration output:

```
Router# show interfaces BDI3
asr2#sh int bdi3
BDI3 is up, line protocol is up
Hardware is BDI, address is cafe.aaaa.0003 (bia 0024.14ab.86bf)
Internet address is 197.1.3.12/24
MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
reliability 255/255, txload 8/255, rxload 8/255
Encapsulation QinQ VLAN, outer ID  1, inner ID 2, loopback not set
Keepalive not supported
ARP type: ARPA, ARP Timeout 04:00:00
Last input 00:19:15, output 00:03:59, output hang never
Last clearing of "show interface" counters 00:17:36
Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/40 (size/max)
5 minute input rate 32947000 bits/sec, 73545 packets/sec
5 minute output rate 32877000 bits/sec, 73391 packets/sec
78126222 packets input, 4375068432 bytes, 0 no buffer
Received 0 broadcasts (0 IP multicasts)
0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
78126268 packets output, 4375071092 bytes, 0 underruns
0 output errors, 0 interface resets
0 unknown protocol drops
.
.
```

The following example shows the BDI interface summary:

```
Router#show interfaces bdi 3 summary
 *: interface is up
 IHQ: pkts in input hold queue     IQD: pkts dropped from input queue
 OHQ: pkts in output hold queue    OQD: pkts dropped from output queue
 RXBS: rx rate (bits/sec)          RXPS: rx rate (pkts/sec)
 TXBS: tx rate (bits/sec)          TXPS: tx rate (pkts/sec)
 TRTL: throttle count
  Interface                  IHQ       IQD       OHQ       OQD      RXBS      L
--------------------------------------------------------------------------------
  BDI3                         0         0         0         0         0      0
```

show interfaces capabilities

To display the interface capabilities for a module, an interface, or all interfaces, use the **showinterfacescapabilities** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **capabilities** [**module** *number*]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **port-channel**, and **ge-wan**.
interface-number	Module and port number; see the "Usage Guidelines" section for valid values.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This output was changed to include information about the following on the Supervisor Engine 720 only: • Port security • dot1x
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2

The *interface-number*argument designates the module and port number. Valid values for *interface-number* depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 2 to 13 and valid values for the port number are from 1 to 48.

The **port-channel** values are from 0 to 282; values from 257 to 282 are supported on the CSM and the FWSM only.

Examples

This example shows how to display the interface capabilities for a module:

```
Router> show interfaces capabilities module 6
FastEthernet6/1
Dot1x: yes
Model: WS-X6248-RJ-45
```

```
Type: 10/100BaseTX
Speed: 10,100,auto
Duplex: half,full
Trunk encap. type: 802.1Q,ISL
Trunk mode: on,off,desirable,nonegotiate
Channel: yes
Broadcast suppression: percentage(0-100)
Flowcontrol: rx-(off,on),tx-(none)
Membership: static
Fast Start: yes
QOS scheduling: rx-(1q4t), tx-(2q2t)
CoS rewrite: yes
ToS rewrite: yes
Inline power: no
SPAN: source/destination
UDLD yes
Link Debounce: yes
Link Debounce Time: no
Ports on ASIC: 1-12
Port-Security: yes
Router#
```

This example shows how to display the interface capabilities for an interface:

```
Router? show interfaces fastethernet 4/1 capabilities
FastEthernet4/1
Model: WS-X6348-RJ-45
Type: 10/100BaseTX
Speed: 10,100,auto
Duplex: half,full
Trunk encap. type: 802.1Q,ISL
Trunk mode: on,off,desirable,nonegotiate
Channel: yes
Broadcast suppression: percentage(0-100)
Flowcontrol: rx-(off,on),tx-(none)
Fast Start: yes
QOS scheduling: rx-(1q4t), tx-(2q2t)
CoS rewrite: yes
ToS rewrite: yes
Inline power: no
SPAN: source/destination
```

This example shows how to display the port-channel interface capabilities:

```
Router> show interfaces port-channel 12 capabilities
Port-channel12
  Model:                 NO IDPROM
  Type:                  unknown
  Speed:                 10,100,1000,auto
  Duplex:                half,full
  Trunk encap. type:     802.1Q,ISL
  Trunk mode:            on,off,desirable,nonegotiate
  Channel:               yes
  Broadcast suppression: percentage(0-100)
  Flowcontrol:           rx-(off,on),tx-(none)
  Fast Start:            yes
  QOS scheduling:        rx-(1q4t), tx-(1q4t)
  CoS rewrite:           yes
  ToS rewrite:           yes
  Inline power:          no
  SPAN:                  source/destination
```

Router#

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.

show interfaces content-engine

To display basic interface configuration information for a content engine (CE) network module, use the **showinterfacescontent-engine** command in privileged EXEC mode.

show interfaces content-engine *slot/unit*

Syntax Description

slot	Number of the router chassis slot for the network module.
unit	Number of the daughter card on the network module. For CE network modules, always use 0.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

The output for this command contains the basic configuration for the interface, as well as the number of packets transmitted, output rate, and so forth.

Examples

The following example displays interface status and data for the CE network module in slot 1 for Cisco 2600 series routers (except the Cisco 2691). Note that the bandwidth is 10 Mbps.

```
Router# show interfaces content-engine 1/0
Content-Engine1/0 is up, line protocol is up
  Hardware is I82559FE, address is 0006.280e.10b0 (bia 0006.280e.10b0)
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:50, output 00:00:04, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue :0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     13 packets input, 5835 bytes, 0 no buffer
     Received 13 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     71 packets output, 6285 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The following example displays interface status and data for a CE network module in slot 3 of a Cisco 2691. This example shows the 100-Mbps bandwidth of a Cisco 2691 and all the other supported routers except the remainder of the Cisco 2600 series.

```
Router# show interfaces content-engine 3/0
Content-Engine3/0 is up, line protocol is up
  Hardware is I82559FE, address is 0004.9a0b.4b30 (bia 0004.9a0b.4b30)
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:41, output 00:00:04, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue :0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     14 packets input, 6176 bytes, 0 no buffer
     Received 14 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     109 packets output, 16881 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 125: show interfaces content-engine Field Descriptions

Field	Description
Content-Engine	Indicates whether the CE interface hardware is currently active. If the CE interface hardware is operational, the output states that "Content-Engine slot/port is up." If it has been taken down by an administrator, the output states that "Content-Engine slot/port is administratively down."
line protocol	Indicates whether the software processes that handle the line protocol consider the line usable or whether the line has been taken down by an administrator.
Hardware...address	Hardware type and address.
MTU	Maximum transmission unit (MTU) of the content engine interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload	Transmit load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
rxload	Receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.

Field	Description
loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set and the interval between keepalives if they have been set.
ARP type...Timeout	Type of Address Resolution Protocol (ARP) assigned and length of timeout.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by the interface and processed locally on the router. This field is useful for detecting when a dead interface failed. **Note** This field is not updated by fast-switched traffic.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. This field is useful for detecting when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because a transmission took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. Asterisks (***) indicate that the elapsed time is too large to be displayed. A time of all zeroes (0:00:00) indicates that the counters were cleared more than 231 ms (and less than 232 ms) ago.
Input queue	Number of packets in the input queue. Each number is followed by a slash, the maximum size of the queue, the number of packets dropped because of a full queue, and the number of times that queued packets have been discarded.
Total output drops	Number of packets in the output queue that have been dropped because of a full queue.
Queueing strategy	Queueing strategy applied to the interface, which is configurable under the interface. The default is FIFO.
Output queue	Number of packets in the output queue. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.

Field	Description
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic that it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within 2 percent of the instantaneous rate of a uniform stream of traffic over that period. **Note** The 5-minute period referenced in this output is a load interval that is configurable under the interface. The default value is 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received...broadcasts	Number of broadcasts received.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
throttles	Number of times that the interface requested another interface within the router to slow down.
input errors	Errors that include runts, giants, no buffer, cyclic redundancy check (CRC), frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Errors created when the CRC generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station that is transmitting bad data.
frame	Number of packets received incorrectly that have a CRC error and a non integer number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.

Field	Description
overrun	Number of times that the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets that were ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from system buffer space described. Broadcast storms and bursts of noise can cause the ignored count to increase.
input packets with dribble condition detected	Number of packets with dribble condition. Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages that have been transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, that have been transmitted by the system.
underruns	Number of times that the transmitter has run faster than the router could handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the content engine that is being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages that have been retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets that were queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles	Count of frames greater than 1518 bytes that have been transmitted, indicating that the transmitter has been on the interface longer than the time necessary to transmit the largest frame.
late collision	Number of late collisions. A collision becomes a late collision when it occurs after the preamble has been transmitted.
deferred	Deferred indicates that the chip, while ready to transmit a frame, had to defer because the carrier was asserted.
lost carrier	Number of times that the carrier was lost during transmission.

Field	Description
no carrier	Number of times that the carrier was not present during the transmission.
output buffer failures, output buffers swapped out	Number of failed buffers and number of buffers swapped out.

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show controllers content-engine	Displays controller information for CE network modules.

show interfaces counters nonzero

To get the counter information for ports which have non zero values, use the **showinterfacescountersnonzero** command in user EXEC or privileged EXEC mode.

show interfaces counters nonzero [**module** *number*]

Syntax Description

module	(Optional) Limits display to interfaces on module.
number	The module number has a range from 1 to 6.

Command Default

This command has no default settings.

Command Modes

EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXF	This command was introduced for Cisco IOS Release 12.2(18)SXF.
12.2(32)SX	This command was integrated into Cisco IOS Release 12.2(32)SX.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(32)XJC	This command was integrated into Cisco IOS Release 12.2(32)XJC.

Usage Guidelines

Use the **showinterfacescountersnonzero** command to get the counter information for ports which have non zero values.

Examples

The following example shows the output of **showinterfacescountersnonzero** command. The output is displayed only if any one of the counters is non zero. The counters are checked for all the ports present in the router.

```
Router#sh interfaces counters nonzero
Port               InOctets   InUcastPkts   InMcastPkts   InBcastPkts
Fa3/1             110519159        253605       1276951           574
Gi6/2             120329657        213823       1294339         67009
Port              OutOctets  OutUcastPkts  OutMcastPkts  OutBcastPkts
Fa3/1              15950485           142         41048             1
Gi6/2              15475538           431         41036             6
Port     Last-Clear-Counters
Gi1/1         never
Gi1/2         never
Gi1/3         never
Gi1/4         never
Gi1/5         never
Gi1/6         never
Gi1/7         never
Gi1/8         never

Router#
```

Related Commands

Command	Description
show interfaces counters	Displays the traffic seen by the physical interface.

show interfaces ctunnel

To display information about an IP over Connectionless Network service (CLNS) tunnel (CTunnel), use the **showinterfacesctunnel** command in privileged EXEC mode.

show interfaces ctunnel *interface-number* [**accounting**]

Syntax Description

interface-number	Virtual interface number.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

For the **showinterfacesctunnel** command, all output that relates to a physical medium is irrelevant and should be ignored because the CTunnel is a virtual interface.

Examples

The following is sample output from the **showinterfacesctunnel** command:

```
Router# show interfaces ctunnel 1
CTunnel1 is up, line protocol is up
  Hardware is CTunnel
  Internet address is 10.0.0.1/24
  MTU 1514 bytes, BW 9 Kbit, DLY 500000 usec,
      reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation TUNNEL, loopback not set
  Keepalive set (10 sec)
  Tunnel destination 49.0001.2222.2222.2222.cc
  Last input never, output 00:00:05, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/0, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     1 packets output, 104 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

*Table 126: **show interfaces ctunnel** Field Descriptions*

Field	Description
CTunnel is {up | down | administratively down}	Interface is currently active (up) or inactive (down). Shows interface is administratively down if disabled.
line protocol is {up | down}	Shows line protocol up if a valid route is available to the CLNS tunnel (CTunnel) destination. Shows line protocol down if no route is available, or if the route would be recursive.
Hardware	Type of interface, in this instance CTunnel.
Internet address	IP address of the interface.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth, as specified by the user, that is available on the link.
DLY	Delay of the interface, in microseconds.
Encapsulation	Encapsulation method is always TUNNEL for tunnels.
Loopback	Shows whether loopback is set or not.
Keepalive	Shows whether keepalives are set or not.
Tunnel destination	The NSAP address of the tunnel destination. The N-Selector part of the displayed NSAP address is set by the router and cannot be changed.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates that the elapsed time is too large to be displayed. 0:00:00 indicates that the counters were cleared more than 231 ms (and less than 232 ms) ago.
Queueing strategy	Type of queueing active on this interface.
Output queue, drops Input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.

Field	Description
Five minute input rate, Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of 4 time constants must pass before the average will be within 2 percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no memory buffer available.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	This field does not apply to the CTunnel virtual interface.
giants	This field does not apply to the CTunnel virtual interface.
throttles	This field does not apply to the CTunnel virtual interface.
input errors	This field does not apply to the CTunnel virtual interface.
CRC	This field does not apply to the CTunnel virtual interface.
frame	This field does not apply to the CTunnel virtual interface.
overrun	This field does not apply to the CTunnel virtual interface.
ignored	This field does not apply to the CTunnel virtual interface.
abort	This field does not apply to the CTunnel virtual interface.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes transmitted by the system.
underruns	This field does not apply to the CTunnel virtual interface.
output errors	This field does not apply to the CTunnel virtual interface.
collisions	This field does not apply to the CTunnel virtual interface.
interface resets	Number of times an interface has been reset. The interface may be reset manually by the administrator or automatically by the system when an internal error occurs.
output buffer failures	Number of buffer failures.
output buffers swapped out	Number of output buffer allocation failures.

Related Commands

Command	Description
show interfaces	Displays the statistical information specific to interfaces.

show interfaces debounce

To display the status and configuration for the debounce timer, use the **showinterfacesdebounce** command in user EXEC or privileged EXEC mode.

show interfaces [{*interface interface-number* | **null** *interface-number* | **vlan** *vlan-id*}] **debounce** [**module** *num*]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **port-channel**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
null *interface-number*	(Optional) Specifies the null interface; the valid value is **0**.
vlan *vlan-id*	(Optional) Specifies the VLAN; valid values are from 1 to 4094.
module *num*	(Optional) Limits the display to interfaces on the specified module.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The debounce timer is not supported on the 10-Gigabit Ethernet module (WSX-6502-10GE).

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

The port-channel values are from 0 to 282; values from 257 to 282 are supported on the CSM and the FWSM only.

Examples

This example shows how to display the debounce configuration of an interface:

```
Router> show interfaces GigabitEthernet 1/1 debounce
Port   Debounce time   Value
```

```
Gi1/1   enable          100
Router>
```

Related Commands

Command	Description
link debounce	Enables the debounce timer on an interface.

show interfaces description

To display a description and a status of an interface, use the **showinterfacesdescription** command in user EXEC or privileged EXEC mode.

show interfaces [*interface*] **description**

Syntax Description

interface	(Optional) Interface type; for a list of valid values, see the "Usage Guidelines" section .

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When you enter the *interface* value, these formats can be used:

- *card-type slot* /*first-port* - *last-port*
- *card-type slot* /*first-port* - *last-port*

You can define a single port range per command entry. If you specify a range of ports, the range must consist of the same slot and port type. When you define a range, you must enter a space before and after the hyphen (-) as follows:

```
show interfaces gigabitethernet7/1 - 7 counters broadcast
```

Possible valid values for *card-type* are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **port-channel**, **pos**, **atm**, and **ge-wan**

The **pos**, **atm**, and **ge-wan** keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The port-channel values are from 0 to 282; values from 257 to 282 are supported on the CSM and the FWSM only.

Examples

This example shows how to display the information for all interfaces:

```
Router> show interfaces description
 Interface Status         Protocol Description
 PO0/0     admin down     down     First POS interface
 PO0/1     admin down     down
 Gi1/0     up             up       GigE to server farm
Router>
```

Related Commands

Command	Description
description	Includes a specific description about the DSP interface.

show interfaces ethernet

To display information about an Ethernet interface on the router, use the **showinterfacesethernet** command in privileged EXEC mode.

Standard Syntax
show interfaces ethernet [*number*] [**accounting**]

Cisco 7200 and 7500 Series
show interfaces : ethernet accounting optionshow interfaces ethernet [*slot/port*] [**accounting**]

Cisco 7500 Series with Ports on VIPs
show interfaces ethernet [*slot/port-adapter/port*]

Catalyst 6500 Series Switches
show interfaces ethernet [**vlan** *vlan*]

Syntax Description

number	(Optional) Port number on the selected interface.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
/ *port*	(Optional) Port number. Refer to the appropriate hardware manual for slot and port information.
/ *port-adapter*	(Optional) Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.
vlan *vlan*	(Optional) Specifies a VLAN. Limits the display of switch port information to the specified VLAN. Range: 1 to 4094.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SXI	This command was changed to add the optional **vlan***vlan* keyword and argument.

Usage Guidelines

If you do not provide values for the *number*argument (or *slot*, *port*, and *port-adapter* arguments), the command displays statistics for all network interfaces. The optional keyword **accounting** displays the number of packets of each protocol type that have been sent through the interface.

Cisco IOS Release 12.2(33)SXI and later releases allow you to limit the display of switch port information to the specified VLAN.

Examples

The following is sample output from the **showinterfacesethernet**command for Ethernet interface 0:

```
Router# show interfaces ethernet 0
Ethernet0 is up, line protocol is up
  Hardware is Lance, address is 0060.3ef1.702b (bia 0060.3ef1.702b)
  Internet address is 172.21.102.33/24
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:20, output 00:00:06, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     115331 packets input, 27282407 bytes, 0 no buffer
     Received 93567 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 input packets with dribble condition detected
     143782 packets output, 14482169 bytes, 0 underruns
     0 output errors, 1 collisions, 5 interface resets
     0 babbles, 0 late collision, 7 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes significant fields shown in the display.

*Table 127: **show interfaces ethernet** Field Descriptions*

Field	Description
Ethernet ... is up ... is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator. “Disabled” indicates the router has received over 5000 errors in a keepalive interval, which is 10 seconds by default.
line protocol is {up | down | administratively down}	Indicates whether the software processes that handle the line protocol believe the interface is usable (that is, whether keepalives are successful) or if it has been taken down by an administrator.
Hardware	Hardware type (for example, MCI Ethernet, SCI, cBus Ethernet) and address.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.

Field	Description
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
ARP type:	Type of Address Resolution Protocol assigned.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last five minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The five-minute input and output rates should be used only as an approximation of traffic per second during a given five-minute period. These rates are exponentially weighted averages with a time constant of five minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.

Field	Description
bytes input	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffers	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
Received ... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
input error	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.

Field	Description
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages transmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times a Type 2 Ethernet controller was restarted because of errors.
babbles	The transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.
deferred	Deferred indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
output buffer failures	Number of failed buffers and number of buffers swapped out.

Example on Cisco 7500 Series Routers

The following sample output illustrates the **showinterfacesethernet** command on a Cisco 7500 series router:

```
Router# show interfaces ethernet 4/2
Ethernet4/2 is up, line protocol is up
  Hardware is cxBus Ethernet, address is 0000.0c02.d0ce (bia 0000.0c02.d0ce)
  Internet address is 10.108.7.1, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 4:00:00
  Last input 0:00:00, output 0:00:09, output hang never
  Last clearing of "show interface" counters 0:56:40
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 3000 bits/sec, 4 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     4961 packets input, 715381 bytes, 0 no buffer
```

```
     Received 2014 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     567 packets output, 224914 bytes, 0 underruns
     0 output errors, 168 collisions, 0 interface resets, 0 restarts
     0 babbles, 2 late collision, 7 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

Example with Accounting Option

The following is sample output from the **showinterfacesethernet** command with the **accounting** option on a Cisco 7500 series router:

```
Router# show interfaces ethernet 4/2 accounting
Ethernet4/2
       Protocol    Pkts In   Chars In   Pkts Out  Chars Out
             IP       7344    4787842       1803    1535774
      Appletalk      33345    4797459      12781    1089695
        DEC MOP          0          0        127       9779
            ARP          7        420         39       2340
```

The table below describes the fields shown in the display.

*Table 128: **show interfaces ethernet** Field Descriptions--Accounting*

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

Catalyst 6500 Series Switches

The following is sample output from the **showinterfacesethernet**command for VLAN 2:

```
Router# show interfaces ethernet vlan 2
```

show interfaces fastethernet

To display information about the Fast Ethernet interfaces, use the **showinterfacesfastethernet** command in user EXEC or privileged EXEC mode.

Standard Syntax
show interfaces fastethernet [*number*]

Cisco 7200 and Cisco 7500 Series
show interfaces fastethernet [*slot*/*port*]

Cisco 7500 Series with a VIP
show interfaces fastethernet [*slot*/*port-adapter*/*port*]

Syntax Description

number	(Optional) Port, connector, or interface card number. On a Cisco 4700 series routers, specifies the network interface module (NIM) or NPM number. The numbers are assigned at the factory at the time of installation or when added to a system.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
port	(Optional) Port number. Refer to the appropriate hardware manual for slot and port information.
port-adapter	(Optional) Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showinterfacesfastethernet** command on a Cisco 4700 series router:

```
Router# show interfaces fastethernet 0
Fast Ethernet0 is up, line protocol is up
  Hardware is DEC21140, address is 0000.0c0c.1111 (bia 0002.eaa3.5a60)
  Internet address is 10.0.0.1 255.0.0.0
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive not set, hdx, 100BaseTX
  ARP type: ARPA, ARP Timeout 4:00:00
  Last input never, output 0:00:16, output hang 0:28:01
  Last clearing of "show interface" counters 0:20:05
```

```
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 1786161921 ignored, 0 abort
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     67 packets output, 8151 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets, 0 restarts
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The following is sample output from the **showinterfacesfastethernet** command on a Cisco AS5300 access server:

```
Router# show interfaces fastethernet 0
Fast Ethernet0 is up, line protocol is up
  Hardware is DEC21140AD, address is 00e0.1e3e.c179 (bia 00e0.1e3e.c179)
  Internet address is 10.17.30.4/16
  MTU 1500 bytes, BW 10000 Kbit, DLY 1000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  Half-duplex, 10Mb/s, 100BaseTX/FX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:00, output 00:00:03, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/120, 8 drops
  5 minute input rate 2000 bits/sec, 3 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     158773 packets input, 17362631 bytes, 4 no buffer
     Received 158781 broadcasts, 0 runts, 0 giants, 7 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     6299 packets output, 622530 bytes, 0 underruns
     1 output errors, 0 collisions, 3 interface resets
     0 babbles, 0 late collision, 0 deferred
     1 lost carrier, 1 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The following shows information specific to the first Fast Ethernet Interface Processor (FEIP) port in slot 0 on a Cisco 7500 series router:

```
Router# show interfaces fastethernet 0/1
Fast Ethernet0/1 is administratively down, line protocol is down
  Hardware is cxBus Fast Ethernet, address is 0000.0c35.dc16 (bia 0000.0c35.dc16)
  Internet address is 10.1.0.64 255.255.0.0
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive not set, half-duplex, RJ45 (or MII)
  ARP type: ARPA, ARP Timeout 4:00:00
  Last input never, output 2:03:52, output hang never
  Last clearing of "show interface" counters never
  Output queue 0/40, 0 drops; input queue 0/75, 1 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     5 packets output, 805 bytes, 0 underruns
```

```
0 output errors, 0 collisions, 4 interface resets, 0 restarts
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier
0 output buffer failures, 0 output buffers swapped out
```

The table below describes the fields shown in these displays.

*Table 129: **show interfaces fastethernet** Field Descriptions*

Field	Description
Fast Ethernet0 is ... is up ...is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type (for example, MCI Ethernet, SCI, cBus Ethernet) and address.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
ARP type	Type of Address Resolution Protocol assigned.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.

Field	Description
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received ... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.

Field	Description
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Number of packets whose receipt was aborted.
watchdog	Number of times watchdog receive timer expired. It happens when receiving a packet with length greater than 2048.
multicast	Number of multicast packets received.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times a Type 2 Ethernet controller was restarted because of errors.
babbles	The transmit jabber timer expired.

Field	Description
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.
deferred	Deferred indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
output buffer failures	Number of failed buffers and number of buffers swapped out.

The following example of the **showinterfacesfastethernet**command shows all the information specific to the first PA-12E/2FE interface port (interface port 0) in port adapter slot 3:

```
Router# show interfaces fastethernet 3/0
Fast Ethernet3/0 is up, line protocol is up
  Hardware is TSWITCH, address is 00e0.f7a4.5130 (bia 00e0.f7a4.5130)
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  Half-duplex, 100BaseTX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:05:30, output 00:00:00, output hang never
  Last clearing of “show interface” counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     312 packets input, 18370 bytes, 0 no buffer
     Received 216 broadcasts, 0 runts, 0 giants, 0 throttles
     3 input errors, 0 CRC, 0 frame, 0 overrun, 3 ignored, 0 abort
     0 input packets with dribble condition detected
     15490 packets output, 1555780 bytes, 0 underruns
     2 output errors, 0 collisions, 2 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     2 output buffer failures, 0 output buffers swapped out
```

The table below describes the fields shown in this display.

Table 130: show interfaces fastethernet Field Descriptions--PA-12E/2FE

Field	Description
Fast Ethernet... is up ...is administratively down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type (for example, MCI Ethernet, SCI, cBus Ethernet) and address.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.

Field	Description
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
ARP type	Type of Address Resolution Protocol assigned.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.

Field	Description
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received ... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.

Field	Description
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Number of packets whose receipt was aborted.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles	Transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.
deferred	Deferred indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.

show interfaces fddi

To display information about the FDDI interface, use the **showinterfacesfddi**command in user EXEC or privileged EXEC mode.

Standard Syntax
show interfaces fddi *number* [**accounting**]

Cisco 7000 and Cisco 7200 Series
show interfaces : fddi accounting optionshow interfaces fddi [*slot*/*port*] [**accounting**]

Cisco 7500 Series
show interfaces fddi [*slot*/*port-adapter*/*port*] [**accounting**]

Syntax Description

number	Port number on the selected interface.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
port	(Optional) Port number. Refer to the appropriate hardware manual for slot and port information.
port-adapter	(Optional) Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.3	This command was modified to include support for FDDI full-duplex, single- and multimode port adapters (PA-F/FD-SM and PA-F/FD-MM).
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is a sample partial display of FDDI-specific data from the **showinterfacesfddi** command on a Cisco 7500 series router:

```
Router# show interfaces fddi 3/0/0

Fddi3/0/0 is up, line protocol is up
  Hardware is cxBus Fddi, address is 0000.0c02.adf1 (bia 0000.0c02.adf1)
  Internet address is 10.108.33.14, subnet mask is 255.255.255.0
```

```
  MTU 4470 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation SNAP, loopback not set, keepalive not set
  ARP type: SNAP, ARP Timeout 4:00:00
  Phy-A state is active, neighbor is   B, cmt signal bits 008/20C, status ILS
  Phy-B state is active, neighbor is   A, cmt signal bits 20C/008, status ILS
  ECM is in, CFM is thru, RMT is ring_op
  Token rotation 5000 usec, ring operational 21:32:34
  Upstream neighbor 0000.0c02.ba83, downstream neighbor 0000.0c02.ba83
  Last input 0:00:05, output 0:00:00, output hang never
  Last clearing of "show interface" counters 0:59:10
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 69000 bits/sec, 44 packets/sec
  Five minute output rate 0 bits/sec, 1 packets/sec
     113157 packets input, 21622582 bytes, 0 no buffer
     Received 276 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     4740 packets output, 487346 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets, 0 restarts
     0 transitions, 2 traces, 3 claims, 2 beacons
```

The following is sample output from the **showinterfacesfddi**command for the full-duplex FDDI port adapter on a Cisco 7500 series router:

```
Router# show interfaces fddi 0/1/0
Fddi0/1/0 is up, line protocol is up
  Hardware is cxBus FDDI, address is 0060.3e33.3608 (bia 0060.3e33.3608)
  Internet address is 10.1.1.1/24
  MTU 4470 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation SNAP, loopback not set, keepalive not set
  ARP type: SNAP, ARP Timeout 04:00:00
  FDX supported, FDX enabled, FDX state is operation
  Phy-A state is maintenance, neighbor is Unknown, status HLS
  Phy-B state is active, neighbor is A, status SILS
  ECM is in, CFM is c_wrap_b, RMT is ring_op,
  Requested token rotation 5000 usec, negotiated 4997 usec
  Configured tvx is 2500 usec
  LER for PortA = 0A, LER for PortB = 0A ring operational 00:02:45
  Upstream neighbor 0060.3e73.4600, downstream neighbor 0060.3e73.4600
  Last input 00:00:12, output 00:00:13, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     62 packets input, 6024 bytes, 0 no buffer
     Received 18 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     71 packets output, 4961 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     3 transitions, 0 traces, 100 claims, 0 beacon
```

The table below describes thefields shown in the display.

Table 131: show interfaces fddi Field Descriptions

Field	Description
Fddi is {up | down | administratively down	Gives the interface processor unit number and tells whether the interface hardware is currently active and can transmit and receive or if it has been taken down by an administrator.

Field	Description
line protocol is {up | down}	Indicates whether the software processes that handle the line protocol consider the interface usable.
Hardware	Provides the hardware type, followed by the hardware address.
Internet address	IP address, followed by subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
loopback	Indicates whether or not loopback is set.
keepalive	Indicates whether or not keepalives are set.
ARP type	Type of Address Resolution Protocol assigned.
FDX	Displays full-duplex information. Values are: not supported or supported. When the value is supported, the display indicates whether full-duplex is enabled or disabled. When enabled, the state of the FDX negotiation process is displayed. The negotiation states only relate to the full-duplex negotiation process. You must also ensure that the interface is up and working by looking at other fields in the **showinterfacesfddi** command such as line protocol and RMT. Negotiation states are: • idle--Interface is working but not in full-duplex mode yet. If persistent, it could mean that the interface did not meet all negotiation conditions (for example, there are more than two stations in the ring). • request--Interface is working but not in full-duplex mode yet. If persistent, it could mean that the remote interface does not support full-duplex or full-duplex is not enabled on the interface. • confirm--Transient state. • operation--Negotiations completed successfully, and both stations are operating in full-duplex mode.
Phy-{A | B}	Lists the state the Physical A or Physical B connection is in; one of the following: off, active, trace, connect, next, signal, join, verify, or break.

Field	Description
neighbor	State of the neighbor: • A--Indicates that the connection management (CMT) process has established a connection with its neighbor. The bits received during the CMT signaling process indicate that the neighbor is a Physical A type dual attachment station (DAS) or concentrator that attaches to the primary ring IN and the secondary ring OUT when attaching to the dual ring. • S--Indicates that the CMT process has established a connection with its neighbor and that the bits received during the CMT signaling process indicate that the neighbor is one Physical type in a single attachment station (SAS). • B--Indicates that the CMT process has established a connection with its neighbor and that the bits received during the CMT signaling process indicate that the neighbor is a Physical B dual attachment station or concentrator that attaches to the secondary ring IN and the primary ring OUT when attaching to the dual ring. • M--Indicates that the CMT process has established a connection with its neighbor and that the bits received during the CMT signaling process indicate that the router's neighbor is a Physical M-type concentrator serving as a Master to a connected station or concentrator. • unk--Indicates that the network server has not completed the CMT process and, as a result, does not know about its neighbor. See the section "Setting Bit Control" for an explanation of the bit patterns.
cmt signal bits	Shows the transmitted/received CMT bits. The transmitted bits are 0x008 for a Physical A type and 0x20C for Physical B type. The number after the slash (/) is the received signal bits. If the connection is not active, the received bits are zero (0); see the line beginning Phy-B in the display. This applies to FIP interfaces only.

Field	Description
status	Status value displayed is the actual status on the fiber. The FDDI standard defines the following values: • LSU--Line State Unknown, the criteria for entering or remaining in any other line state have not been met. • NLS--Noise Line State is entered upon the occurrence of 16 potential noise events without satisfying the criteria for entry into another line state. • MLS--Master Line State is entered upon the receipt of eight or nine consecutive HQ or QH symbol pairs. • ILS--Idle Line State is entered upon receipt of four or five idle symbols. • HLS--Halt Line State is entered upon the receipt of 16 or 17 consecutive H symbols. • QLS--Quiet Line State is entered upon the receipt of 16 or 17 consecutive Q symbols or when carrier detect goes low. • ALS--Active Line State is entered upon receipt of a JK symbol pair when carrier detect is high. • OVUF--Elasticity buffer Overflow/Underflow. The normal states for a connected Physical type are ILS or ALS. If the report displays the QLS status, this indicates that the fiber is disconnected from Physical B, or that it is not connected to another Physical type, or that the other station is not running.
ECM is...	ECM is the SMT entity coordination management, which overlooks the operation of CFM and PCM. The ECM state can be one of the following: • out--Router is isolated from the network. • in--Router is actively connected to the network. This is the normal state for a connected router. • trace--Router is trying to localize a stuck beacon condition. • leave--Router is allowing time for all the connections to break before leaving the network. • path_test--Router is testing its internal paths. • insert--Router is allowing time for the optical bypass to insert. • check--Router is making sure optical bypasses switched correctly. • deinsert--Router is allowing time for the optical bypass to deinsert.

Field	Description
CFM is...	Contains information about the current state of the MAC connection. The Configuration Management state can be one of the following: • isolated--MAC is not attached to any Physical type. • wrap_a--MAC is attached to Physical A. Data is received on Physical A and transmitted on Physical A. • wrap_b--MAC is attached to Physical B. Data is received on Physical B and transmitted on Physical B. • wrap_s--MAC is attached to Physical S. Data is received on Physical S and transmitted on Physical S. This is the normal mode for a single attachment station (SAS). • thru--MAC is attached to Physical A and B. Data is received on Physical A and transmitted on Physical B. This is the normal mode for a dual attachment station (DAS) with one MAC. The ring has been operational for 1 minute and 42 seconds.
RMT is...	RMT (Ring Management) is the SMT MAC-related state machine. The RMT state can be one of the following: • isolated--MAC is not trying to participate in the ring. This is the initial state. • non_op--MAC is participating in ring recovery, and ring is not operational. • ring_op--MAC is participating in an operational ring. This is the normal state while the MAC is connected to the ring. • detect--Ring has been nonoperational for longer than normal. Duplicate address conditions are being checked. • non_op_dup--Indications have been received that the address of the MAC is a duplicate of another MAC on the ring. Ring is not operational. • ring_op_dup--Indications have been received that the address of the MAC is a duplicate of another MAC on the ring. Ring is operational in this state. • directed--MAC is sending beacon frames notifying the ring of the stuck condition. • trace--Trace has been initiated by this MAC, and the RMT state machine is waiting for its completion before starting an internal path test.
token rotation	Token rotation value is the default or configured rotation value as determined by the **fdditoken-rotation-time** command. This value is used by all stations on the ring. The default is 5000 microseconds. For FDDI full-duplex, this indicates the value in use prior to entering full-duplex operation.
negotiated	Actual (negotiated) target token rotation time.
ring operational	When the ring is operational, the displayed value will be the negotiated token rotation time of all stations on the ring. Operational times are displayed by the number of hours:minutes:seconds the ring has been up. If the ring is not operational, the message “ring not operational” is displayed.

Field	Description
Configured tvx	Transmission timer.
LER	Link error rate.
Upstream | downstream neighbor	Displays the canonical MAC address of outgoing upstream and downstream neighbors. If the address is unknown, the value will be the FDDI unknown address (0x00 00 f8 00 00 00).
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue, input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
5 minute input rate 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The five-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.

Field	Description
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the media.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly that have a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device. On an FDDI LAN, this also can be the result of a failing fiber (cracks) or a hardware malfunction.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of transmit aborts (when the router cannot feed the transmitter fast enough).
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, because some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Because an FDDI ring cannot have collisions, this statistic is always zero.
interface resets	Number of times an interface has been reset. The interface may be reset by the administrator or automatically when an internal error occurs.
restarts	Should always be zero for FDDI interfaces.

Field	Description
output buffer failures	Number of no resource errors received on the output.
output buffers swapped out	Number of packets swapped to DRAM.
transitions	The number of times the ring made a transition from ring operational to ring nonoperational, or vice versa. A large number of transitions indicates a problem with the ring or the interface.
traces	Trace count applies to both the FCI, FCIT, and FIP. Indicates the number of times this interface started a trace.
claims	Pertains to FCIT and FIP only. Indicates the number of times this interface has been in claim state.
beacons	Pertains to FCIT and FIP only. Indicates the number of times the interface has been in beacon state.

The following is sample output that includes the **accounting** option. When you use the **accounting** option, only the accounting statistics are displayed.

```
Router# show interfaces fddi 3/0 accounting
Fddi3/0
       Protocol    Pkts In   Chars In   Pkts Out  Chars Out
             IP       7344    4787842       1803    1535774
     Appletalk       33345    4797459      12781    1089695
        DEC MOP          0          0        127       9779
            ARP          7        420         39       2340
```

The table below describes thefields shown in the display.

*Table 132: **show interfaces fddi** Field Descriptions--Accounting*

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

show interfaces flowcontrol

To display flow-control information, use the **showinterfacesflowcontrol** command in user EXEC or privileged EXEC mode.

show interfaces [*interface* [*mod*]] **flowcontrol** [{**module** *number* | **vlan** *vlan*}]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **port-channel**, **vlan** , **pos**, **atm**, and **ge-wan** **Note** The show interfaces vlan vlan flowcontrol command displays the interface VLAN information.
mod	(Optional) Module and port number.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.
vlan **Note** The show interfaces flowcontrol vlan vlan command limits the display to interfaces on the specified VLAN.	(Optional) Limits the display of switch port information to the specified VLAN. Range: 1 to 4094

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was changed to add the optional **vlan***vlan* keyword and argument.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on systems that are configured with a Supervisor Engine 2

The *mod*argument designates the module and port number. Valid values for *mod* depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

The **module***number* keyword and argument designate the module number and limit the display to interfaces on the module. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

The port-channel values are from 0 to 282; values from 257 to 282 are supported on the CSM and the FWSM only.

Cisco IOS Release 12.2(33)SXI and later releases allow you to limit the display of switch port information to the specified VLAN.

Examples

This example shows how to display flow-control information for all interfaces:

```
Router> show interfaces flowcontrol
Port  Send    FlowControl Receive FlowControl RxPause TxPause
      admin     oper      admin     oper
----- --------  --------  --------  --------  -------  -------
Gi1/1 desired   off       off       off       0        0
Gi1/2 desired   off       off       off       0        0
Gi3/1 on        on        on        on        0        0
.
.
.
Gi8/2 desired   off       off       off       0        0
Gi8/3 desired   off       off       off       0        0
Gi8/4 desired   off       off       off       0        0
Router>
```

This example shows how to display flow-control information for a specific interface:

```
Router> show interfaces gigabitethernet 8/2 flowcontrol
Port  Send    FlowControl Receive FlowControl RxPause TxPause
      admin     oper      admin     oper
----- --------  --------  --------  --------  -------  -------
Gi8/2 desired   off       off       off       0        0
Router>
```

This example shows how to limit the display flow-control information for interfaces on a specific VLAN:

```
Router> show interfaces flowcontrol vlan 22
Router>
```

The table below describes the fields that are shown in the example.

Table 133: show port flowcontrol Command Output Fields

Field	Description
Port	Interface type and module and port number.
Send admin	Flow-control operation for admin state. Possible settings: on indicates that the local port is allowed to send pause frames to remote ports; off indicates that the local port is prevented from sending pause frames to remote ports; desired indicates predictable results whether a remote port is set to **receiveon**, **receiveoff**, or **receivedesired**.

Field	Description
Send oper	Current flow-control operation. Possible settings: on indicates that the local port is allowed to send pause frames to remote ports; off indicates that the local port is prevented from sending pause frames to remote ports; desired indicates predictable results whether a remote port is set to **receiveon**, **receiveoff**, or **receivedesired**.
Receive admin	Flow-control operation for admin state. Possible settings: on indicates that the local port is allowed to process pause frames that a remote port sends; off indicates that the local port is prevented from sending pause frames to remote ports; desired indicates predictable results whether a remote port is set to **sendon**, **sendoff**, or **senddesired**.
Receive oper	Current flow-control operation. Possible settings: on indicates that the local port is allowed to process pause frames that a remote port sends; off indicates that the local port is prevented from sending pause frames to remote ports; desired indicates predictable results whether a remote port is set to **sendon**, **sendoff**, or **senddesired**.
RxPause	Number of pause frames that are received.
TxPause	Number of pause frames that are transmitted.

Related Commands

Command	Description
flowcontrol	Configures a port to send or receive pause frames.

show interfaces gigabitethernet

To check the status of and configuration settings on a router that supports Gigabit Ethernet Shared Port Adapters (SPA), use the **show interfaces gigabitethernet** command in the privileged EXEC mode.

Cisco 7200 Series Router
show interfaces gigabitethernet *slot/port*

Cisco ASR 1000 Series Aggregation Services Router
show interfaces gigabitethernet *slot/subslot/port*

Syntax Description

slot	Chassis slot number. (Refer to the appropriate hardware manual for slot information. For SPA Interface Processors (SIPs), refer to the platform-specific SPA hardware installation guide or the platform-specific SPA software configuration guide.)
subslot	Secondary slot number on a SIP in which a SPA is installed. (Refer to the platform-specific SPA hardware installation guide or the platform-specific SPA software configuration guide for subslot information.)
port	Port number or interface number. (Refer to the appropriate hardware manual for port information. For SPAs, refer to the platform-specific SPA software configuration guide.)

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.1CC	This command was introduced.
12.1(3A)E	The command was modified to support Cisco 7200-I/O-GE+E Controller.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(20)S2	This command was integrated into Cisco IOS Release 12.2(20)S2. It was modified to include a new address format and output for the interfaces on the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 Routers. The *subslot* argument was also added.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support the Gigabit Ethernet SPAs on the Cisco 12000 Series Routers.
12.2(18)SXF	This command was integrated into Cisco IOS Release 12.2(18)SXF to support the Gigabit Ethernet SPAs on the Cisco 7600 Series Routers and the Cisco Catalyst 6500 Series Switches.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

This command is used in Cisco 7200-I/O-GE+E Controller and the Cisco ASR 1000 Series Aggregation Services Routers to display the configuration status of a Gigabit Ethernet interface.

> **Note:** On Cisco 7200-I/O-GE+E Controller, *slot 0* is always reserved for the Gigabit Ethernet port on the I/O controller.

Cisco 7200-I/O-GE+E Controller Example

The following is sample output from the **show interfaces gigabitethernet** command:

```
Router# show interfaces gigabitethernet 5/1

GigabitEthernet5/1 is up, line protocol is up
Hardware is C6k 1000Mb 802.3, address is 0015.c620.b580 (bia 0015.c620.b580)
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 1000Mb/s
  input flow-control is off, output flow-control is off
  Clock mode is auto
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     0 input packets with dribble condition detected
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

Cisco ASR 1000 Series Aggregation Services Router Example

The following is sample output from the **show interfaces gigabitethernet** command:

```
Router# show interface gigabitethernet 0/0/0

GigabitEthernet0/0/0 is up, line protocol is up
  Hardware is SPA-2X1GE-V2, address is 001f.6c25.c400 (bia 001f.6c25.c400)
  Description: Connected to CE28_C2811 GE 0/0/0
  Internet address is 192.168.128.43/24
  MTU 2000 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not supported
  Full Duplex, 1000Mbps, link type is auto, media type is SX
  output flow-control is on, input flow-control is on
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:46, output 00:09:07, output hang never
```

```
  Last clearing of "show interface" counters never
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     673295 packets input, 70811204 bytes, 0 no buffer
     Received 1 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 104296 multicast, 0 pause input
     1310016 packets output, 99574303 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets
     0 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

Gigabit Ethernet SPA Example

The following is sample output from the **show interfaces gigabitethernet** command for the first interface *port 0* in a 2-port 10/100/1000 Gigabit Ethernet SPA located in the top *subslot 0* of the MSC that is installed in *slot 4* on a Cisco 7304 Router:

```
Router# show interfaces gigabitethernet 4/0/0

GigabitEthernet4/0/0 is up, line protocol is down
  Hardware is SPA-2GE-7304, address is 00b0.64ff.5a80 (bia 00b0.64ff.5a80)
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Half-duplex, 1000Mb/s, link type is auto, media type is RJ45
  output flow-control is unsupported, input flow-control is unsupported
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output 00:00:09, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicast)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     109 packets output, 6540 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets
     0 babbles, 0 late collision, 0 deferred
     1 lost carrier, 0 no carrier, 0 PAUSE output
     0 output buffer failures, 0 output buffers swapped out
```

Note There will be variations in the output of the **show interfaces** command, depending on the platform, type of interface, and other features that you might have configured, such as Quality of Service (QoS). Therefore, some additional output fields might appear in your **show interfaces** command output. For more information about these fields, see the **show interfaces** command description in the *Cisco IOS Interface and Hardware Component Command Reference* document at: http://www.cisco.com/en/US/docs/ios-xml/ios/interface/command/ir-s4.html#wp2987586133

The following table describes the significant fields shown in the displays:

Table 134: show interfaces gigabitethernet Field Descriptions

Field	Description
GigabitEthernet...is up ...is administratively down	Indicates whether the interface hardware is currently active or if it has been taken down by an administrator.
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable, or if it has been taken down by an administrator.
Hardware	Hardware type, for example, SPA-2GE-7304, and MAC address.
Description	Alphanumeric string identifying the interface. It is displayed only if the **description** interface configuration command has been configured on the interface.
Internet address	Internet address followed by the subnet mask.
MTU	Maximum transmission unit of the interface. The default is 1500 bytes for the 2-port 10/100/1000 Gigabit Ethernet SPA.
BW	Bandwidth of the interface, in kilobits, per second.
DLY	Delay in the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload, rxload	Load on the interface (in the transmit "tx" and receive "rx" directions) as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether or not loopback is set.
Keepalive	Indicates whether or not keepalives are set, and the time interval.
Half-duplex, Full-duplex	Indicates the duplex mode of the interface.
1000Mb/s, 100Mb/s, 10Mb/s	Speed of the interface, in megabits, per second.
link type	Specifies whether or not auto negotiation is being used on the link.
media type	Interface port media type: RJ45, SX, LX, or ZX.
ARP type	Type of Address Resolution Protocol (ARP) assigned, and the timeout period.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by the interface and processed locally on a router. Useful for knowing when a dead interface failed. This field is not updated by fast-switched traffic.

Field	Description
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is displayed. If that field overflows, asterisks are displayed. **Note** This field does not apply to the SPA interfaces.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in the report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. A series of asterisks (***) indicates that the elapsed time is too large to be displayed. 0:00:00 indicates that the counters were cleared more than 231 ms (and less than 232 ms) ago.
Input queue (size/max/drops/flushes)	Packet statistics on the input queue are reported as: • Size—Number of packets in the input queue. • Max—Maximum size of the queue. • Drops—Number of packets dropped because of a full input queue. • Flushes—Number of packets dropped as part of selective packet discard (SPD). SPD implements a selective packet drop policy on a router's IP process queue. Therefore, it only applies to process-switched traffic.
Total output drops	Total number of packets dropped because of a full output queue.
Queueing strategy	Type of Layer 3 queueing active on this interface. The default is first-in, first-out (FIFO).
Output queue (size/max)	Number of packets in the output queue (size), and the maximum size of the queue (max).
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in the promiscuous mode, it senses the network traffic it sends and receives (rather than all the network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average can be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.

Field	Description
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
Received...broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is smaller than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is larger than 1536 bytes is considered a giant. **Note** In the 2-port 10/100/1000 Gigabit Ethernet SPA, the default is that a giant is any packet greater than 1536 bytes. However, if you modify the maximum transmission unit (MTU) for the interface, this counter increments when you exceed the specified MTU for the interface.
throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.
input errors	Includes runts, giants, no buffer, cyclic redundancy check (CRC), frame, overrun, oversubscription counters, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error. Therefore, this sum may not balance with the sum of enumerated input error counts. **Note** The oversubscription counters are included only on the Cisco ASR 1000 Series Aggregation Services Routers.
CRC	Cyclic redundancy check generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand the received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data. The overrun also includes the interface oversubscription counters. **Note** The interface oversubscription counters are included only on the Cisco ASR 1000 Series Aggregation Services Routers.
ignored	Number of received packets ignored by the interface because the interface hardware is running low on internal buffers. These buffers are different from the system buffers. Broadcast storms and bursts of noise may cause the ignored count to be increased.

Field	Description
watchdog	Number of times the watchdog receive timer expires. Expiration occurs when receiving a packet with a length that is greater than 2048 bytes.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly longer than usual. This frame error counter is incremented for informational purposes only; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times the transmitter has been running faster than the speed a router can handle.
output errors	Sum of all the errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN, for example, an Ethernet or transceiver cable that is too long, more than two repeaters between stations, or too many cascaded multiport transceivers. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface is completely reset. This may occur if packets that are queued for transmission were not sent within several seconds. Interface resets may occur when an interface is looped back or shut down.
babbles	Transmit jabber timer expired.
late collision	Number of late collisions. Late collision occurs when a collision takes place after the preamble is transmitted.
deferred	Number of times the interface had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission. **Note** This field does not apply to SPA interfaces.
output buffer failures, output buffers swapped out	These counters are not used by the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 Routers.

Related Commands

Command	Description
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show interfaces	Displays the statistics for the interfaces configured on a router, switch, or access server.

show interfaces hssi

To display information about the high-speed serial interface (HSSI), use the **showinterfaceshssi**command in privileged EXEC mode.

Standard Syntax
show interfaces hssi *number* [**accounting**]

Cisco 7500 Series
show interfaces hssi [*slot*/*port*] [**accounting**]

Syntax Description

number	Port number on the selected interface.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
port	(Optional) Port number. Refer to the appropriate hardware manual for slot and port information.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showinterfaceshssi** command when HSSI is enabled:

```
Router# show interfaces hssi 0
HSSI 0 is up, line protocol is up
 Hardware is cBus HSSI
 Internet address is 10.136.67.190, subnet mask is 255.255.255.0
 MTU 4470 bytes, BW 45045 Kbit, DLY 20000 usec, rely 255/255, load 1/255
 Encapsulation HDLC, loopback not set, keepalive set (10 sec)
 Last input 0:00:03, output 0:00:00, output hang never
 Output queue 0/40, 0 drops; input queue 0/75, 0 drops
 Five minute input rate 0 bits/sec, 0 packets/sec
 Five minute output rate 0 bits/sec, 0 packets/sec
      0 packets input, 0 bytes, 0 no buffer
      Received 0 broadcasts, 0 runts, 0 giants
              0 parity, 0 rx disabled
 0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
 17 packets output, 994 bytes, 0 underruns
 0 output errors, 0 applique, 4 interface resets, 0 restarts
 2 carrier transitions
```

The table below describes significant fields shown in the display.

*Table 135: **show interfaces hssi** Field Descriptions*

Field	Description
HSSI is {up | down | administratively down}	Indicates whether the interface hardware is currently active (whether carrier detect is present) and whether it has been taken down by an administrator. "Disabled" indicate that the router has received over 5000 errors in a keepalive interval, which is 10 seconds by default.
line protocol is {up | down | administratively down}	Indicates whether the software processes that handle the line protocol consider the line usable (that is, whether keepalives are successful).
Hardware	Specifies the hardware type.
Internet address	Lists the Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
loopback	Indicates whether loopback is set and type of loopback test.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.

Field	Description
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, drops Input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
Five minute input rate, Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes input	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
parity	Report of the parity errors on the HSSI.
rx disabled	Indicates that the HSSI could not find a free buffer on the ciscoBus controller to reserve for use for the HSSI receiver. When this happens, the HSSI shuts down its receiver and waits until a buffer is available. Data is not lost unless a packet comes in and overflows the HSSI FIFO. Usually, the receive disables are frequent but do not last for long, and the number of dropped packets is less than the count in the “rx disabled” field. A receive disabled condition can happen in systems that are under heavy traffic load and that have shorter packets. In this situation, the number of buffers available on the ciscoBus controller is at a premium. One way to alleviate this problem is to reduce the maximum transmission unit (MTU) on the HSSI interface from 4500 (FDDI size) to 1500 (Ethernet size). Doing so allows the software to take the fixed memory of the ciscoBus controller and divide it into a larger number of smaller buffers, rather than a small number of large buffers. Receive disables are not errors, so they are not included in any error counts.

Field	Description
input errors	Sum of all errors that prevented the receipt of datagrams on the interface being examined. This may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
CRC	Cyclic redundancy checksum (CRC) generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link CRCs usually indicate noise, gain hits, or other transmission problems on the data link. CRC errors are also reported when a far-end abort occurs, and when the idle flag pattern is corrupted. This makes it possible to get CRC errors even when there is no data traffic.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the ability of the receiver to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Number of packets whose receipt was aborted.
packets output	Total number of messages transmitted by the system.
bytes output	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router receiver can handle.
congestion drop	Number of messages discarded because the output queue on an interface grew too long. This can happen on a slow, congested serial link.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
applique	Indicates that an unrecoverable error has occurred on the High-System Availability (HSA) applique. The system then invokes an interface reset.

Field	Description
interface resets	Number of times that an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds time. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times that the controller was restarted because of errors.
carrier transitions	Number of times that the carrier detect signal of the interface has changed state. Indicates modem or line problems if the carrier detect line is changing state often.

The following is sample output from the **showinterfaceshssi** command on a Cisco 7500 series router:

```
Router# show interfaces hssi 1/0
Hssi1/0 is up, line protocol is up
  Hardware is cxBus HSSI
  Internet address is 10.108.38.14, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 45045 Kbit, DLY 1000000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive set (10 sec)
  Last input 0:00:00, output 0:00:08, output hang never
  Last clearing of "show interface" counters never
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 1000 bits/sec, 2 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     630573548 packets input, 2077237628 bytes, 0 no buffer
     Received 2832063 broadcasts, 0 runts, 0 giants
              0 parity, 1970 rx disabled
     113 input errors, 20 CRC, 93 frame, 0 overrun, 0 ignored, 0 abort
     629721628 packets output, 1934313295 bytes, 0 underruns
     0 output errors, 0 applique, 62 interface resets, 0 restarts
     309 carrier transitions
```

The following is sample output from the **showinterfaceshssi** command with the **accounting** option on a Cisco 7500 series router:

```
Router# show interfaces hssi 1/0 accounting
HIP1/0
       Protocol    Pkts In   Chars In   Pkts Out  Chars Out
             IP       7344    4787842       1803    1535774
      Appletalk      33345    4797459      12781    1089695
        DEC MOP          0          0        127       9779
            ARP          7        420         39       2340
```

The table below describes thefields shown in the display.

*Table 136: **show interfaces hssi** Field Descriptions--Accounting*

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.

Field	Description
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

show interfaces integrated-service-engine

To show the Cisco wireless LAN controller network module (WLCM) interfaces on the router, use the **showinterfacesintegrated-service-engine** command in privileged EXEC mode.

show interfaces integrated-service-engine slot/**unit** {**aaa** | **accounting** | **counters** | **crb** | **dampening** | **description** | **etherchannel** | **irb** | **mac-accounting** | **mpls-exp** | **precedence** | **pruning** | **rate-limit** | **stats** | **status** | **summary** | **switching** | **switchport** | **trunk**}

Syntax Description

slot/unit	Specifies the router slot and unit numbers.
aaa	Shows the dot11 aaa information.
accounting	Shows the interface accounting information.
counters	Shows the interface counters.
crb	Shows the interface routing and bridging information.
dampening	Shows the interface dampening information.
description	Shows the interface description.
etherchannel	Shows the interface Ethernet channel information.
irb	Shows the interface routing and bridging information.
mac-accounting	Shows the interface MAC accounting information.
mpls-exp	Shows the interface MPLS experimental accounting information.
precedence	Shows the interface precedence accounting information.
pruning	Shows the interface trunk VTP pruning information.
rate-limit	Shows the interface rate-limit information.
stats	Shows the interface in and out packets and octets by switching path.
status	Shows the interface line status.
summary	Shows the interface summary.
switching	Shows the interface switching.
switchport	Shows the interface switchport information.
trunk	Shows the interface trunk information.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(15)T	This command was introduced.

Examples

The following example shows how to read the interface information about the WLCM in the router:

```
Router# show interfaces integrated-service-engine
 1/0
integrated-service-engine 1/0 is up, line protocol is up
  Hardware is I82559FE, address is 0005.9a3d.7450 (bia 0005.9a3d.7450)
  Internet address is 30.0.0.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation 802.1Q Virtual LAN, Vlan ID  1., loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, 100BaseTX/FX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:05, output 00:00:03, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     2400779 packets input, 143127299 bytes
     Received 2349587 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog
     0 input packets with dribble condition detected
     468232 packets output, 106333102 bytes, 0 underruns
     0 output errors, 0 collisions, 3 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 1 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

Related Commands

interface integrated-service-engine

show interfaces ism

To display status, traffic data, and configuration information about the internal service module (ISM) interface, use the **showinterfacesism** command in user EXEC or privileged EXEC mode.

show interfaces ism *slot*/*port*

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

The ISM interface is the Gigabit Ethernet interface on the router that connects to the ISM.

Examples

The following example displays status, traffic data, and configuration information about the interface to the ISM installed in the router.

```
Router# show interfaces ism 0/0
ISM0/0 is up, line protocol is up
  Hardware is PSE2, address is 001e.4a97.646d (bia 001e.4a97.646d)
  Internet address is 20.0.0.1/24
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 1000Mb/s, media type is internal
  output flow-control is XON, input flow-control is XON
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:11, output 00:00:11, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/60 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     329 packets input, 34641 bytes, 0 no buffer
     Received 109 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     0 input packets with dribble condition detected
     241 packets output, 79646 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 unknown protocol drops
     0 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 137: show interfaces ism Field Descriptions

Field	Description
Hardware, address	Hardware type and address.
MTU	Maximum transmission unit (MTU) of the service module interface.
BW	Bandwidth of the interface, in kbps.
DLY	Delay of the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload	Transmit load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
rxload	Receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether or not loopback is set.
Keepalive	Indicates whether or not keepalives are set and the interval between keepalives if they have been set.
ARP type...ARP Timeout	Type of Address Resolution Protocol (ARP) assigned and length of timeout.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by the interface and processed locally on the router. This field is useful for detecting when a dead interface failed. **Note** This field is not updated by fast-switched traffic.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. This field is useful for detecting when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because a transmission took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. Asterisks (***) indicate that the elapsed time is too large to be displayed.

Field	Description
Input queue	Number of packets in the input queue. Each number is followed by a slash, the maximum size of the queue, the number of packets dropped because of a full queue, and the number of times that queued packets have been discarded.
Total output drops	Number of packets in the output queue that have been dropped because of a full queue.
Queueing strategy	Queueing strategy applied to the interface, which is configurable under the interface. The default is FIFO (first-in, first-out).
Output queue	Number of packets in the output queue, and the maximum size of the queue. Each number is followed by a slash.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic that it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within 2 percent of the instantaneous rate of a uniform stream of traffic over that period. **Note** The 5-minute period referenced in this output is a load interval that is configurable under the interface. The default value is 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received...broadcasts	Number of broadcasts received.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
throttles	Number of times that the interface requested another interface within the router to slow down.

Field	Description
input errors	Errors that include runts, giants, no buffer, cyclic redundancy checksum (CRC), frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Errors created when the CRC generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station that is transmitting bad data.
frame	Number of packets received incorrectly that have a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times that the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets that were ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from system buffer space described. Broadcast storms and bursts of noise can cause the ignored count to increase.
input packets with dribble condition detected	Number of packets with dribble condition. Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages that have been transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, that have been transmitted by the system.
underruns	Number of times that the transmitter has run faster than the router could handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface that is being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages that have been retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.

Field	Description
interface resets	Number of times an interface has been completely reset. This can happen if packets that were queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles	Count of frames greater than 1518 bytes that have been transmitted, indicating that the transmitter has been on the interface longer than the time necessary to transmit the largest frame.
late collision	Number of late collisions. A collision becomes a late collision when it occurs after the preamble has been transmitted.
deferred	Deferred indicates that the chip, while ready to transmit a frame, had to defer because the carrier was asserted.
lost carrier	Number of times that the carrier was lost during transmission.
no carrier	Number of times that the carrier was not present during the transmission.
output buffer failures, output buffers swapped out	Number of failed buffers and number of buffers swapped out.

Related Commands

Command	Description
show controllers ism	Displays controller information for the service module interface.

show interfaces lex

To display statistics about a LAN Extender interface, use the **showinterfaceslex** command in EXEC mode.

show interfaces lex commandshow interfaces lex *number* [{**ethernet** | **serial**}]

Syntax Description

number	Number of the LAN Extender interface that resides on the core router about which to display statistics.
ethernet	(Optional) Displays statistics about the Ethernet interface that resides on the LAN Extender chassis.
serial	(Optional) Displays statistics about the serial interface that resides on the LAN Extender chassis.

Command Modes

EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco IOS Mainline or Technology-based releases. It may conintue to appear in Cisco IOS 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

To display statistics about the LAN Extender interface on the core router, use the **showinterfaceslex** command without any keywords.

Administratively, the physical serial interface that connects the core router to the LAN Extender is completely hidden. The **showinterfacesserial**command will show only that the serial interface is present. However, it will not report any statistics about the traffic passing over the physical line. All statistics are report by the **showinterfaceslex** command.

Examples

The following is sample output from the **showinterfaceslex** command, showing the LAN Extender interface on the host router. Note the “Bound to ...” field, which is displayed only on a LAN Extender interface.

```
Router# show interfaces lex 0
Lex0 is up, line protocol is up
  Hardware is Lan Extender, address is 0204.0301.1526 (bia 0000.0000.0000)
  MTU 1500 bytes, BW 10000 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set
  ARP type: ARPA, ARP Timeout 4:00:00
  Bound to Serial3
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 1000 bits/sec, 0 packets/sec
```

```
  Five minute output rate 0 bits/sec, 0 packets/sec
     1022 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     2070 packets output, 23663 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets, 0 restarts
```

The following is sample output from the **showinterfaceslex** command when you specify the **ethernet** keyword:

```
Router# show interfaces lex 0 ethernet
Lex0-Ethernet0 is up, line protocol is up
  Hardware is LAN-Extender, address is 0000.0c01.1526 (bia 0000.0c01.1526)
  Last input 6w3d, output 6w3d
  Last clearing of "show interface" counters 0:02:30
  Output queue 40/50, 60 drops; input queue 10/40, 2 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     3916 packets input, 960303 bytes, 3 no buffer
     Received 2 broadcasts, 3 runts, 3 giants
     2 input errors, 1 CRC, 1 frame, 1 overrun, 3 ignored, 2 abort
     2500 packets output, 128288 bytes, 1 underruns
     1 output errors, 1 collisions, 0 interface resets, 0 restarts
```

The following is sample output from the **showinterfaceslex** command when you specify the **serial** keyword:

```
Router# show interfaces lex 0 serial
Lex0-Serial0 is up, line protocol is up
  Hardware is LAN-Extender
  Last input 6w3d, output 6w3d
  Last clearing of "show interface" counters 0:03:05
  Input queue: 5/15/4 (size/max/drops); Total output drops: 450
  Output queue: high 25/35/90, medium 70/80/180, normal 40/50/120, low 10/20/60
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     1939 packets input, 30998 bytes, 6 no buffer
     Received 4 broadcasts, 6 runts, 6 giants
     4 input errors, 2 CRC, 2 frame, 2 overrun, 6 ignored, 4 abort
     1939 packets output, 219535 bytes, 2 underruns
     2 output errors, 2 collisions, 0 interface resets, 0 restarts
     2 carrier transitions
```

The table below describes the fields shown in the preceding displays.

Table 138: show interfaces lex Field Descriptions

Field	Description
Lex0 is up, line protocol is up	Indicates whether the logical LAN Extender interface on the core router is currently active (that is, whether carrier detect is present), inactive, or has been taken down by an administrator.
Lex0-Ethernet0 is up, line protocol is up Lex0-Serial0 is up, line protocol is up	Indicates whether the physical Ethernet and serial interfaces on the LAN Extender chassis are currently active (that is, whether carrier detect is present) and whether it has been taken down by an administrator.
Hardware is LAN-Extender	Hardware type of the interfaces on the LAN Extender.

Field	Description
address is ...	Logical MAC address of the interface.
bia	Burned-in MAC address of the interface. The LAN Extender interface does not have a burned in address; hence it appears as all zeroes.
MTU	Maximum transmission unit size of the interface.
BW	Value of the bandwidth parameter that has been configured for the interface (in kilobits per second). The bandwidth parameter is used to compute IGRP metrics only. If the interface is attached to a serial line with a line speed that does not match the default (1536 or 1544 for T1 and 56 for a standard synchronous serial line), use the **bandwidth** command to specify the correct line speed for this serial line.
DLY	Delay of the interface in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
ARP type	Type of Address Resolution Protocol assigned.
ARP Timeout	Number of hours, minutes, and seconds an ARP cache entry will stay in the cache.
Bound to ...	Number of the serial interface to which the logical LAN Extender interface is bound.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process switched, not when packets are fast switched.
output	Number of hours, minutes, and seconds (or never) since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process switched, not when packets are fast switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.

Field	Description
Last clearing of "show interface" counters	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
Five minute input rate Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
Received ... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating station or far-end device does not match the checksum calculated from the data received. On a serial link, CRCs usually indicate noise, gain hits, or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.

Field	Description
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Illegal sequence of one bits on a serial interface. This usually indicates a clocking problem between the serial interface and the data link equipment.
input packets with dribble condition detected	Does not apply to a LAN Extender interface.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This might never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. Some collisions are normal. However, if your collision rate climbs to around 4 or 5 percent, you should consider verifying that there is no faulty equipment on the segment and/or moving some existing stations to a new segment. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds' time. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times the controller was restarted because of errors.

show interfaces loopback

To display information about the loopback interface, use the **showinterfacesloopback**command in privileged EXEC mode.

show interfaces loopback commandshow interfaces loopback [*number*] [**accounting**]

Syntax Description

number	(Optional) Port number on the selected interface.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showinterfacesloopback** command:

```
Router# show interfaces loopback 0
Loopback0 is up, line protocol is up
  Hardware is Loopback
  MTU 1500 bytes, BW 1 Kbit, DLY 50 usec, rely 255/255, load 1/255
  Encapsulation UNKNOWN, loopback not set, keepalive set (10 sec)
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Output queue 0/0, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets, 0 restarts
```

The following is sample output when the **accounting** keyword is included:

```
Router# show interfaces loopback 0 accounting
Loopback0
                Protocol    Pkts In   Chars In   Pkts Out  Chars Out
No traffic sent or received on this interface.
```

The table below describes significant fields shown in the displays.

*Table 139: **show interfaces loopback** Field Descriptions*

Field	Description
Loopback is {up | down | administratively down}	Indicates whether the interface hardware is currently active (whether carrier detect is present), is currently inactive, or has been taken down by an administrator.
line protocol is {up | down | administratively down}	Indicates whether the software processes that handle the line protocol consider the line usable (that is, whether keepalives are successful).
Hardware	Hardware is Loopback.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
loopback	Indicates whether loopback is set and type of loopback test.
keepalive	Indicates whether keepalives are set or not.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.

Field	Description
Output queue, drops; Input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
Five minute input rate, Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes input	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
input errors	Sum of all errors that prevented the receipt of datagrams on the interface being examined. This may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits, or other transmission problems on the data link. CRC errors are also reported when a far-end abort occurs, and when the idle flag pattern is corrupted. This makes it possible to get CRC errors even when there is no data traffic.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Number of packets whose receipt was aborted.

Field	Description
packets output	Total number of messages transmitted by the system.
bytes output	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle. This may never happen (be reported) on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Loopback interface does not have collisions.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds time. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times the controller was restarted because of errors.
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

show interfaces port-channel

To display the information about the Fast EtherChannel on Cisco 7000 series routers with the RSP7000 and RSP7000CI, Cisco 7200 series routers, and Cisco 7500 series routers, use the **showinterfacesport-channel** command in user EXEC or privileged EXEC mode.

show interfaces port-channel commandshow interfaces port-channel [*channel-number*]

Syntax Description

channel-number	(Optional) Port channel number. Range is from 1 to 4.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.1 CA	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.2(02)SA	This command was implemented on the Cisco ME 2600X Series Ethernet Access Switches.

Examples

The following is sample output from the **showinterfacesport-channel** command:

Note By default the hardware type is set to Fast EtherChannel.The default MTU is set to 1500 bytes. The maximum MTU size that can be configured on the native Gigabit Ethernet ports on the Cisco 7200 series router is 9216. The range of configurable MTU value is from 1500 to 9216.

```
Router# show interfaces port-channel 1
Port-channel1 is up, line protocol is up
  Hardware is FEChannel, address is 0000.0ca8.6220 (bia 0000.0000.0000)
  MTU 1500 bytes, BW 400000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive not set, fdx
  ARP type: ARPA, ARP Timeout 04:00:00
    No. of active members in this channel: 4
        Member 0 : Fast Ethernet1/0/0
        Member 1 : Fast Ethernet1/1/0
        Member 2 : Fast Ethernet4/0/0
        Member 3 : Fast Ethernet4/1/0
  Last input 01:22:13, output never, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     223 packets input, 11462 bytes, 0 no buffer
     Received 1 broadcasts, 0 runts, 0 giants
```

```
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 watchdog, 0 multicast
     0 input packets with dribble condition detected
     192 packets output, 13232 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The following sample output from the **showinterfacesport-channel** shows Gigabit EtherChannel as hardware type and the MTU value as 9216:

```
Router# show interface port-channel 1
Port-channel1 is up, line protocol is up
  Hardware is GEChannel
, address is 0001.c929.c41b (bia 0001.c929.c41b)
  MTU 9216 bytes
, BW 1000000 Kbit, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Unknown duplex, Unknown Speed, media type is unknown media type
  output flow-control is unsupported, input flow-control is unsupported
  ARP type: ARPA, ARP Timeout 04:00:00
    No. of active members in this channel: 1
        Member 0 : GigabitEthernet0/1 , Full-duplex, 1000Mb/s
    No. of Non-active members in this channel: 0
  Last input 00:00:04, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     95 packets input, 34383 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     0 input packets with dribble condition detected
     1 packets output, 77 bytes, 0 underruns
     2 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes significant fields shown in the display.

*Table 140: **show interfaces port-channel** Field Descriptions*

Field	Description
Port-channel1 is up, line protocol is up	Indicates if the interface hardware is currently active and can transmit and receive or if it has been taken down by an administrator.
Hardware is	Hardware type (Fast EtherChannel).
address is	Address being used by the interface.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.

Field	Description
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates if loopbacks are set.
keepalive	Indicates if keepalives are set.
fdx	Indicates the interface is operating in full-duplex mode.
ARA type	ARP type on the interface.
ARP timeout	Number of hours, minutes, and seconds an ARP cache entry will stay in the cache.
No. of active members in this channel: 4	Number of Fast Ethernet interfaces that are currently active (not down) and part of the Fast EtherChannel group.
Member 0: Fast Ethernet1/0/0	Specific Fast Ethernet interface that is part of the Fast EtherChannel group.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms)) ago.

Field	Description
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.
abort	Illegal sequence of ones bit on the interface.

Field	Description
watchdog	Number of times watchdog receive timer expired. It happens when receiving a packet with length greater than 2048.
multicast	Number of multicast packets received.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
babbles	The transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.
deferred	Deferred indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
output buffer failures	Number of times that a packet was not output from the output hold queue because of a shortage of MEMD shared memory.
output buffers swapped out	Number of packets stored in main memory when the output queue is full; swapping buffers to main memory prevents packets from being dropped when output is congested. The number is high when traffic is bursty.

Related Commands

Command	Description
interface multilink	Specifies a Fast EtherChannel and enters interface configuration mode.

show interfaces port-channel etherchannel

To display the load-balancing bucket distribution currently in use for a Gigabit EtherChannel (GEC) interface, use the **showinterfacesport-channeletherchannel** command in user EXEC or privileged EXEC mode.

show interfaces port-channel *channel-number* **etherchannel**

Syntax Description

channel-number	Port-channel group number. Range: 1 to 64.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.
Cisco IOS XE Release 2.5	This command was modified. Information about flow-based load balancing was added to the output.

Usage Guidelines

The **showinterfacesport-channeletherchannel** command shows the bucket-to-member link mappings for load balancing on the GEC interface.

Load balancing uses the concept of buckets to map traffic flows to the member links of a port channel. The different traffic flows are mapped to buckets and each bucket has one active member link associated with it. All traffic flows that are mapped to a bucket use the member link assigned to the bucket.

There are two methods of load balancing on a GEC interface:

- VLAN-manual--All packets forwarded over the same VLAN subinterface are considered part of the same flow and are mapped to the member link specified in the configuration.
- Flow-based--Traffic flows are mapped to different member links based on the packet header.

Examples

The following example shows output from this command for a port channel with VLAN-manual load balancing configured:

```
Router# show interfaces port-channel 2 etherchannel

 All IDBs List contains 3 configured interfaces
  Port: GigabitEthernet2/1/6 (index: 0)
  Port: GigabitEthernet2/1/7 (index: 1)
  Port: GigabitEthernet2/1/0 (index: 2)

 Active Member List contains 1 interfaces
  Port: GigabitEthernet2/1/0

 Passive Member List contains 2 interfaces
  Port: GigabitEthernet2/1/6
    VLAN 1 (Pri, Ac, D, P)    VLAN 50 (Sec, St, D, P)
  Port: GigabitEthernet2/1/7
    VLAN 1 (Sec, St, D, P)    VLAN 50 (Pri, Ac, C, P)
 Load-Balancing method applied: vlan-manual

 Bucket Information for VLAN Manual LB:
```

```
   Bucket 0   (p=GigabitEthernet2/1/6, s=GigabitEthernet2/1/6) active GigabitEthernet2/1/6

   Bucket 1   (p=GigabitEthernet2/1/6, s=GigabitEthernet2/1/7) active GigabitEthernet2/1/6

   Bucket 2   (p=GigabitEthernet2/1/6, s=GigabitEthernet2/1/0) active GigabitEthernet2/1/0

   Bucket 4   (p=GigabitEthernet2/1/7, s=GigabitEthernet2/1/6) active GigabitEthernet2/1/7

   Bucket 5   (p=GigabitEthernet2/1/7, s=GigabitEthernet2/1/7) active GigabitEthernet2/1/7

   Bucket 6   (p=GigabitEthernet2/1/7, s=GigabitEthernet2/1/0) active GigabitEthernet2/1/0

   Bucket 8   (p=GigabitEthernet2/1/0, s=GigabitEthernet2/1/6) active GigabitEthernet2/1/0

   Bucket 9   (p=GigabitEthernet2/1/0, s=GigabitEthernet2/1/7) active GigabitEthernet2/1/0

   Bucket 10   (p=GigabitEthernet2/1/0, s=GigabitEthernet2/1/0) active GigabitEthernet2/1/0
```

The following example shows output for a port channel with flow-based load balancing configured:

```
Router(config)# show interfaces port-channel 2 etherchannel

 All IDBs List contains 3 configured interfaces
  Port: GigabitEthernet2/1/6 (index: 0)
  Port: GigabitEthernet2/1/7 (index: 1)
  Port: GigabitEthernet2/1/0 (index: 2)

 Active Member List contains 1 interfaces
  Port: GigabitEthernet2/1/0

 Passive Member List contains 2 interfaces
  Port: GigabitEthernet2/1/6

  Port: GigabitEthernet2/1/7

 Load-Balancing method applied: flow-based

 Bucket Information for Flow-Based LB:
 Interface:                                Buckets
    GigabitEthernet2/1/0:
                          Bucket 0 , Bucket 1 , Bucket 2 , Bucket 3
                          Bucket 4 , Bucket 5 , Bucket 6 , Bucket 7
                          Bucket 8 , Bucket 9 , Bucket 10, Bucket 11
                          Bucket 12, Bucket 13, Bucket 14, Bucket 15
```

The table below describes the significant fields shown in the display.

Table 141: show interfaces port-channel etherchannel Field Descriptions

Field	Description
Active Member List	List of active physical interfaces in the GEC bundle.
Passive Member List	List of passive (backup) physical interfaces in the GEC bundle.
Load-Balancing method applied	The load-balancing method configured on the interface, either flow-based or vlan-manual.
Bucket Information	Lists the bucket information across the active member links.

Related Commands

Command	Description
load-balancing	Applies a load-balancing method to a GEC interface.
port-channel load-balancing vlan-manual	Applies the VLAN-manual load-balancing method globally to all GEC interfaces.
show etherchannel load-balancing	Displays the load-balancing method applied to GEC interfaces.

show interfaces pos

To display configuration information and statistics for a Packet over SONET (POS) interface, use the **showinterfacespos** command in user EXEC or privileged EXEC configuration mode.

Cisco 7000 and Cisco 7500 Series with VIPs
show interfaces pos commandshow interfaces pos [*slot* / *port-adapter* / *port*]

POS Shared Port Adapters
show interfaces pos [*slot* / *subslot* / *port* [/ *sub_int*]]

Syntax Description

slot / *port-adapter* / *port*	**(Optional) Cisco 7000 or Cisco 7500 Series Routers** Number of the chassis slot that contains the POS interface (for example, 2/0/0), where: • *slot* --Chassis slot number. • / *port-adapter*-- Port adapter number. • / *port*-- Port or interface number. Refer to the appropriate hardware manual for slot and port information, and port adapter compatibility.
slot / *subslot* / *port* / *sub_int*	**(Optional) POS Shared Port Adapters** Number of the chassis slot that contains the POS interface (for example 4/3/0), where: • *slot* --Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. • / *subslot*-- Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information. • / *port* --Port or interface number. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide. • / *sub_int* -- (Optional) Subinterface number.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.2	The **showinterfaceposi** command was introduced.
11.3	The name of the command was modified from **showinterfaceposi**to **showinterfacespos**, and the sample output was updated.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 router. The command was modified to support a new addressing format for SPAs.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.

Examples

Cisco 7513 Example

The following is sample output from the **showinterfacespos** command on a Cisco 7513 router with one Packet OC-3 Interface Processor (POSIP):

```
Router# show interfaces pos 2/0/0
POS2/0/0 is up, line protocol is up
  Hardware is cyBus Packet over Sonet
  Description: PRI-T1 net to zippy (4K) to Pac-Bell
  Internet address is 10.1.1.1/27
  MTU 4470 bytes, BW 1000 Kbit, DLY 40000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive set (3 sec)
  Last input 00:00:00, output 00:00:00, output hang never
  Last clearing of "show interface" counters 00:23:09
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 1 packets/sec
  5 minute output rate 1000 bits/sec, 1 packets/sec
     1046 packets input, 54437 bytes, 0 no buffer
     Received 485 broadcasts, 0 runts, 0 giants, 0 parity
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     4013 packets output, 1357412 bytes, 0 underruns
     0 output errors, 0 applique, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

Cisco 7600 Series Router and Catalyst 6500 Series Switch POS Shared Port Adapter Example

The following is sample output from the **showinterfacespos** command on a Cisco 7600 series router or Catalyst 6500 series switch for POS interface 4/3/0 (which is the interface for port 0 of the SPA in subslot 3 of the SIP in chassis slot 4):

```
Router# show interfaces pos 4/3/0

POS4/3/0 is up, line protocol is up  (APS working - active)
  Hardware is Packet over SONET
  Internet address is 10.0.0.1/8
  MTU 4470 bytes, BW 622000 Kbit, DLY 100 usec, rely 255/255, load 1/255
```

```
  Encapsulation HDLC, crc 16, loopback not set
  Keepalive not set
  Scramble disabled
  Last input 00:00:34, output 04:09:06, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy:fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
        Available Bandwidth 622000 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     782 packets input, 226563 bytes, 0 no buffer
     Received 0 broadcasts, 1 runts, 0 giants, 0 throttles
              0 parity
     1 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     271 packets output, 28140 bytes, 0 underruns
     0 output errors, 0 applique, 2 interface resets
     0 output buffer failures, 0 output buffers swapped out
     2 carrier transitions
```

Cisco 12000 Series Router POS Shared Port Adapter Example

The following is sample output from the **showinterfacespos** command on a Cisco 12000 series router for POS interface 1/1/0 (which is the interface for port 0 of the SPA in subslot 1 of the SIP in chassis slot 1):

```
Router# show interfaces pos 1/1/0

POS1/1/0 is up, line protocol is up
  Hardware is Packet over SONET
  Internet address is 10.41.41.2/24
  MTU 4470 bytes, BW 9952000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation HDLC, crc 32, loopback not set
  Keepalive not set
  Scramble enabled
  Last input 00:00:59, output 00:00:11, output hang never
  Last clearing of "show interface" counters 00:00:14
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
        Available Bandwidth 9582482 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
              0 parity
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     1 packets output, 314 bytes, 0 underruns
     0 output errors, 0 applique, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
```

The table below describes the significant fields shown in these displays.

*Table 142: **show interfaces pos** Field Descriptions*

Field	Description
POSx/y/z is up, line protocol is up	Indicates whether the interface hardware is currently active and can transmit and receive or whether it has been taken down by an administrator.

Field	Description
Hardware is. . .	Hardware type: • For POSIP-- cyBus Packet over Sonet • For POS SPAs--Packet over SONET
Internet address is	Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to interface.
Loopback	Indicates whether loopbacks are set.
Keepalive	Indicates whether keepalives are set.
Scramble	Indicates whether or not SONET payload scrambling is enabled. SONET scrambling is disabled by default. For the POS SPAs on the Cisco 12000 series routers, scrambling is enabled by default.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
(Last) output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the “last” fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.

Field	Description
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 2231 ms (and less than 232 ms) ago.
Queueing strategy	First-in, first-out (FIFO) queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
throttles	Not supported for POS interfaces.
parity	Report of the parity errors on the interface.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits or other transmission problems on the data link.

Field	Description
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.
abort	Illegal sequence of one bits on the interface.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
applique	Indicates an unrecoverable error has occurred on the POSIP applique. The system then invokes an interface reset.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
output buffer failures	Not supported for POS interfaces.
output buffers swapped out	Not supported for POS interfaces.
carrier transitions	Number of times the carrier detect signal of the interface has changed state.

Related Commands

Command	Description
interface	Configures an interface type and enters interface configuration mode.

show interfaces private-vlan mapping

To display the information about the private virtual local area network (PVLAN) mapping for VLAN SVIs, use the **showinterfacesprivate-vlanmapping** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **private-vlan mapping** [**active**]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
active	(Optional) Displays the active interfaces only.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

This command displays SVI information only.

The *interface-number*argument designates the module and port number. Valid values for *interface-number* depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

Examples

This example shows how to display the information about the PVLAN mapping:

```
Router# show interfaces private-vlan mapping
Interface Secondary VLAN Type
--------- -------------- -----------------
vlan2     301            community
vlan2     302            community
Router#
```

Related Commands

Command	Description
private-vlan	Configures PVLANs and the association between a PVLAN and a secondary VLAN.

Command	Description
private-vlan mapping	Creates a mapping between the primary and the secondary VLANs so that both VLANs share the same primary VLAN SVI.

show interfaces satellite

To display general interface settings and traffic rates for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **showinterfacessatellite** command in user EXEC or privileged EXEC mode.

Syntax:

show interfaces satellite *slot* / *unit*

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.

Command Default

No default behavior or values.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **showinterfacessatellite** command shows these items:

- Basic configuration information for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT)
- Traffic statistics, including the number of packets transmitted, input and output rate, and errors
- Interface and line protocol status (up or down), with the following exceptions:
    - *Line Protocol Status Exception - Hub Dial Backup Mode*
    - *Line Protocol Status Exception - Hot Standby Router Protocol (HSRP) Standby Mode*

Line Protocol Status Exception--Hub Dial Backup Mode

If you configure hub dial backup mode on the satellite interface, then the **showinterfacessatellite** command always displays Line Protocol Up status, even when the line protocol is down. To view the actual line protocol status, enter the **showcontrollerssatellite** command or the **service-modulesatellite***slot***/0status** command in privileged EXEC mode.

Line Protocol Status Exception--Hot Standby Router Protocol (HSRP) Standby Mode

If the router is in a hot standby group and is in standby mode, then the **showinterfacessatellite** command displays “line protocol is up (standby)”, even though a link to the hub is not established from the standby router. To view the actual line protocol status, enter the **showcontrollerssatellite** command or the **service-modulesatellite***slot***/0status** command in privileged EXEC mode.

Examples

For output field descriptions, see the table below.

This section provides the following examples:

Normal Operation or Hub Dial Backup Mode Example

In the following example, the satellite interface is up and the line protocol is up.

If you configure hub dial backup for the NM-1VSAT-GILAT network module, the line protocol appears to be up even if the satellite link is actually down. To view the actual line protocol status while hub dial backup mode is configured, use the **showcontrollerssatellite** command or the **service-modulesatellite***slot*/**0status** command instead.

```
Router# show interfaces satellite 2/0

Satellite2/0 is up
, line protocol is up
  Hardware is I82559FE, address is 0008.e35f.7370 (bia 0008.e35f.7370)
  Internet address is 10.22.1.2/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not set
  ARP type:ARPA, ARP Timeout 04:00:00

  Last clearing of "show interface" counters never
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo
  Output queue:0/40 (size/max)
  5 minute input rate 13000 bits/sec, 6 packets/sec
  5 minute output rate 8000 bits/sec, 9 packets/sec
     419433 packets input, 108329352 bytes, 0 no buffer
     Received 11792 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     650568 packets output, 73969720 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

Satellite Backup for a Terrestrial Link--Standby Mode Example

In the following example, the satellite interface is in standby mode because the primary terrestrial link is up:

```
Router# show interfaces satellite 1/0

Satellite1/0 is standby mode
, line protocol is down

  Hardware is I82559FE, address is 00e0.f7ff.f310 (bia 00e0.f7ff.f310)
  Internet address is 10.0.0.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not set
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input 00:00:00, output 00:00:03, output hang never
  Last clearing of "show interface" counters 00:00:04
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo
```

```
  Output queue:0/40 (size/max)
  30 second input rate 13000 bits/sec, 6 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
     30 packets input, 7474 bytes, 0 no buffer
     Received 1 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     1 packets output, 82 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

Hot Standby Router Protocol (HSRP)--Standby Mode Example

In the following example, homogeneous HSRP is configured on two routers, each of which contains an NM-1VSAT-GILAT network module that connects to the same dish antenna (ODU). The following output from the standby router shows that the line protocol is "up (standby)," even though the satellite link on the standby router is actually down. To view the actual line protocol status, use the **showcontrollerssatellite** command or the **service-modulesatellite***slot*/**0status** command.

```
Router# show interfaces satellite 2/0

Satellite2/0 is up
, line protocol is up (standby)
  Hardware is I82559FE, address is 0008.e35f.7370 (bia 0008.e35f.7370)
  Internet address is 10.22.1.2/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not set
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input 00:00:02, output 00:00:00, output hang never
  Last clearing of "show interface" counters never
  Input queue:0/75/0/0 (size/max/drops/flushes); Total output drops:0
  Queueing strategy:fifo
  Output queue:0/40 (size/max)
  5 minute input rate 13000 bits/sec, 6 packets/sec
  5 minute output rate 8000 bits/sec, 9 packets/sec
     419433 packets input, 108329352 bytes, 0 no buffer
     Received 11792 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 input packets with dribble condition detected
     650568 packets output, 73969720 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 143: show interfaces satellite Field Descriptions

Field	Description
Satellite2/0 is... • up • down • standby mode	State of the interface hardware: • Currently active. • Has been taken down by an administrator. • In HSRP standby mode when two HSRP-redundant NM-1VSAT-GILAT network modules (in separate routers) connect to one dish antenna (ODU).
line protocol is	State of the backbone link to the hub: up or down. See the following exceptions:
Hardware is	Hardware type (for example, Fast Ethernet) and address.
Internet address	Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload and rxload	Transmitted and received load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
ARP type	Type of Address Resolution Protocol assigned.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.

Field	Description
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 2 31 ms (and less than 2 32 ms) ago.
Input queue	Input queue information: • Size--Number of packets in the input queue • Max--Maximum size of the queue • Drops--Number of packets discarded because of a full queue • Flushes--Number of times data on queue has been discarded
Total output drops	Total number of output packets dropped.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies you might see are priority-list, custom-list, and weighted fair).
Output queue	Number of packets in the output queue and the maximum size of the queue,
5 minute input rate 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.

Field	Description
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the media.
giants	Number of packets that are discarded because they exceed the maximum packet size of the media.
throttles	Number of times that the interface requested another interface within the router to slow down.
input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver’s ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can increase the ignored count.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.

Field	Description
collisions	Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal, or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles **Note** This field applies to the router internal interface that connects to the installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT). This field typically does not apply to the external satellite interface.	Indicates that the transmit jabber timer expired.
late collision	Number of late collisions. Late collision happens when a collision occurs after the preamble has been transmitted. The most common cause of late collisions is that your Ethernet cable segments are too long for the speed at which you are transmitting.
deferred	Deferred indicates that the chip had to defer transmission while ready to transmit a frame, because the carrier was asserted.
lost carrier	Number of times the carrier was lost during transmission.
no carrier	Number of times the carrier was not present during the transmission.
output buffer failures	Number of failed buffers.
output buffers swapped out	Number of buffers swapped out.

Related Commands

Command	Description
service-module satellite status	Displays status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters.

Command	Description
show controllers satellite	Displays controller information about the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

show interfaces serial

To display information about a serial interface, use the**showinterfacesserial** command in privileged EXEC mode. When using Frame Relay encapsulation, use the **showinterfacesserial** command in user EXEC or privileged EXEC mode to display information about the multicast data-link connection identifier (DLCI), the DLCIs used on the interface, and the DLCI used for the Local Management Interface (LMI).

Cisco 4000 Series
show interfaces serial accounting commandshow interfaces serial [*number* [**:** *channel-group*]] [**accounting**]

Cisco 7200 Series
show interfaces serial [*slot*/*port*] [**accounting**]

Cisco 7000 and Cisco 7500 Series with the RSP7000, RSP7000CI, or Ports on VIPs
show interfaces serial [*slot*/*port-adapter*/*port*]

Cisco 7500 Series
show interfaces serial [*slot*/*port* [**:** *channel-group*]] [**accounting**]

Cisco 7500 Series with a CT3IP
show interfaces serial [*slot*/*port-adapter*/*port*] [**:** *t1-channel*] [{**accounting** | **crb**}]

Cisco AS5350 and Cisco AS5400 Universal Gateways
show interfaces serial *slot*/*port*

Cisco AS5800 Access Servers
show interfaces serial *dial-shelf*/*slot*/*t3-port* **:** *t1-num* **:** *chan-group*

Syntax Description

number	(Optional) Number of the port being displayed.
: *channel-group*	(Optional) On the Cisco 4000 series with a Network Management Processor (NPM) or the Cisco 7500 series routers with a MultiChannel Interface Processor (MIP), specifies the T1 channel-group number in the range of 0 to 23 defined with the **channel-group** controller configuration command.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
slot	(Optional) Number of the slot being displayed. Refer to the appropriate hardware manual for slot and port information.
/ *port*	(Optional) Number of the port being displayed. Refer to the appropriate hardware manual for slot and port information.
/ *port-adapter*	(Optional) Number of the port adapter being displayed. Refer to the appropriate hardware manual for information about port adapter compatibility.

: *t1-channel*	(Optional) T1 channel number. For the CT3IP, the T1 channel is a number between 1 and 28. T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.
crb	(Optional) Displays interface routing and bridging information.
dial-shelf	Dial shelf chassis in the Cisco AS5800 access server that contains the CT3 interface card.
slot	Location of the CT3 interface card in the dial shelf chassis.
t3-port	T3 port number. The only valid value is 0.
: *t1-num*	T1 time slot in the T3 line. The value can be from 1 to 28.
: *chan-group*	Channel group identifier.

Command Modes

User EXEC (when Frame Relay encapsulation is used) Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced on the Cisco 4000 series routers.
11.0	This command was implemented on the Cisco 7000 series routers.
11.1CA	This command was modified to include sample output for the PA-2JT2, PA-E3, and PA-T3 serial port adapters.
11.3	This command was modified to include the CT3IP.
12.0(3)T	This command was implemented on the Cisco AS5800 access servers.
12.0(4)T	This command was modified to include enhanced display information for dialer bound interfaces.
12.2(11)T	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(13)T	This command was modified to display information about Frame Relay interface queueing and fragmentation.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Frame Relay

Use this command to determine the status of the Frame Relay link. This display also indicates Layer 2 status if switched virtual circuits (SVCs) are configured.

Channel Groups as Virtual Serial Interfaces

To find out about channel groups configured as virtual serial interfaces, to verify that the router has High-Level Data Link Control (HDLC) encapsulation on the interface, and to verify that the interface sees the loopback, use the **showinterfacesserial** command in privileged EXEC mode.

Examples

Example of Synchronous Serial Interface

The following is sample output from the **showinterfacesserial** command for a synchronous serial interface:

```
Router# show interfaces serial
Serial 0 is up, line protocol is up
   Hardware is MCI Serial
   Internet address is 192.168.10.203, subnet mask is 255.255.255.0
   MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
   Encapsulation HDLC, loopback not set, keepalive set (10 sec)
   Last input 0:00:07, output 0:00:00, output hang never
   Output queue 0/40, 0 drops; input queue 0/75, 0 drops
   Five minute input rate 0 bits/sec, 0 packets/sec
   Five minute output rate 0 bits/sec, 0 packets/sec
       16263 packets input, 1347238 bytes, 0 no buffer
       Received 13983 broadcasts, 0 runts, 0 giants
       2 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 2 abort
1 carrier transitions
     22146 packets output, 2383680 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets, 0 restarts
```

The table below describes significant fields shown in the display.

Table 144: show interfaces serial Field Descriptions--Synchronous Serial Interface

Field	Description
Serial ... is {up | down} ... is administratively down	Indicates whether the interface hardware is currently active (whether carrier detect is present), is currently inactive, or has been taken down by an administrator.
line protocol is {up | down}	Indicates whether the software processes that handle the line protocol consider the line usable (that is, whether keepalives are successful) or whether the line has been taken down by an administrator.
Hardware is	Specifies the hardware type.
Internet address is	Specifies the Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Indicates the value of the bandwidth parameter that has been configured for the interface (in kbps). If the interface is attached to a serial line with a line speed that does not match the default (1536 or 1544 kbps for T1 and 56 kbps for a standard synchronous serial line), use the **bandwidth**command to specify the correct line speed for this serial line.
DLY	Delay of the interface, in microseconds.

Field	Description
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
loopback	Indicates whether or not loopback is set.
keepalive	Indicates whether or not keepalives are set.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
5 minute input rate 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
Received... broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.

Field	Description
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.
CRC	Cyclic redundancy checksum generated by the originating station or far-end device does not match the checksum calculated from the data received. On a serial link, CRCs usually indicate noise, gain hits, or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Illegal sequence of one bits on a serial interface. This usually indicates a clocking problem between the serial interface and the data link equipment.
carrier transitions	Number of times the carrier detect signal of a serial interface has changed state. For example, if data carrier detect (DCD) goes down and comes up, the carrier transition counter will increment two times. Indicates modem or line problems if the carrier detect line is changing state often.
packets output	Total number of messages transmitted by the system.
bytes output	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the transmitter has been running faster than the router can handle. This might never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface from being examined. Note that this might not balance with the sum of the enumerated output errors because some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. Some collisions are normal. However, if your collision rate climbs to around 4 or 5 percent, you should consider verifying that there is no faulty equipment on the segment and/or moving some existing stations to a new segment. A packet that collides is counted only once in output packets.

Field	Description
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds' time. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
restarts	Number of times the controller was restarted because of errors.
alarm indications, remote alarms, rx LOF, rx LOS	Number of CSU/DSU alarms and number of occurrences of receive loss of frame and receive loss of signal.
BER inactive, NELR inactive, FELR inactive	Status of G.703-E1 counters for bit-error rate (BER) alarm, near-end loop remote (NELR), and far-end loop remote (FELR). Note that you cannot set the NELR or FELR.

Example of PA-2JT2 Serial Interface

The following is sample output from the **showinterfacesserial** command for a PA-2JT2 serial interface:

```
Router# show interfaces serial 3/0/0
Serial3/0/0 is up, line protocol is up
  Hardware is cyBus Serial
  Internet address is 10.0.0.1/8
  MTU 1500 bytes, BW 6312 Kbit, DLY 20000 usec, rely 255/255, load 26/255
  Encapsulation HDLC, loopback not set, keepalive not set
  Last input 00:04:31, output 00:04:31, output hang never
  Last clearing of "show interface" counters 00:06:07
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 162000 bits/sec, 8 packets/sec
  5 minute output rate 162000 bits/sec, 8 packets/sec
     20005 packets input, 20080520 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     20005 packets output, 20080520 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions
     0 cv errors, 0 crc5 errors, 0 frame errors
     rxLOS inactive, rxLOF inactive, rxPAIS inactive
     rxAIS inactive, rxRAI inactive, rxHBER inactive
```

The table below describes significant fields shown in the display that are different from the fields described in the table above.

Table 145: show interfaces serial Field Descriptions--PA-2JT2

Field	Description
Last clearing of “show interface” counters	Time the counters were last cleared.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies that you might see are priority-list, custom-list, and weighted fair).
output buffer failures	Number of “no resource” errors received on the output.
output buffers swapped out	Number of packets swapped to DRAM.
carrier transitions	Number of times the carrier detect signal of a serial interface has changed state. For example, if data carrier detect (DCD) goes down and comes up, the carrier transition counter will increment two times. Indicates modem or line problems if the carrier detect line is changing state often.
cv errors	B8ZS/B6ZS (zero suppression) coding violation counter.
crc5 errors	CRC-5 error counter.
frame errors	Framing error counter.
rxLOS	Receive loss of signal alarm. Values are active or inactive.
rxLOF	Receive loss of frame alarm. Values are active or inactive.
rxPAIS	Receive loss of payload alarm indication signal (AIS). Values are active or inactive.
rxAIS	Receive loss of physical AIS. Values are active or inactive.
rxRAI	Receive remote AIS. Values are active or inactive.
rxHBER	Receive high bit-error rate alarm. Values are active or inactive.

Example of PA-E3 Serial Port Adapter

The following is sample output from the **showinterfacesserial** command for a PA-E3 serial port adapter installed in chassis slot 2:

```
Router# show interfaces serial 2/0
Serial2/0 is up, line protocol is up
  Hardware is M1T-E3 pa
  Internet address is 172.17.1.1/24
  MTU 4470 bytes, BW 34010 Kbit, DLY 200 usec, rely 128/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive not set
  Last input 1w0d, output 00:00:48, output hang never
  Last clearing of “show interface” counters 1w0d
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
```

```
    20 packets input, 2080 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 parity
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
    11472 packets output, 3824748 bytes, 0 underruns
    0 output errors, 0 applique, 0 interface resets
    0 output buffer failures, 0 output buffers swapped out
    0 carrier transitions
  rxLOS inactive, rxLOF inactive, rxAIS inactive
  txAIS inactive, rxRAI inactive, txRAI inactive
```

Table 3 describes significant fields shown in the display that are different from the fields described in Table 1.

*Table 146: **show interfaces serial** Field Descriptions--PA-E3*

Field	Description
Last clearing of "show interface" counters	Time the counters were last cleared.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies that you might see are priority-list, custom-list, and weighted fair).
parity	Number of the parity errors on the interface.
applique	Indicates that an unrecoverable error has occurred on the E3 applique. The router then invokes an interface reset.
output buffer failures	Number of "no resource" errors received on the output.
output buffers swapped out	Number of packets swapped to DRAM.
rxLOS, rxLOF, rxAIS	Receive loss of signal, loss of frame, and alarm indication signal status. Values are inactive or active.
txAIS, rxRAI, txRAI	Transmit alarm indication signal, receive remote alarm indicator, and transmit remote alarm indicator status. Values are inactive or active. When the router receives an LOS, LOF, or AIS, the txRAI is active. When the remote router receives an LOS, LOF, or AIS, the rxRAI is active.

Example of 1-Port PA-T3 Serial Port Adapter Installed in a VIP2

The following is sample output from the **showinterfacesserial** command for a 1-port PA-T3 serial port adapter installed in a VIP2 in chassis slot 1, in port adapter slot 0:

```
Router# show interfaces serial 1/0/0
Serial1/0/0 is up, line protocol is up
  Hardware is cyBus PODS3 Serial
  Internet address is 172.18.1.1/24
  MTU 4470 bytes, BW 44736 Kbit, DLY 200 usec, rely 255/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive set (10 sec)
  Last input 00:00:05, output 00:00:02, output hang never
  Last clearing of "show interface" counters 5d02h
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 27269 drops
```

```
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     79039 packets input, 14195344 bytes, 0 no buffer
     Received 84506 broadcasts, 0 runts, 0 giants
              0 parity
     9574 input errors, 6714 CRC, 0 frame, 1 overrun, 0 ignored, 2859 abort
     62472 packets output, 13751644 bytes, 0 underruns
     0 output errors, 0 applique, 10 interface resets
     0 output buffer failures, 0 output buffers swapped out
     16 carrier transitions
   rxLOS inactive, rxLOF inactive, rxAIS inactive
   txAIS inactive, rxRAI inactive, txRAI inactive
```

The table below describes significant fields shown in the display that are different from the fields described in the tables above.

Table 147: show interfaces serial Field Descriptions--PA-T3

Field	Description
Last clearing of "show interface" counters	Time the counters were last cleared.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies that you might see are priority-list, custom-list, and weighted fair).
parity	Number of the parity errors on the interface.
applique	Indicates that an unrecoverable error has occurred on the T3 applique. The router then invokes an interface reset.
output buffer failures	Number of "no resource" errors received on the output.
output buffers swapped out	Number of packets swapped to DRAM.
rxLOS, rxLOF, rxAIS	Receive loss of signal, loss of frame, and alarm indication signal status. Values are inactive or active.
txAIS, rxRAI, txRAI	Transmit alarm indication signal, receive remote alarm indicator, and transmit remote alarm indicator status. Values are inactive or active. When the router receives an LOS, LOF, or AIS, the txRAI is active. When the remote router receives an LOS, LOF, or AIS, the rxRAI is active.

Example of CT3IP Serial Interface

The following is sample output from the **showinterfacesserial** command for the CT3IP serial interface:

```
Router# show interfaces serial 3/0/0:25
Serial3/0/0:25 is up, line protocol is up
  Hardware is cyBus T3
  Internet address is 10.25.25.2/24
  MTU 1500 bytes, BW 1536 Kbit, DLY 20000 usec, rely 255/255, load 12/255
  Encapsulation HDLC, loopback not set, keepalive not set
  Last input 00:19:01, output 00:11:49, output hang never
```

```
  Last clearing of "show interface" counters 00:19:39
  Input queue: 0/75/0 (size/max/drops); Total output drops: 0
  Queueing strategy: weighted fair
  Output queue: 0/64/0 (size/threshold/drops)
     Conversations 0/1 (active/max active)
     Reserved Conversations 0/0 (allocated/max allocated)
  5 minute input rate 69000 bits/sec, 90 packets/sec
  5 minute output rate 71000 bits/sec, 90 packets/sec
     762350 packets input, 79284400 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     150 input errors, 0 CRC, 0 frame, 150 overrun, 0 ignored, 0 abort
     763213 packets output, 80900472 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     0 carrier transitions no alarm present
  Timeslot(s) Used:1-24, Transmitter delay is 0 flags, transmit queue length 5
  non-inverted data
```

The table below describes significant fields relevant to the CT3IP shown in the display that are different from the fields described in the tables above.

*Table 148: **show interfaces serial** Field Descriptions--CT3IP*

Field	Description
Timeslot(s) Used	Number of time slots assigned to the T1 channel.
Transmitter delay	Number of idle flags inserted between each HDLC frame.
transmit queue length	Number of packets allowed in the transmit queue.
non-inverted data	Indicates whether or not the interface is configured for inverted data.

Example of an HDLC Synchronous Serial Interface on a Cisco 7500 Series Router

The following is sample output from the **showinterfacesserial** command for an HDLC synchronous serial interface on a Cisco 7500 series router:

```
Router# show interfaces serial 1/0
Serial1/0 is up, line protocol is up
  Hardware is cxBus Serial
  Internet address is 172.19.190.203, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive set (10 sec)
  Last input 0:00:07, output 0:00:00, output hang never
  Last clearing of "show interface" counters 2w4d
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     16263 packets input, 1347238 bytes, 0 no buffer
     Received 13983 broadcasts, 0 runts, 0 giants
     2 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 2 abort
     22146 packets output, 2383680 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets, 0 restarts
     1 carrier transitions
```

The tables above describes significant fields shown in the display.

Example of HDLC Encapsulation

The following example displays High-Level Data Link Control (HDLC) encapsulation on serial interface 0:

```
Router# show interfaces serial 0
Serial0 is up, line protocol is up (looped)
Hardware is HD64570
Internet address is 10.1.1.1, subnet mask is 255.255.255.0
MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
Encapsulation HDLC, loopback set, keepalive set (10 sec)
```

The tables above describes significant fields shown in the display.

Example of a G.703 Interface with Framing

The following is sample output from the **showinterfacesserial** command for a G.703 interface on which framing is enabled:

```
Router# show interfaces serial 2/3
Serial2/3 is up, line protocol is up
  Hardware is cxBus Serial
  Internet address is 10.4.4.1, subnet mask is 255.255.255.0
  MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
  Encapsulation HDLC, loopback not set, keepalive not set
  Last input 0:00:21, output 0:00:21, output hang never
  Last clearing of "show interface" counters never
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     53 packets input, 7810 bytes, 0 no buffer
     Received 53 broadcasts, 0 runts, 0 giants
     2 input errors, 2 CRC, 0 frame, 0 overrun, 0 ignored, 2 abort
     56 packets output, 8218 bytes, 0 underruns
     0 output errors, 0 collisions, 2 interface resets, 0 restarts
     1 carrier transitions
     2 alarm indications, 333 remote alarms, 332 rx LOF, 0 rx LOS
     RTS up, CTS up, DTR up, DCD up, DSR up
     BER inactive, NELR inactive, FELR inactive
```

The tables above describes significant fields shown in the display.

Example with Frame Relay Encapsulation

When using Frame Relay encapsulation, use the **showinterfacesserial**command to display information on the multicast data-link connection identifier (DLCI), the DLCI of the interface, and the DLCI used for the local management interface (LMI).

The multicast DLCI and the local DLCI can be set using the **frame-relaymulticast-dlci** and **frame-relaylocal-dlci** configuration commands. The status information is taken from the LMI, when active.

The following is sample output from the **showinterfacesserial** command when Frame Relay encapsulation and LMI are enabled:

```
Router# show interfaces serial
Serial 2 is up, line protocol is up
   Hardware type is MCI Serial
   Internet address is 172.20.122.1, subnet mask is 255.255.255.0
   MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
   Encapsulation FRAME-RELAY, loopback not set, keepalive set (10 sec)
   multicast DLCI 1022, status defined, active
   source DLCI    20, status defined, active
   LMI DLCI 1023, LMI sent 10, LMI stat recvd 10, LMI upd recvd 2
   Last input 7:21:29, output 0:00:37, output hang never
   Output queue 0/100, 0 drops; input queue 0/75, 0 drops
   Five minute input rate 0 bits/sec, 0 packets/sec
   Five minute output rate 0 bits/sec, 0 packets/sec
       47 packets input, 2656 bytes, 0 no buffer
       Received 5 broadcasts, 0 runts, 0 giants
       5 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 57 abort
       518 packets output, 391205 bytes
       0 output errors, 0 collisions, 0 interface resets, 0 restarts
       1 carrier transitions
```

In this display, the multicast DLCI has been changed to 1022 using the **frame-relaymulticast-dlci** interface configuration command.

The display shows the statistics for the LMI as the number of status inquiry messages sent (LMI sent), the number of status messages received (LMI recvd), and the number of status updates received (upd recvd). Refer to the Frame Relay Interface specification for additional explanations of this output.

Example with Frame Relay Queueing and Fragmentation at the Interface

The default mode for Frame Relay interfaces on serial SPAs is transparent mode. When FRF.12 configuration is applied to these SPA interfaces, then the SPA interface mode changes to end-to-end.

With end-to-end configuration on CEs, L2VPN cloud on GSR PEs can transparently forward the FRF.12 fragments to remote CE by default. In case of L2VPN on Cisco 12000 series Internet router, FRF.12 configuration should not be applied on the main or sub-interfaces of SPA interfaces. Otherwise the FRF.12 fragments get dropped in ingress interface on SPA on the ingress PE.

For L3VPN to work on Cisco 12000 series Internet router, FRF.12 configuration needs to be applied to the L3VPN SPA interface (main or sub-interface). L3VPN will not work without FRF.12 configuration.

L2VPN requires the SPA interface to be in transparent mode. L3VPN requires the SPA interface to be in end-to-end mode. At physical interface level, either L2VPN or L3VPN works at a time. Both L2VPN and L3VPN will not work simultaneously on a single physical interface. FRF.12 configuration applied on a L3VPN sub-interface, changes the mode of the entire physical interface to end-to-end and all L2VPN sub-interface traffic on this physical interface gets dropped.

If L2VPN circuits are already present on a SPA interface and FRF.12 configuration is applied on this interface, then the following error message will be displayed to indicate FRF.12 fragment drops on L2VPN circuits.

SLOT 3:2d08h: %GLCFR-3-FR_MODE: (bflc_fr_xdr_cmd_vc_status)FRF12 fragments will be dropp

The following is sample output from the **showinterfacesserial** command when low-latency queueing and FRF.12 end-to-end fragmentation are configured on a Frame Relay interface:

```
Router# show interfaces serial 3/2
Serial3/2 is up, line protocol is up
  Hardware is M4T
  MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation FRAME-RELAY, crc 16, loopback not set
  Keepalive set (10 sec)
  LMI enq sent  0, LMI stat recvd 0, LMI upd recvd 0, DTE LMI up
  LMI enq recvd 0, LMI stat sent  0, LMI upd sent  0
  LMI DLCI 1023  LMI type is CISCO  frame relay DTE
  Fragmentation type: end-to-end, size 80, PQ interleaves 0
  Broadcast queue 0/64, broadcasts sent/dropped 0/0, interface broadcasts 0
  Last input 2d15h, output 2d15h, output hang never
  Last clearing of "show interface" counters 00:01:31
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: weighted fair
  Output queue: 0/1000/64/0 (size/max total/threshold/drops)
     Conversations  0/0/256 (active/max active/max total)
     Reserved Conversations 0/0 (allocated/max allocated)
     Available Bandwidth 1094 kilobits/sec
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 1 interface resets
     0 output buffer failures, 0 output buffers swapped out
     1 carrier transitions     DCD=up  DSR=up  DTR=up  RTS=up  CTS=up
```

The table below describes significant fields shown in the display that are different from the fields described in the tables above.

*Table 149: **show interfaces serial** Field Descriptions--Frame Relay Interface Queueing and Fragmentation*

Field	Description
txload	Interface load in the transmit direction.
rxload	Interface load in the receive direction.
crc	Length the cyclic redundancy check (CRC) used on the interface.
LMI enq sent	Number of Frame Relay status inquiry messages sent.
LMI stat recvd	Number of Frame Relay status request messages received.
LMI upd recvd	Number of single PVC asynchronous status messages received.
DTE LMI up	LMI peers are synchronized.
LMI enq recvd	Number of Frame Relay status inquiry messages received.
LMI stat sent	Number of Frame Relay status request messages sent.
LMI upd sent	Number of single PVC asynchronous status messages sent.
Fragmentation type	Type of fragmentation: end-to-end, Cisco, or VoFR

Field	Description
size	Fragmentation size.
PQ interleaves	Number of priority queue frames that have interleaved data fragments.
Broadcast queue	Number on queue/queue depth.
broadcasts sent/dropped	Number of broadcasts sent and dropped.
interface broadcasts	Number of broadcasts sent on interface.
Input queue	size--Current size of the input queue. max--Maximum size of the queue. drops--Number of messages discarded. flushes--Number of times that data on queue has been discarded.
Queueing strategy	Type of queueing configured on the interface.
Output queue	size--Current size of the output queue. max total--Maximum number of frames that can be queued. threshold--Congestive-discard threshold. Number of messages in the queue after which new messages for high-bandwidth conversations are dropped. drops--Number of dropped messages.
Conversations	active--Number of currently active conversations. max active--Maximum number of conversations that have ever occurred at one time. max total--Maximum number of active conversations allowed.
throttles	Number of times the receiver on the port was disabled, possibly because of processor or buffer overload.
output buffer failures	Number of “no resource” errors received on the output.
output buffers swapped out	Number of packets swapped to DRAM.

Example with ANSI LMI

For a serial interface with the ANSI Local Management Interface (LMI) enabled, use the **showinterfacesserial**command to determine the LMI type implemented. The following is sample output from the **showinterfacesserial**command for a serial interface with the ANSI LMI enabled:

```
Router# show interfaces serial
Serial 1 is up, line protocol is up
   Hardware is MCI Serial
   Internet address is 172.18.121.1, subnet mask is 255.255.255.0
   MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
   Encapsulation FRAME-RELAY, loopback not set, keepalive set
   LMI DLCI    0, LMI sent 10, LMI stat recvd 10
   LMI type is ANSI Annex D
   Last input 0:00:00, output 0:00:00, output hang never
   Output queue 0/40, 0 drops; input queue 0/75, 0 drops

   Five minute input rate 0 bits/sec, 1 packets/sec
   Five minute output rate 1000 bits/sec, 1 packets/sec
       261 packets input, 13212 bytes, 0 no buffer
```

```
Received 33 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
238 packets output, 14751 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets, 0 restarts
```

Notice that the **showinterfacesserial**output for a serial interface with ANSI LMI shown in this display is very similar to that for encapsulation set to Frame Relay, as shown in the previous display. The table below describes the few differences that exist.

Table 150: show interfaces serial Field Descriptions--ANSI LMI

Field	Description
LMI DLCI 0	Identifies the DLCI used by the LMI for this interface. The default is 1023.
LMI sent 10	Number of LMI packets that the router sent.
LMI type is ANSI Annex D	Indicates that the interface is configured for the ANSI-adopted Frame Relay specification T1.617 Annex D.

Example with LAPB Encapsulation

Use the **showinterfacesserial**command to display operation statistics for an interface that uses Link Access Procedure, Balanced (LAPB) encapsulation. The following is partial sample output from the **showinterfacesserial** command for a serial interface that uses LAPB encapsulation:

```
Router# show interfaces serial 1
LAPB state is SABMSENT, T1 3000, N1 12056, N2 20, k7,Protocol ip
VS 0, VR 0, RCNT 0, Remote VR 0, Retransmissions 2
IFRAMEs 0/0 RNRs 0/0 REJs 0/0 SABMs 3/0 FRMRs 0/0 DISCs 0/0
```

The table below shows the fields relevant to all LAPB connections.

Table 151: show interfaces serial Field Descriptions--LAPB

Field	Description
LAPB state is	State of the LAPB protocol.
T1 3000, N1 12056, ...	Current parameter settings.
Protocol	Protocol encapsulated on a LAPB link; this field is not present on interfaces configured for multiprotocol LAPB or X.25 encapsulations.
VS	Modulo 8 frame number of the next outgoing information frame.
VR	Modulo 8 frame number of the next information frame expected to be received.
RCNT	Number of received information frames that have not yet been acknowledged.
Remote VR	Number of the next information frame that the remote device expects to receive.
Retransmissions	Count of current retransmissions because of expiration of T1.

Field	Description
Window is closed	No more frames can be transmitted until some outstanding frames have been acknowledged. This message should be displayed only temporarily.
IFRAMEs	Count of information frames in the form of sent/received.
RNRs	Count of Receiver Not Ready frames in the form of sent/received.
REJs	Count of Reject frames in the form of sent/received.
SABMs	Count of Set Asynchronous Balanced Mode commands in the form of sent/received.
FRMRs	Count of Frame Reject frames in the form of sent/received.
DISCs	Count of Disconnect commands in the form of sent/received.

Example with PPP Encapsulation

The output for an interface configured for synchronous PPP encapsulation differs from the standard **showinterfacesserial** output. An interface configured for PPP might include the following information:

```
Router# show interfaces serial 1
lcp state = OPEN
ncp ipcp state = OPEN   ncp osicp state = NOT NEGOTIATED
ncp ipxcp state = NOT NEGOTIATED   ncp deccp state = NOT NEGOTIATED
ncp bridgecp state = NOT NEGOTIATED   ncp atalkcp state = NOT NEGOTIATED
```

The table below show the fields relevant to PPP connections.

Table 152: show interfaces serial Field Descriptions--PPP Encapsulation

Field	Description
lcp state	Link Control Protocol.
ncp ipcp state	Network Control Protocol Internet Protocol Control Protocol.
ncp osicp state	Network Control Protocol OSI (CLNS) Control Protocol.
ncp ipxcp state	Network Control Protocol IPX (Novell) Control Protocol.
ncp deccp state	Network Control Protocol DECnet Control Protocol.
ncp bridgecp state	Network Control Protocol Bridging Control Protocol.
ncp atalkcp state	Network Control Protocol AppleTalk Control Protocol.

Example with SDLC Connections

Use the **showinterfacesserial**command to display the Synchronous Data Link Control (SDLC) information for a given SDLC interface. The following is sample output from the **showinterfacesserial**command for an SDLC primary interface that supports the SDLLC function:

```
Router# show interfaces serial
Serial 0 is up, line protocol is up
Hardware is MCI Serial
MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
Encapsulation SDLC-PRIMARY, loopback not set
    Timers (msec): poll pause 100 fair poll 500. Poll limit 1
    [T1 3000, N1 12016, N2 20, K 7] timer: 56608 Last polled device: none
    SDLLC [ma: 0000.0C01.14--, ring: 7 bridge: 1, target ring: 10
             largest token ring frame 2052]
SDLC addr C1 state is CONNECT
     VS 6, VR 3, RCNT 0, Remote VR 6, Current retransmit count 0
     Hold queue: 0/12 IFRAMEs 77/22 RNRs 0/0 SNRMs 1/0 DISCs 0/0
     Poll: clear, Poll count: 0, chain: p: C1 n: C1
     SDLLC [largest SDLC frame: 265, XID: disabled]
 Last input 00:00:02, output 00:00:01, output hang never
 Output queue 0/40, 0 drops; input queue 0/75, 0 drops
 Five minute input rate 517 bits/sec, 30 packets/sec
 Five minute output rate 672 bits/sec, 20 packets/sec
     357 packets input, 28382 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     926 packets output, 77274 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets, 0 restarts
     2 carrier transitions
```

The table below shows the fields relevant to all SDLC connections.

Table 153: show interfaces serial Field Descriptions--SDLC Enabled

Field	Description
Timers (msec): poll pause, fair poll, Poll limit	Current values of these timers for the primary SDLC interface.
T1, N1, N2, K	Values for these parameters for the primary SDLC interface.

The table below shows other data given for each SDLC secondary interface configured to be attached to the serial interface.

Table 154: SDLC Secondary Interface Descriptions

Field	Description
addr	Address of this SDLC secondary interface.

Field	Description
state is	Current state of this connection, which is one of the following: • DISCONNECT--No communication is being attempted to this secondary. • CONNECT--A normal connect state exists between this router and this secondary. • DISCSENT--This router has sent a disconnect request to this secondary and is awaiting its response. • SNRMSENT--This router has sent a connect request (SNRM) to this secondary and is awaiting its response. • THEMBUSY--This secondary has told this router that it is temporarily unable to receive any more information frames. • USBUSY--This router has told this secondary that it is temporarily unable to receive any more information frames. • BOTHBUSY--Both sides have told each other that they are temporarily unable to receive any more information frames. • ERROR--This router has detected an error and is waiting for a response from the secondary acknowledging this.
VS	Sequence number of the next information frame that this station sends.
VR	Sequence number of the next information frame from this secondary that this station expects to receive.
Remote VR	Last frame transmitted by this station that has been acknowledged by the other station.
Current retransmit count:	Number of times the current I-frame or sequence of I-frames has been retransmitted.
Hold Queue	Number of frames in hold queue and maximum size of hold queue.
IFRAMEs, RNRs, SNRMs, DISCs	Sent/received count for these frames.
Poll	“Set” if this router has a poll outstanding to the secondary; “clear” if it does not.
Poll Count	Number of polls in a row that have been given to this secondary at this time.
Chain	Shows the previous (p) and next (n) secondary address on this interface in the *roundrobinloop* of polled devices.

Example with SDLLC

Use the **showinterfacesserial**command to display the SDLLC statistics for SDLLC-configured interfaces. The following is sample output from the **showinterfacesserial**command for a serial interface configured for SDLLC:

```
Router# show interfaces serial
Serial 0 is up, line protocol is up
   Hardware is MCI Serial
   MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec, rely 255/255, load 1/255
   Encapsulation SDLC-PRIMARY, loopback not set
       Timers (msec): poll pause 100 fair poll 500. Poll limit 1
       [T1 3000, N1 12016, N2 20, K 7] timer: 56608 Last polled device: none
       SDLLC [ma: 0000.0C01.14--, ring: 7 bridge: 1, target ring: 10
             largest token ring frame 2052]
   SDLC addr C1 state is CONNECT
       VS 6, VR 3, RCNT 0, Remote VR 6, Current retransmit count 0
       Hold queue: 0/12 IFRAMEs 77/22 RNRs 0/0 SNRMs 1/0 DISCs 0/0
       Poll: clear, Poll count: 0, chain: p: C1 n: C1
       SDLLC [largest SDLC frame: 265, XID: disabled]
   Last input 00:00:02, output 00:00:01, output hang never
   Output queue 0/40, 0 drops; input queue 0/75, 0 drops
   Five minute input rate 517 bits/sec, 30 packets/sec
   Five minute output rate 672 bits/sec, 20 packets/sec
       357 packets input, 28382 bytes, 0 no buffer
       Received 0 broadcasts, 0 runts, 0 giants
       0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
       926 packets output, 77274 bytes, 0 underruns
       0 output errors, 0 collisions, 0 interface resets, 0 restarts
       6608 Last polled device: none
       SDLLC [ma: 0000.0C01.14--, ring: 7 brid2 carrier transitions
```

Most of the output shown in the display is generic to all SDLC-encapsulated interfaces and is described in the *CiscoIOS Bridging and IBM Networking Command Reference* , *Volume 2 of 2: IBM Networking* . The table below shows the parameters specific to SDLLC.

Table 155: SDLLC Parameter Descriptions

Field	Description
SDLLC ma	Lists the MAC address configured for this interface. The last byte is shown as "--" to indicate that it is filled in with the SDLC address of the connection.
ring, bridge, target ring	Lists the parameters as configured by the **sdllctraddr**command.
largest token ring frame	Shows the largest Token Ring frame that is accepted on the Logical Link control, type 2 (LLC2) side of the connection.
largest SDLC frame	Shows the largest SDLC frame that is accepted and will be generated on the SDLC side of the connection.
XID	Enabled or disabled: Shows whether XID processing is enabled on the SDLC side of the connection. If enabled, it will show the XID value for this address.

Example with X.25

The following is partial sample output from the **showinterfacesserial**command for a serial X.25 interface:

```
Router# show interfaces serial 1
X25 address 000000010100, state R1, modulo 8, idle 0, timer 0, nvc 1
  Window size: input 2, output 2, Packet size: input 128, output 128
  Timers: T20 180, T21 200, T22 180, T23 180, TH 0
  Channels: Incoming-only none, Two-way 1-1024, Outgoing-only none
(configuration on RESTART: modulo 8,
  Window size: input 2 output 2, Packet size: input 128, output 128
  Channels: Incoming-only none, Two-way 5-1024, Outgoing-only none)
  RESTARTs 3/2 CALLs 1000+2/1294+190/0+0/ DIAGs 0/0
```

The stability of the X.25 protocol requires that some parameters not be changed without a restart of the protocol. Any change to these parameters is held until a restart is sent or received. If any of these parameters changes, information about the router configuration at restart will be displayed as well as the values that are currently in effect.

The table below describes significant fields shown in the display.

Table 156: show interfaces serial Field Descriptions--X.25 Enabled

Field	Description
X25 address	Address used to originate and accept calls.
state	State of the interface. Possible values follow: • R1 is the normal ready state. • R2 is the DTE restarting state. • R3 is the DCE restarting state. If the state is R2 or R3, the interface is awaiting acknowledgment of a Restart packet.
modulo	Modulo value; determines the packet sequence numbering scheme used.
idle	Number of minutes for which the Cisco IOS software waits before closing idle virtual circuits that it originated or accepted.
timer	Value of the interface timer, which is zero unless the interface state is R2 or R3.
nvc	Default maximum number of simultaneous virtual circuits permitted to and from a single host for a particular protocol.
Window size: input, output	Default window sizes (in packets) for the interface. The **x25facility** interface configuration command can be used to override these default values for the switched virtual circuits originated by the router.
Packet size: input, output	Default maximum packet sizes (in bytes) for the interface. The **x25facility** interface configuration command can be used to override these default values for the switched virtual circuits originated by the router.

Field	Description
Timers:	Values of the X.25 timers: • T10 through T13 for a DCE device • T20 through T23 for a DTE device
TH	Packet acknowledgment threshold (in packets). This value determines how many packets are received before an explicit acknowledgment is sent. The default value (0) sends an explicit acknowledgment only when the incoming window is full.
Channels: Incoming-only, Two-way, Outgoing-only	Displays the virtual circuit ranges for this interface.
RESTARTs	Shows Restart packet statistics for the interface using the format Sent/Received.
CALLs	Successful calls sent + failed calls/calls received + calls failed/calls forwarded + calls failed. Calls forwarded are counted as calls sent.
DIAGs	Diagnostic messages sent and received.

Example with Accounting Option

The following example illustrates the **showinterfacesserial** command with the **accounting** option on a Cisco 7500 series routers:

```
Router# show interfaces serial 1/0 accounting
Serial1/0
       Protocol    Pkts In   Chars In   Pkts Out  Chars Out
             IP       7344    4787842       1803    1535774
      Appletalk      33345    4797459      12781    1089695
        DEC MOP          0          0        127       9779
            ARP          7        420         39       2340
```

The table below describes thefields shown in the display.

*Table 157: **show interfaces serial** Field Descriptions--Accounting*

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

Example with Cisco AS5800 Access Server

The following example shows the activity that occurred on the serial interface in shelf 1, slot 4, port 0 for time slot 2 in group 23:

```
Router# show interfaces serial 1/4/0:2:23
Serial1/4/0:2:23 is up, line protocol is up (spoofing)
 Hardware is DS-T1
 MTU 1500 bytes, BW 64 Kbit, DLY 20000 usec, rely 255/255, load 1/255
 Encapsulation HDLC, loopback not set
 Last input 00:00:01, output 00:00:01, output hang never
 Last clearing of "show interface" counters 22:24:30
 Queueing strategy: fifo
 Output queue 0/40, 0 drops; input queue 0/75, 0 drops
 5 minute input rate 0 bits/sec, 0 packets/sec
 5 minute output rate 0 bits/sec, 0 packets/sec
     5274 packets input, 20122 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     5274 packets output, 30836 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 output buffer failures, 0 output buffers swapped out
     2 carrier transitions no alarm present
 Timeslot(s) Used:24, subrate: 64Kb/s, transmit delay is 0 flags
```

The table below describes the significant fields shown in thedisplay that are different from the fields described in the tables above.

Table 158: show interfaces serial Command Field Descriptions--Cisco AS5800

Field	Description
Last clearing of “show interface” counters	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) were last reset to zero.
Queueing strategy	Displays the type of queueing configured for this interface. In the example output, the type of queueing configured is FIFO.
throttles	Number of times that the receiver on the port was disabled, possibly because of buffer or processor overload.
output buffer failures	Number of times that the output buffer has failed.
output buffer swapped out	Number of times that the output buffer has been swapped out.
Timeslot(s) Used	Number of time slots assigned to the T1 channel.
subrate	Bandwidth of each time slot.
transmit delay is ...	Number of idle flags inserted between each frame.

Related Commands

Command	Description
show controllers serial	Displays information about the virtual serial interface.

show interfaces sm

To display status, traffic data, and configuration information about the SM-SRE service module interface, use the **showinterfacessm** command in user EXEC or privileged EXEC mode.

show interfaces sm *slot*/*port*

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

The service module interface is the Gigabit Ethernet interface on the router that connects to the SM-SRE.

Examples

The following example displays status, traffic data, and configuration information about the interface to the SM-SRE installed in the router.

```
Router# show interfaces sm 1/0
SM1/0 is up, line protocol is up
  Hardware is PSE2, address is 001e.4a97.644d (bia 001e.4a97.644d)
  Internet address is 30.0.0.1/24
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 1000Mb/s, media type is internal
  output flow-control is XON, input flow-control is XON
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:13, output 00:00:04, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/60 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     22 packets input, 1398 bytes, 0 no buffer
     Received 3 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 0 multicast, 0 pause input
     0 input packets with dribble condition detected
     134 packets output, 42720 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 unknown protocol drops
     0 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 159: show interfaces sm Field Descriptions

Field	Description
Hardware, address	Hardware type and address.
MTU	Maximum transmission unit (MTU) of the service module interface.
BW	Bandwidth of the interface, in kbps.
DLY	Delay of the interface, in microseconds.
reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
txload	Transmit load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
rxload	Receive load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates whether or not loopback is set.
Keepalive	Indicates whether or not keepalives are set and the interval between keepalives if they have been set.
ARP type...ARP Timeout	Type of Address Resolution Protocol (ARP) assigned and length of timeout.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by the interface and processed locally on the router. This field is useful for detecting when a dead interface failed. **Note** This field is not updated by fast-switched traffic.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. This field is useful for detecting when a dead interface failed.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because a transmission took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. Asterisks (***) indicate that the elapsed time is too large to be displayed.

Field	Description
Input queue	Number of packets in the input queue. Each number is followed by a slash, the maximum size of the queue, the number of packets dropped because of a full queue, and the number of times that queued packets have been discarded.
Total output drops	Number of packets in the output queue that have been dropped because of a full queue.
Queueing strategy	Queueing strategy applied to the interface, which is configurable under the interface. The default is FIFO (first-in, first-out).
Output queue	Number of packets in the output queue, and the maximum size of the queue. Each number is followed by a slash.
5 minute input rate, 5 minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. If the interface is not in promiscuous mode, it senses network traffic that it sends and receives (rather than all network traffic). The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within 2 percent of the instantaneous rate of a uniform stream of traffic over that period. **Note** The 5-minute period referenced in this output is a load interval that is configurable under the interface. The default value is 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernets and bursts of noise on serial lines are often responsible for no input buffer events.
Received...broadcasts	Number of broadcasts received.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium. For instance, any Ethernet packet that is less than 64 bytes is considered a runt.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium. For example, any Ethernet packet that is greater than 1518 bytes is considered a giant.
throttles	Number of times that the interface requested another interface within the router to slow down.

Field	Description
input errors	Errors that include runts, giants, no buffer, cyclic redundancy checksum (CRC), frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Errors created when the CRC generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station that is transmitting bad data.
frame	Number of packets received incorrectly that have a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
overrun	Number of times that the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets that were ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different from system buffer space described. Broadcast storms and bursts of noise can cause the ignored count to increase.
input packets with dribble condition detected	Number of packets with dribble condition. Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages that have been transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, that have been transmitted by the system.
underruns	Number of times that the transmitter has run faster than the router could handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface that is being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages that have been retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.

Field	Description
interface resets	Number of times an interface has been completely reset. This can happen if packets that were queued for transmission were not sent within several seconds. On a serial line, this can be caused by a malfunctioning modem that is not supplying the transmit clock signal or by a cable problem. If the system notices that the carrier detect line of a serial interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an interface is looped back or shut down.
babbles	Count of frames greater than 1518 bytes that have been transmitted, indicating that the transmitter has been on the interface longer than the time necessary to transmit the largest frame.
late collision	Number of late collisions. A collision becomes a late collision when it occurs after the preamble has been transmitted.
deferred	Deferred indicates that the chip, while ready to transmit a frame, had to defer because the carrier was asserted.
lost carrier	Number of times that the carrier was lost during transmission.
no carrier	Number of times that the carrier was not present during the transmission.
output buffer failures, output buffers swapped out	Number of failed buffers and number of buffers swapped out.

Related Commands

Command	Description
show controllers sm	Displays controller information for the service module interface.

show interfaces status

To display the interface status or a list of interfaces in an error-disabled state on local area network (LAN) ports only, use the **showinterfacesstatus** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **status** [{**err-disabled** | **module** *number* | **vlan** *vlan*}]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
err-disabled	(Optional) Displays the LAN ports in an error-disabled state.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.
vlan *vlan*	(Optional) Specifies a VLAN. Limits the display of switch port information to the specified VLAN. Range: 1 to 4094.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17b)SXA	This command was changed to include the packet-buffer error status in the **showinterfacesstatuserr-disabled** output.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB. This command was changed to include the type string of the receive-only transceivers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was changed to add the optional **vlan***vlan* keyword and argument.

Usage Guidelines

The *interface-number*argument designates the module and port number. Valid values for *interface-number* depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

This command is supported on LAN ports only.

The **module***number* keyword and argument designate the module number and limit the display to the interfaces on the module. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

To find out if an interface is inactive, enter the **showinterfacesstatus** command. If the interface is inactive, the Status field displays "inactive." If the port is not inactive, the Status field displays "none."

To find the packet and byte count, you can enter the **showinterfacescounters** command or the show **interfaces***interfaceinterface-number* status command. The **showinterfacescounters** command is the preferred command to use. In some cases, the packet and byte count of the show **interfaces***interfaceinterface-number* status command is incorrect.

Examples

This example shows how to display the status of all LAN ports:

```
Router>
show interfaces status
Port    Name               Status     Vlan       Duplex Speed Type
Gi1/1                      disabled   routed       full  1000 missing
Gi1/2                      notconnect 1            full  1000 unknown (4)
Fa5/1                      disabled   routed       auto  auto 10/100BaseTX
.
.
.
Port    Name               Status       Vlan       Duplex  Speed Type
Fa5/18                     disabled     1          auto    auto  10/100BaseTX
Fa5/19                     disabled     1          auto    auto  10/100BaseTX
Gi7/1                      disabled     1          full    1000  WDM-RXONLY
Gi7/2                      disabled     1          full    1000  No Transceiver
Router>
```

This example shows how to display the packet and byte count of a specific LAN port:

```
Router
> show interfaces fastethernet 5/2 status
FastEthernet5/2
Switching path    Pkts In   Chars In   Pkts Out  Chars Out
               Processor         17       1220         20       2020
             Route cache          0          0          0          0
       Distributed cache         17       1220  206712817 2411846570
                   Total         34       2440  206712837 2411848590
Router>
```

This example shows how to display the status of LAN ports in an error-disabled state:

```
Router>

show interfaces status
 err-disabled
Port    Name               Status       Reason
Fa9/4                      notconnect   link-flap
informational error message when the timer expires on a cause
--------------------------------------------------------------
5d04h:%PM-SP-4-ERR_RECOVER:Attempting to recover from link-flap err-disable state on Fa9/4
Router>
```

Catalyst 6500 Series Switches

The following shows how to display the **showinterfacesstatus**for VLAN 2:

```
Router# show interfaces status vlan 2
```

Related Commands

Command	Description
errdisable detect cause	Enables the error-disable detection.
show errdisable recovery	Displays the information about the error-disable recovery timer.

show interfaces summary

To display a summary of statistics for one interface or for all interfaces that are configured on a networking device, use the **show interfaces summary** command in privileged EXEC mode. For Cisco 7600 series routers, the command can also be used in user EXEC mode.

show interfaces summary

Cisco 7600 Series
show interfaces [*type number*] **summary** [**vlan**]

Syntax Description

type	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
number	(Optional) Module and port number of the specified interface.
vlan	(Optional) Displays the total number of VLAN interfaces .

Command Default

This command has no default settings.

Command Modes

Privileged EXEC. User EXEC (Cisco 7600 series only)

Command History

Release	Modification
12.2	This command was introduced.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command was introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Usage Guidelines

Cisco 7600 Series

On a Cisco 7600 series router, you can display summary information for a single interface by specifying the interface type and number. Separate counters for subinterfaces are not maintained and are not displayed in the output.

Examples

The following is sample output from the **show interfaces summary** command:

```
Router# show interfaces summary
 *: interface is up
 IHQ: pkts in input hold queue     IQD: pkts dropped from input queue
 OHQ: pkts in output hold queue    OQD: pkts dropped from output queue
 RXBS: rx rate (bits/sec)          RXPS: rx rate (pkts/sec)
 TXBS: tx rate (bits/sec)          TXPS: tx rate (pkts/sec)
 TRTL: throttle count
  Interface          IHQ   IQD  OHQ   OQD  RXBS RXPS  TXBS TXPS  TRTL
```

```
----------------------------------------------------------------------
* FastEthernet0/0       0     0    0     0     0    0     0    0   0
  Serial0/0             0     0    0     0     0    0     0    0   0
  FastEthernet0/1       0     0    0     0     0    0     0    0   0
  Serial0/1             0     0    0     0     0    0     0    0   0
NOTE:No separate counters are maintained for subinterfaces
     Hence Details of subinterface are not shown.
```

This example shows how to display the total number of VLAN interfaces on a Cisco 7600 series router:

```
Router# show interfaces summary vlan
Total number of Vlan interfaces: 7
Vlan interfaces configured:
1,5,20,2000,3000-3001,4000
Router#
```

This example shows how to display the total number of VLAN interfaces on a Cisco 7600 series router:

```
Router# show interfaces summary vlan
Total number of Vlan interfaces: 7
Vlan interfaces configured:
1,5,20,2000,3000-3001,4000
Router#
```

This example shows how to display a summary of the interfaces on a Cisco 4400 Series Integrated Services Router.

```
#show interfaces summary

 *: interface is up
 IHQ: pkts in input hold queue     IQD: pkts dropped from input queue
 OHQ: pkts in output hold queue    OQD: pkts dropped from output queue
 RXBS: rx rate (bits/sec)          RXPS: rx rate (pkts/sec)
 TXBS: tx rate (bits/sec)          TXPS: tx rate (pkts/sec)
 TRTL: throttle count

  Interface                  IHQ       IQD       OHQ       OQD      RXBS      RXPS
TXBS      TXPS      TRTL
-----------------------------------------------------------------------------------------

  GigabitEthernet0/0/0         0         0         0         0         0         0
  0         0         0
  GigabitEthernet0/0/1         0         0         0         0         0         0
  0         0         0
  GigabitEthernet0/0/2         0         0         0         0         0         0
  0         0         0
  GigabitEthernet0/0/3         0         0         0         0         0         0
  0         0         0
* Serial1/0/0                  0         0         0         0         0         0
  0         0         0
* GigabitEthernet0             0         0         0         0     31000        60
  0         0         0
```

Related Commands

Command	Description
show interfaces	Displays the statistical information specific to interfaces.
show interfaces atm	Displays information about the ATM interfaces.
show interfaces ethernet	Displays information about the Ethernet interfaces.
show interfaces fastethernet	Displays information about the Fast Ethernet interfaces.
show interfaces serial	Displays information about the serial interfaces.

show interfaces switchport

To display the administrative and operational status of a switching (nonrouting) port, use the **showinterfacesswitchport** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **switchport** [**brief**] [**module** *number*]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
brief	(Optional) Displays a brief summary of information.
module *number*	(Optional) Limits the display to interfaces on a specified module; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17a)SX	The Administrative Trunking Encapsulation field was changed to dot1q EtherType.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed to include the **brief** keyword on the Supervisor Engine 720 only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *interface-number* designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

Examples

This example shows how to display switch-port information using the **include** output modifier:

```
Router>
show interfaces switchport
| include VLAN
Name: Fa5/6
Access Mode VLAN: 200 (VLAN0200)
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: ALL
.
.
```

```
.
Router>
```

This example shows how to display the configurations of two multiple VLAN access ports:

```
Router>
show interfaces switchport
Name: Fa5/1
Switchport: Enabled
Administrative Mode: access
Operational Mode: access
Dot1q Ethertype: 0x8200
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: off
Access Mode VLAN: 100
Voice VLAN: 102
Trunking Native Mode VLAN: 1 (default)
Administrative private-vlan host-association: none
Administrative private-vlan mapping: 900 ((Inactive)) 901 ((Inactive))
Operational private-vlan: none
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
Capture Mode Disabled
Capture VLANs Allowed: ALL
Name: Fa5/2
Switchport: Enabled
Administrative Mode: access
Operational Mode: down
Dot1q Ethertype: 0x8200
Operational Trunking Encapsulation: native
Negotiation of Trunking: Off
Access Mode VLAN: 100
Voice VLAN: 103 ((inactive))
Trunking Native Mode VLAN: 1 (default)
.
.
.
```

This example shows how to display a brief summary of information:

```
Router> show interfaces switchport
 brief module 3
Port Status Op.Mode Op.Encap Channel-id Vlan
Fa3/1 connected access native -- 1
Fa3/7 disabled -- dot1q Po26 1
Fa3/13 connected access native -- 666
Router>
```

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.

show interfaces switchport backup

To display Flexlink pairs, use the **showinterfacesswitchportbackup** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **switchport backup**

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *interface-number* designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

Examples

This example shows how to display all Flexlink pairs:

```
Router> show interfaces switchport backup
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
FastEthernet3/1         FastEthernet4/1         Active Up/Backup Standby
FastEthernet5/1         FastEthernet5/2         Active Down/Backup Up
FastEthernet3/2         FastEthernet5/4         Active Standby/Backup Up
Po1                     Po2                     Active Down/Backup Down
Router>
```

This example shows how to display a specific Flexlink port:

```
Router> show interfaces fastethernet 4/1 switchport backup
Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
FastEthernet3/1       FastEthernet4/1           Active Up/Backup Standby
Router>
```

Related Commands

Command	Description
switchport backup	Configures an interface as a Flexlink backup interface.

show interfaces tokenring

To display information about the Token Ring interface and the state of source route bridging, use the **showinterfacestokenring** command in privileged EXEC mode.

Standard Syntax
show interfaces tokenring *number* [**accounting**]

Cisco 7200 and Cisco 7500 Series
show interfaces tokenring *slot/port* [**accounting**]

Cisco 7500 Series with Ports on VIPs
show interfaces tokenring [*slot/port-adapter/port*]

Syntax Description

number	Interface port line number.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
slot	On the Cisco 7000 series routers, slot location of the interface processor. On the Cisco 7000, the value can be 0, 1, 2, 3, or 4. On the Cisco 7010, the value can be 0, 1, or 2. On the Cisco 7200 series routers, slot location of the port adapter; the value can be 1, 2, 3, 4, 5, or 6.
/ *port*	Port number on the interface. On the Cisco 7000 series routers this argument is required, and the values can be 0, 1, 2, or 3. (Optional) For the VIP, this argument is optional, and the port value can be 0, 1, 2, or 3 for 4-port Token Ring interfaces. On the Cisco 7200 series routers, the number depends on the type of port adapter installed.
/ *port-adapter*	(Optional) On the Cisco 7000 series and Cisco 7500 series routers, specifies the ports on a VIP. The value can be 0 or 1.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.3(3)T	The information was modified to include the PA-4R-FDX full-duplex Token Ring port adapter.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not provide values for the *slot* and *port*arguments, the command displays statistics for all the network interfaces. The optional **accounting** keyword displays the number of packets of each protocol type that have been sent through the interface.

Examples

The following is sample output from the **showinterfacestokenring** command:

```
Router# show interfaces tokenring
TokenRing 0 is up, line protocol is up
Hardware is 16/4 Token Ring, address is 5500.2000.dc27 (bia 0000.3000.072b)
    Internet address is 10.136.230.203, subnet mask is 255.255.255.0
    MTU 8136 bytes, BW 16000 Kbit, DLY 630 usec, rely 255/255, load 1/255
    Encapsulation SNAP, loopback not set, keepalive set (10 sec)
    ARP type: SNAP, ARP Timeout 4:00:00
    Ring speed: 16 Mbps
    Single ring node, Source Route Bridge capable
    Group Address: 0x00000000, Functional Address: 0x60840000
    Last input 0:00:01, output 0:00:01, output hang never
    Output queue 0/40, 0 drops; input queue 0/75, 0 drops
    Five minute input rate 0 bits/sec, 0 packets/sec
    Five minute output rate 0 bits/sec, 0 packets/sec
    16339 packets input, 1496515 bytes, 0 no buffer
          Received 9895 broadcasts, 0 runts, 0 giants
          0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     32648 packets output, 9738303 bytes, 0 underruns
0 output errors, 0 collisions, 2 interface resets, 0 restarts
     5 transitions
```

The table below describes the significant fields shown in the displays.

Table 160: show interfaces tokenring Field Descriptions

Field	Description
Token Ring is {up | down}	Interface is either currently active and inserted into ring (up) or inactive and not inserted (down). On the Cisco 7500 series routers, gives the interface processor type, slot number, and port number.
Token Ring is Reset	Hardware error has occurred.
Token Ring is Initializing	Hardware is up, in the process of inserting the ring.
Token Ring is Administratively Down	Hardware has been taken down by an administrator.
line protocol is {up | down | administratively down}	Indicates whether the software processes that handle the line protocol believe the interface is usable (that is, whether keepalives are successful).
Hardware	Hardware type. “Hardware is Token Ring” indicates that the board is a CSC-R board. “Hardware is 16/4 Token Ring” indicates that the board is a CSC-R16 board. Also shows the address of the interface.
Internet address	Lists the Internet address followed by subnet mask.
MTU	Maximum transmission unit of the interface.

Field	Description
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to interface.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
ARP type	Type of Address Resolution Protocol assigned.
Ring speed	Speed of Token Ring--4 or 16 Mbps.
{Single ring | multiring node}	Indicates whether a node is enabled to collect and use source routing information (RIF) for routable Token Ring protocols.
Group Address	Interface's group address, if any. The group address is a multicast address; any number of interfaces on the ring may share the same group address. Each interface may have at most one group address.
Functional Address:	Bit-significant group address. Each "on" bit represents a function performed by the station.
Ethernet Transit OUI:	The Organizational Unique Identifier (OUI) code to be used in the encapsulation of Ethernet Type II frames across Token Ring backbone networks.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
Last output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.

Field	Description
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, drops Input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
Five minute input rate, Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes input	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the of them medium maximum packet size.
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.

Field	Description
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
packets output	Total number of messages transmitted by the system.
bytes output	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, as some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Since a Token Ring cannot have collisions, this statistic is nonzero only if an unusual event occurred when frames were being queued or dequeued by the system software.
interface resets	Number of times an interface has been reset. The interface may be reset by the administrator or automatically when an internal error occurs.
restarts	Should always be zero for Token Ring interfaces.
transitions	Number of times the ring made a transition from up to down, or vice versa. A large number of transitions indicates a problem with the ring or the interface.

The following is sample output from the **showinterfacestokenring** command on a Cisco 7500 series routers:

```
Router# show interfaces tokenring 2/0
TokenRing2/0 is administratively down, line protocol is down
  Hardware is cxBus Token Ring, address is 0000.3040.8b4a (bia 0000.3040.8b4a)
  MTU 8136 bytes, BW 16000 Kbit, DLY 630 usec, rely 255/255, load 1/255
  Encapsulation SNAP, loopback not set, keepalive set (10 sec)
  ARP type: SNAP, ARP Timeout 4:00:00
  Ring speed: 0 Mbps
  Single ring node, Source Route Transparent Bridge capable
  Ethernet Transit OUI: 0x0000F8
  Last input never, output never, output hang never
  Last clearing of “show interface” counters never
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  Five minute input rate 0 bits/sec, 0 packets/sec
  Five minute output rate 0 bits/sec, 0 packets/sec
     0 packets input, 0 bytes, 0 no buffer
     Received 0 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
```

```
     0 output errors, 0 collisions, 1 interface resets, 0 restarts
     1 transitions
```

The following example on the Cisco 7500 series routers includes the **accounting** option. When you use the accounting option, only the accounting statistics are displayed.

```
Router# show interfaces tokenring 2/0 accounting
TokenRing2/0
       Protocol    Pkts In   Chars In   Pkts Out  Chars Out
             IP       7344    4787842       1803    1535774
      Appletalk      33345    4797459      12781    1089695
        DEC MOP          0          0        127       9779
            ARP          7        420         39       2340
```

The table below describes thefields shown in the display.

*Table 161: **show interfaces tokenring** Field Descriptions--Accounting*

Field	Description
Protocol	Protocol that is operating on the interface.
Pkts In	Number of packets received for that protocol.
Chars In	Number of characters received for that protocol.
Pkts Out	Number of packets transmitted for that protocol.
Chars Out	Number of characters transmitted for that protocol.

show interfaces transceiver

To display information about the optical transceivers that have digital optical monitoring (DOM) enabled, use the **showinterfacestransceiver** command in privileged EXEC mode.

Catalyst 6500 Series Switches and Cisco 7600 Series Routers
show interfaces [*interface interface-number*] **transceiver** [{**threshold violations** | **properties**}] [{**detail** | **module** *number*}]

Cisco 7200 VXR
show interfaces [*interface interface-number*] **transceiver**

Cisco ASR 901 Routers
show interfaces [*interface interface-number*] **transceiver** [{**threshold** {**table** | **violations**} | **detail** | **supported-list**}]

Cisco ASR 1000 Routers
show interfaces transceiver

Syntax Description

interface	(Optional) Interface type; possible valid values are **gigabitethernet** and **tengigabitethernet**.
interface-number	Module and port number; see the "Usage Guidelines" section for valid values.
threshold violations	(Optional) Displays information about the interface transceiver threshold violations.
properties	(Optional) Displays information about the port speed and duplex autonegotiation status.
detail	(Optional) Displays detailed information about the interface transceiver.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.
threshold {**table** | **violations**}	(Optional) Displays information about the transceiver threshold. • **table**—Displays the alarm and warning threshold table. • **violations**—Displays the alarm and warning threshold violations.
supported-list	(Optional) Displays a list of all supported DOM transceivers.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(17d)SXB2	Support for this command was introduced on the Supervisor Engine 720 and the Supervisor Engine 2.
12.2(18)SXE	This command was changed to support DOM for GBICs and XENPAKs.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T for the Cisco 7200 VXR with the NPE-G2 network processing engine.
12.2(33)SXI	This command was changed to display the port speed and duplex autonegotiation status
15.2(2)SNI	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.
Cisco IOS XE Gibraltar 16.10.1	This command was implemenred on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

After a transceiver is inserted, the software waits approximately 10 seconds before reading the diagnostic monitoring information. If you enter the **showinterfacestransceiver** command before the software has read the diagnostic monitoring information, the following message is displayed:

```
Waiting for diagnostic monitoring information to settle down.
Please try again after a few seconds.
```

Wait a few seconds and re-enter the **showinterfacestransceiver** command.

The *interfaceinterface-number* arguments are supported on interfaces that have a transceiver that has diagnostic monitoring enabled and the transceiver is in a module that supports the reading of diagnostic monitoring information. The transceiver periodically polls operating conditions such as temperature and power levels. The show interfaces transceiver command allows the router to display these operating conditions while the transceiver is in service.

Examples

This example shows how to display transceiver information:

```
Router# show interfaces transceiver
If device is externally calibrated, only calibrated values are printed.
++ : high alarm, +  : high warning, -  : low warning, -- : low alarm.
NA or N/A: not applicable, Tx: transmit, Rx: receive.
mA: milliamperes, dBm: decibels (milliwatts).
                                          Optical   Optical
         Temperature  Voltage  Current    Tx Power  Rx Power
Port     (Celsius)    (Volts)  (mA)       (dBm)     (dBm)
-------  -----------  -------  --------   --------  --------
Gi1/1      40.6       5.09       0.4      -25.2      N/A
Gi2/1      35.5       5.05       0.1      -29.2      N/A
Gi2/2      49.5       3.30       0.0        7.1     -18.7
```

This example shows how to display detailed transceiver information:

```
Router# show interfaces transceiver detail
mA: milliamperes, dBm: decibels (milliwatts), NA or N/A: not applicable.
++ : high alarm, +  : high warning, -  : low warning, -- : low alarm.
A2D readouts (if they differ), are reported in parentheses.
The threshold values are calibrated.
```

```
                             High Alarm  High Warn  Low Warn   Low Alarm
        Temperature          Threshold   Threshold  Threshold  Threshold
Port     (Celsius)           (Celsius)   (Celsius)  (Celsius)  (Celsius)
------- ------------------  ----------  ---------  ---------  ---------
Gi1/1     48.1                100.0       100.0        0.0        0.0
Gi1/2     34.9                100.0       100.0        0.0        0.0
Gi2/1     43.5                 70.0        60.0        5.0        0.0
Gi2/2     39.1                 70.0        60.0        5.0        0.0

Cisco ASR 901 Routers

show interfaces [*interface interface-number*] **transceiver** [{**threshold** {**table** | **violations**} | **detail** | **supported-list**}]

Cisco 7200 VXR

This example shows static information and current status information for the transceiver. The static information is a description of the transceiver and its physical capabilities, which is provided by the manufacturer in EEPROM. The status information shows current operating conditions, as well as alarm and warning threshold ranges.

Alarms indicate conditions that might be associated with a non-operational link and are cause for immediate action. Warnings indicate conditions outside the normally guaranteed ranges but are not necessarily causes of immediate link failures. Certain warnings can also be defined by the manufacturer as end-of-life indicators, such as higher than expected bias currents in a constant power control loop.

In this example, the fiber optic cable is disconnected and the appropriate alarms and warnings are displayed.

```
Router# show interfaces g0/3 transceiver
Static information

```

The table below describes the significant fields shown in the display.

Table 162: show interfaces transceiver Field Descriptions

Field	Description
Diagnostics calibration	Indicates whether diagnostic information (temperature, voltage, bias, and power) is calibrated internally or externally. Internal calibration means that measurements are calibrated over vendor-specified operating temperature and voltage. External calibration means that measurements are raw analog/digital values and are converted to common units of measure, such as volts and amperes, using calibration constants stored in EEPROM.
Temperature	Internally-measured transceiver temperature.
Voltage in transceiver	Internally-measured supply voltage.
TX bias	Measured transmitter laser bias current.
TX power	Measured coupled transmit output power.
RX power	Measured received optical power.

Field	Description
UDI	Unique device identifier.

show interfaces transceiver details

The show interfaces transceiver details command displays combined results of **show hw-mod subslot transceiver idprom brief** and **show hw-mod sub transceiver idprom dump** commands. The output also includes error optics information from the line card console and information is displayed for all the transceivers in the router. The output also includes alarm status if CPAK transceivers are installed in the router..

show interfaces transceiverdetails

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Gibraltar 16.10.1	This command was introduced.

Examples

The following is the sample output from the **show interfaces transceiver details** command:.

```
Router# show interfaces transceiver details
IDPROM for transceiver HundredGigE1/0/0:

show interfaces transceiver slot

The show interfaces transceiver slot command displays combined results of **show hw-module subslot transceiver status** and show hw-module subslot transceiver idprom brief commands along with the threshold range details. The output is displayed for the transceivers in a specific slot on the router.

show interfaces transceiver slot[{*slot-number*}]

Syntax Description

slot-number	Chassis slot-number.

Command Modes

Privileged EXEC(#)

Command History

Release	Modification
Cisco IOS XE Gibraltar 16.10.1	This command was introduced.

Examples

The following is sample output from the **show interfaces transceiver slot** comman::

```
Router# show interfaces transceiver slot 2The Transceiver in slot 2 subslot 0 port 0 is
enabled.
Module temperature = +31.714 C [Range: -5 C to 85 C (extended)]
Transceiver Tx supply voltage = 3331.8 mVolts [Range: 3140.0 to 3470.0 mVolts]
Transceiver Tx bias current = 3112 uAmps [Range: 2400 to 11900 uAmps]
Transceiver Tx power = -5.8 dBm [Range: -9.5 to -3.0 dBm]
Transceiver Rx optical power = -7.4 dBm [Range: -17.0 to 0.0 dBm]
IDPROM for transceiver GigabitEthernet2/0/0:

Diagnostics are internally calibrated
Rx power measured is "Average power"
```

show interfaces <interface> transceiver

The **show interfaces <interface> transceiver** command displays combined results of **show hw-module subslot transceiver status** and **show hw-module subslot transceiver idprom brief** commands along with threshold range details. The output is displayed for a specific interface on the router.

show interfaces[{*interface-typeslot/subslot/port*}] **transceiver**

Syntax Description

interface-type	Interface type; possible valid values are pos, atm, ethernet, fastethernet, gigabitethernet, tengigabitethernet, fortygigabitethernet, hundredGigE.
slot	Number of the router slot.
subslot	Secondary slot number on a SIP where a SPA is installed.
port	Port number

Command Modes

Privileged EXEC(#)

Command History

Release	Modification
Cisco IOS XE Gibraltar 16.10.1	This command was introduced.

Examples

The following is sample output from the **show interfaces <interface> transceiver** command:

```
Router# show interfaces hundredGigE 1/0/0 transceiver
The Transceiver in slot 1 subslot 0 port 0 is enabled.
Module temperature = +33.238 C [Range: +0.000 to +70.000 C]
Transceiver Tx supply voltage = 3.2967 Volts [Range: 3.1350 to 3.4650 Volts]
Transceiver Tx power = -4.1 dBm
Transceiver Rx optical power = -6.1 dBm
Tx power Network Lane[00] = -2.3 dBm (0.5823 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[01] = -2.1 dBm (0.6182 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[02] = -2.0 dBm (0.6332 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[03] = -1.9 dBm (0.6522 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[04] = -2.3 dBm (0.5827 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[05] = -2.0 dBm (0.6324 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[06] = -2.0 dBm (0.6251 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[07] = -1.9 dBm (0.6519 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[08] = -2.2 dBm (0.6070 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[09] = -2.1 dBm (0.6148 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[10] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[11] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[12] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[13] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[14] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Tx power Network Lane[15] = -40.0 dBm (0.0 in units of mW) [Range:-7.6 to -0.5 dBm]
Rx power Network Lane[00] = -4.3 dBm (0.3675 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[01] = -3.6 dBm (0.4325 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[02] = -5.3 dBm (0.2963 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[03] = -3.1 dBm (0.4851 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[04] = -6.6 dBm (0.2183 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[05] = -4.0 dBm (0.4015 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[06] = -3.9 dBm (0.4109 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[07] = -4.6 dBm (0.3431 in units of mW) [Range:-9.5 to 2.4 dBm]
```

```
Rx power Network Lane[08] = -3.5 dBm (0.4448 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[09] = -3.1 dBm (0.4895 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[10] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[11] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[12] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[13] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[14] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Rx power Network Lane[15] = -40.0 dBm (0.0 in units of mW) [Range:-9.5 to 2.4 dBm]
Bias Current Network Lane[00] = 6.262 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[01] = 5.756 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[02] = 6.304 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[03] = 6.178 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[04] = 6.194 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[05] = 6.84 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[06] = 6.198 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[07] = 6.176 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[08] = 6.160 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[09] = 5.556 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[10] = 0.0 (in units of mA) [Range:0.0 to 43.520 mA]
Bias Current Network Lane[11] = 0.0 (in units of mA) [Range:0.0 to 43.520 mA]

```

show interfaces trunk

To display the interface-trunk information, use the **showinterfacestrunk** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **trunk** [{**module** *number* | **vlan** *vlan*}]

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.
vlan *vlan*	(Optional) Limits the display of switch port information to the specified VLAN. Range: 1 to 4094.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was changed to add the optional **vlan***vlan* keyword and argument.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on systems that are configured with a Supervisor Engine 2.

If you do not specify a keyword, only information for trunking ports is displayed.

The *interface-number* designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

The **module***number* keyword and argument designate the module number and limit the display to interfaces on the module. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

Examples

This example shows how to display the interface-trunk information for module 5:

```
Router#
show interfaces trunk module 5
Port      Mode         Encapsulation  Status        Native vlan
```

```

Fa5/48    none
Router#
```

This example shows how to display the trunking information for active trunking ports:

```
Router#
show interfaces trunk
Port      Mode         Encapsulation  Status        Native vlan
Fa5/9     desirable    n-isl          trunking      1
Port      Vlans allowed on trunk
Fa5/9     1-1005
Port      Vlans allowed and active in management domain
Fa5/9     1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-8
02,850,917,999,1002-1005
Port      Vlans in spanning tree forwarding state and not pruned
Fa5/9     1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-8
02,850,917,999,1002-1005
Router#
```

This example shows how to limit the display information for interfaces on a specific VLAN:

```
Router> show interfaces trunk vlan 22
Router>
```

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.

show interfaces tunnel

To display tunnel interface information, use the **showinterfacestunnel** command in privileged EXEC mode.

show interfaces tunnel *number* [**accounting**]

Syntax Description

number	Port line number.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	Support was added to display traffic information when the **tunnelroute-via** command is present in the configuration file.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 3.11S	This command was integrated into Cisco IOS XE Release 3.11S. The output was modified to display information about tunnel entropy calculation.

Examples

The following is sample output from the **showinterfacestunnel** command.

```
Device# show interfaces tunnel 4

Tunnel4 is up, line protocol is down
Hardware is Routing Tunnel
MTU 1500 bytes, BW 9 Kbit, DLY 500000 usec, rely 255/255, load 1/255
Encapsulation TUNNEL, loopback not set, keepalive set (10 sec)
Tunnel source 0.0.0.0, destination 0.0.0.0
Tunnel protocol/transport GRE/IP, key disabled, sequencing disabled
Tunnel Entropy Calculation Enabled (24-bit Key)
Last input never, output never, output hang never
Last clearing of “show interface” counters never
Output queue 0/0, 0 drops; input queue 0/75, 0 drops
Five minute input rate 0 bits/sec, 0 packets/sec
Five minute output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts, 0 runts, 0 giants
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
```

```
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets, 0 restarts

Device# show interfaces tunnel 0 | include route-via

Tunnel route-via feature is on [Ethernet0, preferred]

Device# show interfaces tunnel 0 | include route-via

Tunnel route-via feature is on [Ethernet0, mandatory]
```

The table below describes significant fields shown in the display.

*Table 163: **show interfaces tunnel** Field Descriptions*

Field	Description
Tunnel is {up | down}	Interface is currently active and inserted into ring (up) or inactive and not inserted (down). On the Cisco 7500 series routers, gives the interface processor type, slot number, and port number.
line protocol is {up | down | administratively down}	Shows line protocol up if a valid route is available to the tunnel destination. Shows line protocol down if no route is available or if the route would be recursive.
Hardware	Specifies the hardware type.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method is always TUNNEL for tunnels.
loopback	Indicates whether loopback is set or not.
keepalive	Indicates whether keepalives are set or not.
Tunnel source	IP address used as the source address for packets in the tunnel.
destination	IP address of the host destination.
Tunnel protocol	Tunnel transport protocol (the protocol that the tunnel is using). This is based on the **tunnelmode**command, which defaults to GRE.
key	ID key for the tunnel interface, unless disabled.
Tunnel Entropy Calculation	Achieves load balancing of tunnel packets in a network.

Field	Description
sequencing	Indicates whether the tunnel interface drops datagrams that arrive out of order. Can be disabled.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates that the counters were cleared more than 231 ms (and less than 232 ms) ago.
Output queue, drops Input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because of a full queue.
Five minute input rate, Five minute output rate	Average number of bits and packets transmitted per second in the last 5 minutes. The 5-minute input and output rates should be used only as an approximation of traffic per second during a given 5-minute period. These rates are exponentially weighted averages with a time constant of 5 minutes. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period.
packets input	Total number of error-free packets received by the system.
bytes	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of them medium.

Field	Description
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
CRC	Number of cyclic redundancy checksums generated by the originating LAN station or far-end device that do not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of a station transmitting bad data.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be increased.
abort	Illegal sequence of one bits on a serial interface. This usually indicates a clocking problem between the serial interface and the data link equipment.
packets output	Total number of messages transmitted by the system.
bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle. This may never be reported on some interfaces.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error, and others may have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. Some collisions are normal. However, if your collision rate climbs to around 4 or 5 percent, you should consider verifying that there is no faulty equipment on the segment and/or moving some existing stations to a new segment. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been reset. The interface may be reset by the administrator or automatically when an internal error occurs.
restarts	Number of times that the controller was restarted because of errors.
preferred	If the route is not available, forwards the traffic using any available route.

Field	Description
mandatory	Drops the traffic if the route is not available.

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on the router or access server.
show ip route	Displays the current state of the routing table.

show interfaces ucse

To display Cisco UCS E-Series Server interface statistics, use the **show interfaces ucse** command in privileged EXEC mode.

show interfaces ucse *slot/subslot/ucse-interface* [{**accounting** | **controller** | **counters** | **crb** | **dampening** | **description** | **etherchannel** | **history** | **irb** | **mac-accounting** | **monitor** | **mpls-exp** | **precedence** | **stats** | **summary** | **switchport**}]

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
ucse-interface	Number of the UCSE interface. **Note** For Cisco UCS E-Series Servers, the UCSE interface number can be 0 or 1.
accounting	(Optional) Displays the number of packets of each protocol type that have been sent through the interface.
controller	(Optional) Displays the interface, configuration, and controller status.
counters	(Optional) Displays the interface counters.
crb	(Optional) Displays interface routing or bridging information.
dampening	(Optional) Displays interface dampening information.
description	(Optional) Displays the interface description.
etherchannel	(Optional) Displays interface Ether Channel information.
history	(Optional) Displays interface history.
irb	(Optional) Displays interface routing or bridging information.
mac-accounting	(Optional) Displays interface MAC accounting information.
monitor	(Optional) Displays interface continuously.
mpls-exp	(Optional) Displays interface Multiprotocol Label Switching (MPLS) experimental accounting information.
precedence	(Optional) Displays interface precedence accounting information.
stats	(Optional) Displays the switching path, the packets in and packets out, and the characters in and characters out.

summary	(Optional) Displays the interface summary.
switchport	(Optional) Displays the switch port interface information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Examples

The following example provides sample output from the **show interfaces ucse** *slot*/**0/0 switchport** command in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# show interfaces ucse 1/0/0 switchport

 Name: ucse 1/0/0
 Switchport: Enabled
 Administrative mode: trunk
 Operational Mode: trunk
 Administrative Trunking Encapsulation: dot1q
 Operational Trunking Encapsulation: native
 Negotiation of Trunking: Disabled
 Trunking Native Mode VLAN: 2352
 Trunking VLANs Enabled: 1-2349,2450-4094
 Voice VLAN: none
```

show interfaces unidirectional

To display the operational state of an interface with a receive-only transceiver, use the **showinterfacesunidirectional** command in user EXEC or privileged EXEC mode.

show interfaces [*interface interface-number*] **unidirectional** [**module** *number*]

Syntax Description

interface	(Optional) Interface type; possible valid values are **gigabitethernet** and **tengigabitethernet**
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you do not specify a keyword, only information for trunking ports is displayed.

The *interface-number* designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 2 to 13 and valid values for the port number are from 1 to 48.

The **module***number* keyword and argument designate the module number and limit the display to interfaces on the module. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 2 to 13.

Examples

This example shows how to display the operational state of an interface with a receive-only transceiver:

```
Router# show interfaces gigabitethernet 5/2 unidirectional
Unidirectional configuration mode: send only
Unidirectional operational mode: receive only
CDP neighbour unidirectional configuration mode: off
Router#
```

Related Commands

Command	Description
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.
unidirectional	Configures the software-based UDE.

show interfaces vg-anylan

To display the information about the 100VG-AnyLAN port adapter on Cisco 7200 series routers and Cisco 7500 series routers, use the **showinterfacesvg-anylan** command in user EXEC or privileged EXEC mode.

Cisco 7200 Series
show interfaces vg-anylan [*slot*/*port*]

Cisco 7500 Series with VIPs
show interfaces vg-anylan [*slot*/*port-adapter*/*port*]

Syntax Description

slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
port	(Optional) Port number. Refer to the appropriate hardware manual for slot and port information.
port-adapter	(Optional) Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showinterfacesvg-anylan** command:

```
Router# show interfaces vg-anylan 3/0/0
VG-AnyLAN3/0/0 is up, line protocol is up
  Hardware is cyBus VG-AnyLAN Interface
  Frame type is 802.3, address is 0060.3e64.2460 (bia 0060.3e64.2460)
  Internet address is 10.1.1.5/16
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec, rely 255/255, load 1/255
  Encapsulation ARPA, loopback not set, keepalive set (10 sec)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:26, output 00:00:09, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     5316 packets input, 857349 bytes, 0 no buffer
     Received 5310 broadcasts, 0 runts, 0 giants
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 input packets with dribble condition detected
     7920 packets output, 754259 bytes, 0 underruns
```

```
0 output errors, 0 collisions, 2 interface resets
0 output buffer failures, 0 output buffers swapped out
0 vg alignment error, 0 vg balance error
0 vg invalid ipm error, 0 vg symbol error
0 vg skew error, 0 vg frame delimit error
0 vg high priority packets, 0 vg high priority octets
0 output errors, 0 collisions, 2 interface resets
0 output buffer failures, 0 output buffers swapped out
0 vg alignment error, 0 vg balance error
0 vg invalid ipm error, 0 vg symbol error
0 vg skew error, 0 vg frame delimit error
0 vg high priority packets, 0 vg high priority octets
```

The table below describes significant fields shown in the display.

*Table 164: **show interfaces vg-anylan** Field Descriptions*

Field	Description
VG-AnyLAN3/0/0 is up, line protocol is up	Indicates if the interface hardware is currently active and can transmit and receive or if it has been taken down by an administrator.
Hardware is cyBus VG-AnyLAN	Hardware type.
Frame type is 803.2	Currently the frame type supported is 803.2.
Internet address	Internet address and subnet mask.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface, in kilobits per second.
DLY	Delay of the interface, in microseconds.
rely	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes.
load	Load on the interface as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes. The calculation uses the value from the **bandwidth** interface configuration command.
Encapsulation	Encapsulation method assigned to the interface.
loopback	Indicates if loopbacks are set.
keepalive	Indicates if keepalives are set.
ARA type	ARP type on the interface.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This counter is updated only when packets are process-switched, not when packets are fast-switched.

Field	Description
output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by an interface. This counter is updated only when packets are process-switched, not when packets are fast-switched.
output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is printed. If that field overflows, asterisks are printed.
last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. *** indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Queueing strategy	First-in, first-out queueing strategy (other queueing strategies that you might see are priority-list, custom-list, and weighted fair).
Output queue, drops input queue, drops	Number of packets in output and input queues. Each number is followed by a slash, the maximum size of the queue, and the number of packets dropped because a queue was full.
5 minute input rate 5 minute output rate	Average number of bits and packets received or transmitted per second in the last 5 minutes.
packets input	Total number of error-free packets received by the system.
bytes (input)	Total number of bytes, including data and MAC encapsulation, in the error-free packets received by the system.
no buffer	Number of received packets discarded because there was no buffer space in the main system. Compare with ignored count. Broadcast storms on Ethernet networks and bursts of noise on serial lines are often responsible for no input buffer events.
broadcasts	Total number of broadcast or multicast packets received by the interface.
runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	Number of packets that are discarded because they exceed the maximum packet size of the medium.
input errors	Total number of no buffer, runts, giants, CRCs, frame, overrun, ignored, and abort counts. Other input-related errors can also increment the count, so that this sum might not balance with the other counts.

Field	Description
CRC	Cyclic redundancy checksum generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data. On a serial link, CRCs usually indicate noise, gain hits or other transmission problems on the data link.
frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a serial line, this is usually the result of noise or other transmission problems.
overrun	Number of times the serial receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers mentioned previously in the buffer description. Broadcast storms and bursts of noise can cause the ignored count to be incremented.
abort	Illegal sequence of one bits on the interface.
input packets with dribble condition detected	Dribble bit error indicates that a frame is slightly too long. This frame error counter is incremented just for informational purposes; the router accepts the frame.
packets output	Total number of messages transmitted by the system.
bytes (output)	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
underruns	Number of times that the far-end transmitter has been running faster than the near-end router's receiver can handle.
output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this might not balance with the sum of the enumerated output errors, as some datagrams can have more than one error, and others can have errors that do not fall into any of the specifically tabulated categories.
collisions	Number of messages retransmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within a certain interval. If the system notices that the carrier detect line of an interface is up, but the line protocol is down, it periodically resets the interface in an effort to restart it. Interface resets can also occur when an unrecoverable interface processor error occurred, or when an interface is looped back or shut down.
output buffer failures	Number of times that a packet was not output from the output hold queue because of a shortage of MEMD shared memory.

Field	Description
output buffers swapped out	Number of packets stored in main memory when the output queue is full; swapping buffers to main memory prevents packets from being dropped when output is congested. The number is high when traffic is bursty.
vg alignment error	Number of nonoctets received.
vg balance error	Number of incorrect balanced symbols received.
vg invalid ipm error	Number of packets received with an invalid packet marker (IPM).
vg symbol error	Number of symbols received that were not correctly decoded.
vg skew error	Number of skews between four pairs of twisted-pair wire that exceeded the allowable skew.
vg frame delimit error	Number of start-of-frame errors or false-start errors received.
vg high priority packets	Number of high-priority packets received.
vg high priority octets	Number of high-priority octets received.

Related Commands

Command	Description
interface vg-anylan	Specifies the interface on a 100VG-AnyLAN port adapter and enters interface configuration mode on Cisco 7200 series routers and Cisco 7500 series routers.

show interfaces vlan mapping through show scp

show interface gigabitethernet

To display the first front panel interface (port 0) in a Cisco 4451 ISR, use the **showinterfaces gigabitethernet** command in privileged EXEC mode.

show interfaces gigabitethernet {**ports**}

Syntax Description

interface gigabitethernet	Displays interface hardware.
ports	Displays local and registered IPC ports.

Command Modes

Privileged EXEC

Command History

Release	Modification
XE 16.11.1	This command was introduced.

Usage Guidelines

You can use the **show interfaces gigabitethernet** command to display the first front panel interface (port 0) in a Cisco ISR4451-X router

Examples

The following is sample output from the showcommand with the **ports**keyword displays he first front panel interface (port 0) in a Cisco ISR4451-X router::

```
Router# show interfaces gigabitethernet GigabitEthernet0/0/0 is down, line protocol is down

  Hardware is ISR4451-X-4x1GE, address is 003a.7d5e.8b40 (bia 003a.7d5e.8b40)
  Internet address is 10.20.30.40/24
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive not supported
  Full Duplex, 1000Mbps, link type is auto, media type is SX
  output flow-control is off, input flow-control is off
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 02:45:34, output 02:00:47, output hang never
  Last clearing of "show interface" counters 1d16h
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
     618 packets input, 52156 bytes, 0 no buffer
     Received 447 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog, 145 multicast, 118 pause input
     189 packets output, 18556 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 unknown protocol drops
     0 babbles, 0 late collision, 0 deferred
     597 lost carrier, 0 no carrier, 0 pause output
     0 output buffer failures, 0 output buffers swapped out
```

The table below describes the significant fields shown in the display.

Table 165: show interfaces gigabitethernet Field Descriptions-Front Panel Gigabit Ethernet Port

Field	Description
GigabitEthernet0/0/0 is down, line protocol is down	Indicates whether the interface hardware is currently active and if it has been taken down by an administrator..
line protocol is	Indicates whether the software processes that handle the line protocol consider the line usable or if it has been taken down by an administrator.
Hardware	Hardware type and MAC address.
Description	Alphanumeric string identifying the interface. This appears only if the description interface configuration command has been configured on the interface.
Internet address	Sequence number of the in-sequence message that was last heard.
MTU	Maximum transmission unit of the interface.
BW	Bandwidth of the interface in kilobits per second.
DLY	Delay of the interface in microseconds.
Reliability	Reliability of the interface as a fraction of 255 (255/255 is 100 percent reliability), calculated as an exponential average over 5 minutes
Rxload and Rxload	Load on the interface (in the transmit “tx” and receive “rx” directions) as a fraction of 255 (255/255 is completely saturated), calculated as an exponential average over 5 minutes.
Encapsulation	Encapsulation method assigned to the interface.
Loopback	Indicates whether loopback is set.
Keepalive	Indicates whether keepalives are set, and the time interval.
Half-duplex, Full-duplex	Indicates the duplex mode for the interface.
1Gb/s	Speed of the interface in Gigabits per second.
Input Flow Rate…	Specifies if input flow control is on or off.
ARP Type	Type of ARP assigned and the timeout period.
Last input	Number of hours, minutes, and seconds since the last packet was successfully received by an interface and processed locally on the router. Useful for knowing when a dead interface failed. This field is not updated by fast-switched traffic
Output	Number of hours, minutes, and seconds since the last packet was successfully transmitted by the interface. Useful for knowing when a dead interface failed.

Field	Description
Output hang	Number of hours, minutes, and seconds (or never) since the interface was last reset because of a transmission that took too long. When the number of hours in any of the "last" fields exceeds 24 hours, the number of days and hours is displayed. If that field overflows, asterisks are printed
Last clearing	Time at which the counters that measure cumulative statistics (such as number of bytes transmitted and received) shown in this report were last reset to zero. Note that variables that might affect routing (for example, load and reliability) are not cleared when the counters are cleared. A series of asterisks (***) indicates the elapsed time is too large to be displayed. 0:00:00 indicates the counters were cleared more than 231 ms (and less than 232 ms) ago.
Input queue (size/max/drops/flushes)	Packet statistics on the input queue reported as: • Size--Number of packets in the input queue. • Max--Maximum size of the queue. • Drops--Number of packets dropped because of a full input queue. • Flushes--Number of packets dropped as part of SPD. SPD implements a selective packet drop
Total Output Drops	Total number of packets dropped because of a full output queue.
Queueing Strategy	Type of Layer 3 queueing active on this interface. The default is FIFO.
Output queue (size/max)	Number of packets in the output queue (size), and the maximum size of the queue (max).
30 second input rate, 30 second output rate	Average number of bits and packets transmitted per second in the last 30 seconds. If the interface is not in promiscuous mode, it senses network traffic it sends and receives (rather than all network traffic). The 30 second input and output rates should be used only as an approximation of traffic per second during a given 30 second period. These rates are exponentially weighted averages with a time constant of 30 seconds. A period of four time constants must pass before the average will be within two percent of the instantaneous rate of a uniform stream of traffic over that period. The calculated input rate includes packets counted as input errors.
Packets Input	Total number of packets received by the system.
Bytes	Total number of bytes, including data and MAC encapsulation, in all packets received by the system.
Received…Broadcasts	Total number of broadcast or multicast packets received by the interface.
Runts	Number of packets that are discarded because they are smaller than the minimum packet size of the medium.
giants	

Field	Description
Throttles	Number of times the receiver on the port was disabled, possibly because of buffer or processor overload.
Input errors	Includes runts, giants, no buffer, CRC, frame, overrun, and ignored counts. Other input-related errors can also cause the input errors count to be increased, and some datagrams may have more than one error; therefore, this sum may not balance with the sum of enumerated input error counts.
CRC	Cyclic redundancy check generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
Frame	Number of packets received incorrectly having a CRC error and a noninteger number of octets. On a LAN, this is usually the result of collisions or a malfunctioning Ethernet device.
Overrun	Number of times the receiver hardware was unable to hand received data to a hardware buffer because the input rate exceeded the receiver's ability to handle the data.
Ignored	Number of received packets ignored by the interface because the interface hardware ran low on internal buffers. These buffers are different than the system buffers. Broadcast storms and bursts of noise can cause the ignored count to be increased.
Watchdog	Number of times the watchdog receive timer expired.
Multicast	Number of multicast packets.
Pause input	Number of pause packets received.
Packets output	Total number of messages transmitted by the system.
Bytes	Total number of bytes, including data and MAC encapsulation, transmitted by the system.
Underruns	Number of times that the transmitter has been running faster than the router can handle.
Output errors	Sum of all errors that prevented the final transmission of datagrams out of the interface being examined. Note that this may not balance with the sum of the enumerated output errors, because some datagrams may have more than one error and others may have errors that do not fall into any of the specifically tabulated categories.
Collisions	Number of messages retransmitted because of an Ethernet collision. This is usually the result of an overextended LAN (Ethernet or transceiver cable too long, more than two repeaters between stations, or too many cascaded multiport transceivers). A packet that collides is counted only once in output packets.

Field	Description
Interface resets	Number of times an interface has been completely reset. This can happen if packets queued for transmission were not sent within several seconds. Interface resets can occur when an interface is looped back or shut down.
Babbles	Transmit jabber timer expired.
Late collision	Number of late collisions. Late collision happens when a collision occurs after transmitting the preamble.
Deferred	Number of times that the interface had to defer while ready to transmit a frame because the carrier was asserted.
Lost carrier	Number of times the carrier was lost during transmission.
No carrier	Number of times the carrier was not present during the transmission.
Pause output	Number of pause packets transmitted.
Output buffer failures, Output buffers swapped out	Number of output butters failures and output buffers swapped out.

Related Commands

Command	Description
show ip interface	Display the usability status of interfaces configured for IP,.

show interfaces vlan mapping

To display the status of a virtual local area network (VLAN) mapping on a port, use the **showinterfacesvlanmapping** command in user EXEC or privileged EXEC mode.

show interfaces *interface interface-number* **vlan mapping**

Syntax Description

interface	Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	Module and port number; see the “Usage Guidelines” section for valid values.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(17b)SXA	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **pos**, **atm**, and **ge-wan** keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The *interface-number* designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13 and valid values for the port number are from 1 to 48.

Examples

This example shows how to list all of the VLAN mappings that are configured on a port and indicate whether such mappings are enabled or disabled on the port:

```
Router# show interfaces gigabitethernet 5/2 vlan mapping
State: enabled
Original VLAN Translated VLAN
------------- ---------------
  1649           755
Router#
```

Related Commands

Command	Description
show vlan mapping	Registers a mapping of an 802.1Q VLAN to an ISL VLAN.
switchport vlan mapping enable	Enables VLAN mapping per switch port.

show interfaces wlan-controller

To show the Cisco Wireless Local Area Network (WLAN) controller network module interfaces on the router, use the **showinterfaceswlan-controller** command in privileged EXEC mode.

show interfaces wlan-controller slot/unit

Syntax Description

slot/unit	Specifies the router slot and unit numbers for the WLAN controller network module.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(2)XA1	This command was introduced on the router software.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.

Examples

The following example shows how to read the hardware information about the interface WLAN controller in the router:

```
Router# show interfaces wlan-controller 1/0
wlan-controller1/0 is up, line protocol is up
  Hardware is I82559FE, address is 0005.9a3d.7450 (bia 0005.9a3d.7450)
  Internet address is 30.0.0.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation 802.1Q Virtual LAN, Vlan ID  1., loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, 100BaseTX/FX
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:05, output 00:00:03, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     2400779 packets input, 143127299 bytes
     Received 2349587 broadcasts, 0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
     0 watchdog
     0 input packets with dribble condition detected
     468232 packets output, 106333102 bytes, 0 underruns
     0 output errors, 0 collisions, 3 interface resets
     0 babbles, 0 late collision, 0 deferred
     0 lost carrier, 1 no carrier
     0 output buffer failures, 0 output buffers swapped out
```

show ip interface

To display the usability status of interfaces configured for IP, use the **show ip interface** command in privileged EXEC mode.

show **ip** **interface** [*type* *number*] [**brief**]

Syntax Description

type	(Optional) Interface type.
number	(Optional) Interface number.
brief	(Optional) Displays a summary of the usability status information for each interface.

Command Default

The full usability status is displayed for all interfaces configured for IP.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
10.0	This command was introduced.
12.0(3)T	The command output was modified to show the status of the **ip wccp redirect out** and **ip wccp redirect exclude add in** commands.
12.2(14)S	The command output was modified to display the status of NetFlow on a subinterface.
12.2(15)T	The command output was modified to display the status of NetFlow on a subinterface.
12.3(6)	The command output was modified to identify the downstream VPN routing and forwarding (VRF) instance in the output.
12.3(14)YM2	The command output was modified to show the usability status of interfaces configured for Multiprocessor Forwarding (MPF) and implemented on the Cisco 7301 and Cisco 7206VXR routers.
12.2(14)SX	This command was implemented on the Supervisor Engine 720.
12.2(17d)SXB	This command was integrated into Cisco IOS 12.2(17d)SXB on the Supervisor Engine 2, and the command output was changed to include NDE for hardware flow status.
12.4(4)T	This command was integrated into Cisco IOS Release 12.4(4)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	The command output was modified to display information about the Unicast Reverse Path Forwarding (RPF) notification feature.

Release	Modification
12.4(20)T	The command output was modified to display information about the Unicast RPF notification feature.
12.2(33)SXI2	This command was modified. The command output was modified to display information about the Unicast RPF notification feature.
Cisco IOS XE Release 2.5	This command was modified. This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco 4400 Series ISRs.

Usage Guidelines

The Cisco IOS software automatically enters a directly connected route in the routing table if the interface is usable (which means that it can send and receive packets). If an interface is not usable, the directly connected routing entry is removed from the routing table. Removing the entry lets the software use dynamic routing protocols to determine backup routes to the network, if any.

If the interface can provide two-way communication, the line protocol is marked "up." If the interface hardware is usable, the interface is marked "up."

If you specify an optional interface type, information for that specific interface is displayed. If you specify no optional arguments, information on all the interfaces is displayed.

When an asynchronous interface is encapsulated with PPP or Serial Line Internet Protocol (SLIP), IP fast switching is enabled. A **show ip interface** command on an asynchronous interface encapsulated with PPP or SLIP displays a message indicating that IP fast switching is enabled.

You can use the **show ip interface brief** command to display a summary of the router interfaces. This command displays the IP address, the interface status, and other information.

The **show ip interface brief** command does not display any information related to Unicast RPF.

Examples

The following example shows configuration information for interface Gigabit Ethernet 0/3. In this example, the IP flow egress feature is configured on the output side (where packets go out of the interface), and the policy route map named PBRNAME is configured on the input side (where packets come into the interface).

```
Router# show running-config interface gigabitethernet 0/3
interface GigabitEthernet0/3
 ip address 10.1.1.1 255.255.0.0
 ip flow egress
 ip policy route-map PBRNAME
 duplex auto
 speed auto
 media-type gbic
 negotiation auto
end
```

The following example shows interface information on Gigabit Ethernet interface 0/3. In this example, MPF is enabled, and both Policy Based Routing (PBR) and NetFlow features are not supported by MPF and are ignored.

```
Router# show ip interface gigabitethernet 0/3
```

```
GigabitEthernet0/3 is up, line protocol is up
  Internet address is 10.1.1.1/16
  Broadcast address is 255.255.255.255
  Address determined by setup command
  MTU is 1500 bytes
  Helper address is not set
  Directed broadcast forwarding is disabled
  Outgoing access list is not set
  Inbound access list is not set
  Proxy ARP is enabled
  Local Proxy ARP is disabled
  Security level is default
  Split horizon is enabled
  ICMP redirects are always sent
  ICMP unreachables are always sent
  ICMP mask replies are never sent
  IP fast switching is enabled
  IP fast switching on the same interface is disabled
  IP Flow switching is disabled
  IP CEF switching is enabled
  IP Feature Fast switching turbo vector
  IP VPN Flow CEF switching turbo vector
  IP multicast fast switching is enabled
  IP multicast distributed fast switching is disabled
  IP route-cache flags are Fast, CEF
  Router Discovery is disabled
  IP output packet accounting is disabled
  IP access violation accounting is disabled
  TCP/IP header compression is disabled
  RTP/IP header compression is disabled
  Policy routing is enabled, using route map PBR
  Network address translation is disabled
  BGP Policy Mapping is disabled
  IP Multi-Processor Forwarding is enabled
     IP Input features, "PBR",
         are not supported by MPF and are IGNORED
     IP Output features, "NetFlow",
         are not supported by MPF and are IGNORED
```

The following example identifies a downstream VRF instance. In the example, "Downstream VPN Routing/Forwarding "D"" identifies the downstream VRF instance.

```
Router# show ip interface virtual-access 3
Virtual-Access3 is up, line protocol is up
  Interface is unnumbered. Using address of Loopback2 (10.0.0.8)
  Broadcast address is 255.255.255.255
  Peer address is 10.8.1.1
  MTU is 1492 bytes
  Helper address is not set
  Directed broadcast forwarding is disabled
  Outgoing access list is not set
  Inbound  access list is not set
  Proxy ARP is enabled
  Local Proxy ARP is disabled
  Security level is default
  Split horizon is enabled
  ICMP redirects are always sent
  ICMP unreachables are always sent
  ICMP mask replies are never sent
  IP fast switching is enabled
  IP fast switching on the same interface is enabled
  IP Flow switching is disabled
  IP CEF switching is enabled
```

```
  IP Feature Fast switching turbo vector
  IP VPN CEF switching turbo vector
  VPN Routing/Forwarding "U"
  Downstream VPN Routing/Forwarding "D"
  IP multicast fast switching is disabled
  IP multicast distributed fast switching is disabled
  IP route-cache flags are Fast, CEF
  Router Discovery is disabled
  IP output packet accounting is disabled
  IP access violation accounting is disabled
  TCP/IP header compression is disabled
  RTP/IP header compression is disabled
  Policy routing is disabled
  Network address translation is disabled
  WCCP Redirect outbound is disabled
  WCCP Redirect inbound is disabled
  WCCP Redirect exclude is disabled
  BGP Policy Mapping is disabled
```

The following example shows the information displayed when Unicast RPF drop-rate notification is configured:

```
Router# show ip interface ethernet 2/3
Ethernet2/3 is up, line protocol is up
  Internet address is 10.0.0.4/16
  Broadcast address is 255.255.255.255
  Address determined by non-volatile memory
  MTU is 1500 bytes
  Helper address is not set
  Directed broadcast forwarding is disabled
  Outgoing access list is not set
  Inbound  access list is not set
  Proxy ARP is enabled
  Local Proxy ARP is disabled
  Security level is default
  Split horizon is enabled
  ICMP redirects are always sent
  ICMP unreachables are always sent
  ICMP mask replies are never sent
  IP fast switching is disabled
  IP Flow switching is disabled
  IP CEF switching is disabled
  IP Null turbo vector
  IP Null turbo vector
  IP multicast fast switching is disabled
  IP multicast distributed fast switching is disabled
  IP route-cache flags are No CEF
  Router Discovery is disabled
  IP output packet accounting is disabled
  IP access violation accounting is disabled
  TCP/IP header compression is disabled
  RTP/IP header compression is disabled
  Probe proxy name replies are disabled
  Policy routing is disabled
  Network address translation is disabled
  WCCP Redirect outbound is disabled
  WCCP Redirect inbound is disabled
  WCCP Redirect exclude is disabled
  BGP Policy Mapping is disabled
```

Unicast RPF Information

```
  Input features: uRPF
  IP verify source reachable-via RX, allow default
   0 verification drops
   0 suppressed verification drops
   0 verification drop-rate
Router#
```

The following example shows how to display the usability status for a specific VLAN:

```
Router# show ip interface vlan 1
Vlan1 is up, line protocol is up
  Internet address is 10.0.0.4/24
  Broadcast address is 255.255.255.255
Address determined by non-volatile memory
  MTU is 1500 bytes
  Helper address is not set
  Directed broadcast forwarding is disabled
  Outgoing access list is not set
  Inbound  access list is not set
  Proxy ARP is enabled
  Local Proxy ARP is disabled
  Security level is default
  Split horizon is enabled
  ICMP redirects are always sent
  ICMP unreachables are always sent
  ICMP mask replies are never sent
  IP fast switching is enabled
  IP fast switching on the same interface is disabled
  IP Flow switching is disabled
  IP CEF switching is enabled
  IP Fast switching turbo vector
  IP Normal CEF switching turbo vector
  IP multicast fast switching is enabled
  IP multicast distributed fast switching is disabled
  IP route-cache flags are Fast, CEF
  Router Discovery is disabled
  IP output packet accounting is disabled
  IP access violation accounting is disabled
  TCP/IP header compression is disabled
  RTP/IP header compression is disabled
  Probe proxy name replies are disabled
  Policy routing is disabled
  Network address translation is disabled
  WCCP Redirect outbound is disabled
  WCCP Redirect inbound is disabled
  WCCP Redirect exclude is disabled
  BGP Policy Mapping is disabled
  Sampled Netflow is disabled
  IP multicast multilayer switching is disabled
  Netflow Data Export (hardware) is enabled
```

The table below describes the significant fields shown in the display.

Table 166: show ip interface Field Descriptions

Field	Description
Virtual-Access3 is up	Shows whether the interface hardware is usable (up). For an interface to be usable, both the interface hardware and line protocol must be up.
Broadcast address is	Broadcast address.
Peer address is	Peer address.
MTU is	MTU value set on the interface, in bytes.
Helper address	Helper address, if one is set.
Directed broadcast forwarding	Shows whether directed broadcast forwarding is enabled.
Outgoing access list	Shows whether the interface has an outgoing access list set.
Inbound access list	Shows whether the interface has an incoming access list set.
Proxy ARP	Shows whether Proxy Address Resolution Protocol (ARP) is enabled for the interface.
Security level	IP Security Option (IPSO) security level set for this interface.
Split horizon	Shows whether split horizon is enabled.
ICMP redirects	Shows whether redirect messages will be sent on this interface.
ICMP unreachables	Shows whether unreachable messages will be sent on this interface.
ICMP mask replies	Shows whether mask replies will be sent on this interface.
IP fast switching	Shows whether fast switching is enabled for this interface. It is generally enabled on serial interfaces, such as this one.
IP Flow switching	Shows whether Flow switching is enabled for this interface.
IP CEF switching	Shows whether Cisco Express Forwarding switching is enabled for the interface.
Downstream VPN Routing/Forwarding "D"	Shows the VRF instance where the PPP peer routes and AAA per-user routes are being installed.
IP multicast fast switching	Shows whether multicast fast switching is enabled for the interface.
IP route-cache flags are Fast	Shows whether NetFlow is enabled on an interface. Displays "Flow init" to specify that NetFlow is enabled on the interface. Displays "Ingress Flow" to specify that NetFlow is enabled on a subinterface using the **ip flow ingress**command. Shows "Flow" to specify that NetFlow is enabled on a main interface using the **ip route-cache flow** command.

Field	Description
Router Discovery	Shows whether the discovery process is enabled for this interface. It is generally disabled on serial interfaces.
IP output packet accounting	Shows whether IP accounting is enabled for this interface and what the threshold (maximum number of entries) is.
TCP/IP header compression	Shows whether compression is enabled.
WCCP Redirect outbound is disabled	Shows the status of whether packets received on an interface are redirected to a cache engine. Displays "enabled" or "disabled."
WCCP Redirect exclude is disabled	Shows the status of whether packets targeted for an interface will be excluded from being redirected to a cache engine. Displays "enabled" or "disabled."
Netflow Data Export (hardware) is enabled	NetFlow Data Expert (NDE) hardware flow status on the interface.

The table below describes the significant fields shown in the display.

Display a Summary of Interfaces on Cisco 4400 Series ISR: Example

The following is a sample out of the **show ip interface brief** command displaying a summary of the interfaces and their status on the device.

```
Router#show ip interface brief
Interface              IP-Address      OK? Method Status                Protocol
GigabitEthernet0/0/0   unassigned      YES NVRAM  down                  down
GigabitEthernet0/0/1   unassigned      YES NVRAM  down                  down
GigabitEthernet0/0/2   unassigned      YES NVRAM  down                  down
GigabitEthernet0/0/3   unassigned      YES NVRAM  down                  down
Serial1/0/0            unassigned      YES unset  down                  down
GigabitEthernet0       unassigned      YES NVRAM  up                    up
```

Display a Summary of the Usability Status: Example

The following example shows how to display a summary of the usability status information for each interface:

```
Router# show ip interface brief
Interface     IP-Address     OK?  Method  Status                  Protocol
Ethernet0     10.108.00.5    YES  NVRAM   up                      up
Ethernet1     unassigned     YES  unset   administratively down   down
Loopback0     10.108.200.5   YES  NVRAM   up                      up
Serial0       10.108.100.5   YES  NVRAM   up                      up
Serial1       10.108.40.5    YES  NVRAM   up                      up
Serial2       10.108.100.5   YES  manual  up                      up
Serial3       unassigned     YES  unset   administratively down   down
```

Table 167: show ip interface brief Field Descriptions

Field	Description
Interface	Type of interface.
IP-Address	IP address assigned to the interface.
OK?	"Yes" means that the IP Address is valid. "No" means that the IP Address is not valid.
Method	The Method field has the following possible values: • RARP or SLARP--Reverse Address Resolution Protocol (RARP) or Serial Line Address Resolution Protocol (SLARP) request. • BOOTP--Bootstrap protocol. • TFTP--Configuration file obtained from the TFTP server. • manual--Manually changed by the command-line interface. • NVRAM--Configuration file in NVRAM. • IPCP--**ip address negotiated** command. • DHCP--**ip address dhcp** command. • unset--Unset. • other--Unknown.
Status	Shows the status of the interface. Valid values and their meanings are: • up--Interface is up. • down--Interface is down. • administratively down--Interface is administratively down.
Protocol	Shows the operational status of the routing protocol on this interface.

Related Commands

Command	Description
ip address	Sets a primary or secondary IP address for an interface.
ip vrf autoclassify	Enables VRF autoclassify on a source interface.
match ip source	Specifies a source IP address to match to required route maps that have been set up based on VRF connected routes.
route-map	Defines the conditions for redistributing routes from one routing protocol into another or to enable policy routing.
set vrf	Enables VPN VRF selection within a route map for policy-based routing VRF selection.

Command	Description
show ip arp	Displays the ARP cache, in which SLIP addresses appear as permanent ARP table entries.
show route-map	Displays static and dynamic route maps.

show ipc

To display interprocess communication (IPC) statistics, use the **showipc** command in privileged EXEC mode.

show ipc {**nodes** | **ports** [**open**] | **queue** | **status** [**cumulative**] | **zones**}

Syntax Description

nodes	Displays participating nodes.
ports	Displays local and registered IPC ports.
open	(Optional) Displays local IPC ports that have been opened by the current seat (node).
queue	Displays information about the IPC retransmission queue and the IPC message queue.
status	Displays the status of the local IPC server.
cumulative	(Optional) Displays cumulative totals for the status counters of the local IPC server since the router was rebooted.
zones	Displays information about the IPC zones and seats.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(12c)EW	This command was introduced.
12.2(15)T	The **cumulative** keyword was added.
12.3(7)T	The **zones** keyword was added.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to 12.2(17d)SXB.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.

Usage Guidelines

The Cisco IOS version of IPC provides a reliable ordered delivery of messages using an underlying platform driver transport or User Datagram Protocol (UDP) transport protocol.

Nodes

A node (referred to as a seat) is an intelligent element like a processor that can communicate using IPC services. A seat is where entities and ports reside. A seat manager performs all the interprocessor communications by receiving messages from the network and forwarding the messages to the appropriate port.

Ports

IPC communication endpoints (ports) receive and queue received IPC messages.

Queue

Use the **queue** keyword to display information about the IPC retransmission queue and the IPC message queue.

Status

Use the**status** keyword to display the IPC statistics that have been generated since a **clearipcstatistics** command was entered. The **showipcstatus** command with the **cumulative** keyword displays the IPC statistics that have been gathered since the router was rebooted, regardless of how many times the statistics have been cleared.

Zones

The IPC zone manager allows more than one group of IPC seats to exist to enable direct communication between line cards and the route processor. Use the**zones** keyword to display the IPC zone and seat information.

Examples

The following is sample output from the **showipc**command with the **nodes**keyword displaying the participating seats (nodes):

```
Router# show ipc nodes
There are 6 nodes in this IPC realm.
   ID      Type       Name                      Last  Last
                                                Sent Heard
0.10000    Local      IPC Master                  0     0
0.1060000  RSP-CY     RSP IPC card slot 6         9    79
0.1050000  RSP-CY     RSP IPC card slot 5        21    22
0.1080000  RSP-CY     RSP IPC card slot 8        21    22
1.10000    Local      IPC Master: -Zone#1         0     0
2.10000    Local      IPC Master: -Zone#2
```

The table below describes the significant fields shown in the display.

Table 168: show ipc nodes Field Descriptions

Field	Description
ID	Port ID, which consists of a zone ID followed by the seat ID.
Type	Type of seat (node).
Name	Seat name.
Last Sent	Sequence number of the message that was last sent.
Last Heard	Sequence number of the in-sequence message that was last heard.

The following is sample output from the **showipc**command with the **ports**keyword displaying the local and registered IPC ports:

```
Router# show ipc ports
There are 11 ports defined.

Port ID     Type    Name            (current/peak/total)
1.10000.1   unicast IPC Master:Zone
1.10000.2   unicast IPC Master:Echo
1.10000.3   unicast IPC Master:Control
1.10000.4   unicast Remote TTY Server Port
1.10000.5   unicast GALIOS RF :Active
index = 0 seat_id = 0x2020000 last sent = 0 heard = 1635 0/1/1635
1.10000.6   unicast GALIOS RED:Active
```

```
index = 0 seat_id = 0x2020000 last sent = 0 heard = 2 0/1/2

2.2020000.3 unicast GALIOS IPC:Card 2:Control
2.2020000.4 unicast GALIOS RFS :Standby
2.2020000.5 unicast Slave: Remote TTY Client Port
2.2020000.6 unicast GALIOS RF :Standby
2.2020000.7 unicast GALIOS RED:Standby
RPC packets: current/peak/total 0/1/17
```

The table below describes the significant fields shown in the display.

Table 169: show ipc ports Field Descriptions

Field	Description
Port ID	Port ID, which consists of a zone ID followed by the seat ID.
Type	Type of port.
Name	Port name.
current/peak/total	Displays information about the number of messages held by this IPC session.

The following is sample output from the **showipc**command with the **queue**keyword displaying information about the IPC retransmission queue and the IPC message queue:

```
Router# show ipc queue
There are 0 IPC messages waiting for acknowledgement in the transmit queue.
There are 0 IPC messages waiting for a response.
There are 0 IPC messages waiting for additional fragments.
There are 0 IPC messages currently on the IPC inboundQ.
There are 0 messages currently in use by the system.
```

The following is sample output from the **showipc**command with the **status**keyword displaying information about the local IPC server:

```
Router# show ipc status
IPC System Status
Time last IPC stat cleared : never
This processor is the IPC master server.
Do not drop output of IPC frames for test purposes.
1000 IPC Message Headers Cached.

```

The table below describes the significant fields shown in the display.

Table 170: show ipc status Field Descriptions

Field	Description
Time last IPC stat cleared	Displays the time, in dd:hh:mm (or never), since the IPC statistics were last cleared.
This processor is	Shows whether the processor is the IPC master or an IPC slave.
IPC Message Headers Cached	Number of message headers available in the IPC message cache.
Rx Side	Information about IPC messages received.
Tx Side	Information about IPC messages sent.
Service Usage	Number of IPC messages received or sent via connectionless or connection-oriented protocols.
IPC Protocol Version 0	Number of acknowledgements and negative acknowledgements received or sent by the system.
Device Drivers	Number of IPC messages received or sent using the underlying device drivers.
Reliable Tx Statistics	Number of IPC messages that were retransmitted or that timed out on retransmission using a reliable connection-oriented protocol.
Rx Errors	Number of IPC messages received that displayed various internal frame or delivery errors.
Tx Errors	Number of IPC messages sent that displayed various transmission errors.
Buffer Errors	Number of message allocation failures from the IPC message cache, IPC emergency message cache, IPC frame allocation cache, and IPC frame memory allocation cache.
Misc Errors	Various miscellaneous errors that relate to the IPC open queue, to the hardware queue, or to other hardware failures.

Field	Description
Tx Driver Errors	Number of messages that relate to IPC transmission driver failures including messages to or from a destination without a valid transport entity from the seat; number of messages dropped because the packet size is larger than the maximum transmission unit (MTU); and number of messages without a valid destination address.

The following example shows how to display cumulative IPC counters for the local IPC server. Note that the recent IPC clearing has not cleared the IPC counters because the **cumulative** keyword displays the IPC statistics that have been generated since the router was rebooted.

```
Router# show ipc status cumulative
IPC System Status
Time last IPC stat cleared : 00:00:05
This processor is the IPC master server.
Do not drop output of IPC frames for test purposes.
1000 IPC Message Headers Cached.
                                                      Rx Side     Tx Side

```

The following is sample output from the **showipc**command with the **zones**keyword displaying information about the IPC zones and seats:

```
Router# show ipc zones
There are 3 Zones in this IPC realm.
```

```
Zone ID   Seat ID   Name
      0    10000    IPC Default Zone
      1    10000    IPC TEST ZONE#1
      2    10000    IPC TEST ZONE#2
```

The table below describes the significant fields shown in the display.

Table 171: show ipc zones Field Descriptions

Field	Description
Zone ID	Zone number.
Seat ID	Seat number.
Name	Zone name.

Related Commands

Command	Description
clear ipc statistics	Clears and resets the IPC statistics.

show ipc hog-info

To provide information about interprocess communication (IPC) messages that consume excessive CPU, use the **showipchog-info**command in privileged EXEC mode.

show ipc hog-info

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The Cisco IOS version of IPC provides a reliable ordered delivery of messages using an underlying platform driver transport or User Datagram Protocol (UDP) transport protocol.

The show ipc hog-info command displays information about IPC messages that are being processed when a CPUHOG error occurs, indicating that the client processing an IPC message is using too much CPU, or when an IPC message callback exceeds 200 milliseconds.

Examples

The following example shows that the IPC process has had a CPUHOG error or the message callback exceeded the 200-millisecond threshold:

```
Router# show ipc hog-info
Time last IPC process hogged CPU: 00:05:09
IPC Messages Processed:
Source       Destination  Name                         Message-Type  Time-taken
                                                           (0x)       (msec)
 1030000     10000.14    ISSU Process: Active Por         0         864
 1030000     10000.D     RF : Active                      0           0
```

In the following example, the show ipc status command shows a counter incrementing whenever a callback exceeds 200 milliseconds:

```
Router# show ipc status
                            IPC System Status
 Time last IPC stat cleared : never
 This processor is the IPC master server.
 Do not drop output of IPC frames for test purposes.
 1000 IPC Message Headers Cached.

Related Commands

Command	Description
show ipc	Displays IPC statistics.

show ipv6 ospf interface

To display Open Shortest Path First (OSPF)-related interface information, use the **showipv6ospfinterface** command in user EXEC or privileged mode.

show ipv6 ospf [*process-id*] [*area-id*] **interface** [*type number*] [**brief**]

Syntax Description

process-id	(Optional) Internal identification. It is locally assigned and can be any positive integer. The number used here is the number assigned administratively when the OSPF routing process is enabled.
area-id	(Optional) Displays information about a specified area only.
type number	(Optional) Interface type and number.
brief	(Optional) Displays brief overview information for OSPF interfaces, states, addresses and masks, and areas on the router.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.0(24)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)S.
12.3(4)T	Command output is changed when authentication is enabled.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(25)SG	This command was integrated into Cisco IOS Release 12.2(25)SG.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(9)T	Command output is changed when encryption is enabled.
12.2(33)SRB	The **brief** keyword was added.
12.4(15)XF	Output displays were modified so that VMI PPPoE interface-based local state values are displayed in the command output when a VMI interface is specified.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
Cisco IOS XE Release 2.1	Command output was updated to display graceful restart information.
12.2(33)SRE	This command was modified. It was integrated into Cisco IOS Release 12.2(33)SRE.

Release	Modification
15.1(1)SY	This command was was modified. It was integrated into Cisco IOS Release 15.1(1)SY.

Examples

show ipv6 ospf interface Standard Output Example

The following is sample output from the **showipv6ospfinterface** command:

```
Router# show ipv6 ospf interface
ATM3/0 is up, line protocol is up
  Link Local Address 2001:0DB1:205:5FFF:FED3:5808, Interface ID 13
  Area 1, Process ID 1, Instance ID 0, Router ID 172.16.3.3

  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 172.16.6.6  (Designated Router)
  Suppress hello for 0 neighbor(s)
```

The table below describes the significant fields shown in the display.

Table 172: show ipv6 ospf interface Field Descriptions

Field	Description
ATM3/0	Status of the physical link and operational status of protocol.
Link Local Address	Interface IPv6 address.
Area 1, Process ID 1, Instance ID 0, Router ID 172.16.3.3	The area ID, process ID, instance ID, and router ID of the area from which this route is learned.
Network Type POINT_TO_POINT, Cost: 1	Network type and link-state cost.

Field	Description
Transmit Delay	Transmit delay, interface state, and router priority.
Designated Router	Designated router ID and respective interface IP address.
Backup Designated router	Backup designated router ID and respective interface IP address.
Timer intervals configured	Configuration of timer intervals.
Hello	Number of seconds until the next hello packet is sent out this interface.
Neighbor Count	Count of network neighbors and list of adjacent neighbors.

Cisco IOS Release 12.2(33)SRB Example

The following is sample output of the **showipv6ospfinterface** command when the **brief** keyword is entered.

```
Router# show ipv6 ospf interface brief

Interface    PID   Area            Intf ID    Cost  State Nbrs F/C
VL0          6     0               21         65535 DOWN  0/0
Se3/0        6     0               14         64    P2P   0/0
Lo1          6     0               20         1     LOOP  0/0
Se2/0        6     6               10         62    P2P   0/0
Tu0          1000  0               19         11111 DOWN  0/0
```

OSPF with Authentication on the Interface Example

The following is sample output from the **showipv6ospfinterface** command with authentication enabled on the interface:

```
Router# show ipv6 ospf interface
Ethernet0/0 is up, line protocol is up
  Link Local Address 2001:0DB1:A8BB:CCFF:FE00:6E00, Interface ID 2
  Area 0, Process ID 1, Instance ID 0, Router ID 10.10.10.1
  Network Type BROADCAST, Cost:10
  MD5 Authentication SPI 500, secure socket state UP (errors:0)
  Transmit Delay is 1 sec, State BDR, Priority 1
  Designated Router (ID) 10.11.11.1, local address 2001:0DB1:A8BB:CCFF:FE00:6F00
  Backup Designated router (ID) 10.10.10.1, local address
2001:0DB1:A8BB:CCFF:FE00:6E00
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:01
  Index 1/1/1, flood queue length 0
  Next 0x0(0)/0x0(0)/0x0(0)
  Last flood scan length is 1, maximum is 1
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 10.11.11.1  (Designated Router)
  Suppress hello for 0 neighbor(s)
```

OSPF with Null Authentication Example

The following is sample output from the **showipv6ospfinterface** command with null authentication configured on the interface:

```
Router# show ipv6 ospf interface
Ethernet0/0 is up, line protocol is up
  Link Local Address 2001:0DB1:A8BB:CCFF:FE00:6E00, Interface ID 2
  Area 0, Process ID 1, Instance ID 0, Router ID 10.10.10.1
  Network Type BROADCAST, Cost:10
  Authentication NULL
  Transmit Delay is 1 sec, State BDR, Priority 1
  Designated Router (ID) 10.11.11.1, local address 2001:0DB1:A8BB:CCFF:FE00:6F00
  Backup Designated router (ID) 10.10.10.1, local address
2001:0DB1:A8BB:CCFF:FE00:6E00
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:03
  Index 1/1/1, flood queue length 0
  Next 0x0(0)/0x0(0)/0x0(0)
  Last flood scan length is 1, maximum is 1
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 10.11.11.1  (Designated Router)
  Suppress hello for 0 neighbor(s)
```

OSPF with Authentication for the Area Example

The following is sample output from the **showipv6ospfinterface** command with authentication configured for the area:

```
Router# show ipv6 ospf interface
Ethernet0/0 is up, line protocol is up
  Link Local Address 2001:0DB1:A8BB:CCFF:FE00:6E00, Interface ID 2
  Area 0, Process ID 1, Instance ID 0, Router ID 10.10.10.1
  Network Type BROADCAST, Cost:10
  MD5 Authentication (Area) SPI 1000, secure socket state UP (errors:0)
  Transmit Delay is 1 sec, State BDR, Priority 1
  Designated Router (ID) 10.11.11.1, local address 2001:0DB1:A8BB:CCFF:FE00:6F00
  Backup Designated router (ID) 10.10.10.1, local address
FE80::A8BB:CCFF:FE00:6E00
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:03
  Index 1/1/1, flood queue length 0
  Next 0x0(0)/0x0(0)/0x0(0)
  Last flood scan length is 1, maximum is 1
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 10.11.11.1  (Designated Router)
  Suppress hello for 0 neighbor(s)
```

OSPF with Dynamic Cost Example

The following display shows sample output from the **showipv6ospfinterface** command when the OSPF cost dynamic is configured.

```
Router1# show ipv6 ospf interface serial 2/0
```

```
Serial2/0 is up, line protocol is up
   Link Local Address 2001:0DB1:A8BB:CCFF:FE00:100, Interface ID 10
   Area 1, Process ID 1, Instance ID 0, Router ID 172.1.1.1
   Network Type POINT_TO_MULTIPOINT, Cost: 64 (dynamic), Cost Hysteresis: 200
   Cost Weights: Throughput 100, Resources 20, Latency 80, L2-factor 100
   Transmit Delay is 1 sec, State POINT_TO_MULTIPOINT,
   Timer intervals configured, Hello 30, Dead 120, Wait 120, Retransmit 5
     Hello due in 00:00:19
   Index 1/2/3, flood queue length 0
   Next 0x0(0)/0x0(0)/0x0(0)
   Last flood scan length is 0, maximum is 0
   Last flood scan time is 0 msec, maximum is 0 msec
   Neighbor Count is 0, Adjacent neighbor count is 0
   Suppress hello for 0 neighbor(s)
```

OSPF Graceful Restart Example

The following display shows sample output from the **showipv6ospfinterface** command when the OSPF graceful restart feature is configured:

```
Router# show ipv6 ospf interface
Ethernet0/0 is up, line protocol is up
  Link Local Address FE80::A8BB:CCFF:FE00:300, Interface ID 2
  Area 0, Process ID 1, Instance ID 0, Router ID 10.3.3.3
  Network Type POINT_TO_POINT, Cost: 10
  Transmit Delay is 1 sec, State POINT_TO_POINT,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
   Graceful Restart p2p timeout in 00:00:19
    Hello due in 00:00:02
  Graceful Restart helper support enabled
  Index 1/1/1, flood queue length 0
  Next 0x0(0)/0x0(0)/0x0(0)
  Last flood scan length is 1, maximum is 1
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 10.1.1.1
  Suppress hello for 0 neighbor(s)
```

Example of an Enabled Protocol

The following display shows that the OSPF interface is enabled for Bidirectional Forwarding Detection (BFD):

```
Router# show ipv6 ospf interface
Serial10/0 is up, line protocol is up
  Link Local Address FE80::A8BB:CCFF:FE00:6500, Interface ID 42
  Area 1, Process ID 1, Instance ID 0, Router ID 10.0.0.1
  Network Type POINT_TO_POINT, Cost: 64
  Transmit Delay is 1 sec, State POINT_TO_POINT, BFD enabled
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:07
  Index 1/1/1, flood queue length 0
  Next 0x0(0)/0x0(0)/0x0(0)
  Last flood scan length is 1, maximum is 1
  Last flood scan time is 0 msec, maximum is 0 msec
  Neighbor Count is 1, Adjacent neighbor count is 1
    Adjacent with neighbor 10.1.0.1
  Suppress hello for 0 neighbor(s)
```

Related Commands

Command	Description
show ipv6 ospf graceful-restart	Displays OSPFv3 graceful restart information.

show l2protocol-tunnel

To display the protocols that are tunneled on an interface or on all interfaces, use the **showl2protocol-tunnel** command.

show l2protocol-tunnel [{**interface** *interface mod/port* | **summary** | **vlan** *vlan*}]

Syntax Description

interface *interface-id*	(Optional) Specifies the interface type; possible valid values are **ethernet**, **FastEthernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**
mod/port	Module and port number.
summary	(Optional) Displays a summary of a tunneled port.
vlan*vlan*	(Optional) Limits the display to interfaces on the specified VLAN. Valid values are from 1 to 4094.

Command Modes

EXEC (>)

Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17a)SX	The **showl2protocol-tunnelsummary** command output was changed to display the following information: • Global drop-threshold setting • Up status of a Layer 2-protocol interface tunnel
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to the 12.2 SX release.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was changed to add the optional **vlan***vlan* keyword and argument.
15.2(2)T	This command was integrated into Cisco IOS Release 15.2(2)T.

Usage Guidelines

After enabling Layer 2 protocol tunneling on an access or IEEE 802.1Q tunnel port by using the l2protocol-tunnel interface configuration command, you can configure some or all of these parameters:

- Protocol type to be tunneled
- Shutdown threshold
- Drop threshold

The **showl2protocol-tunnel** command displays only the ports that have protocol tunneling enabled.

The **showl2protocol-tunnelsummary** command displays the ports that have protocol tunneling enabled, regardless of whether the port is down or currently configured as a trunk.

Examples

The following example is an output from the show l2protocol-tunnel command:

```
Router# show l2protocol-tunnel
COS for Encapsulated Packets: 5
Drop Threshold for Encapsulated Packets: 0
```

Port	Protocol	Shutdown Threshold	Drop Threshold	Encapsulation Counter	Decapsulation Counter	Drop Counter
Fa0/3	---	----	----	----	----	----
	---	----	----	----	----	----
	---	----	----	----	----	----
	pagp	----	----	0	242500	
	lacp	----	----	24268	242640	
	udld	----	----	0	897960	
Fa0/4	---	----	----	----	----	----
	---	----	----	----	----	----
	---	----	----	----	----	----
	pagp	1000	----	24249	242700	
	lacp	----	----	24256	242660	
	udld	----	----	0	1344820	
Gi0/3	cdp	----	----	134482	1344820	
	---	----	----	----	----	----
	---	----	----	----	----	----
	pagp	1000	----	0	242500	

	lacp	500	----	0	485320	
	udld	300	----	44899	448980	
Gi0/3	cdp	----	----	134482	1344820	
	---	----	----	----	----	----
	---	----	----	----	----	----
	pagp	----	1000	0	242700	
	lacp	----	----	0	485220	
	udld	300	----	44899	448980	

This example shows how to display a summary of Layer 2-protocol tunnel ports:

```
Router# show l2protocol-tunnel summary
COS for Encapsulated Packets:5
Drop Threshold for Encapsulated Packets:0
Port    Protocol    Shutdown         Drop             Status
                    Threshold        Threshold
                    (cdp/stp/vtp)    (cdp/stp/vtp)
------- ----------- ---------------- ---------------- ----------
Fa9/1   --- stp --- ----/----/----   ----/----/----   down
Fa9/9   cdp stp vtp ----/----/----   ----/----/----   up
Fa9/47  --- --- --- ----/----/----   1500/1500/1500   down(trunk)
Fa9/48  cdp stp vtp ----/----/----   ----/----/----   down(trunk)
```

This example shows how to display Layer 2-protocol tunnel information on interfaces for a specific VLAN:

```
Router# show l2protocol-tunnel vlan 1
COS for Encapsulated Packets: 5
Drop Threshold for Encapsulated Packets: 0
Protocol Drop Counter
-------- -------------
 cdp                 0
 lldp                0
 stp                 0
 vtp                 0
Port                Protocol Thresholds          Counters
                             Shutdown  Drop      Encap     Decap     Drop
------------------- -------- --------- --------- --------- --------- ---------
```

Related Commands

Command	Description
debug l2protocol-tunnel	Displays the debugging options for L2PT.
l2protocol-tunnel	Enables the protocol tunneling on an interface and specifies the type of protocol to be tunneled.

Command	Description
l2protocol-tunnel drop-threshold	Specifies the maximum number of packets that can be processed for the specified protocol on that interface before being dropped.
l2protocol-tunnel global drop-threshold	Enables rate limiting at the software level.
l2protocol-tunnel shutdown-threshold	Specifies the maximum number of packets that can be processed for the specified protocol on that interface in 1 second.

show l3-mgr

To display the information about the Layer 3 manager , use the **showl3-mgr** command in user EXEC or privileged EXEC mode.

show l3-mgr status
show l3-mgr {**interface** **interface** **interface-number** | **null** **interface-number** | **port-channel** **number** | **vlan** **vlan-id** | **status**}

Syntax Description

status	Displays information about the global variable.
interface	Displays information about the Layer 3 manager .
interface	Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	Module and port number; see the “Usage Guidelines” section for valid values.
null *interface-number*	Specifies the null interface; the valid value is **0**.
port-channel *number*	Specifies the channel interface; valid values are a maximum of 64 values ranging from 1 to 282.
vlan *vlan-id*	Specifies the VLAN; valid values are from 1 to 4094.
status	Displays status information about the Layer 3 manager.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

The **port-channel***number*values from 257 to 282 are supported on the CSM and the FWSM only.

Examples

This example shows how to display the status of the Layer 3 manager:

```
Router#
```

```
show l3-mgr status
l3_mgr_state:         2
l3_mgr_req_q.count:   0
l3_mgr_req_q.head:    0
l3_mgr_req_q.tail:    0
l3_mgr_max_queue_count:  1060
l3_mgr_shrunk_count:  0
l3_mgr_req_q.ip_inv_count:    303
l3_mgr_req_q.ipx_inv_count:   0
l3_mgr_outpak_count:  18871
l3_mgr_inpak_count:   18871
l3_mgr_max_pending_pak: 4
l3_mgr_pending_pak_count: 0
nde enable statue:    0
current nde addr:     0.0.0.0
Router#
```

This example shows how to display the information about the Layer 3 manager for a specific interface:

```
Router#
show l3-mgr interface fastethernet 5/40
vlan:                 0
ip_enabled:         1
ipx_enabled:        1
bg_state:           0 0 0 0
hsrp_enabled:       0
hsrp_mac:           0000.0000.0000
state:              0
up:                 0
Router#
```

show l3vpn encapsulation ip

To display the L3VPN encapsulation profile health and the underlying tunnel interface, use the **showl3vpnencapsulationip** command in privileged EXEC mode.

show l3vpn encapsulation ip [*profile name*]

Syntax Description

profile name	(Optional) Name of the Layer 3 encapsulation profile.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRE	This command was introduced.

Examples

The following is a sample output from the **showl3vpnencapsulationip** command:

```
Router# show l3vpn encapsulation ip tunnelencap
Profile: tunnelencap
    transport ipv4 source Loopback0
    protocol gre key 500
  Tunnel Tunnel0 Created [OK]
  Tunnel Linestate
  Tunnel Transport Source Loopback0
```

show lacp

To display Link Aggregation Control Protocol (LACP) and multi-chassis LACP (mLACP) information, use the **show lacp** command in either user EXEC or privileged EXEC mode.

show lacp {*channel-group-number* {**counters** | **internal** [**detail**] | **neighbor** [**detail**]} | **multi-chassis** [**load-balance**] {**group** *number* | **port-channel** *number*} | **sys-id**}

Cisco ASR 901 Series Aggregation Services Router

show lacp {*channel-group-number* {**counters** | **internal** [**detail**] | **neighbor** [**detail**] | **sys-id**}}

Syntax Description

channel-group- number	(Optional) Number of the channel group. The following are valid values: • Cisco IOS 12.2 SB and Cisco IOS XE 2.4 Releases--from 1 to 64 • Cisco IOS 12.2 SR Releases--from 1 to 308 • Cisco IOS 12.2 SX Releases--from 1 to 496 • Cisco IOS 15.1S Releases—from 1 to 564 • Cisco ASR 901 Series Aggregation Services Router—from 1 to 8
counters	Displays information about the LACP traffic statistics.
internal	Displays LACP internal information.
neighbor	Displays information about the LACP neighbor.
detail	(Optional) Displays detailed internal information when used with the **internal** keyword and detailed LACP neighbor information when used with the **neighbor** keyword.
multi-chassis	Displays information about mLACP.
load-balance	Displays mLACP load balance information.
group	Displays mLACP redundancy group information,
number	Integer value used with the **group** and **port-channel** keywords. • Values from 1 to 4294967295 identify the redundancy group. • Values from 1 to 564 identify the port-channel interface.
port-channel	Displays mLACP port-channel information.
sys-id	Displays the LACP system identification. It is a combination of the port priority and the MAC address of the device

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	Support for this command on the Cisco 7600 router was integrated into Cisco IOS Release 12.2(33)SRB.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.
12.2(33)SRE	This command was modified. The **multi-chassis**, **group**, and **port-channel**keywords and *number* argument were added.
15.1(3)S	This command was modified. The **load-balance** keyword was added.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use the **show lacp** command to troubleshoot problems related to LACP in a network.

If you do not specify a value for the argument *channel-group-number*, all channel groups are displayed. Values in the range of 257 to 282 are supported on the CSM and the FWSM only.

Examples

show lacp sys-id Example

This example shows how to display the LACP system identification using the **show lacp sys-id**command:

```
Device> show lacp sys-id
```

```
8000,AC-12-34-56-78-90
```

The system identification is made up of the system priority and the system MAC address. The first two bytes are the system priority, and the last six bytes are the globally administered individual MAC address that is associated to the system.

LACP Statistics for a Specific Channel Group Examples

This example shows how to display the LACP statistics for a specific channel group:

```
Device# show lacp 1 counters
```

```
              LACPDUs         Marker       LACPDUs
Port       Sent   Recv     Sent   Recv     Pkts Err
---------------------------------------------------
Channel group: 1
```

```
  Fa4/1    8       15       0       0          3    0
  Fa4/2    14      18       0       0          3    0
  Fa4/3    14      18       0       0          0
  Fa4/4    13      18       0       0          0
```

The output displays the following information:

- The LACPDUs Sent and Recv columns display the LACPDUs that are sent and received on each specific interface.
- The LACPDUs Pkts and Err columns display the marker-protocol packets.

The following example shows output from a **show lacp***channel-group-number***counters**command:

```
Device1# show lacp 5 counters

             LACPDUs         Marker      Marker Response    LACPDUs
Port       Sent   Recv     Sent   Recv     Sent   Recv      Pkts Err
---------------------------------------------------------------------
Channel group: 5
Gi5/0/0     21     18        0      0        0      0          0
```

The following table describes the significant fields shown in the display.

Table 173: show lacp channel-group-number counters Field Descriptions

Field	Description
LACPDUs Sent Recv	Number of LACP PDUs sent and received.
Marker Sent Recv	Attempts to avoid data loss when a member link is removed from an LACP bundle.
Marker Response Sent Recv	Cisco IOS response to the Marker protocol.
LACPDUs Pkts Err	Number of LACP PDU packets transmitted and the number of packet errors.

The following example shows output from a **show lacp internal**command:

```
Device1# show lacp 5 internal

Flags:  S - Device is requesting Slow LACPDUs
        F - Device is requesting Fast LACPDUs
        A - Device is in Active mode       P - Device is in Passive mode
Channel group 5
                            LACP port     Admin     Oper    Port        Port
Port      Flags   State     Priority      Key       Key     Number      State
Gi5/0/0   SA      bndl      32768         0x5       0x5     0x42        0x3D
```

The following table describes the significant fields shown in the display.

Table 174: show lacp internal Field Descriptions

Field	Description
Flags	Meanings of each flag value, which indicates a device activity.
Port	Port on which link bundling is configured.

Field	Description
Flags	Indicators of device activity.
State	Activity state of the port. States can be any of the following: • Bndl--Port is attached to an aggregator and bundled with other ports. • Susp--Port is in suspended state, so it is not attached to any aggregator. • Indep--Port is in independent state (not bundled but able to switch data traffic). This condition differs from the previous state because in this case LACP is not running on the partner port. • Hot-sby--Port is in hot standby state. • Down--Port is down.
LACP port Priority	Priority assigned to the port.
Admin Key	Defines the ability of a port to aggregate with other ports.
Oper Key	Determines the aggregation capability of the link.
Port Number	Number of the port.
Port State	State variables for the port that are encoded as individual bits within a single octet with the following meaning: • bit0: LACP_Activity • bit1: LACP_Timeout • bit2: Aggregation • bit3: Synchronization • bit4: Collecting • bit5: Distributing • bit6: Defaulted • bit7: Expired

Internal Information About a Specific Channel Group Example

This example shows how to display internal information for the interfaces that belong to a specific channel:

```
Device# show lacp 1 internal

Flags:  S - Device sends PDUs at slow rate. F - Device sends PDUs at fast rate.
        A - Device is in Active mode.       P - Device is in Passive mode.
Channel group 1
                            LACPDUs     LACP Port    Admin   Oper    Port     Port
```

```
Port      Flags    State    Interval    Priority     Key     Key     Number   State
Fa4/1     saC      bndl     30s         32768        100     100     0xc1     0x75
Fa4/2     saC      bndl     30s         32768        100     100     0xc2     0x75
Fa4/3     saC      bndl     30s         32768        100     100     0xc3     0x75
Fa4/4     saC      bndl     30s         32768        100     100     0xc4     0x75
Device#
```

The following table describes the significant fields shown in the display.

Table 175: show lacp internal Field Descriptions

Field	Description
State	Current state of the port; allowed values are as follows: • bndl--Port is attached to an aggregator and bundled with other ports. • susp--Port is in a suspended state; it is not attached to any aggregator. • indep--Port is in an independent state (not bundled but able to switch data traffic. In this case, LACP is not running on the partner port). • hot-sby--Port is in a hot-standby state. • down--Port is down.
LACPDUs Interval	Interval setting.
LACP Port Priority	Port-priority setting.
Admin Key	Defines the ability of a port to aggregate with other ports.
Oper Key	Determines the aggregation capability of the link.
Port Number	Port number.
Port State	Activity state of the port. • See the Port State description in the show lacp internal Field Descriptions table for state variables.

Information About LACP Neighbors for a Specific Port Example

This example shows how to display the information about the LACP neighbors for a specific port channel:

```
Device# show lacp 1 neighbors

Flags:  S - Device sends PDUs at slow rate. F - Device sends PDUs at fast rate.
        A - Device is in Active mode.       P - Device is in Passive mode.
Channel group 1 neighbors
          Partner                  Partner
Port      System ID                Port Number     Age     Flags
Fa4/1     8000,00b0.c23e.d84e      0x81            29s     P
Fa4/2     8000,00b0.c23e.d84e      0x82            0s      P
Fa4/3     8000,00b0.c23e.d84e      0x83            0s      P
Fa4/4     8000,00b0.c23e.d84e      0x84            0s      P
```

```
         Port         Admin     Oper      Port
         Priority     Key       Key       State
Fa4/1    32768        200       200       0x81
Fa4/2    32768        200       200       0x81
Fa4/3    32768        200       200       0x81
Fa4/4    32768        200       200       0x81
Device#
```

The following table describes the significant fields shown in the display.

Table 176: show lacp neighbors Field Descriptions

Field	Description
Port	Port on which link bundling is configured.
Partner System ID	Peer's LACP system identification (sys-id). It is a combination of the system priority and the MAC address of the peer device.
Partner Port Number	Port number on the peer device
Age	Number of seconds since the last LACP PDU was received on the port.
Flags	Indicators of device activity.
Port Priority	Port priority setting.
Admin Key	Defines the ability of a port to aggregate with other ports.
Oper Key	Determines the aggregation capability of the link.
Port State	Activity state of the port. See the Port State description in the show lacp internal Field Descriptions table for state variables.

If no PDUs have been received, the default administrative information is displayed in braces.

Related Commands

Command	Description
clear lacp counters	Clears the statistics for all interfaces belonging to a specific channel group.
lacp port-priority	Sets the priority for the physical interfaces.
lacp system-priority	Sets the priority of the system.

show link state group

To display the link-state group information., use the **showlinkstategroup** command in user EXEC or privileged EXEC mode .

show link state group detail

Syntax Description

detail	Displays the detailed information about the group.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

Link State Ttracking (LST), also known as trunk failover, is a feature that binds the link state of multiple interfaces. When you configure LST for the first time, add upstream interfaces to the link state group before adding the downstream interface, otherwise the downstream interfaces would move into error-disable mode. The maximum number of link state groups configurable is 10.

Examples

The following example displays the link-state group information:

```
Router# enable
Router# show link state group 1
Link State Group: 1 Status: Enabled, Down
Router> show link state group detail
(Up):Interface up (Dwn):Interface Down (Dis):Interface disabled
Link State Group: 1 Status: Enabled, Down
Upstream Interfaces : Gi3/5(Dwn) Gi3/6(Dwn)
Downstream Interfaces : Gi3/1(Dis) Gi3/2(Dis) Gi3/3(Dis) Gi3/4(Dis)
Link State Group: 2 Status: Enabled, Down
Upstream Interfaces : Gi3/15(Dwn) Gi3/16(Dwn) Gi3/17(Dwn)
Downstream Interfaces : Gi3/11(Dis) Gi3/12(Dis) Gi3/13(Dis) Gi3/14(Dis)
(Up):Interface up (Dwn):Interface Down (Dis):Interface disabled
```

Related Commands

Command	Description
link state track	Configures the link state tracking number.
link state group	Configures the link state group and interface, as either an upstream or downstream interface in the group.

show mac-address-table dynamic

To display dynamic MAC address table entries only, use the **showmac-address-tabledynamic** command in privileged EXEC mode.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

show mac-address-table dynamic [{**address** *mac-addr* | **interface** *interface type slot/number* | **vlan** *vlan*}]

Catalyst Switches

show mac-address-table dynamic [{**address** *mac-addr* | **detail** | **interface** *interface number***protocol** *protocol* | **module** *number* | **vlan** *vlan*}][{**begin** | **exclude** | **include***expression*}]

Catalyst 6500 Series Switches

show mac-address-table dynamic [{**address** *mac-addr* | **interface** *interface interface-number* [{**all** | **module** *number*}] | **module** *num* | **vlan** *vlan-id* [{**all** | **module** *number*}]}]

Syntax Description

address *mac -address*	(Optional) Specifies a 48-bit MAC address; valid format is H.H.H.
detail	(Optional) Specifies a detailed display of MAC address table information.
interface *type number*	(Optional) Specifies an interface to match; valid type values are FastEthernet and GigabitEthernet, valid number values are from 1 to 9.
interface *type*	(Optional) Specifies an interface to match; valid type values are FastEthernet and GigabitEthernet.
slot	(Optional) Adds dynamic addresses to module in slot 1 or 2.
port	(Optional) Port interface number ranges based on type of Ethernet switch network module used: • 0 to 15 for NM-16ESW • 0 to 35 for NM-36ESW • 0 to 1 for GigabitEthernet
protocol *protocol*	(Optional) Specifies a protocol. See the "Usage Guidelines" section for keyword definitions.
module *number*	(Optional) Displays information about the MAC address table for a specific Distributed Forwarding Card (DFC) module.
vlan *vlan*	(Optional) Displays entries for a specific VLAN; valid values are from 1 to 1005.
begin	(Optional) Specifies that the output display begin with the line that matches the expression.
exclude	(Optional) Specifies that the output display exclude lines that match the expression.

include	(Optional) Specifies that the output display include lines that match the specified expression.
expression	Expression in the output to use as a reference point.
all	(Optional) Specifies that the output display all dynamic MAC-address table entries.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(7)XE	This command was introduced on Catalyst 6000 series switches.
12.2(2)XT	This command was implemented on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(14)SX	Support for this command was introduced on the Catalyst 6500 series switch.
12.2(33)SXH	This command was changed to support the **all** keyword on the Catalyst 6500 series switch.

Usage Guidelines

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

The **showmac-address-tabledynamic** command output for an EtherChannel interface changes the port-number designation (for example, 5/7) to a port-group number.

Catalyst Switches

The keyword definitions for the protocol argument are:

- **ip** --Specifies IP protocol
- **ipx** --Specifies Internetwork Packet Exchange (IPX) protocols
- **assigned** --Specifies assigned protocol entries
- **other** --Specifies other protocol entries

The **showmac-address-tabledynamic** command output for an EtherChannel interface changes the port-number designation (for example, 5/7) to a port-group number.

Catalyst 6500 Series Switches

The *mac-address*is a 48-bit MAC address and the valid format is H.H.H.

The optional **module***num* keyword and argument are supported only on DFC modules. The **module***num*keyword and argument designate the module number.

Examples

The following examples show how to display all dynamic MAC address entries. The fields shown in the various displays are self-explanatory.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

```
Router# show mac-address-table dynamic

Non-static Address Table:
Destination Address  Address Type  VLAN  Destination Port
-------------------  ------------  ----  --------------------
000a.000a.000a          Dynamic       1     FastEthernet4/0
002a.2021.4567          Dynamic       2     FastEthernet4/0
```

Catalyst Switches

```
Router# show mac-address-table dynamic
vlan   mac address     type    protocol  qos             ports
-----+---------------+--------+---------+---+--------------------------------
 200  0010.0d40.37ff  dynamic        ip  --  5/8
   1  0060.704c.73ff  dynamic        ip  --  5/9
4095  0000.0000.0000  dynamic        ip  --  15/1
   1  0060.704c.73fb  dynamic     other  --  5/9
   1  0080.1c93.8040  dynamic        ip  --  5/9
4092  0050.f0ac.3058  dynamic        ip  --  15/1
   1  00e0.4fac.b3ff  dynamic     other  --  5/9
```

The following example shows how to display dynamic MAC address entries with a specific protocol type (in this case, assigned).

```
Router# show mac-address-table dynamic protocol assigned
vlan   mac address     type    protocol  qos             ports
-----+---------------+--------+---------+---+--------------------------------
4092  0000.0000.0000  dynamic  assigned  --  Router
4092  0050.f0ac.3059  dynamic  assigned  --  Router
   1  0010.7b3b.0978  dynamic  assigned  --  Fa5/9
Router#
```

The following example shows the detailed output for the previous example.

```
Router# show mac-address-table dynamic protocol assigned detail
MAC Table shown in details

Related Commands

Command	Description
show mac -address-tableaddress	Displays MAC address table information for a specific MAC address.
show mac -address-tableaging-time	Displays the MAC address aging time.
show mac -address-tablecount	Displays the number of entries currently in the MAC address table.
show mac -address-tabledetail	Displays detailed MAC address table information.
show mac -address-tableinterface	Displays the MAC address table information for a specific interface.
show mac -address-tablemulticast	Displays multicast MAC address table information.
show mac -address-tableprotocol	Displays MAC address table information based on protocol.
show mac -address-tablestatic	Displays static MAC address table entries only.
show mac -address-tablevlan	Displays the MAC address table information for a specific VLAN.

show mls asic

To display the application-specific integrated circuit (ASIC) version, use the **showmlsasic** command in user EXEC or privileged EXEC mode.

show mls asic

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the ASIC versions on a Supervisor Engine 2:

```
Router#
show mls asic
  Cafe version: 2
  Centauri version: 1
  Perseus version: 0/0
  Titan version: 1
Router#
```

This example shows how to display the ASIC versions on a Supervisor Engine 720:

```
Router#
show mls asic
Earl in Module 2
 Tycho - ver:1 Cisco-id:1C8 Vendor-id:49
Router#
```

Related Commands

Command	Description
show mls df-table	Displays information about the DF table.
show mls ip	Displays the Multilayer Switching (MLS) IP information.
show mls ipx	Displays the Multilayer Switching (MLS) IPX information.
show mls qos	Displays Multilayer Switching (MLS) quality of service (QoS) information
show mls statistics	Displays the Multilayer Switching (MLS) statistics for the Internet Protocol (IP)

show mls ip

To display the Multilayer Switching (MLS) IP information, use the **showmlsip** command in user EXEC or privileged EXEC mode.

show mls ip [{**any** | **destination** {*hostnameip-address*} | **detail** | **flow** {**tcp** | **udp**} | {**vlan** *vlan-id* | **macd** *destination-mac-address* | **macs** *source-mac-address* | **module** *number* | **source** {*hostnameip-address*}} | **count** | **static**}]
show mls ip {**ipv6** | **mpls**}

Syntax Description

any	(Optional) Displays any MLS IP information.
destination *hostname*	(Optional) Displays the entries for a specific destination hostname.
destination *ip-address*	(Optional) Displays the entries for a specific destination IP address.
detail	(Optional) Specifies a detailed output.
flow	(Optional) Specifies the flow type.
tcp | **udp**	Selects the flow type.
vlan *vlan-id*	(Optional) Specifies the virtual local area network (VLAN) ID; valid values are from 1 to 4094.
macd *destination-mac-address*	(Optional) Specifies the destination MAC address.
macs *source- mac-address*	(Optional) Specifies the source Media Access Control (MAC) address.
module *number*	(Optional) Displays the entries that are downloaded on the specified module; see the "Usage Guidelines" section for valid values.
source *hostname*	(Optional) Displays the entries for a specific source address.
source *ip-address*	(Optional) Displays the entries for a specific source IP address.
count	(Optional) Displays the total number of MLS entries.
static	(Optional) Displays the total number of static entries.
ipv6	Displays the total number of IPv6 entries.
mpls	Displays the total number of MPLS entries.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.

Release	Modification
12.2(17a)SX	This command is supported on releases prior to Release 12.2(17a)SX only.
12.2(17b)SXA	On Cisco 7600 series routers that are configured with a Supervisor Engine 720, this command is replaced by the show mls netflow ip command.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **static**, **ipv6** and **mpls** keywords are not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48. This definition also applies to the **module***number* keyword and argument.

When you view the output, note that a colon (:) is used to separate the fields.

Examples

This example shows how to display any MLS IP information:

```
Router#
show mls ip
 any
Displaying Netflow entries in Supervisor Earl
DstIP           SrcIP           Prot:SrcPort:DstPort  Src i/f:AdjPtr

Related Commands

Command	Description
show mls asic	display the application-specific integrated circuit (ASIC) version
show mls df-table	Displays information about the DF table.
show mls ipx	Displays the Multilayer Switching (MLS) IPX information.
show mls qos	Displays Multilayer Switching (MLS) quality of service (QoS) information
show mls statistics	Displays the Multilayer Switching (MLS) statistics for the Internet Protocol (IP)

show mls ipx

To display Multilayer Switching (MLS) Internetwork Packet Exchange (IPX) information, use the **showmlsipx** command in user EXEC or privileged EXEC mode.

show mls ipx [{**destination** *ipx-network* | **interface** *interface interface-number* | **vlan** *vlan-id* | **macd** *destination-mac-address* | **macs** *source-mac-address* | **module** *number* | **source** *hostnameipx-network*}] [{**detail** | **count**}]

Syntax Description

destination *ipx-network*	(Optional) Displays the entries for a specific destination network address.
interface	(Optional) Specifies the interface.
interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the “Usage Guidelines” section for valid values.
vlan *vlan-id*	(Optional) Specifies the virtual local area network (VLAN) ID; valid values are from 1 to 4094.
macd *destination-mac-address*	(Optional) Specifies the destination Media Access Control (MAC) address.
macs *source- mac-address*	(Optional) Specifies the source MAC address.
module *number*	(Optional) Displays the entries that are downloaded on the specified slot; see the “Usage Guidelines” section for valid values.
source *hostname*	(Optional) Displays the entries for a specific source address.
source *ipx-network*	(Optional) Displays the entries for a specific destination network address.
detail	(Optional) Displays the detailed list of entries.
count	(Optional) Displays the total number of MLS entries.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 720 with a PFC2.

When you enter the *ipx-network* value, the format is N.H.H.H.

When you enter the *destination-mac-address* value, the format for the 48-bit MAC address is H.H.H.

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48. These valid values also apply when entering the **module***number* keyword and argument.

Examples

This example shows how to display MLS IPX information:

```
Router#
show mls ipx
DstNet-DstNode          SrcNet   Dst i/f:DstMAC      Pkts         Bytes
-----------------------------------------------------------------------
SrcDstPorts   SrcDstEncap Age   LastSeen
----------------------------------------
 Number of Entries Found = 0
Router#
```

This example shows how to display the total number of MLS entries:

```
Router#
show mls ipx
 count
Number of shortcuts = 66
Router#
```

Related Commands

Command	Description
mls ipx	Enables MLS IPX on the interface.
show mls asic	display the application-specific integrated circuit (ASIC) version
show mls df-table	Displays information about the DF table.
show mls ip	Displays the Multilayer Switching (MLS) IP information.
show mls qos	Displays Multilayer Switching (MLS) quality of service (QoS) information
show mls statistics	Displays the Multilayer Switching (MLS) statistics for the Internet Protocol (IP)

show mobility

To display information about the Layer 3 mobility and the wireless network, use the **showmobility** command in privileged EXEC mode.

show mobility {**ap** [*ip-address*] | **mn** [**ip** *ip-address*] | **mac** *mac-address* | **network** *network-id* | **status**}

Syntax Description

ap	Displays information about the access point.
ip-address	(Optional) IP address.
mn	Displays information about the mobile node.
ip *ip-address*	(Optional) Displays information about the IP database thread.
mac *mac-address*	Displays information about the MAC database thread.
network *network-id*	Displays information for a specific wireless network ID.
status	Displays status information.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXD	This command was introduced on the Supervisor Engine 720.
12.2(18)SXD3	The output of this command was changed to include the TCP adjust-mss status.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a WLSM only.

Examples

This example shows how to display information about the access point:

```
Router# show mobility
 ap
AP IP Address   AP Mac Address Wireless Network-ID
--------------- -------------- -------------------
10.1.1.2 000d.29a2.a852 101 102 109 103

```

Related Commands

Command	Description
mobility	Configures the wireless mGRE tunnels.

show module

To display the module status and information, use the **show** module command in user EXEC or privileged EXEC mode.

show module [{**mod-num** | **all** | **provision** | **version**}]

Syntax Description

mod -num	(Optional) Number of the module.
all	(Optional) Displays the information for all modules.
provision	(Optional) Displays the status about the module provisioning.
version	(Optional) Displays the version information.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

In the Mod Sub-Module fields, the **show module** command displays the supervisor engine number but appends the uplink daughter card's module type and information.

Entering the **show module** command with no arguments is the same as entering the **show module all** command.

Examples

This example shows how to display information for all modules on a Cisco 7600 series router that is configured with a Supervisor Engine 720:

```
Router#
show module

Related Commands

Command	Description
show interfaces	Displays the status and statistics for the interfaces in the chassis.
show environment alarm	Displays the information about the environmental alarm.
show fm summary	Displays a summary of FM Information.
show environment status	Displays the information about the operational FRU status.

show msfc

To display Multilayer Switching Feature Card (MSFC) information, use the **show msfc** command in user EXEC or privileged EXEC mode.

show msfc {**buffers** | **eeprom** | **fault** | **netint** | **tlb**}

Syntax Description

buffers	Displays buffer-allocation information.
eeprom	Displays the internal information.
fault	Displays fault information.
netint	Displays network-interrupt information.
tlb	Displays information about the TLB registers.

Command Default

This command has no default settings.

Command	Description
show environment alarm	Displays the information about the environmental alarm.
show fm summary	Displays a summary of FM Information.
show environment status	Displays the information about the operational FRU status.

show network-clocks

To display the current configured and active network clock sources, use the**shownetwork-clocks** command in privileged EXEC mode.

show network-clocks

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SRD1	This command was introduced to display BITS clock information for the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG.

Usage Guidelines

On the Cisco MC3810, this command applies to Voice over Frame Relay, Voice over ATM, and Voice over HDLC. The Cisco MC3810 has a background task that verifies whether a valid clocking configuration exists every 120 seconds. If this task detects an error, you will be reminded every 120 seconds until the error is corrected. A clocking configuration error may be generated for various reasons. Using the **shownetwork-clocks** command, you can display the clocking configuration status.

On the Cisco 7600 series routers, this command applies to the following:

- The clock source from the POS SPAs on the SIP-200 and the SIP-400.
- The 24-Port Channelized T1/E1 ATM CEoP SPA and the 1-Port Channelized OC-3 STM1 ATM CEoP SPA on the SIP-400.
- The 7600-ES+ITU-2TG and 7600-ES+ITU-4TG line cards.

Examples

The following is sample output from the **shownetwork-clocks** EXEC command:

```
Router# show network-clocks
Priority 1 clock source: ATM3/0/0
Priority 2 clock source: System clock
Priority 3 clock source: System clock
Priority 4 clock source: System clock
Current clock source:ATM3/0/0, priority:1
```

The following is sample output from the **shownetwork-clocks** command on the Cisco MC3810:

```
Router# show network-clocks
Priority 1 clock source(inactive config): T1 0
Priority 1 clock source(active config) : T1 0
```

```
Clock switch delay: 10
Clock restore delay: 10
T1 0 is clocking system bus for 9319 seconds.
Run Priority Queue: controller0
```

In this display, inactive configuration is the new configuration that has been established. Active configuration is the run-time configuration. Should an error be made in the new configuration, the inactive and active configurations will be different. In the previous example, the clock priority configuration is valid, and the system is being clocked as indicated.

The following is another sample output from the **shownetwork-clocks** command:

```
Router# show network-clocks
Priority 1 clock source(inactive config) : T1 0
Priority 2 clock source(inactive config) : T1 1
Priority 1 clock source(active config) : T1 0
Clock switch delay: 10
Clock restore delay: 10
T1 0 is clocking system bus for 9319 seconds.
Run Priority Queue: controller0
```

In this display, the new clocking configuration has an error for controller T1 1. This is indicated by checking differences between the last valid configuration (active) and the new proposed configuration (inactive). The error may result from hardware (the system controller board or MFT) unable to support this mode, or controller T1 1 is currently configured as “clock source internal.”

Since the active and inactive configurations are different, the system will periodically display the warning message about the wrong configuration.

The following is another sample output from the **shownetwork-clocks** command for the 7600-ES+ITU-2TG or 7600-ES+ITU-4TG:

```
Router# show network-clocks
 Active source = Slot 1 BITS 0
 Active source backplane reference line = Primary Backplane Clock
 Standby source = Slot 9
 Standby source backplane reference line = Secondary Backplane Clock
(Standby source not driving backplane clock currently)
 All Network Clock Configuration
---------------------------------
 Priority  Clock Source            State                       Reason
 1         POS3/0/1                Valid but not present
 2         Slot 1 BITS 0           Valid
 3         Slot 9                  Valid
 Current operating mode is Revertive
 Current OOR Switchover mode is Switchover
There are no slots disabled from participating in network clocking
 BITS Port Configuration
-------------------------
 Slot    Port    Signal Type/Mode        Line Build-Out Select
```

1 0 T1 ESF DSX-1 (533 to 655 feet)

Related Commands

Command	Description
clock source	Specifies the interface clock source type.
network-clock	Configures BITS port signaling types.

Command	Description
network-clock select	Selects a source of network clock.
network-clock-select (ATM)	Establishes the sources and priorities of the requisite clocking signals for an ATM-CES port adapter.
show platform hardware network-clocks	Displays network clocks for an ES+ line card.

show pagp

To display port-channel information, use the **show pagp** command in user EXEC or privileged EXEC mode.

show pagp [*group-number*] {**counters** | **internal** | **neighbor** | **pgroup**}

Syntax Description

group-number	(Optional) Channel-group number; valid values are a maximum of 64 values from 1 to 282.
counters	Displays the traffic information.
internal	Displays the internal information.
neighbor	Displays the neighbor information.
pgroup	Displays the active port channels.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can enter any **show pagp** command to display the active port-channel information. To display the nonactive information, enter the **show pagp** command with a group.

The **port-channel** *number*values from 257 to 282 are supported on the CSM and the FWSM only.

Examples

This example shows how to display information about the PAgP counters:

```
Router#
show pagp
 counters
           Information        Flush
Port       Sent   Recv      Sent   Recv
--------------------------------------
Channel group: 1
  Fa5/4    2660   2452      0      0
  Fa5/5    2676   2453      0      0
Channel group: 2
  Fa5/6    289    261       0      0
  Fa5/7    290    261       0      0
Channel group: 1023
  Fa5/9    0      0         0      0
Channel group: 1024
  Fa5/8    0      0         0      0
Router#
```

This example shows how to display internal PAgP information:

```
Router# show pagp
 1 internal
Flags:  S - Device is sending Slow hello.  C - Device is in Consistent state.
        A - Device is in Auto mode.
Timers: H - Hello timer is running.        Q - Quit timer is running.
        S - Switching timer is running.    I - Interface timer is running.
Channel group 1
                                Hello    Partner  PAgP     Learning
Port      Flags State   Timers  Interval Count   Priority  Method
Fa5/4     SC    U6/S7           30s      1        128      Any
Fa5/5     SC    U6/S7           30s      1        128      Any
Router#
```

This example shows how to display PAgP-neighbor information for all neighbors:

```
Router# show pagp
 neighbor
Flags:  S - Device is sending Slow hello.  C - Device is in Consistent state.
        A - Device is in Auto mode.        P - Device learns on physical port.

Related Commands

Command	Description
pagp learn-method	Learns the input interface of the incoming packets.
pagp port-priority	Selects a port in hot standby mode.

show pas caim

To show debug information about the data compression Advanced Interface Module (CAIM) daughter card, use the **showpascaim**command in user EXEC or privileged EXEC mode.

show pas caim {**rings** | **dma** | **coprocessor** | **stats** | **cnxt_table** | **page_table**} *element-number*

Syntax Description

rings *element-number*	Displays current content of the Direct Memory Access (DMA) ring buffer.
dma *element-number*	Displays registers of the Jupiter DMA controller.
coprocessor *element-number*	Displays registers of the Hifn 9711 compression coprocessor.
stats *element-number*	Displays statistics that describes operation of the data compression Advanced Interface Module (AIM).
cnxt_table *element-number*	Displays the context of the specific data compression AIM element.
page_table *element-number*	Displays the page table for each CAIM element.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command displays performance statistics that describe the operation of the CAIM. This command is primarily intended for engineering debug, but it can also be useful to Cisco support personnel and to Cisco customers in troubleshooting network problems. The table below lists the output values for this command.

Table 177: show pas caim Output Values and Descriptions

Value	Description
uncomp paks in	Number of packets containing uncompressed data input to the CAIM for compression.
comp paks out	Number of packets containing uncompressed data that were successfully compressed.
comp paks in	Number of packets containing compressed data input to the CAIM for compression.
uncomp paks out	Number of packets containing compressed data that were successfully decompressed.

Value	Description
uncomp bytes in / comp bytes out	Summarizes the compression performance of the CAIM. The “uncomp bytes in” statistic gives the total number of uncompressed bytes submitted to the CAIM for compression. The “Comp bytes out” statistic gives the resulting number of compressed bytes output by the CAIM. If one forms the ratio of “uncomp bytes in” to “comp bytes out”, one obtains the average compression ratio achieved by the CAIM.
comp bytes in / uncomp bytes out	Summarizes the decompression performance of the CAIM. The “comp bytes in” statistic gives the total number of compressed bytes submitted to the CAIM for decompression. The “uncomp bytes out” statistic gives the resulting number of uncompressed bytes output by the CAIM. The average decompression ratio achieved can be computed as the ratio of “uncomp bytes out” to “comp bytes in”. Note that each packet submitted for compression or decompression has a small header at the front which is always clear data and hence never compressed nor decompressed. The “comp bytes in / uncomp bytes out” and “uncomp bytes in / comp bytes out” statistics do not include this header.
uncomp paks/sec in	A time average of the number of packets per second containing uncompressed data submitted as input to the CAIM for compression. It is computed as the ratio of the “uncomp paks in” statistic to the “seconds since last clear” statistic.
comp paks/sec out	A time average of the number of packets per second containing uncompressed data which were successfully compressed by the CAIM. It is computed as the ratio of the “comp paks out” statistic to the “seconds since last clear” compressed by the CAIM. It is computed as the ratio of the “comp paks out” statistic to the “seconds since last clear” statistic.
comp paks/sec in	A time average of the number of packets per second containing compressed data submitted as input to the CAIM for decompression. It is computed as the ratio of the “comp paks in” statistic to the “seconds since last clear” statistic.
uncomp paks/sec out	A time average of the number of packets per second containing compressed data which were successfully decompressed by the CAIM. It is computed as the ratio of the “uncomp paks out” statistic to the “seconds since last clear” statistic. Note that the “uncomp paks/sec in”, “comp paks/sec out”, “comp paks/sec in”, and “uncomp paks/sec out” statistics are averages over the entire time since the last “clear count” command was issued. This means that as time progresses, these statistics become averages over an ever larger time interval. As time progresses, these statistics become ever less sensitive to current prevailing conditions. Note also that the “uncomp paks in”, “comp paks out”, “comp paks in”, and “uncomp paks out” statistics are 32-bit counters and can roll over from 0xffff ffff to 0. When they do so, the “uncomp paks/sec in”, “comp paks/sec out”, “comp paks/sec in”, and “uncomp paks/sec out” statistics can be rendered meaningless. It is therefore recommend that one issue a “clear count” command before sampling these statistics.
uncomp bits/sec in	A time average of the number of bits per second of uncompressed data which were submitted to the CAIM for compression. It is computed as the ratio of the “uncomp bytes in” statistic, times 8, to the “seconds since last clear” statistic.

Value	Description
comp bits/sec out	A time average of the number of bits per second of uncompressed data which were successfully compressed by the CAIM. It is computed as the ratio of the "comp bytes out" statistic, times 8, to the "seconds since last clear" statistic.
comp bits/sec in	A time average of the number of bits per second of compressed data which were submitted to the CAIM for decompression. It is computed as the ratio of the "comp bytes in" statistic, times 8, to the "seconds since last clear" statistic.
uncomp bits/sec out	A time average of the number of bits per second of compressed data which were successfully decompressed by the CAIM. It is computed as the ratio of the "uncomp bytes in" statistic, times 8, to the "seconds since last clear" statistic. Note again that these "bits/sec" statistics are time averages over the "seconds since last clear" statistics, and therefore become less and less sensitive to current conditions as time progresses. Also, these "bits/sec" statistics are computed from 32-bit counters, and when the counters roll over from the maximum 32-bit value to 0, the "bits/sec" statistics become inaccurate. It is again recommended that one issue the "clear count" command before sampling the "bits/sec" statistics.
The remaining statistics summarize operational state and error conditions encountered by the CAIM, and have the following interpretations:	
holdq	Gives the number of packets occupying the "hold queue" of the CAIM. The hold queue is a holding area, or "overflow" area, for packets to be processed by the CAIM. Normally, the CAIM is fast enough that no overflow into the hold queue occurs, and so normally this statistic should show zero.
hw_enable	Flag indicating if the CAIM is disabled or not. Zero implies disabled; one implies enabled. The CAIM can become disabled if certain fatal hardware error conditions are detected. It can be reenabled by issuing the **clearaim***element-number* command.
src_limited	Flag indicating if the CAIM is in "source limited" mode. In source limited mode, the CAIM can only process a single command at a time. In non source limited mode, the CAIM can process several commands at a time using a pipeline built into the 9711 coprocessor. Note that the normal mode of operation is "non-source limited", and there is no command to place the CAIM in "source limited" mode. Hence, this statistic should always read zero.
num cnxts	Gives the number of "contexts" which are currently open on the CAIM. Each interface configured for compression opens two contexts, one for each direction of data transfer.
no data	Counts the number of times in which the CAIM performed either a compress or decompression operation, and the output data length was reported with a length of zero. In normal operation, this statistic should always read zero. A nonzero value is an indication of a malfunctioning CAIM.

Value	Description
drops	Counts the total number of times in which the CAIM was forced to drop a packet it was asked to compress or decompress. This can happen for a number of reasons, and the remaining statistics summarize these reasons. This statistic indicates that the CAIM is being overloaded with requests for compression/decompression.
nobuffers	Counts the total number of times the CAIM needed to allocate memory for buffers but could not obtain memory. The CAIM allocates memory for buffers for holding the results of compression or decompression operations. In normal operation, there is plenty of memory available for holding CAIM results. This statistic, if nonzero, indicates that there is a significant backup in memory, or perhaps a memory leak.
enc adj errs	Each packet compressed or decompressed involves an adjustment of the encapsulation of the packet between the LZS-DCP, FRF9, or MPPC encapsulation used to transport compressed packets to the standard encapsulation used to transport clear data. This statistic counts the number of times this encapsulation adjustment failed. In normal operation, this statistic should be zero. A nonzero value indicates that we are short in a specific memory resource referred to as “paktypes”, and that packets are being dropped because of this shortage.
fallbacks	Number of times the data compression AIM card could not use its pre-allocated buffers to store compression results and had to “fallback” to using a common buffer pool.
no replace	Each time a compression or decompression operation is completed and the resultant data fill up a buffer, the CAIM software allocates a new buffer to replace the buffer filled. If no buffers are available, then the packet involved in this operation is dropped and the old buffer reused. This statistic thus represents the number of times such an allocation failure occurred. In normal operation there is plenty of memory available for these buffers. A nonzero value for this statistic is thus a serious indication of a memory leak or other backup in buffer usage somewhere in the system.
num seq errs	This statistic is incremented when the CAIM produces results in a different order than that in which the requests were submitted. Packets involved in such errors are dropped. A nonzero value in this statistic indicates a serious malfunction in the CAIM.
num desc errs	Incremented when the CAIM reports error in a compression or decompression operation. Such errors are most likely bus errors, and they indicate a serious malfunction in the CAIM.
cmds complete	Reports the number of compression/decompression commands completed. This statistic should steadily increase in normal operation (assuming that the CAIM is continuously being asked to perform compression or decompression). If this statistic is not steadily increasing or decreasing when a steady stream of compression/decompression is expected, this is an indication of a malfunctioning CAIM.
bad reqs	Reports the number of compression/decompression requests that the CAIM software determined it could not possibly handle. This occurs only if a severely scattered packet (with more than 64 “particles”, or separate buffers of data) is handed to the CAIM to compress or decompress. This statistic should not increment during normal operation. A nonzero value indicates a software bug.

Value	Description
dead cntxts	Number of times a packet was successfully compressed or decompressed, only to find that the software "context", or stream sourcing the packet, was no longer around. In such a case the packet is dropped. This statistic can be incremented at times when a serial interface is administratively disabled. If the timing is right, the CAIM may be right in the middle of operating on a packet from that interface when the disable takes effect. When the CAIM operation completes, it finds that the interface has been disabled and all "compression contexts" pertaining to that interface have been deleted. Another situation in which this can occur is when a Frame Relay DLC goes down. This is a normal and tolerable. If this statistic is incrementing when no such situations exist, it is an indication of a software bug.
no paks	If a packet to be compressed or decompressed overflows into the hold queue, then it must undergo an operation called "reparenting". This involves the allocation of a "paktype" structure for the packet. If no paktype structures are available, then the packet is dropped and this statistic is incremented. A nonzero value of this statistic indicates that the CAIM is being overtaxed, that is, it is being asked to compress/decompress at a rate exceeding its capabilities.
enq errors	Closely related to the "no paks" statistic. The hold queue for the CAIM is limited in length, and if the hold queue grows to this length, no further packets may be placed on it. A nonzero value of this statistic therefore also indicates that the CAIM is being overtaxed.
rx pkt drops	Contains the total number of packets dropped because of "no paks" or "enq errors", which were destined to be decompressed.
tx pkt drops	Contains the total number of packets dropped because of "no paks" or "enq errors", which were destined to be compressed
dequeues	Indicates the total number of packets which were removed from the CAIM hold queue when the CAIM became available for servicing its hold queue.
requeues	Indicates the total number of packets that were removed from the hold queue, only to find that the necessary CAIM resources were not available (it is not possible to determine whether CAIM resources are available until the packet is dequeued). Such packets are requeued onto the hold queue, with order in the queue preserved.
drops disabled	Indicates the total number of packets which were submitted for compression or decompression, but that were dropped because the CAIM was disabled.
clears	Indicates the number of times the CAIM was reset using the **clearaim***element-number*command.
# ints	Indicates the number of interrupts serviced by the CAIM software. This statistic should steadily increase (assuming that the CAIM workload is steady). If this statistic is not incremented when expected, it indicates a severe CAIM malfunction.

Value	Description
# purges	Indicates the total number of times the compression history for a session had to be purged. This statistic is incremented a couple of times at startup. Thereafter, any increase in this statistic is an indication that the other side of the serial link detected bad data or gaps in the compressed packets being passed to it, and hence signalled a request to purge compression history in order to get back in synchronization. This can indicate that the CAIM is being overtaxed or that the serial interface is overtaxed and being forced to drop output packets.
no cnxts	Indicates the total number of times a request was issued to open a context, but the CAIM could not support any more contexts. Recall that two contexts are required for each interface configured for compression.
bad algos	Indicates the total number of times a request was issued to open a context for a compression algorithm not supported by the CAIM. Recall that the CAIM supports the LZS and MPPC algorithms only.
no crams	Indicates the total number of times a request was issued to open a context but there was insufficient compression DRAM to open another context. The CAIM software is set up to run out of contexts before it runs out of compression DRAM, so this statistic should always be zero.
bad paks	Indicates the total number of times a packet was submitted for compression or decompression to the CAIM, but the packet had an invalid size.
# opens	Indicates the total number of times a context was opened.
# closes	Indicates the total number of times a context was closed.
# hangs	Indicates the total number of times a CAIM appeared hung up, necessitating a clear of the CAIM.

Examples

The **showpascaimrings***element-number* command displays the current state of the DMA ring buffers maintained by the CAIM software. These rings feed the CAIM with data and commands. It is intended for an engineering debug of the compression AIM. It produces the following output:

```
Router# show pas caim rings 0
CAIM Command Ring: 0x01A2BC00  Stack: 0x01A2BE40  Shadow: 0x80F88BAC
 Head: 0021  Tail: 0021  Count: 0000
CAIM Source Ring:  0x01A2C900  Shadow: 0x80F88BAC
 Head: 0021  Tail: 0021  Num: 0000
CAIM Results Ring: 0x01A2C280  Stack: 0x01A2C4C0
 Head=021  Tail=021
CAIM Dest Ring:    0x01A2CB40  Shadow: 0x80F892D8  Head=021  Tail=000
  Desc: 0x01A2CBE8  flags: 0x8000060C  dptr: 0x019E7EB8  part: 0x80F84BE0
  Desc: 0x01A2CBF0  flags: 0x8000060C  dptr: 0x019FC63C  part: 0x80F85240
.
.
.
```

The table below describes the significant fields shown in the display.

Table 178: show pas caim rings Field Descriptions

Field	Description
CAIM Command Ring	Feeds commands to the CAIM.
command ring address	Address of the command ring.
Command Ring Stack	Ring that feeds additional commands to the CAIM.
command ring stack address	Address of the command ring stack.
Command Ring Shadow	Software ring that stores additional information about each command.
command ring shadow address	Address of the command ring shadow.
Command Ring Head	Index into the Source Ring, specifying where the next entry will be extracted from.
Command Ring Tail	Index into the Source Ring, specifying where the next entry will be inserted.
CAIM Source Ring	Feeds information about input data to the CAIM.
source ring address	Address of the source ring.
Source Ring Shadow	Ring that contains additional information about each source buffer.
source ring shadow address	Address of the source ring shadow.
Source Ring Head	Specifies where the next entry will be extracted from.
Source Ring Tail	Specifies where the next entry will be inserted.
CAIM Results Ring	Receives information about each CAIM command as it is completed.
results ring address	Address of the results ring.
Results Ring Stack	Ring that receives additional information about each completed command.
results ring stack address	Address of the results ring stack.
Results Ring Head	Specifies where the next entry will be extracted from.
Results Ring Tail	Specifies where the next entry will be inserted.
CAIM Dest Ring	Holds information about the buffers available to the CAIM for output data.
dest ring address	Address of the dest ring.
Dest Ring Shadow	Ring that holds additional information about each output buffer.

Field	Description
dest ring shadow address	Address of the dest ring shadow.
Dest Ring Head	Index into the Source Ring, specifying where the next entry will be extracted from.
Dest Ring Tail	Index into the Source Ring, specifying where the next entry will be inserted.
The remaining fields describe each output data buffer.	
dest	Address of a so-called descriptor, used by the Jupiter DMA engine.
flags	Contains flags describing attributes of the buffer.
dptr	Displays the actual address of the output buffer.
part	Displays the address of the corresponding particle type structure, a software-defined structure that describes a buffer when it is a component of a network data buffer.

The **show pas caim dma** *element-number*command displays the registers of the Jupiter DMA Controller. These registers control the operation of the Jupiter DMA Controller. This command is intended for Engineering debug of the CAIM. You can find detailed descriptions of the various fields in the Jupiter DMA Controller specification. It produces the following output:

```
Router# show pas caim dma 0
Jupiter DMA Controller Registers: (0x40200000
        Cmd Ring: 0x01A2BCA8  Src Ring: 0x01A2C9A8
        Res Ring: 0x01A2C328  Dst Ring: 0x01A2CBE8
        Status/Cntl: present: 0x80808084  last int: 0x80808084
        Inten: 0x10100000  config: 0x00100003
        Num DMA ints: 143330469
```

The show pas caim compressor element-number command displays the registers of the Hifn 9711 compression coprocessor. These registers control the operation of the Hifn 9711 part. This command is intended for engineering to debug the CAIM. Detailed descriptions of the various fields may be found in the Hifn 9711 data book. It produces the following output:

```
Router# show pas caim compressor 0
Hifn9711 Data Compression Coprocessor Registers (0x40201000):
        Config: 0x000051D4  Inten: 0x00000E00
        Status: 0x00004000  FIFO status: 0x00004000
        FIFO config: 0x00000101
```

The table below describes the fields shown in the preceding display.

Table 179: show pas caim compressor Field Descriptions

Field	Description
Hifn9711 Data Compression Coprocessor Registers	Controls the operation of the Hifn 9711 part.

Field	Description
registers address	Address of the registers in the address space of the processor.
Config	Displays the current contents of the 9711 configuration register.
Inten	Displays the contents of the 9711 interrupt enable register.
Status	Displays the contents of the 9711 status register.
FIFO status	Contents of the 9711 FIFO Status register.
FIFO config	Contents of the 9711 FIFO Config register.

The show pas caim cnxt_table element-number command displays the context table for the specified CAIM element. The context table is a table of information concerning each compression context. It produces the following output:

```
Router# show pas caim cnxt_table 0
CAIM0 Context Table
Context: 0x8104F320  Type: Compr   Algo: Stac
    Hdrlen: 0006  History: 0x0000
    Callback: 0x8011D68C  Shutdown: x8011EBE4  Purge: N
    Comp_db: 0x81034BC0  idb: 0x81038084  ds: 0x8104E514
Context: 0x8104F340  Type: Decomp  Algo: Stac
    Hdrlen: 0002  History: 0x0000
    Callback: 0x8011E700  Shutdown: x8011EBE4  Purge: N
    Comp_db: 0x81034BC0  idb: 0x81038084  ds: 0x8104E514
```

The table below describes the fields shown in the preceding display.

Table 180: show pas caim cnxt_table Fields Descriptions

Field	Description
Context	Numeric internal reference for the compression context.
Type	Gives the type of context: • Compr--compression context • Decomp--decompression context
Algo	Gives the compression algorithm used: • Stac • Mppc
Hdrlen	Gives the number of bytes in the compression header for each compressed packet.
History	Gives the 16-KB page number in compression RAM for the context.
Callback	Gives an internal numeric reference for a control structures or procedure to facilitate debugging.
Shutdown	Gives an internal numeric reference for a control structures or procedure to facilitate debugging.

Field	Description
Comp_db	Gives an internal numeric reference for a control structures or procedure to facilitate debugging.
idb	Gives an internal numeric reference for a control structures or procedure to facilitate debugging.
idb	Gives an internal numeric reference for a control structures or procedure to facilitate debugging.
Purge	Indicates whether the compression context has been flagged to have its history purged.

The show pas caim page_table element-number command displays the page table for the selected CAIM element. The page table is a table of entries describing each page in compression RAM. It produces the following output:

```
Router# show pas caim page_table 0
CAIM0 Page Table
    Page  0x0000 Comp cnxt: 8104F320  Decmp cnxt: 8104F340  Algo: Stac
```

The table below describes the fields shown in the preceding display.

Table 181: show pas caim page_table Field Descriptions

Field	Description
Page	16 KB page number of the page.
Comp cnxt	Contains an internal numeric reference to the context structures using this page.
Decmp cnxt	Contains an internal numeric reference to the context structures using this page.
Algo	Gives the compression algorithm used: • Stac • Mppc

The following example shows statistics of an active data compression AIM session:

```
Router# show pas caim stats 0

Related Commands

Command	Description
show compress	Displays compression statistics.

show pas eswitch address

To display the Layer 2 learned addresses for an interface, use the **showpaseswitchaddress** command in user EXEC or privileged EXEC mode.

show pas eswitch address commandshow pas eswitch address [{**ethernet**|**fastethernet**}] [*slot*/*port*]

Syntax Description

ethernet | **fastethernet**	(Optional) Type of interface.
slot	(Optional) Slot number of the interface.
port	(Optional) Interface number.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.2P	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following sample output shows that the first PA-12E/2FE interface (listed below as port 0) in port adapter slot 3 has learned the Layer 2 address 00e0.f7a4.5100 for bridge group 30 (listed below as BG 30):

```
Router# show pas eswitch address fastethernet 3/0
U 00e0.f7a4.5100, AgeTs 56273 s, BG 30 (vLAN 0), Port 0
```

show pas i82543 interface

To display interface information that is specific to Fast Ethernet or Gigabit Ethernet port adapters with an Intel 82543 processor on Cisco 7200 series routers, use the **showpasi82543interface**command in privileged EXEC mode.

show pas i82543 interface {**fastethernet** | **gigabitethernet**} *slot/port* [{**multicast-table** | **receive-address** | **statistics**}]

Syntax Description

fastethernet	Displays i82543-specific information for Fast Ethernet interfaces.
gigabitethernet	Displays i82543-specific information for Gigabit Ethernet interfaces.
slot	Slot number.
/ *port*	Port number. The slash mark is required between the *slot* argument and the *port* argument.
multicast-table	(Optional) Displays i82543-specific multicast address table information. **Note** In Cisco IOS Release 12.2 S, this keyword is **MTA**.
receive-address	(Optional) Displays the contents of the receive address registers on the i82543 chip.
statistics	(Optional) Displays i82543-specific statistical information.

Command Modes

Privileged EXEC(#)

Command History

Release	Modification
12.2(20)S	This command was introduced on Cisco 7200 series routers.
12.1(20)E	This command was integrated into Cisco IOS Release 12.1(20)E on Cisco 7200 series routers.
12.0(27)S	This command was integrated into Cisco IOS Release 12.0(27)S on Cisco 7200 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 7200 series routers.

Usage Guidelines

Use the **showpasi82543interface** command with the **statistics** keyword to determine what types of packets are being processed. Similar statistical information is displayed by the **showcontrollersfastethernet** and **showcontrollersgigabitethernet** commands.

Note We recommend that the **multicast-table** and **receive-address** keywords for this command be used only under the supervision of a Cisco engineer because of the cryptic output.

Examples

The following sample output shows the contents of the multicast address table present on the i82543 processor.

```
Router# show pas i82543 interface fastethernet 6/0 multicast-table
Multicast Table Entry #0 = 0x10000
Multicast Table Entry #1 = 0x1
Multicast Table Entry #84 = 0x8000
```

The following sample output shows the contents of the Receive Address High (RAH) and Receive Address Low (RAL) registers on the i82543 processor.

```
Router# show pas i82543 interface fastethernet 6/0 receive-address
#1 RAH 0x8000A8FC RAL 0x67B60900
#3 RAH 0x0003FFFF RAL 0xFF45F75B
#5 RAH 0x0003FFFF RAL 0xCBEE539A
#7 RAH 0x0003FFFF RAL 0x5ABDADEB
#9 RAH 0x0003FFFF RAL 0x365B5ACF
#11 RAH 0x0003FFFF RAL 0xB2D9B0CE
#13 RAH 0x0003FFFF RAL 0x12A91CF6
#15 RAH 0x0003FFFF RAL 0xEF4A3125
#17 RAH 0x0003FFFF RAL 0x1A07EB7D
#19 RAH 0x0003FFFF RAL 0xFF9B6EF8
#21 RAH 0x0003FFFF RAL 0xB7C2AFC9
#23 RAH 0x0003FFFF RAL 0x14F4FB0A
#25 RAH 0x0003FFFF RAL 0xC60D6706
#27 RAH 0x0003FFFF RAL 0x5E9DE230
#29 RAH 0x0003FFFF RAL 0x5FEF9FBE
#31 RAH 0x0003FFFF RAL 0xBBCCC57E
```

The following sample output shows packet statistics of the i82543 processor.

```
Router# show pas i82543 interface fastethernet 6/0 statistics
i82543 (Livengood) Statistics
  CRC error         0             Symbol error     0
  Missed Packets    0             Single Collision 0
  Excessive Coll    0             Multiple Coll    0
  Late Coll         0             Collision        0
  Defer             0             Receive Length   0

  TCP Segmentation  0             TCP Seg Failed   0
```

The table below describes significant fields shown in the display.

Table 182: ***show pas i82543 interface statistics*** *Field Descriptions*

Field	Description
CRC error	Cyclic redundancy checksum (CRC) generated by the originating LAN station or far-end device does not match the checksum calculated from the data received. On a LAN, this usually indicates noise or transmission problems on the LAN interface or the LAN bus itself. A high number of CRCs is usually the result of collisions or a station transmitting bad data.
Symbol error	Number of symbol errors between reads.
Missed Packets	Indicates whether the software processes that handle the line protocol believe that the interface is usable (that is, whether keepalives are successful) or if it has been taken down by an administrator.
Single Collision	Number of times that a transmit operation encountered a single collision.
Excessive Coll	This counter is incremented after a transmit operation has encountered more than 16 collisions.
Multiple Coll	Number of times that a transmit operation encountered more than 1 collision, but less than 16 collisions.
Late Coll	Number of late collisions. A late collision happens when a collision occurs after transmitting the preamble. The most common cause of late collisions is Ethernet cable segments that are too long for the speed at which you are transmitting.
Collision	Number of messages transmitted because of an Ethernet collision. A packet that collides is counted only once in output packets.
Defer	Defer indicates that the chip had to defer while ready to transmit a frame because the carrier was asserted.
Receive Length	Number of receive length error events. A receive length error occurs if an incoming packet passes the filter criteria but is either oversized or undersized. Packets less than 64 bytes are undersized. Packets over 1522 bytes are oversized if LongPacketEnable (LPE) is 0. If LPE is 1, a packet is considered oversized if it exceeds 16,384 bytes.
Sequence Error	Number of sequence error events.
XON RX	Number of XON packets received.
XON TX	Number of XON packets transmitted.
XOFF RX	Number of XOFF packets received.
XOFF TX	Number of XOFF packets transmitted.
FC RX Unsupport	Number of unsupported flow control frames received.
Packet RX	Number of received packets of the following lengths in bytes: 64, 127, 255, 511, 1023, 1522.
Good Packet RX	Number of received packets without errors.

Field	Description
Broadcast RX	Number of broadcast packets received.
Multicast RX	Number of multicast packets received.
Good Packet TX	Number of transmitted packets without errors.
Good Octets	Number of good (without errors) octets received (RX) or transmitted (TX).
RX No Buff	Number of times that frames were received when there were no available buffers in host memory to store those frames. The packet will be received if there is space in FIFO memory.
RX Undersize	Number of received frames that passed through address filtering and were less than the minimum size of 64 bytes (from destination address through CRC, inclusively), but that contained a valid CRC.
RX Fragment	Number of received frames that passed through address filtering and were less than the minimum size of 64 bytes (from destination address through CRC, inclusively), but that contained a bad CRC.
RX Oversize	Number of received frames that passed through address filtering and were greater than the maximum size.
RX Octets	Total number of octets received.
TX Octets	Total number of octets transmitted.
TX Packet	Number of transmitted packets.
RX Packet	Number of received packets.
TX Broadcast	Number of broadcast packets transmitted.
TX Multicast	Number of multicast packets transmitted.
Packet TX	Number of transmitted packets of the following lengths in bytes: 64, 127, 255, 511, 1023, 1522.
TX Underruns	Number of times that the transmitter has been running faster than the router can handle. This may never be reported on some interfaces.
TX No CRS	Number of successful packet transmissions in which Carrier Sense (CRS) input from the physical layer was not asserted within one slot time of start of transmission.
RX Error Count	Number of receive packets in which RX_ER was asserted by the physical layer.
RX DMA Underruns	Number of receive direct memory access (DMA) underruns observed by the DMA.
RX Carrier Ext	Number of packets received in which the carrier extension error was signalled across the gigabit medium independent interface (GMII) interface.
TCP Segmentation	Number of TCP segmentation offload transmissions to the hardware.

Field	Description
TCP Seg Failed	Number of TCP segmentation offload transmissions to the hardware that failed to transmit all data in the TCP segmentation context payloads.

Related Commands

Commands	Description

```

The table below describes the significant fields shown in the display.

Table 183: show pas isa interface Field Descriptions

Field	Description
packets in/out	Number of data packets received from, or sent to, the Integrated Service Adapter (ISA).

Field	Description
paks/sec in/out	Number of packets received in, or sent out, with the total number of seconds that the ISA is active.
Kbits/sec in/out	Number of kilobits (Kbits) received in, or sent out, with the total number of seconds that the ISA is active.
commands out	Number of commands going to the ISA. Examples of commands include setting up encryption sessions and retrieving statistics or status from the ISA.
commands acknowledged	Number of commands returning from the ISA. Examples of commands include setting up encryption sessions and retrieving statistics or status from the ISA.
low_pri_pkts_sent	This is a summary counter for number of Internet Key Exchange (IKE) and IPSec commands submitted to ISA.
low_pri_pkts_rcvd	This is a summary counter for number of IKE & IPSEC command responses received from ISA.
invalid_sa	Reference to an unusable security association key pair.
invalid_flow	An invalid packet using an IPSec key is received for encryption or decryption. Example: session has expired.
invalid_dh	Reference to an unusable Diffie-Hellman(DH) key pair.
ah_seq_failure	Unacceptably late Authentication Header (AH) header received.
ah_spi_failure	SPI specified in the AH header does not match the SPI associated with the IPSec AH key.
esp_auth_failure	Number of ESP packets received with authentication failures.
esp_seq_failure	Unacceptably late ESP packet received.
esp_spi_failure	SPI specified in the ESP header does not match the SPI associated with the IPSec ESP key.
esp_protocol_absent	Packet is missing expected ESP header.
ah_protocol_absent	Packet is missing expected AH header.
bad_key_group	Unsupported key group requested during a Diffie-Hellman generation.
no_shared_secret	Attempting to use a Diffie-Hellman shared secret that is not generated.
no_skeyids	Attempting to use a shared secret that is not generated.
pad_size_error	The length of the ESP padding is greater than the length of the entire packet.
cmd_ring_full	New IKE setup messages are not queued for processing until the previous queued requests are processed.

Field	Description
bulk_ring_full	New packets requiring IPSec functionality are not queued to the ISA until the ISA completes the processing of existing requests.
bad_peer_pub_len	Length of peer's DH public key does not match the length specified for the negotiated DH key group.
authentication_failure	Authentication failed.
fallback	The number of instances when the driver is successful in getting a replacement buffer from the global pool.
no_particle	The number of instances when the driver was unable to get a replacement buffer from the driver pool and the global (fallback) pool.

Related Commands

Command	Description
show pas isa controller	Displays controller status information that is specific to the VPN accelerator card.

show pas vam controller

To display controller information that is specific to the VPN Acceleration Module (VAM), use the **showpasvamcontroller** command in privileged EXEC mode.

show pas vam controller

        out_of_handles : 0            compr_cancelled  : 0
        rng_st_fail    : 0            other_errors     : 0
        3420 seconds since last clear of counters
```

The table below describes the significant fields shown in the display.

Table 184: show pas vam interface Field Descriptions

Field	Description
packets in/out	Number of data packets received from, or sent to, the VAM.
bytes in/out	Number of data bytes received from, or sent to, the VAM.
paks/sec in/out	Number of packets received in, or sent out, with the total number of seconds that the VAM is active.
Kbits/sec in/out	Number of kilobits (Kbits) received in, or sent out, with the total number of seconds that the VAM is active.
commands out	Number of commands going to the VAM. Examples of commands include setting up encryption sessions and retrieving statistics or status from the VAM.
commands acknowledged	Number of commands returning from the VAM. Examples of commands include setting up encryption sessions and retrieving statistics or status from the VAM.
ppq_full_err	Number of packets dropped because of a lack of space in the packet processing queues for the VAM. This usually means that input traffic has reached VAM maximum throughput possible.
ppq_rx_err	Summary counter for all errors related to packet processing.
cmdq_full_err	Number of commands dropped because of a lack of space in the command processing queues for the VAM. This error indicates that the input tunnel setup rate has reached the VAM maximum setup rate. The Internet Key Exchange (IKE) process retries the tunnel creation and deletion when commands are dropped by VAM.
cmdq_rx_err	Summary counter for all errors related to command processing (for example, IKE, or IPSec session creation or deletion).
no_buffer	Errors related to the VAM running out of buffers. May occur with large packets. Although VAM buffers cannot be tuned, try tuning buffers for other interfaces.
fallback	Internal VAM buffer pool is completely used up and VAM has to fallback to global buffer pool. This may cause minor performance impact, however, packets are still processed so this error can be ignored.
dst_overflow	Counter that is incremented when the VAM has completed an operation, but there is no available space into which to place the result.
nr_overflow	Counter that is incremented when the VAM has completed an operation, but there is no available space into which to place the result.
sess_expired	Counter that is incremented if the session used to encrypt or decrypt the packet has expired because of time or space limit.
pkt_fragmented	Counter that is incremented when the input packet has to be fragmented after encryption. This counter should always be 0 as fragmentation by VAM is disabled.
out_of_mem	Counter that is incremented when the VAM runs out of memory.

Field	Description
access_denied	Counter that is incremented when the VAM is requested to perform an operation on an object that can not be modified.
invalid_fc	Counter that is incremented when the VAM has received a request that is illegal for the specified object type.
invalid_param	Counter that is incremented when the VAM has received invalid parameters within a command.
invalid_handle	Counter that is incremented when the VAM receives a request for an operation to be performed on an object that does not exist.
output_overrun	Counter that is incremented when the space allocated for a response is not large enough to hold the result posted by the VAM.
input_underrun	Counter that is incremented when the VAM receives a packet for which it finds a premature end to the data, for example, a truncated packet.
input_overrun	Counter that is incremented when the VAM receives a buffer that is too large for the requested operation.
key_invalid	Counter that is incremented when the VAM receives a request for an operation on a key where the key is invalid or of the wrong type.
packet_invalid	Counter that is incremented when the VAM receives a packet whose body is badly formed.
decrypt_failed	Counter that is incremented when the VAM receives a packet that cannot be decrypted because the decrypted data was not properly formatted (for example, padding is wrong).
verify_failed	Counter that is incremented when the VAM receives a packet which could not be verified because the verification of a signature or authentication value failed.
attr_invalid	Counter that is incremented when the VAM receives a packet which specifies an attribute that is not correct for the specified object or operation.
attr_val_invalid	Counter that is incremented when the VAM encounters errors during packet or command processing. The packets or commands are dropped in such cases.
attr_missing	Counter that is incremented when the VAM receives an operation request for which the value of a required attribute is missing.
obj_not_wrap	Counter that is incremented when the VAM receives an operation request to retrieve an object that is hidden or unavailable for export beyond the FIPS boundary of the VPN Module.
bad_imp_hash	Counter that is incremented when the VAM sees a hash miscompare on unwrap.
cant_fragment	Counter that is incremented when the VAM determines a need to fragment a packet, but cannot fragment because the “don’t fragment” bit is set. This counter should always be zero because the fragmentation on the VAM is disabled.

Field	Description
out_of_handles	Counter that is incremented when the VAM has run out of available space for objects of the requested type.
comp_cancelled	Due to the operation of the compression algorithm, some data patterns cannot be compressed. Usually data that has already been compressed or data that does not have a sufficient number of repetitive patterns cannot be compressed and a compress operation would actually result in expansion of the data. There are certain known data patterns which do not compress. In these cases, the compression engine cancels the compression of the data and returns the original, uncompressed data without an IPPCP header. These counters are useful to determine if the content of the traffic on the network is actually benefiting from compression. If a large percentage of the network traffic is already compressed files, these counters may indicate that compression on these streams are not improving the performance of the network.
rng_st_fail	Counter that is incremented when the VAM detects a Random Number Generator self test failure.
pkt_replay_err	Counter that is incremented when a replay error is detected by the VAM.
other_errors	Counter that is incremented when the VAM encounters a packet or command error that is not listed in other error categories. An example could be if the packet IP header checksum is incorrect.

Related Commands

Command	Description
show pas vam controller	Displays controller status information that is specific to the VPN accelerator module.

show pas y88e8k interface

To display the y88e8k Port Adaptor Information (pas) message details of a Gigabit Ethernet interface, use the **showpasy88e8kinterface** command in User EXEC or privileged EXEC mode.

show pas y88e8k interface *type number* {**registers** | **rx_ring** | **statistics** | **tx_ring**}

Syntax Description

type	(Optional) Displays the interface type.
number	(Optional) Displays the interface number.
registers	Displays register values.
rx -ring	Displays the receive ring entries of the interface.
statistics	Displays the y88e8k chip statistics values.
tx -ring	Displays the transmit ring entries of the interface.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.4(22)T	This command was introduced in a release earlier than Cisco IOS Release 12.4(22)T.

Examples

The following is sample output from the **showpasy88e8kinterface** command:

```
Router# show pas y88e8k interface gigabit ethernet 1/0 rx-ring
Rx Ring:
 --------
  ring size = 128, particle size = 2048
  ring head = 0, tail = 127
  Ring entries:
     rxr       next_desc_addr   buf_ctrl   buf_addr_lo frame_sw  rxr_shadow   data_start

Table 1 describes the significant fields shown in the display.

Table 185: show pas y88e8k interface Field Descriptions

Field	Description
ring size	Displays the size of the ring. This is based on the bandwidth of the interface or virtual circuit (VC) and is a power of two.
particle size	Displays the particle size on the receive and transmit paths, in bytes.
ring head	Displays the head of the ring.
tail	Displays the tail of the ring.
rxr	Displays the Rx ring pointer.
next_desc_addr	Displays next Rx buffer descriptor address.
buf_ctrl	Displays the buffer control.
buf_addr_lo	Displays the buffer address.
frame_sw	Displays the Frame status word.
rxr_shadow	Displays the Rx ring shadow.
data_start	Displays the start of data in the particle.
data_bytes	Displays the number of bytes consumed for data storage.

Related Commands

Command	Description
tx-ring-limit	Limits the number of packets that can be used on a transmission ring on the DSL WIC or interface.

show pci aim

To show the IDPROM contents for each compression Advanced Interface Module (AIM) daughter card in the Cisco 2600 router, use the **showpciaim**command in user EXEC or privileged EXEC mode.

show pci aim

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command shows the IDPROM contents for each compression AIM daughtercard present in the system, by AIM slot number (currently 0, since that is the only daughtercard installed for Cisco IOS Release 12.0(1)T). The IDPROM is a small PROM built into the AIM board used to identify it to the system. It is sometimes referred to as an EEPROM because it is implemented using electronically erasable PROM.

Examples

The following example shows the IDPROM output for the installed compression AIM daughter card:

```
Router# show pci aim
AIM Slot 0: ID 0x012D
        Hardware Revision        : 1.0
        EEPROM format version 4
        EEPROM contents (hex):
          0x00: 04 FF 40 01 2D 41 01 00 FF FF FF FF FF FF FF FF
          0x10: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x20: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x30: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x40: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x50: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x60: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
          0x70: FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF FF
```

Related Commands

Command	Description
clear aim	Clears data compression AIM registers and resets the hardware.
test aim eeprom	Tests the data compression AIM after it is installed in a Cisco 2600 series router.

show platform

To display platform information, use the **show platform** command in privileged EXEC mode.

show platform {**buffers** | **copp rate-limit** {**arp** | **dhcp** | **atm-oam** | **ethernet-oam** | **icmp** | **igmp** | **pppoe-discovery** | **atom ether-vc** | **all**} | **np copp** [*ifnum*] [**detail**] | **dma** | **eeprom** | **fault** | **hardware capacity** | **hardware pfc mode** | **internal-vlan** | **interrupts** | **netint** | **software ipv6-multicast connected** | **stats** | **tech-support** {**ipmulticast** [**vrf** *vrf-name*] *group-ip-addr src-ip-addr* | **unicast** [**vrf** *vrf-name*] *destination-ip-addr destination-mask* [**global**]} | **tlb** | **vfi dot1q-transparency** | **vlans**}

Cisco 4400 Series Integrated Services Routers
show platform

Cisco ASR 1000 Series Aggregation Services Routers
show platform

Syntax Description

buffers	Displays buffer-allocation information.
copp rate-limit	Displays Cisco Control Plane Policing (CoPP) rate-limit information on the Cisco 7600 SIP-400.
arp	Specifies Address Resolution Protocol (ARP) packet traffic.
dhcp	Specifies Dynamic Host Configuration Protocol (DHCP) packet traffic.
atm-oam	Specifies ATM Operation, Administration, and Maintenance (OAM) packet traffic.
ethernet-oam	Specifies Ethernet OAM packet traffic.
icmp	Specifies Internet Connection Management Protoocol Rate limiter.
igmp	Specifies Internet Group Management Potocol Rate limiter.
pppoe-discovery	Specifies Point-to-Point Protocol over Ethernet (PPPoE) discovery packet information.
atom ether-vc	Shows whether IP or routed mode interworking is configured.
all	Displays rate-limit information for all protocols.
np copp	Displays debug information for a given CoPP session ID or for all CoPP sessions.
ifnum	(Optional) A session ID.
detail	(Optional) Shows full rate-limited values.
dma	Displays Direct Memory Access (DMA) channel information.
eeprom	Displays CPU EEPROM information.

fault	Displays the fault date.
hardware capacity	Displays the capacities and utilizations for hardware resources; see the **show platform hardware capacity** command.
hardware pfc mode	Displays the type of installed Policy Feature Card (PFC).
internal-vlan	Displays the internal VLAN.
interrupts	Displays m8500 interrupt counters.
netint	Displays the platform network-interrupt information.
software ipv6-multicast connected	Displays all the IPv6 subnet Access Control List (ACL) entries on the Route Processor (RP); see the show platform software ipv6-multicast command.
stats	Displays Constellation WAN (CWAN) statistics.
tech-support ipmulticast	Displays IP multicast-related information for Technical Assistance Center (TAC).
vrf *vrf-name*	(Optional) Displays the Virtual Private Network (VPN) routing and forwarding (VRF) instance.
group-ip-addr	Group IP address.
src-ip-addr	Source IP address.
unicast	Displays IP unicast-related information for TAC.
destination-ip-addr	Destination IP address.
destination-mask	Destination mask.
global	(Optional) Displays global output.
tlb	Displays information about the translation look-aside buffer (TLB) register.
vfi	Displays CWAN virtual forwarding instance (VFI) commands.
dot1q-transparency	Displays the dot1q transparency setting.
vlans	Displays hidden VLAN-to-WAN interface mapping.

Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB. This command was changed to include the **hardware pfc mode**keywords.
12.2(18)SXD	This command was modified to include the software ipv6-multicast connectedkeywords.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRC	This command was modified to include additional keywords to support CoPP enhancements on the Cisco 7600 SIP-400 on the Cisco 7600 series router.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.
12.2(33)SRD	This command was modified. The **atom ether-vc** keyword was added.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.
Cisco IOS XE Gibraltar 16.11.1	Output now indicates when a PSU slot is empty. In earlier releases, the state of an empty PSU slot appeared in the command output as "ps, fail". See the examples for differences in indication options for Cisco ASR 1000 Series and ISR 4000 Series routers.

Usage Guidelines

This command is similar to the **show msfc** command.

This command can be used to verify the existence of a second Cisco IOS process on a single Cisco ASR 1000 RP on a Cisco ASR 1002 router or Cisco ASR 1004 router.

When this command is used with the **atom ether-vc** keyword, it is used on the line-card console.

Examples

The following sample output from the **show platform buffers** command displays buffer-allocation information:

```
Router# show platform buffers
Reg. set    Min    Max
  TX               640
 ABQ        640  16384
   0          0     40
   1       6715   8192
   2          0      0
   3          0      0
   4          0      0
   5          0      0
   6          0      0
   7          0      0
Threshold = 8192

Vlan  Sel  Min  Max  Cnt  Rsvd
1019    1 6715 8192    0     0
Router#
```

Cisco ISR 4400 Series Routers

The following example displays online status information for a Cisco ISR 4451-X/K9.

```
Router# show platform
Chassis type: ISR4451-X/K9

```

The table below describes the fields that appear in the above example

Table 186: show platform Field Descriptions

Field	Description
Slot	Chassis slot number
Type	Type of module
State	Status of the module
Insert time	Period of time ((hh:mm:ss format) since the module has been up and running

Cisco ASR 1000 Series Routers

The following example displays online status information for the shared port adapters (SPAs), Cisco ASR 1000 SPA Interface Processor (SIP), Cisco ASR 1000 Embedded Services Processor (ESP), Cisco ASR 1000 RP, power supplies, and fans. The ESPs are shown as F0 and F1. The RPs are shown as R0 and R1.

The State column should display “ok” for SIPs, SPAs, power supplies, and fans. For RPs and ESPs, the State column should display “ok, active” or “ok, standby.”

```
Router# show platform

R0        ASR1002-X           ok, active            1d18h
F0        ASR1002-X           ok, active            1d18h
P0        ASR1002-PWR-AC      ok                    1d18h
P1        Unknown             empty                 never
```

Cisco ISR 4000 with two PSUs, no power cord attached to P1 or bad input detected

This example shows "fail, badinput" for P1.

On ISR 4000 Series routers, the possible states are:

- "fail, badinput": No power cord attached or bad input detected
- “fail, badoutput”: Bad output detected
- “fail, badcookie”: Failed to read the status of the PSU

```
Device#show platform
```

```
 Chassis type: ISR4431/K9

The table below describes the significant fields shown in the display.

Table 187: show platform Field Descriptions

Field	Description
Slot	Chassis slot.
Type	Hardware type.

Field	Description
State	Online state of the hardware. One of the following values: All Hardware • booting--Hardware is initializing and software is booting. • disabled--Hardware is not operational. • init--Hardware or Cisco IOS process is initializing. • ok--Hardware is operational. • shutdown--Hardware was administratively shut down using the no shutdown command. • unknown--Hardware is not operational; state is unknown. RP or ESP • init, standby--Standby RP or ESP is operational but is not yet in a high availability (HA) state. An RP or ESP switchover is not yet possible. • ok, active--Active RP or ESP is operational. • ok, standby--Standby RP or ESP is operational. The standby RP or ESP is ready to become active in the event of a switchover. SPA • admin down--SPA was disabled using the shutdown command. • inserted--SPA is being inserted. • missing--SPA was removed. • out of service--SPA is not operational. • retrieval error--An error occurred while retrieving the SPA state; state is unknown. • stopped--SPA was gracefully deactivated using the hw-module subslot stop command. Fan or Power Supply • fan, fail--Fan is failing. • Empty--Power supply is missing. • ps, fail--Power supply is failing.
Insert time (ago)	Amount of time (hh:mm:ss format) the hardware has been online.
CPLD Version	Complex programmable logic device version number.
Firmware Version	Firmware (ROMmon) version number.

Cisco 7600 Series Routers with Cisco 7600 SIP-400

The following sample output from the **show platform copp rate-limit arp** command displays the list of interfaces on which a rate limiter is active for ARP, along with the count of confirmed and exceeded packets for the rate limiter:

```
Router# show platform copp rate-limit arp
Rate limiter Information for Protocol arp:
  Rate Limiter Status: Enabled
  Rate : 20 pps
  Max Observation Period : 60 seconds
Per Interface Rate Limiter Information
  Interface              Conformed Pkts  Exceeded Pkts  Enabled  Obs Period (Mts)
  GigabitEthernet5/1         0               0            No         -
  GigabitEhternet5/1.1       14              0            No         -
  GigabitEthernet5/1.2       28              2            No         -
  GigabitEthernet5/2         0               0            No         -
  GigabitEthernet5/2.1       180             4            Yes        35
  GigabitEthernet5/2.2       200             16           Yes        Max
```

The table below describes the significant fields shown in the display.

Table 188: show platform copp rate-limit Field Descriptions

Field	Description
Rate Limiter Status	Indicates if a rate limiter has been enabled on the interface.
Rate	Indicates the configured rate in packets per second (pps) or bits per second (bps).
Max Observation Period	Indicates the configured observation period, in seconds, before the per-interface rate limiter is automatically turned off.
Per Interface Rate Limiter Information	Displays the list of interfaces on which the rate limiter is active. In this example: • GigabitEthernet5/1.1 is free from attack. • GigabitEthernet5/2.1 has an exceed count of 4, and has a rate limiter enabled. The observation period is 35 minutes, which indicates that currently the interface is free from attack and is being kept under observation. The interface will remain under observation for an additional 35 minutes. If it remains free from attack after that time, the rate limiter is automatically removed. • GigabitEthernet5/2.2 has an exceed count of 16 and has a rate limiter enabled. The observation period has been designated as Max. This indicates that the interface is still under attack and has not yet entered the observation time window.

The following sample from the **show platform eeprom** command displays CPU EEPROM information:

```
Router# show platform eeprom

Related Commands

Command	Description
platform copp	Turns on or off rate-limiting for an interface on the Cisco 7600 SIP-400.
platform copp observation period	Sets the observation period before automatically turning off the per-interface rate limiter on the Cisco 7600 SIP-400.
pseudowire class	Specifies the name of a Layer 2 pseudowire class.

Command	Description
show msfc	Displays MSFC information.

show platform acl software-switched

To display whether ACLs are enabled for software-switched WAN packets, use the **showplatformaclsoftware-switched**command in privileged EXEC mode.

show platform acl software-switched

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(50)SY	This command was introduced.
12.2(33)SXI2	This command was integrated into Cisco IOS Release 12.2(33)SXI2.

Usage Guidelines

By default, ACLs are not applied to packets that are software-switched between WAN cards and the route processor. To determine whether ACLs are enabled for software-switched ingress or egress WAN packets, use the **showplatformaclsoftware-switched**command.

Examples

This example shows how to display whether ACLs are enabled for software-switched WAN packets:

```
Router# show platform acl software-switched
 CWAN: ACL treatment for software switched in INGRESS is enabled
 CWAN: ACL treatment for software switched in EGRESS is disabled
```

Related Commands

Command	Description
platform cwan acl software-switched	Allows ACLs to be applied to WAN packets that are software-switched.

show platform atom disp-tbl backup

To display the disposition table on the line card for backup VCs, use the **showplatformatomdisp-tblbackup** command in privileged EXEC mode .

show platform atom disp-tbl backup *pseudo-ckt-index*

Syntax Description

pseudo-ckt-index	Defines the *pseudo-circuit-index*. The acceptable range is between 1 and 65537.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

The show platform atom disp-tbl backup command should be used while using the Hot-Standby Psuedo Wire (HSPW) feature.

Examples

The following example displays the disposition table on the Line Card for backup VCs.

```
Router# show platform atom disp-tbl backup

Pseudo   Dlci or   Local         Outgoing          IW   Backup
Ckt Idx    Vcd     Label         Interface        Type   VC
-------  -------  -------  ---------------------  ----  ------
  32786       2       24                    AC0   L2L    Yes
```

Related Commands

Command	Description
show platform atom disp-tbl local-vc-label	Displays the disposition table on the line card for a VC based on the local label.
show platform atom tbl-summary	Displays the total number of PWs programmed on the Line Card.
show platform atom imp-tbl backup	Displays the imposition table on the line card for backup VCs.
show platform atom imp-tbl remote-vc-label	Displays the imposition table on the line card for a VC based on the remote label.

show platform atom disp-tbl local-vc-label

To display the disposition table on the line card for a VC based local label, use the **showplatformatomdisp-tbllocal-vc-label** command in privileged EXEC mode .

show platform atom disp-tbl local-vc-label *local-vc-label*

Syntax Description

local-vc-label	Defines the VC based local label. The acceptable range is between 15 and 1048575.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

The show platform atom disp-tbl local-vc-label command should be used only if you know the Local VC Label for a VC.

Examples

The following example displays the disposition table on the Line Card for a VC based on the local label.

```
Router# show platform atom imp-tbl remote-vc-label 97
Pseudo Ckt Idx    Dlci or Vcd   Dest Vlanid   LTL Index   # Lbls Imposed   Remote Label
--------------   -------------  ------------  ----------  ---------------  --------------
 49170               2           1028          0xFF             2              97
Local Label  Outgoing Interface   IW Type  Backup VC    AC segment ssm id   Segment Status
----------- --------------------  -------  ---------   -------------------  --------------

   57             Gi4/3/3          L2L       No           20561                 UP
```

Related Commands

Command	Description
show platform atom imp-tbl remote-vc-label	Displays the imposition table on the line card for a VC based on the remote label.
show platform atom tbl-summary	Displays the total number of PWs programmed on the line card.
show platform atom imp-tbl backup	Displays the imposition table on the line card for backup VCs.
show platform atom disp-tbl backup	Displays the disposition table on the line card for backup VCs.

show platform atom imp-tbl backup

To display the imposition table on the line card for backup VCs, use the **showplatformatomimp-tblbackup** command in privileged EXEC mode .

show platform atom imp-tbl backup *pseudo-ckt-index*

Syntax Description

pseudo-ckt-index	Defines the *pseudocircuitindex*. The acceptable range is between 1 and 65537.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

The show platform atom imp-tbl backup command should be used while using the Hot-Standby Psuedo Wire (HSPW) feature.

Examples

The following example displays the imposition table on the Line Card for backup VCs.

```
Router# show platform atom imp-tbl backup

Pseudo Ckt Idx    Dlci or Vcd   Dest Vlanid   LTL Index   # Lbls Imposed   Remote Label

show platform atom imp-tbl remote-vc-label	Displays the imposition table on the line card for a VC based on the remote label.

show platform atom imp-tbl remote-vc-label

To display the imposition table on the line card for a VC based remote label, use the **showplatformatomimp-tblremote-vc-label** command in privileged EXEC mode .

show platform atom imp-tbl *remote-vc-label remote-vc-label*

Syntax Description

remote-vc-label	Defines the remote VC based label. The acceptable range is between 15 and 1048575.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

The **showplatformatomimp-tblremote-vc-label** command should be used only if the Remote VC Label for a VC is known.

Examples

The following example displays the imposition table on the Line Card for a VC based on the remote label.

```
Router# show platform atom imp-tbl remote-vc-label 97
Pseudo Ckt Idx    Dlci or Vcd   Dest Vlanid   LTL Index   # Lbls Imposed   Remote Label
--------------   -------------  ------------  ----------  ---------------  --------------
 49170                2           1028          0xFF            2               97
Local Label  Outgoing Interface   IW Type  Backup VC    AC segment ssm id   Segment Status
----------- --------------------  -------  ---------   -------------------  --------------

   57            Gi4/3/3         L2L      No           20561                UP
```

Related Commands

Command	Description
show platform atom disp-tbl local-vc-label	Displays the disposition table on the line card for a VC based on the local label.
show platform atom tbl-summary	Displays the total number of PWs programmed on the Line Card.
show platform atom imp-tbl backup	Displays the imposition table on the line card for backup VCs.
show platform atom disp-tbl backup	Displays the disposition table on the line card for backup VCs.

show platform atom tbl-summary

To display the total number of pseudowires (PWs) programmed on the line card., use the**showplatformatomtbl-summary** command in privileged EXEC mode .

show platform atom tbl-summary

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

The **showplatformatomtbl-summary** command is used to determine the primaryPWs and backup PWs that are programmed.

Examples

This example displays the total number of PWs programmed on the Line Card.

```
Router# show platform atom tbl-summary

 Total Number of entries(CWAN): 2, AToM Entries(LC): 2 Local Switching Entries(LC): 0
 AToM Entries Primary: 1, Backup: 1
```

Related Commands

Command	Description
show platform atom imp-tbl local-vc-label	Displays the imposition table on the line card for a VC based on the remote label.
show platform atom disp-tbl local-vc-label	Displays the disposition table on the line card for a VC based on the local label.
show platform atom imp-tbl backup	Displays the imposition table on the line card for backup VCs.
show platform atom disp-tbl backup	Displays the disposition table on the line card for backup VCs.

show platform condition

To display the currently active debug configuration, use the **show platform condition** command in privileged EXEC mode.

show platform condition

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE 3.10.0S	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.

Example

The following is sample output of the **show platform condition** command:

```
Router# show platform condition

Conditional Debug Global State: Start

Conditions                                                            Direction
----------------------------------------------------------------------|---------
VoIP-Null0                                & IPV4 [2.2.2.2/24]         both

```

The following table describes the significant fields shown in the display.

Table 189: show platform condition Field Descriptions

Field	Description
Conditions	Condition of platform debug.
Direction	Direction of platform debug.

show platform diag

To display diagnostic and debug information about individual platform components, use the **show platform diag** command in privileged EXEC mode.

show platform diag

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.2	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Usage Guidelines

This command can be used to display the debug and diagnostic information about the Cisco ASR 1000 shared port adapter (SPA) Interface Processor (SIP), SPA, Cisco ASR 1000 Embedded Services Processor (ESP), Cisco ASR 1000 Route Processor (RP), and power supplies. This command also indicates the status of the field replaceable unit (FRU) components in any Cisco ASR 1000 Series Router.

Use the **show platform diag** command to display the debug and diagnostic information related to your Cisco 4400 Series Integrated Services Router (ISR), any connected Service Modules (SM-X) or Network Interface Modules (NIMs), power supply for front panel Gigabit Ethernet (FPGE) ports, Fan Trays and other components of your router.

Examples

The following is sample output from the **show platform diag** command. The Embedded Services Processor (ESP) is shown as F0 or F1. The RPs are shown as R0 or R1. The power supplies are shown as P0 and P1.

```
Device# show platform diag

```

The table below describes the significant fields shown in the display.

Table 190: show platform diag Field Descriptions

Field	Description
Running state	The current online running state of the FRU component.
Internal state	The internal debug state of the FRU component for diagnostic purposes.
Internal operational state	The internal operational state of the FRU component for diagnostic purposes.
Physical insert detect time	The time of the most recent physical insertion of the FRU component detected by the platform code.
Software declared up time	The time that the software on the FRU component was declared running by the platform code.
Hardware ready signal time	The time that the hardware ready signal was detected by the platform code.
Packet ready signal time	The time that the ESP packet ready signal was detected by the platform code.
CPLD version	The Complex Programmable Logic Device (CPLD) version number.
Firmware version	The firmware ROM monitor (ROMMON) version number.
Logical insert detect time	The time that the SPA was logically detected by the platform code.
Became HA Active time	The time that this FRU became High Availability (HA) active.

Related Commands

Command	Description
show platform	Displays platform information.
show platform hardware	Displays platform hardware information.
show platform software	Displays platform software information.

show platform discover-devices

To display PCI device information, use the **showplatformdiscover-devices**command in privileged EXEC mode.

show platform discover-devices

Syntax Description

show platform discover-devices	Displays PCI device information.

Command Modes

Privileged EXEC mode

Command History

Release	Modification
15.1(1)T	This command was introduced for Cisco 3925E and Cisco 3945E Integrated Services Routers.

Usage Guidelines

Use the **showplatformdiscover-devices** command to display information about PCI devices on the router. The output shows the device name, interface slot and port, and detailed hardware information.

Examples

The following sample output shows PCI device information for Cisco 3925E ISR.

```
Router#show platform discover-devices
Discovered PCI device GE 0/0, GE 0/1
  root_port=2, bus_no=1, device_no=0, func_no=0, root_device_id=2
  DeviceID=0x10C9, VendorID=0x8086, Command=0x0146, Status=0x0010
  Class=0x02/0x00/0x00, Revision=0x01, LatencyTimer=0x00, CacheLineSize=0x10
  BaseAddr0=0xFD220000, BaseAddr1=0x00000000
Discovered PCI device GE 0/2, GE 0/3
  root_port=3, bus_no=2, device_no=0, func_no=0, root_device_id=3
  DeviceID=0x10C9, VendorID=0x8086, Command=0x0146, Status=0x0010
  Class=0x02/0x00/0x00, Revision=0x01, LatencyTimer=0x00, CacheLineSize=0x10
  BaseAddr0=0xFD120000, BaseAddr1=0x00000000
Discovered PCI device PLX:
  root_port=6, bus_no=37, device_no=0, func_no=0, root_device_id=6
  DeviceID=0x8509, VendorID=0x10B5, Command=0x0007, Status=0x0010
  Class=0x06/0x04/0x00, Revision=0xAA, LatencyTimer=0x00, CacheLineSize=0x10
  BaseAddr0=0xF8F00000, BaseAddr1=0x00000000

```

Table 191: Show Platform Discover-Devices Field Description

Field	Description
PCI Device	Identifies the PCI device on the router.
Root_port	Defines the root port address on the device.

Field	Description
Bus_no	Defines the bus number on the device.
Device_no	Defines the device number.
Func_no	Defines the function number.
Root_device_id	Defines the root device number.
DeviceID	Defines the device identifcation number.
VendorID	Defines the vendor identifcation number.
Operation Command	Defines the operation command.
Status of Device	Defines the status of device.
Class	Defines the class address.
Revision (type of device)	Defines type of device.
LatencyTimer	Defines the latency timer.
CacheLineSize	Defines cache line size.
Base Address	Address of Base.
Base Address 1	Address of Base 1.
Secondary Latency Timer	Defines secondary latency timer.
SubBus	Defines subordinate Bus number.
SecBus	Defines secondary Bus number.
PrimBus	Defines primary Bus number.
DeviceID	Defines the device identifcation number.
MemLimit	Defines the memory limit.
MemBase	Defines the memory base.
PrefMemLimit	Defines the pre-fetchable memory limit.
PrefMemBase	Defines the pre-fetchable memory base.

Related Commands

Command	Description
show platform cf	Shows CF support-related information.
show platform dma	Show DMA-related information.
show platform hw-module-power	Displays power settings of service modules.

Command	Description
show platform interrupt	Shows Interrupt-related information.
show platform io-controller	Displays IO-controller information.
show platform led	Shows LED-related information.
show platform nvram	Displays NVRAM-related information.
show platform versions	Displays versions/revisions of various modules.
show platform smbdev	Shows smbus slave devices.
show platform mgf	Shows multi-gigabit fabric information.

show platform dwdm alarm history

To display platform DWDM alarm history, use the **showplatformdwdmalarmhistory**command in privileged EXEC mode.

show platform dwdm alarm history [**port index**]

Syntax Description

port index	Specifies the port index. • For a 7600-ES+ITU-2TG, the valid values for the port index are 1, 2. • For a 7600-ES+ITU-4TG, the valid values for the port index are 1, 2, 3, 4.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series routers for the 7600-ES+ITU-2TG and the 7600-ES+ITU-4TG line cards only.

Usage Guidelines

If the port index is not specified, the alarm history (last 32 alarms) for all ports on that line card whose interface transport mode is Optical Transport Network (OTN) is displayed. If a port index is specified, the alarm history (last 32 alarms) for that particular port is displayed, if the interface transport mode of that port is OTN. An alarm is logged in the alarm history only if the reporting for that alarm is enabled. If reporting for an alarm is disabled with the no g709 otu report command or the no g709 odu report command, then neither the alarm declaration nor clearing will be logged in the alarm history.

Examples

The following examples illustrate the command when interface TenGigabitEthernet 2/1 and interface TenGigabitEthernet 2/3 are configured with a transport-mode of OTN. Because the transport modes of interface TenGigabitEthernet 2/2 and interface TenGigabitEthernet 2/4 are not OTN, nothing is displayed for dwdm 2/2 and dwdm 2/4.

```

Related Commands

Command	Description
show controllers dwdm	Displays ITU-T G.709 alarms, alerts, and counters for a DWDM controller.

show platform hardware capacity

To display the capacities and utilizations for the hardware resources, use the **show platform hardware capacity** command in privileged EXEC mode.

show platform hardware capacity [*resource-type*]

Syntax Description

resource-type	(Optional) Hardware resource type; see the "Usage Guidelines" section for the valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXF	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI. Support was added for the **ibc** and **rewrite-engine** keywords.

Usage Guidelines

The valid values for *resource-type* are as follows:

- **acl** --Displays the capacities and utilizations for ACL/QoS TCAM resources.
- **cpu** --Displays the capacities and utilizations for CPU resources.
- **eobc** --Displays the capacities and utilizations for Ethernet out-of-band channel resources.
- **fabric** --Displays the capacities and utilizations for Switch Fabric resources.
- **flash** --Displays the capacities and utilizations for Flash/NVRAM resources.
- **forwarding** --Displays the capacities and utilizations for Layer 2 and Layer 3 forwarding resources.
- **ibc** --Displays the capacities and utilizations for interboard communication resources.
- **interface** --Displays the capacities and utilizations for interface resources.
- **monitor** --Displays the capacities and utilizations for SPAN resources.
- **multicast** --Displays the capacities and utilizations for Layer 3 multicast resources.
- **netflow** --Displays the capacities and utilizations for NetFlow resources.
- **pfc** --Displays the capacities and utilizations for all the PFC resources including Layer 2 and Layer 3 forwarding, NetFlow, CPU rate limiters, and ACL/QoS TCAM resources.
- **power** --Displays the capacities and utilizations for power resources.
- **qos** --Displays the capacities and utilizations for QoS policer resources.
- **rate-limit** --Displays the capacities and utilizations for CPU rate limiter resources.

- **rewrite-engine** --Displays the packet drop and performance counters of the central rewrite engine on supervisors and line cards. For detailed information, see the **show platform hardware capacity rewrite-engine** command documentation.
- **system** --Displays the capacities and utilizations for system resources.
- **vlan** --Displays the capacities and utilizations for VLAN resources.

The **show platform hardware capacity cpu**command displays the following information:

- CPU utilization for the last 5 seconds (busy time and interrupt time), the percentage of the last 1-minute average busy time, and the percentage of the last 5-minute average busy time.
- Processor memory total available bytes, used bytes, and percentage used.
- I/O memory total available bytes, used bytes, and percentage used.

The **show platform hardware capacity eobc**command displays the following information:

- Transmit and receive rate
- Packets received and packets sent
- Dropped received packets and dropped transmitted packets

The **show platform hardware capacity forwarding** command displays the following information:

- The total available entries, used entries, and used percentage for the MAC tables.
- The total available entries, used entries, and used percentage for the FIB TCAM tables. The display is done per protocol base.
- The total available entries, used entries, and used percentage for the adjacency tables. The display is done for each region in which the adjacency table is divided.
- The created entries, failures, and resource usage percentage for the NetFlow TCAM and ICAM tables.
- The total available entries and mask, used entries and mask, reserved entries and mask, and entries and mask used percentage for the ACL/QoS TCAM tables. The output displays the available, used, reserved, and used percentage of the labels. The output displays the resource of other hardware resources that are related to the ACL/QoS TCAMs (such as available, used, reserved, and used percentage of the LOU, ANDOR, and ORAND).
- The available, used, reserved, and used percentage for the CPU rate limiters.

The **show platform hardware capacity interface** command displays the following information:

- Tx/Rx drops--Displays the sum of transmit and receive drop counters on each online module (aggregate for all ports) and provides the port number that has the highest drop count on the module.
- Tx/Rx per port buffer size--Summarizes the port-buffer size on a per-module basis for modules where there is a consistent buffer size across the module.

The **show platform hardware capacity monitor** command displays the following SPAN information:

- The maximum local SPAN sessions, maximum RSPAN sessions, maximum ERSPAN sessions, and maximum service module sessions.

- The local SPAN sessions used/available, RSPAN sessions used/available, ERSPAN sessions used/available, and service module sessions used/available.

The **show platform hardware capacity multicast** command displays the following information:

- Multicast Replication Mode: ingress and egress IPv4 and IPv6 modes.
- The MET table usage that indicates the total used and the percentage used for each module in the system.
- The bidirectional PIM DF table usage that indicates the total used and the percentage used.

The **show platform hardware capacity system**command displays the following information:

- PFC operating mode (PFC Version: PFC3A, PFC3B, unknown, and so forth)
- Supervisor redundancy mode (RPR, RPR+, SSO, none, and so forth)
- Module-specific switching information, including the following information:
    - Part number (WS-SUP720-BASE, WS-X6548-RJ-45, and so forth)
    - Series (supervisor engine, fabric, CEF720, CEF256, dCEF256, or classic)
    - CEF Mode (central CEF, dCEF)

The **show platform hardware capacity vlan** command displays the following VLAN information:

- Total VLANs
- VTP VLANs that are used
- External VLANs that are used
- Internal VLANs that are used
- Free VLANs

Examples

This example shows how to display CPU capacity and utilization information for the route processor, the switch processor, and the LAN module in the Cisco 7600 series router:

```
Router# show platform hardware capacity cpu
CPU Resources
  CPU utilization: Module             5 seconds       1 minute       5 minutes
                   1  RP               0% /  0%             1%              1%
                   1  SP               5% /  0%             5%              4%
                   7                  69% /  0%            69%             69%
                   8                  78% /  0%            74%             74%
  Processor memory: Module   Bytes:       Total           Used           %Used
                    1  RP             176730048       51774704             29%
                    1  SP             192825092       51978936             27%
                    7                 195111584       35769704             18%
                    8                 195111584       35798632             18%
  I/O memory: Module         Bytes:       Total           Used           %Used
              1  RP                    35651584       12226672             34%
              1  SP                    35651584        9747952             27%
              7                        35651584        9616816             27%
              8                        35651584        9616816             27%
Router#
```

This example shows how to display EOBC-related statistics for the route processor, the switch processor, and the DFCs in the Cisco 7600 series router:

```
Router# show platform hardware capacity eobc
EOBC Resources
  Module                     Packets/sec     Total packets     Dropped packets
  1  RP      Rx:                      61            108982                   0
             Tx:                      37             77298                   0
  1  SP      Rx:                      34            101627                   0
             Tx:                      39            115417                   0

```

```
  Destination sessions: 64 maximum, 0 used
    Type                                    Used
    RSPAN destination                          0
    ERSPAN destination (max  24)               0
Router#
```

This example shows how to display the capacity and utilization of resources for Layer 3 multicast functionality:

```
Router# show platform hardware capacity
 multicast
L3 Multicast Resources
  IPv4 replication mode: ingress
  IPv6 replication mode: ingress
  Bi-directional PIM Designated Forwarder Table usage: 4 total, 0 (0%) used
  Replication capability: Module                              IPv4        IPv6
                          5                                 egress      egress
                          9                                ingress     ingress
  MET table Entries: Module                             Total    Used    %Used
                     5                                  65526       6       0%
Router#
```

This example shows how to display information about the system power capacities and utilizations:

```
Router# show platform hardware capacity power
Power Resources
  Power supply redundancy mode: administratively combined
                                                        operationally combined
  System power: 1922W, 0W (0%) inline, 1289W (67%) total allocated
  Powered devices: 0 total
Router#
```

This example shows how to display the capacity and utilization of QoS policer resources per EARL in the Cisco 7600 series router:

```
Router# show platform hardware capacity qos
 QoS Policer Resources
  Aggregate policers: Module                      Total         Used     %Used
                      1                            1024          102       10%
                      5                            1024            1        1%
  Microflow policer configurations: Module        Total         Used     %Used
                                    1                64           32       50%
                                    5                64            1        1%
Router#
```

This example shows how to display information about the key system resources:

```
Router# show platform hardware capacity system
System Resources
  PFC operating mode: PFC3BXL
  Supervisor redundancy mode: administratively rpr-plus, operationally rpr-plus
  Switching Resources: Module   Part number               Series      CEF mode
                       5        WS-SUP720-BASE        supervisor           CEF
                       9        WS-X6548-RJ-45            CEF256           CEF
Router#
```

This example shows how to display VLAN information:

```
Router# show platform hardware capacity vlan
VLAN Resources
```

```
  VLANs: 4094 total, 10 VTP, 0 extended, 0 internal, 4084 free
Router#
```

Related Commands

Command	Description
show msfc	Displays MSFC information.
show platform	Displays platform information.
show platform hardware capacity rewrite-engine	Displays the packet drop and performance counters of the central rewrite engine on supervisors and line cards.

show platform hardware capacity rewrite-engine

To display the packet drop and performance counters of the central rewrite engine on supervisors and line cards, use the **show platform hardware capacity rewrite-engine** command in privileged EXEC mode.

show platform hardware capacity rewrite-engine {**drop** | **performance**} [**slot** *number*] [**rate** [{*sample interval*}]][**details**]

Syntax Description

drop	Displays the central rewrite engine drop counter values.
performance	Displays the central rewrite engine current performance counter values or the performance rate.
slot *number*	(Optional) Displays the counter values for the module in the specified slot. If no slot is specified, the counters are displayed for each slot.
rate [*sample_interval*]	(Optional) Displays the drop rate or rewrite rate for a sample interval in msec between 1 and 1000. The default interval is 50 msec.
details	(Optional) Displays each individual drop counter with its name and register ID number. This keyword is not available with the **performance** keyword.

Command Default

If the sample interval is not specified, the default interval is 50 msec.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(33)SXI	This command was introduced.
15.1(1)S	Support was added for Cisco 7600 routers. This command replaces the **show platform hardware central-rewrite**command.

Usage Guidelines

In the output of the **show platform hardware capacity rewrite-engine performance** command output, a value of �N/A� means the slot/channel has a rewrite engine, but does not support performance counters.

Examples

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays the packet drop counters of the central rewrite engine in all installed supervisors and line cards:

```
Router# show platform hardware capacity rewrite-engine drop
slot channel   packet drops      total overruns
----+---------+-----------------+------------------+
1    0         0                 0
5    0         15440040          22
7    0         44                0
7    1         0                 0
```

Examples

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays the packet drop counters of the central rewrite engine in all installed supervisors and line cards:

```
Router# show platform hardware capacity rewrite-engine drop
slot channel   packet drops      total overruns
----+---------+-----------------+------------------+
1    0         0                 0
5    0         15440040          22
7    0         44                0
7    1         0                 0
```

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays a detailed report of the packet drop counters of the module in slot 1:

```
Router# show platform hardware capacity rewrite-engine drop slot 1 details
slot channel drop_id description          packet drops     total overruns
----+-------+-------+--------------------+----------------+--------------+
1    0       0x5ED   DROP NON BPDU        0                0
1    0       0x5EB   DROP BPDU            0                0
1    1       0x5ED   DROP NON BPDU        0                0
1    1       0x5EB   DROP BPDU            0                0
```

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays the packet drop counters of the module in slot 5 over the default sample interval of 50 msec:

```
Router# show platform hardware capacity rewrite-engine drop slot 5 rate
slot channel   drop rate [pps]        overrun [Y/N]
----+---------+----------------------+-------------+
5    0         120079                 Y
```

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays the packet drop counters of the module in slot 5 over a sample interval of 20 msec:

```
Router# show platform hardware capacity rewrite-engine drop slot 5 rate 20
slot channel   drop rate [pps]        overrun [Y/N]
----+---------+----------------------+-------------+
5    0         180000                 N
```

The following sample output of the **show platform hardware capacity rewrite-engine drop**command displays the performance counters of the central rewrite engine in all installed supervisors and line cards:

```
Router# show platform hardware capacity rewrite-engine performance
slot channel perf_id description          packets          total overruns

Related Commands

Command	Description
clear platform hardware capacity rewrite-engine counter	Clears the packet drop and performance counters of the central rewrite engine on supervisors and line cards.

show platform hardware interface

To display information about an interface, use the **showplatformhardwareinterface**command in privileged EXEC or diagnostic mode.

show platform hardware interface type number plim qos input map

Channelized T3 Shared Port Adapters
show platform hardware interface serial slot/subslot/port/t1-number:channel-group plim qos input map

Channelized T1/E1 Shared Port Adapters
show platform hardware interface serial slot/subslot/port:channel-group plim qos input map

Shared Port Adapters
show platform hardware interface type slot/subslot/port [.subint] plim qos input map

Syntax Description

type	Interface type. The table in the "Usage Guidelines" contains a list of interface types.
number	Port number on the selected interface.
plim qos input map	Physical Line Interface Module (PLIM) QoS input mapping information.
serial	Serial interface.
slot/subslot/port/t1-number:channel-group	The following applies to Channelized T3 shared port adapters: • slot/--Chassis slot where the Cisco ASR 1000 Series SPA interface processor (SIP) is installed. • subslot/--Secondary slot number of the SIP where the Cisco ASR 1000 Series shared port adapter (SPA) is installed. • port/--Interface number on the SPA. • t1-number--T1 time slot in the T3 line. The value can be from 1 to 28. • channel-group--Number 0 to 23 of the DS0 link on the T1 channel. **Note** When a port on a Channelized T3 SPA is configured to be in unchannelized mode, only the slot/subslot/port/ arguments are used to specify the unchannelized T3 interface. The t1-number and channel-group arguments are not used.

slot/subslot/port: channel-group	The following applies to Channelized T1/E1 shared port adapters: • slot/--Chassis slot where the Cisco ASR 1000 Series SPA interface processor (SIP) is installed. • subslot/--Secondary slot number of the SIP where the Cisco ASR 1000 Series shared port adapter (SPA) is installed. • port--Interface number on the SPA. • channel-group--Number 0 to 30 of the DS0 link on the T1 channel.
slot/subslot/port [.subint]	The following applies to shared port adapters other than the Channelized T3 or Channelized T1/E1 shared port adapters: • slot/--Chassis slot where the Cisco ASR 1000 Series SPA interface processor (SIP) is installed. • subslot/--Secondary slot number of the SIP where the Cisco ASR 1000 Series shared port adapter (SPA) is installed. • port--Interface number on the SPA. • (Optional) .subint--Subinterface number (for those SPAs that support subinterface configuration).

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

This command displays platform-specific information and configuration information related to a specific interface.

The table below lists the interface types.

Table 192: Interface Types

Interface Type	Description
async	Asynchronous interface
auto-template	Auto-template interface
bvi	Bridge group virtual interface
ctunnel	Connectionless Network Service (CLNS) tunnel (CTunnel) interface
container	Container interface

Interface Type	Description
dialer	Dialer interface
esconphy	ESCON interface
fastethernet	Fast Ethernet IEEE 802.3 interface
filter	Filter interface
filtergroup	Filter group interface
gigabitethernet	Gigabit Ethernet IEEE 802.3 interface.
group-async	Group asynchronous interface
lex	LAN extender (LEX) interface
longreachethernet	Long Reach Ethernet interface
loopback	Loopback interface
multilink	Multilink group interface
null	Null interface
pos	Packet over SONET (POS) interface
port-channel	Ethernet channel of interfaces
portgroup	Port group interface
pos-channel	POS channel of interfaces
sbc	Session border controller interface
sysclock	Telecom bus clock controller interface
serial	Serial interface
tunnel	Tunnel interface
vif	Pragmatic General Multicast (PGM) host interface
virtual-ppp	Virtual point-to-point (PPP) interface
virtual-template	Virtual template interface
virtual-tokenring	Virtual Token Ring interface
vlan	Catalyst VLAN interface
fcpa	Fiber Channel interface
multiservice	Multiservice interface
voabyapssin	Variable optical attenuator (VOA) bypass-in interface

Interface Type	Description
voabyapssout	VOA bypass-out interface
voafilterin	VOA filter-in interface
voafilterout	VOA filter-out interface
voain	VOA-in interface
voaout	VOA-out interface

Examples

Packets can be classified based on the IP precedence, IPv6 traffic class, MPLS experimental bits, or VLAN TOS bits. In the following example, incoming packets with IP precedence 6 or 7, IPv6 packets with traffic class 46, and MPLS packets with experimental bits 6 or 7 are classified as high priority packets:

```
Router# show platform hardware interface gigabitethernet 0/0/0 plim qos input map
Interface GigabitEthernet0/0/0
Low Latency Queue(High Priority):
IP PREC, 6, 7
IPv6 TC, 46
MPLS EXP, 6, 7
```

Related Commands

Command	Description
show platform hardware port	Displays information about an interface port on a shared port adapter (SPA).
show platform hardware slot	Displays information about the processor in a chassis slot.
show platform hardware subslot	Displays information about a shared port adapter (SPA).

show platform hardware network-clocks

To display network clocks for an ES+ line card, use the **showplatformhardwarenetwork-clocks**command in privileged EXEC mode.

show platform hardware network-clocks [{**bits** | **zl30138**}]

Syntax Description

bits	Specifies uilding Integrated Timing Supply (BITS) element.
zl30138	Specifies ZL30138 SONET/SDH/10GbE System Synchronizer.
sec GNSS	Displays the standby GNSS module device information.

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series routers for ES+ line cards only.

Examples

The following example shows how the **showplatformhardwarenetwork-clocks**command is used to display network clocks:

```
Router# show platform hardware network-clocks

Local Loop Timing:

    Port 1: N    Port 2: N    Port 3: N    Port 4: N

Backplane Bus Status and Source:

    Primary   : Disabled, Port 0 RX_DEMAP Clock
    Secondary : Disabled, Port 0 RX_DEMAP Clock
    BITS      : Disabled, Port 0 RX_DEMAP Clock

ZL30138 Configuration and Status:

    DPLL1: Failure (4)
        Mode of Operation  : Manual Freerun
        Selected Reference : 0
        Ref0 Priority : 15        Ref1 Priority : 15
        Ref2 Priority : 15        Ref3 Priority : 15
        Ref4 Priority : 15        Ref5 Priority : 15
        Ref6 Priority : 15        Ref7 Priority : 15

    Reference Monitoring: Custom A frequency 25000 kHz
        Ref#    SCM    CFM    GST    PFM    Mode      Detected
        ----------------------------------------------------------
        0       1      1      1      1      CustA     38.88 MHz
        1       1      1      1      1      CustA     19.44 MHz
        2       0      0      0      0      Auto      77.76 MHz
        3       1      1      1      1      CustA     not detected
        4       1      1      1      1      Auto      not detected
```

```
        5       1       1       1       1       Auto      not detected
        6       1       1       1       1       Auto      not detected
        7       1       1       1       1       Auto      not detected

BITS Configuration and Status:

    Signal Type   : T1 ESF Framing
    Clock Divider : 1.544 MHz

Router# show platform hardware network-clocks | sec GNSS
GNSS status
  GNSS device: not detected
  Lock status: Disabled

Related Commands

Command	Description
hw-module subslot *slot* / *subslot* **ether-mode 10G**	Configures the 10G mode from 1G mode.
hw-module subslot *slot* / *subslot* **ether-mode 1G**	Configures the 1G mode from 10G mode.

show platform hardware qfp active feature cef-mpls urpf

To confirm and display the hardware information pertaining to Cisco Express Forwarding (CEF) Multiprotocol Label Switching (MPLS) Unicast Reverse Path Forwarding (uRPF) feature on a Cisco QuantumFlow Processor (QFP) of the Cisco ASR 1000 Series Aggregation Services Routers, use the **show platform hardware qfp active feature cef-mpls urpf** command in privileged EXEC mode.

show platform hardware qfp active feature cef-mpls urpf *interface-name ip-version ip version*

Syntax Description

ip-version	Name of the interface.
interface-name	Version of the IP. Valid values are IPv4 and IPv6.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.0S	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following is a sample output of the **show platform hardware qfp active feature cef-mpls urpf** command:

```
Device# show platform hardware qfp active feature cef-mpls urpf GigabitEthernet 0/0/0.777
ipv4

=== uRPF Information ===
  uRPF mode: Strict
  allow_default_route: FALSE
  allow_self_ping: FALSE
```

Related Commands

The table below describes the significant fields shown in the display.

Table 193: show platform hardware qfp active feature cef-mpls urpf Field Descriptions

Field	Description
uRPF mode	Mode of uRPF. Valid values are Strict or Loose..
allow_default_route	State showing whether the QFP allows the use of the default route in the source verification process or not. Valid values are TRUE or FALSE.
allow_self_ping	State showing whether the QFP allows the source of the packet to ping itself during the source verification process or not. Valid values are TRUE or FALSE.

show platform hardware qfp active feature cef-mpls prefix ip

To display the interface name along with the interface descriptor block (IDB) information, use the **showplatformhardwareqfpactivefeaturecef-mplsprefixip** command in privileged EXEC.

show platform hardware qfp active feature cef-mpls prefix ip {*ipv4 prefix* | [**vrf** [{*id*}]] [**exact**] [**brief**]}

Syntax Description

ipv4 prefix	IPv4 address and mask.
vrf	(Optional) Displays information about VPN Routing and Forwarding (VRF).
id	(Optional) Information about the particular VRF instance. The range is from 0 to 4294967295. If no VRF ID is specified, information about the global VRF, which is the prefix in global routing table, is displayed.
exact	(Optional) Find and displays the exact match of the IPV4 prefix.
brief	(Optional) Displays a summary of prefix information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)XNB	This command was introduced on the Cisco ASR 1000 Series Routers.
Cisco IOS XE Release 3.4S	This command was integrated into Cisco IOS Release XE 3.4S. Support for IP Fast Reroute (IP FRR) was added.

Examples

The following is sample output from the**showplatformhardwareqfpactivefeaturecef-mplsprefixip** command:

```
Router# show platform hardware qfp active feature cef-mpls prefix ip 0.0.0.0/1 vrf

```

show platform hardware qfp active feature cef-mpls prefix mpls

To display the complete Output Chain Element (OCE) chains used for handling the incoming Multiprotocol Label Switching (MPLS) packets with a particular label, use the show platform hardware qfp active feature cef-mpls prefix mpls command in the privileged EXEC mode.

show platform hardware qfp active feature cef-mpls prefix mpls mpls-label exact

Syntax Description

mpls-label	MPLS label containing a 20-bit label value, a 3-bit experimental field, a 1-bit bottom-of-stack indicator, and an 8-bit Time-to-Live (TTL) field.
exact	Displays all the OCE chains that are used for handling the incoming MPLS packets with a particular label.

Command Modes

Privileged EXEC (#)

show platform hardware qfp active feature multicast

To display the complete Output Chain Element (OCE) chains that are connected by each leaf node in the multicast replication tree for a particular output path in the Cisco QuantumFlow Processor (QFP) active feature on the Cisco ASR 1000 Series Aggregation Services Routers, use the show platform hardware qfp active feature multicast command in the privileged EXEC mode.

show platform hardware qfp active feature multicast ip-version ip-address-mgroup [**ip-address-source**] **vrf vrf-id extension**

Syntax Description

ip-version	Version of the IP address. It can be one of the following values: • v4mcast—IPv4. • v6mcast—IPv6.
ip-address-mgroup	Multicast group's IP address.
ip-address-source	(Optional) Source prefix for the IP address.
vrf	Displays information present in a particular VRF.
vrf-id	ID of the VRF.
extension	Displays the entire OCE that is connected by each leaf node in the multicast replication tree for a particular output path.

Command Modes

Privileged EXEC (#)

Command History

show platform hardware qfp active infrastructure punt

To display the hardware and infrastructure information for punt statistics and configuration in an active instance of the Cisco Quantum Flow Processor (QFP), use the **show platform hardware qfp active infrastructure punt** command in privileged EXEC mode.

show platform hardware qfp active infrastructure punt [**config** | **internal-interface** | **policer** | **statistics** **{ interface** |**qfp** |**type** [**global-drop** | **inject-drop** | **per-cause** | **punt-drop**] }]

Syntax Description

config	Specifies the entries in the punt table.
internal-interface	Specifies the configuration for an internal interface.
policer	Specifies the punt policer configuration.
statistics	Specifies the punt statistics.
interface	Specifies the punt statistics for an interface.
qfp	Specifies the punt statistics for a specific qfp.
type	Specifies the aggregate statistics.
global-drop	Specifies the aggregate drop statistics.
inject-drop	Specifies the aggregate inject drop statistics.
per-cause	Specifies the aggregate per cause punt statistics.
punt-drop	Specifies the aggregate punt drop statistics.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE 3.2.0S	This command was introduced.
Cisco IOS XE 3.13.0S	This command was integrated into Cisco IOS XE Release 3.13.0S.

Example

The following is sample output of the **show platform hardware qfp active infrastructure punt config** command:

```
Router# show platform hardware qfp active infrastructure punt config
Punt table base addr : 0x89C91010
  punt cause index     96
  punt cause name      VLAN Auto Sense FSOL
  maximum instances    1
  punt table address : 0x89C91190
  instance[0] ptr    : 0x89C919A0
    QFP interface handle : 2
```

```
    Interface name       : internal0/0/rp:0
   instance address        : 0x89C919A0
    fast failover address   : 0x89C8EC94
    Low priority policer    : 128
    High priority policer   : 129
```

The following table describes the significant fields shown in the display.

Table 194: show platform hardware qfp active infrastructure punt config Field Descriptions

Field	Description
Punt table base addr	Base address of the punt table.
punt cause index	Index number of the punt cause
punt cause name	Name of the punt cause.
maximum instances	The number of instances.
punt table address	Address of the punt table.
instance[0] ptr	Address where the packets are stored for each of the punt cause.
QFP interface handle	The handle number of the qfp interface.
Interface name	Name of the interface.
instance address	Points to the address for each instance.
fast failover address	Points to the address for a fast failover.
Low priority policer	Low priority policer number.
High priority policer	High priority policer number.

Example

The following is sample output of the **show platform hardware qfp a infrastructure punt policer** command:

```
Router# show platform hardware qfp active infrastructure punt policer
QFP Punt Policer Config Summary

Policer  Rate      PeakRate   ConformBurst  ExceedBurst   Scaling
Handle   (pps)     (pps)      (pps)         (pps)         Factor
---------------------------------------------------------------------
001      146484    0          2288          2288          0
002      4000      0          4000          0             0
003      3000      0          3000          0             0
004      40000     0          40000         0             0
```

The following table describes the significant fields shown in the display.

Table 195: show platform hardware qfp a infrastructure punt config Field Descriptions

Field	Description
Policer Handle	Indicates the number of the policer handle.
Rate	Indicates the configured rate in packets per second (pps).
Peak Rate	Indicates the peak rate in pps.
Conform Burst	Displays the number of packets marked as conforming to a specified rate.
Exceed Burst	Displays the number of packets marked as exceeding a specified rate.
Scaling Factor	Indicates the scaling factor.

Example

The following is sample output of the **show platform hardware qfp active infrastructure statistics type per-cause** command. The fields in the display are self-explanatory.

```
Router# show platform hardware qfp active infrastructure punt statistics type per-cause

Global Per Cause Statistics

  Number of punt causes =   97

  Per Punt Cause Statistics
                                                       Packets          Packets
  Counter ID  Punt Cause Name                          Received         Transmitted
  -------------------------------------------------------------------------------------
  000         Reserved                                 0                0

```

```
  004         PPP Control                            0
…
```

show platform hardware qfp active interface if-name statistics

To display the statistics of packet drops for each interface in the Packet Processor Engine (PPE), use the **show platform hardware qfp active interface if-name statistics** command in privileged EXEC mode.

show platform hardware qfp active interface if-name *type number* **statistics**

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.0	This command was introduced.

Usage Guidelines

You can use this command for troubleshooting the problems on an interface in a PPE by analyzing the statistics of packet drops.

Examples

The following sample output from the **show platform hardware qfp active interface if-name statistics** command displays the statistics of packet drops on the Gigabit Ethernet interface 0/0/0.781 interface:

```
Router # show platform hardware qfp active GigabitEthernet0/0/0.781 if-name statistics

----------------------------------------------------------------
Receive Stats                                   Packets        Octets
----------------------------------------------------------------
  Ipv4                                              2           322
  Ipv6                                              0             0
  Tag                                               0             0
  McastIpv4                                         0             0
  McastIpv6                                         0             0

      2) the interface stats include the subinterface

Interface                                       Rx Pkts             Tx Pkts
----------------------------------------------------------------------------
GigabitEthernet0/0/0.781                             25                   0
```

The following table describes the fields shown in the display.

Table 196: show platform hardware qfp active interface if-name statistics Field Descriptions

Field	Description
Receive Stats	Number of packets received.
Packets	Number of packets that are received.
Octets	Total number of bytes of the packets that are received.
Transmit Stats	Number of packets that are transmitted on an interface.
Input Drop Stats	The drop cause and the number of incoming packets that are dropped. • pv4uRpfStrictFailed - Specifies the number and bytes of packets that are dropped with this drop cause. • Ipv6uRpfStrictFailed - Specifies the number and bytes of packets that are dropped with this drop cause
Packets	Number of packets that are transmitted. • IPv4uRpfStrictFailed received 5 packets. • IPv6uRpfStrictFailed received 5 packets.
Octets	Total number of bytes of the packets that are received. • IPv4uRpfStrictFailed received 590 bytes of packets. • IPv6uRpfStrictFailed received 590 bytes of packets.
Output Drop Stats	Specifies the drop cause and the number of outgoing packets that are dropped.
Interface	Name of the interface.
Rx Pkts	Number of packets received on an interface.
Tx Pkts	Number of packets transmitted on an interface.

Related Commands

Command	Description
show platform hardware qfp active statistics drop	Displays the statistics of packet drops on all the interfaces in a PPE.

show platform hardware qfp statistics drop

To display the statistics of all the dropped packets on the Embedded Services Processor (ESP), use the **show platform hardwareqfp active statistics drop** command in privileged EXEC mode.

show platform hardware qfp {**active** | **standby**} **statistics drop**

Syntax Description

active	Active forwarding processor.
standby	Standby forwarding processor .

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.0	This command was introduced.
Cisco IOS XE Release 3.5	This command was modified for Cisco ASR 1000 Series Routers. A new drop type, PPPoECAC, was added to the**show platform hardware qfp active statistics drop** command.

Usage Guidelines

You can use this command for troubleshooting the problems on all the interfaces in a PPE by analyzing the statistics of packet drops.

You can use this command for troubleshooting the problems on all the interfaces in a packet processing engine (PPE) by analyzing the statistics of packet drops.

To improve the CPU utilization and memory of the Route Processor (RP) on Cisco ASR 1000 Series Router, the SRSM hardware feature has been implemented. When Call Admission Control (CAC) is enabled and the CAC threshold level is reached, the PPPoE packets are punted on the Embedded Service Processor (ESP) instead of being sent to the RP. Managing the PPPoE packets at the ESP level helps in controlling and minimizing RP CPU and memory utilization. A new drop type, PPPoECAC, is added to the**show platform hardware qfp active statistics drop** command which indicates the number of PPPoE Active Discovery Initiation (PADI) and PPPoE Active Discovery Request (PADR) packets rejected by the hardware due to call admission control.

Note The **show call admission statistics** command shows how many packets were dropped by the RP and the **show platform hardware qfp active statistics drop** command indicates how many packets were dropped by the ESP. A small number of packets are still dropped by the RP because it takes time for the drop message to reach the ESP. The actual number of packets dropped by SRSM is the total number of packets dropped by **show call admission statistics** and **show platform hardware qfp active statistics drop** commands.

Examples

The following sample output from the **show platform hardware qfp active statistics drop** command displays the statistics of packet drops on all the interfaces in a PPPoE:

```
Router# show platform hardware qfp active statistics drop

Global Drop Stats                         Packets              Octets

The following table describes the fields shown in the display.

Table 197: show platform hardware qfp active statistics drop Field Descriptions

Field	Description
Global Drop Stats	The reason for dropping packets. • pv4uRpfStrictFailed - Specifies the number and bytes of packets that are dropped with this drop cause. • Ipv6uRpfStrictFailed - Specifies the number and bytes of packets that are dropped with this drop cause
Packets	Number of packets that are dropped. • IPv4uRpfStrictFailed dropped 10 packets. • IPv6uRpfStrictFailed dropped 10 packets.
Octets	Total number of bytes of the packets that are dropped. • IPv4uRpfStrictFailed dropped 1180 bytes of packets. • IPv6uRpfStrictFailed dropped 1180 bytes of packets.

Related Commands

Command	Description
show platform hardware qfp interface	Displays information about an interface in the target flow processor.
show platform hardware qfp active interface if-name statistics	Displays the statistics of packet drops for each interface in the Packet Processor Engine (PPE).

show platform hardware qfp interface

To display information about an interface in the target flow processor, use the **show platform hardware qfp interface** command in privileged EXEC mode.

show platform hardware qfp {**active** | **standby**} **interface** {**all** [{**summary** | **statistics** [**drop_summary** [{**subinterface**}]] [{**clear_drop**}] [{**detail**}]}] | **dsp** {**client resource** *dsp-resource-id* | **global clear** | **stream** *stream-id*} | {**if-name** *name* | **if-handle** *handle*} [{**info** | **path** | **statistics** [**drop_summary** [{**subinterface**}]] | [{**clear_drop**}] | [{**detail**}]}] | **atm if-name** *name* **statistics** [{**clear_drop**}]}

Syntax Description

active	Specifies the active instance of the processor.
standby	Specifies the standby instance of the processor.
interface	Specifies interfaces.
all	Specifies all interfaces available on the processor.
summary	(Optional) Specifies the interface summary report.
statistics	(Optional) Specifies the statistics of transmitted and received packets.
drop_summary	(Optional) Specifies the drop status summary report.
subinterface	(Optional) Specifies the subinterface and the drop statistics.
clear_drop	(Optional) Clears the drop statistics after reading.
detail	(Optional) Shows drop cause IDs.
dsp	Specifies digital signal processor (DSP) statistics.
client	Specifies DSP client statistics.
resource	Specifies DSP client resource statistics.
dsp-resource-id	Combinet Packet Protocol (CPP) DSP resource ID.
global	Specifies DSP global statistics.
clear	Clears statistics after reading.
stream	Specifies DSP stream statistics.
stream-id	Stream ID.
if-name *name*	Specifies the name of an interface, interface type, and port number of the selected interface.
if-handle *handle*	Specifies the quantum flow processor (QFP) interface handle number.
info	(Optional) Specifies interface information.

path	(Optional) Specifies path information.
atm	Specifies information and statistics for the ATM interface.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.
Cisco IOS XE Release 2.5	This command was modified. The **cpp** keyword was changed to **qfp**.
12.2(33)XNE	This command was integrated into Cisco IOS Release 12.2(33)XNE.
Cisco IOS XE Release 3.8S	This command was modified. The **path** keyword was added.

Usage Guidelines

The **show platform hardware qfp interface** command displays information about the relationship between one interface and another in the target flow processor. In the command output, the main interface is identified if the interface is a subinterface; the group interface is identified if the interface is a member of a group; and the interfaces that are members of the group are identified if the interface is a group, bundle, or multipoint interface.

Examples

The following sample output shows information about the relationship between one interface and the other on the target flow processor:

```
Device# show platform hardware qfp active interface if-name Port-channel1 info

General interface information
  Interface Name: Port-channel1
  Platform interface handle: 36
  QFP interface handle: 36
  Rx uidb: 131064
  Tx uidb: 131036
  Channel: 0
Interface Relationships
  if_h   Member Interface Name
  10      GigabitEthernet0/0/2
  11      GigabitEthernet0/0/3
```

The table below describes the significant fields shown in the display.

Table 198: show platform hardware qfp interface Field Descriptions

Field	Description
Interface Name	Name of the interface requested by the **show platform hardware qfp interface** command.
Platform interface handle	Number of platform interface handles displayed for the interface.
QFP interface handle	Internal identifier assigned by the QFP software for this interface.
Rx uidb	Internal identifier for the receive side of the interface.

Field	Description
Tx uidb	Internal identifier for the transmit side of the interface.
Channel	Internal identifier for the transmit path to which the interface is connected.

The following sample output shows the summary of the drop status of the packets:

```
Device# show platform hardware qfp active statistics drop

Global Drop Stats                         Packets                  Octets

```

The table below describes the significant fields shown in the display.

Table 200: show platform hardware qfp active interface if-name statistics Field Descriptions

Field	Description
Receive Stats	Number of packets received through a protocol.
Packets	Number of packets transmitted through a protocol.
Octets	Total number of bytes of the packets that are dropped.
Transmit Stats	Number of packets that are transmitted on an interface.
Input Drop Stats	Drop cause and the number of incoming packets that are dropped.
Output Drop Stats	Drop cause and the number of outgoing packets that are dropped.
Interface	Name of the interface.
Rx Pkts	Number of packets received on an interface.
Tx Pkts	Number of packets transmitted on an interface.

```
Device# show platform hardware qfp active interface if-handle 10 path

Hardware Path Information: Port type 2 - NGIO
Ingress Path Information:
Interface ID 1
IID table entry address 0x30b61018
Input uIDB 2043
Flow Control ID 0x30b61500
Egress Path Information:
Interface ID 1
FFP output port -2
Module backplane connection index 0
Switch port ID 8
Module number 0
MAC destination address c4: a:cb:56: 0:d5
MAC source address 30:f7: d:53:f4:db
```

The table below describes the significant fields shown in the display.

Table 201: show platform hardware qfp active interface if-handle path Field Descriptions

Field	Description
Hardware Path Information	Type of module on which the interface exists. Possible values are NGIO and BEST_EFFORT.
Ingress Path Information	Ingress path information.
Interface ID	Identifier assigned to the interface by the module. This identifier is local to the module.
IID table entry address	Address of the table of interfaces on the module in the forwarding plane memory.
Input uIDB	Input micro-interface descriptor block (uIDB) assigned to this interface.
Flow Control ID	Identifier for the flow control structure if the interface traffic is flow controlled.
Egress Path Information	Egress path information.
FFP output port	Port of the forwarding process that handles traffic on the interface.
Module backplane connection index	Identifier for the backplane connection of the module that handles the traffic on the interface.
Switch port ID	Identifier for the backplane switchport that handles the traffic for the interface.
Module number	Module identifier.
MAC destination address	MAC address in the headers of the packets that traverse the backplane switch.

```
Device# show platform hardware qfp active interface if-handle 14 path

Hardware Path Information:
Ingress Path Information:
Look-up class 1
Remap table entry:
  SPA Format 2
  Valid flag 1
  Marmot channel 0
  Indirect flag 1
  Input uIDB 1019
Egress Path Information:
Marmot header 0x2000000
SPA type 2
SPA header length 4
SPA header 0x0 0x0 0x0 0x0
  LP small header 0xd2 0xa9 0xe0 0x10
  HP header 0x0 0x0 0x1 0x0
  Cntl header 0xfa 0x28 0xd4 0x10
```

The table below describes the significant fields shown in the display.

Table 202: show platform hardware qfp active interface if-handle path Field Descriptions

Field	Description
Hardware Path Information	Type of module on which the interface exists.
Ingress Path Information	Ingress path information follows.
Look-up class	Look-up method used to identify the ingress interface.
Remap table entry	Entry of the remap table of the interface follows.
SPA format	Format of the Shared Port Adapter (SPA) header.
Valid Flag	Flag indicating whether entry in the remap table is valid. 1 is valid.
Marmot Channel	Channel in the Marmot chip through which traffic passes.
Indirect flag	Flag indicating whether the ingress interface is determined indirectly through the SPA header.
Input uIDB	Input micro-interface descriptor block (uIDB) assigned to the interface.
Egress Path Information	Egress path information follows.
Marmot header	Marmot header in the egress packets.
SPA type	Format of the SPA header.
SPA header length	Length of the egress SPA header, in bytes.
SPA header	Default SPA header of the egress packets.
LP small header	SPA header used for low priority (LP) packets.
HP header	SPA header used for high priority (HP) packets.
Cntl header	SPA header used for control packets.

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on a device or on an access server.

show platform hardware slot

To display information about the processor in a chassis slot, use the **show platform hardware slot** command in privileged EXEC or diagnostic mode.

Cisco ASR 1000 Series SPA Interface Processors
show platform hardware slot *sip* {**dram statistics** | **eobc** {**interface** {**primary** | **standby**} {**rmon** | **status**} | **switch statistics** {**brief** | **detail**}} | **fan status** | **io-port** | **led status** | **mcu status** [**raw**] | **plim** {**buffer settings** [**detail**] | **cpu** | **qos input bandwidth** | **registers** *reg* | **statistics** [**internal**] | **status** [**internal**]} | **sensor** {**consumer** | **producer**} {*id* | **all**} | **serdes** {**registers** *reg* | **statistics** [**internal**] | **status** [**brief**]} | **spa** {**attributes** | **oir-statistics** | **status**}}

Syntax Description

sip	Type of Cisco ASR 1000 Series SPA interface processor (SIP) with one of the following values: • **0**—SIP in chassis slot 0. • **1**—SIP in chassis slot 1. • **2**—SIP in chassis slot 2. • **P0**—Power supply slot 0. • **P1**—Power supply slot 1. • **P2**—Power supply slot 2. • **P3**—Power supply slot 3.
dram statistics	Displays error-correcting code (ECC) error statistics for DRAM (for Cisco Technical Support only).
eobc	Displays Ethernet out-of-band channel (EOBC) information.
interface primary	Displays primary EOBC interface information.

interface standby	Displays standby EOBC interface information.
rmon	Displays EOBC interface remote monitoring (RMON) information (for Cisco Technical Support only).
status	Displays EOBC interface status information (Physical Line Interface Module [PLIM] status and serializer/deserializer [SerDes] status are for Cisco Technical Support only).
switch statistics	Displays EOBC switch statistics.
brief	Displays summary information.
detail	Displays detailed information (for Cisco Technical Support only). This keyword is optional for PLIM buffer settings.
fan status	Displays fan software status.
io-port	Displays I/O port information.
led status	Displays LED states.
mcu status	Displays microcontroller unit (MCU) hardware status (for Cisco Technical Support only).
raw	(Optional) Displays MCU unparsed raw data (for Cisco Technical Support only).
plim	Displays PLIM information.
buffer settings	Displays PLIM buffer settings (for Cisco Technical Support only).
cpu	Displays CPU hyper threading (HT) bus information (for Cisco Technical Support only).
qos input bandwidth	Displays PLIM quality of service (QoS) input bandwidth information.
registers *reg*	It is the register name (for Cisco Technical Support only).
statistics	Displays statistics information.
internal	(Optional) Displays Cisco internal information (for Cisco Technical Support only).
sensor	Displays sensor information (for Cisco Technical Support only).
consumer	Displays sensor information from the consumer process (for Cisco Technical Support only).
producer	Displays sensor information from the producer process (for Cisco Technical Support only).
id	Displays the consumer or producer sensor ID number (for Cisco Technical Support only).
all	Displays a brief view of all sensors (for Cisco Technical Support only).
serdes	Displays serializer/deserializer (SerDes) information.

spa	Displays Cisco ASR 1000 Series SPA information.
attributes	Displays SPA attribute information (for Cisco Technical Support only).
oir-statistics	Displays SPA online insertion and removal (OIR) counters.
esp	Type of Cisco ASR 1000 Series Embedded Services Processor (ESP) with one of the following values: • **f0**—ESP in ESP slot 0. • **f1**—ESP in ESP slot 1.
rp	Type of Cisco ASR 1000 Series Route Processor (RP) with one of the following values: • **r0**—RP in RP slot 0. • **r1**—RP in RP slot 1.
alarms	Displays alarm states information (for Cisco Technical Support only). To display alarm status, use the **show facility-alarm status** command.
audible	Displays audible alarm states (for Cisco Technical Support only) information.
visual	Displays LED alarm states (for Cisco Technical Support only) information.
sm	Type of Cisco ISR 4400 Series Routers interface with one of the following values: • **0**—SM-Inter-Processor slot 0. • **F0**—Embedded Service Processor slot 0. • **P0**—Power supply slot 0. • **P1**—Power supply slot 1. • **P2**—Power supply slot 2. • **R0**—Route Processor slot 0.
i95 stats	Displays i95 driver statistics.
network-clocks	Displays network clock devices.
pcie status	Displays Peripheral Component Interconnect Express (PCIE) information.
pcie driver layers	Displays PCIE driver stacking information.
pcie driver statistics	Displays PCIE driver statistics.
rommon status	Displays ROM Monitor (ROMMON) status.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.

Release	Modification
15.0(1)S	This command was modified. The minimum bandwidth and the priority mode that cannot be configured in Strict Priority mode are not displayed in the output. The HP policer BW field was added to the output.
Cisco IOS XE Release 3.8S	This command was modified. References to SIP (Cisco ASR 1000 Series Shared Port Adaptor Interface Processors) in command options were replaced with SM (Cisco Services-Ready Engine [SRE] service module) for Cisco ISR 4400 Series Routers only.

Examples

The following sample output from the **show platform hardware slot 0 eobc interface primary status** command displays EOBC interface status for a SIP in chassis slot 0. This command provides the status of the EOBC in the indicated slot.

```
Device# show platform hardware slot 0 eobc interface primary status

EOBC interface status
  EOBC : eth0, status : Active
    Line State : Up, Speed : 1Gbps, Link mode : Full
    Line Type : AUI, Autoneg : Disabled
    Addr : 10.0.3.0, Netmask : 255.255.0.0, HW Addr : 0000.0300.0000
    Rx pkts : 1292995, bytes : 316283357, dropped : 0 errors : 0
    Tx pkts : 1124534, bytes : 270172949, dropped : 0 errors : 0
```

The table below describes the significant fields shown in the display.

Table 203: show platform hardware slot 0 eobc interface primary status Field Descriptions

Field	Description
EOBC: eth0	Ethernet port.
status	Port status. “Active” or “Standby.”
Line State	Line status. “Up” or “Down.”
Speed	Bandwidth in gigabits per second (Gbps).
Link mode	Transmission mode. “Full” (full duplex) or “Half” (half duplex).
Line Type	Type of transceiver. “AUI” (attachment unit interface), “TP” (twisted pair), “MII” (media independent interface), “FIBER” (fiber optic), or “BNC” (Bayonette Neil-Concelman).
Autoneg	Autonegotiation. “Enabled” or “Disabled.”
Addr	IP address of the port.
Netmask	IP addressing netmask of the port.
HW Addr	MAC address of the port.
Rx pkts/bytes	Number of packets and bytes received.
Tx pkts/bytes	Number of packets and bytes transmitted.

Field	Description
Rx dropped	Number of received packets that were dropped.
Tx dropped	Number of transmitted packets that were dropped.
Rx errors	Number of packets received with errors.
Tx errors	Number of packets transmitted with errors.

The following sample output from the **show platform hardware slot 0 eobc switch statistics brief** command displays brief EOBC switch statistics for a SIP in chassis slot 0:

```
Device# show platform hardware slot 0 eobc switch statistics brief

Port: 4, Link state: Up, Mode: Full Duplex, Speed: 1000 Mbps
Ingress bytes  :            276915312    Egress bytes  :           349585709
Ingress packets:              1151944    Egress packets:             1320618
```

The table below describes the significant fields shown in the display.

Table 204: show platform hardware slot 0 eobc switch statistics brief Field Descriptions

Field	Description
Port	Port on the EOBC switch.
Link state	Link status. “Up” or “Down.”
Mode	Transmission mode. “Full Duplex” or “Half Duplex.”
Speed	Bandwidth in megabits per second (Mbps).
Ingress bytes	Number of bytes received on this port.
Egress bytes	Number of bytes transmitted through this port.
Ingress packets	Number of packets received on this port.
Egress packets	Number of packets transmitted through this port.

The following sample output from the **show platform hardware slot 0 fan status** command displays fan operation status for a SIP in chassis slot 0:

```
Device# show platform hardware slot 0 fan status

Fan speed: 65%
Fan 0: Normal
Fan 1: Normal
Fan 2: Normal
```

The table below describes the significant fields shown in the display.

Table 205: show platform hardware slot 0 fan status Field Descriptions

Field	Description
Fan speed	Speed at which the fans are spinning as a percentage of their maximum speed.
Fan 0, 1, 2	Specifies whether a fan is encountering a fault condition. “Normal” or “Fail.”

The following sample output from the **show platform hardware slot 0 plim qos input bandwidth** command displays the ingress arbiter settings for all PLIM buffers that are in use for a SIP in chassis slot 0:

```
Device# show platform hardware slot 0 plim qos input bandwidth

Ingress QOS Scheduling Mode: Strict Priority

0/0, SPA-3XOC3-ATM-V2
  Interface 0/0/0
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   100000 Kbps, HP Policer BW:
155520 Kbps
  Interface 0/0/1
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   155000 Kbps, HP Policer BW:
155520 Kbps
  Interface 0/0/2
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   155000 Kbps, HP Policer BW:
155520 Kbps
```

The table below describes the significant fields shown in the display.

Table 206: show platform hardware slot 0 plim qos input bandwidth Field Descriptions

Field	Description
Ingress QOS Scheduling Mode	Current scheduler operation mode.
BW	Interface bandwidth in kilobits per second (kb/s).
Min BW	Guaranteed bandwidth assigned on this interface in Kbps.
Excessive Weight	Excessive bandwidth assigned on this interface in Kbps.
HP Policer BW	Bandwidth assigned for processing high-priority traffic on this interface in Kbps.

The following sample output from the **show platform hardware slot 0 plim statistics** command displays PLIM statistics for a SIP in chassis slot 0. Interprocess communication (IPC) packets are internal control packets. The first set of RX and TX packet counts include both user packets and IPC packets. In this example, the RX/TX and RX IPC/TX IPC packet counts are the same because only IPC packets are being passed (no user packets).

```
Device# show platform hardware slot 0 plim statistics

1/0, 2XOC3-POS, Online
  RX Pkts 739     Bytes 54564
  TX Pkts 739     Bytes 30752
  RX IPC Pkts 739     Bytes 54564
  TX IPC Pkts 739     Bytes 30752
```

The table below describes the significant fields shown in the display.

Table 207: show platform hardware slot 0 plim statistics Field Descriptions

Field	Description
RX Pkts	Packets (user data and IPC data) received by the PLIM from the indicated SPA.
TX Pkts	Packets (user data and IPC data) transmitted from the PLIM to the indicated SPA.
RX IPC Pkts	IPC packets received by the PLIM from the indicated SPA.
TX IPC Pkts	IPC packets transmitted from the PLIM to the indicated SPA.

The following is sample output from the **show platform hardware slot f0 serdes statistics** command for Cisco ASR1000-ESP20 and later versions of the ESP. This output displays the byte counters and packet counters associated with the Enhanced SerDes Interconnect (ESI) links for the ESP. The output includes information about drop counters and the number of link-level flow control messages. Information is displayed from the standpoint of the card (in this example, ESP0), where the command is run. An ESP displays information from all the cards with active ESI links connected to it. A SIP or an RP displays statistics from each ESP.

```
Device# show platform hardware slot f0 serdes statistics

From Slot R0
  Pkts High: 0 Low: 0 Bad: 0 Dropped: 0
  Bytes High: 0 Low: 0 Bad: 0 Dropped: 0
  Pkts Looped: 0 Error: 0
  Bytes Looped 0
  Qstat count: 0 Flow ctrl count: 25671
To Slot R0
  Pkts High: 0 Low: 0
From Slot 0
  Pkts High: 0 Low: 0 Bad: 0 Dropped: 0
  Bytes High: 0 Low: 0 Bad: 0 Dropped: 0
  Pkts Looped: 0 Error: 0
  Bytes Looped 0
  Qstat count: 0 Flow ctrl count: 25674
To Slot 0
  Pkts High: 0 Low: 0
```

The table below describes the significant fields shown in the display.

Table 208: show platform hardware slot f0 serdes statistics Field Descriptions

Field	Description
From Slot	Information on data passed from the indicated processor to the card where the command is run and over the SerDes.
To Slot	Information on data passed to the indicated processor from the card where the command is run and over the SerDes.
Pkts/Bytes High	Number of packets and bytes of high priority data payload.
Pkts/Bytes Low	Number of packets and bytes of low priority data payload.

Field	Description
Pkts/Bytes Bad	Number of packets received with packet length errors or cyclic redundacy check (CRC) errors.
Pkts/Bytes Dropped	Number of bit bucket packets or bytes dropped.
Pkts/Bytes Looped	Number of packets looped back in loopback mode.
Pkts Error	Number of packets with errors.
Qstat count	Number of queue status messages received.
Flow ctrl count	Number of link-level flow control messages.

The following is sample output from the **show platform hardware slot f0 serdes statistics** command for the Cisco ASR1000-ESP10.

```
Device# show platform hardware slot f0 serdes statistics

From Slot R0
  Pkts High: 0 Low: 0 Bad: 0 Dropped: 0
  Bytes High: 0 Low: 0 Bad: 0 Dropped: 0
  Pkts Looped: 0 Error: 0
  Bytes Looped 0
  Qstat count: 0 Flow ctrl count: 25671
From Slot 0
  Pkts High: 0 Low: 0 Bad: 0 Dropped: 0
  Bytes High: 0 Low: 0 Bad: 0 Dropped: 0
  Pkts Looped: 0 Error: 0
  Bytes Looped 0
  Qstat count: 0 Flow ctrl count: 25674
```

The following is sample output from the **show platform hardware slot f0 serdes statistics internal** command for the Cisco ASR 1000-ESP10.

```
Device# show platform hardware slot f0 serdes statistics internal

The following sample output from the **show platform hardware slot 0 spa oir-statistics** command displays the OIR statistics of SPAs installed in a SIP in chassis slot 0:

```
Device# show platform hardware slot 0 spa oir-statistics

 SPA OIR requests: : 3
SPA OIR responses: : 3
   SPA insertions: : 0
     SPA removals: : 0
SPA driver starts: : 0
 SPA driver stops: : 0
SPA driver deaths: : 0
```

The table below describes the significant fields shown in the display.

Table 209: show platform hardware slot 0 spa oir-statistics Field Descriptions

Field	Description
SPA OIR requests	Number of times the chassis software on the SIP made a request to the chassis software on the RP to allow a SPA to come online.
SPA OIR responses	Number of times the chassis software on the RP sent a response to an OIR request to the chassis software on the SIP.
SPA insertions	Number of SPA insertions since the last boot. The number is zero for SPAs that were in the chassis when the chassis booted.
SPA removals	Number of SPA removals since the last boot.
SPA driver starts	Number of times the SPA driver started.
SPA driver stops	Number of times the SPA driver stopped.
SPA driver deaths	Number of time the SPA driver reloaded.

The following sample output from the **show platform hardware slot P0 mcu status** displays the MCU hardware status and power supply in the slot:

If you use the **show platform hardware slot** *sip* **mcu status** command or the **show platform hardware slot** *sip* **fan status** command on the Cisco ASR 1000 Series Router, we recommend that you use the value “Px” rather than “0” or other numeric values to specify the power supply slot. This command displays the MCU hardware status or fan status and references the power supply in the slot.

```
Device# show platform hardware slot P0 mcu status

Model ID: 5
12V I: 31
12V V: 11
Temp: 29
Input V: 218
Fan speed: 65%
```

The table below describes the significant fields shown in the display.

Table 210: show platform hardware slot mcu status Field Descriptions

Field	Description
Model ID	Model ID of the card slot.
12V	Power supply in the slot in voltage.
Temp	Chassis temperature.
Input V	Voltage input for power supply.
Fan speed	Speed at which the fans are spinning as a percentage of their maximum speed.

Related Commands

Command	Description
show platform hardware interface	Displays information about an interface.
show platform hardware port	Displays information about an interface port on an SPA.
show platform hardware subslot	Displays information about an SPA.

show platform hardware throughput crypto

To display throughput information on a physical router, use the **show platform hardware throughput crypto** command in privileged EXEC mode. The output displays the configured throughput level, indicates if hardware throttling is effective and what the system-imposed limit is, the default throughput level for the device, and the configured boot level license.

show platform hardware throughput crypto

Command Default

Privileged EXEC (#)

Command Modes

No default behavior or values.

Command History

Release	Modification
Cisco IOS XE Amsterdam 17.3.2	This command was introduced on Cisco Catalyst 8300, and 8500 Series Edge Platforms.
Cisco IOS XE Bengaluru 17.4.1	This command was introduced on the Cisco Catalyst 8200 Series Edge Platforms
Cisco IOS XE Cupertino 17.9.3a	The text in the output was modified to make it easier to understand.

Usage Guidelines

The output of the command provides the following information related to the throughput level on a physical router:

- It displays the throughput level that is currently effective. This value is configured with the **platform hardware throughput crypto** command in global configuration mode. If a level is not configured, the default is effective.

  The value here can be a numeric value or a tier-based throughput value. Support for tier-based throughput values was introduced in Cisco IOS XE Cupertino 17.7.1a. For more information, see Tier and Numeric Throughput Mapping for Physical Platforms, Cisco IOS XE Cupertino 17.8.1a and Later Releases.

- It indicates if the value is saved in the startup configuration file. If a configured value is not saved, it does not persist across reloads.

- It displays the hardware throttling limit that the configured value falls under. This is system-determined. See device-specific details in the following table: Throughput and System Hardware Throttling Specifications in the Autonomous Mode.

- It specifies the throttling limit that is finally effective. This value will account for aggregate throughput throttling if it is effective. Support for aggregate throughput throttling was introduced in Cisco IOS XE Cupertino 17.8.1a.

- It displays the default throughput level of the device.

- It displays the boot-level DNA license that is configured on the device.

The following is sample output of the **show platform hardware throughput crypto** command on a Cisco Catalyst 8300 Series Edge Platform (C8300-2N2S-4T2X). The software version running on the device is earlier than Cisco IOS XE Cupertino 17.9.3a:

```
Device# show platform hardware throughput crypto
Current configured crypto throughput level: 250M
     Level is saved, reboot is not required
Current enforced crypto throughput level: 250M
Crypto Throughput is throttled at 250M
Default Crypto throughput level: 10M
Current boot level is network-advantage
```

The following is sample output of the **show platform hardware throughput crypto** command on a Cisco Catalyst 8300 Series Edge Platform (C8300-2N2S-4T2X). The software version running on the device is Cisco IOS XE Cupertino 17.9.3a. From the output you can derive these key conclusions:

- The throughput level that is effective is 10 Mbps.
- Configuration is saved in the startup configuration file; the configured value will therefore persist across reloads.
- From table Throughput and System Hardware Throttling Specifications in the Autonomous Mode, we know that on a C8300-2N2S-4T2X, for any throughput level up to 250 Mbps, the hardware-imposed throttling limit is 250 Mbps.
- Throughput is throttled at 250 Mpbs. Note that aggregate throughput throttling is not applicable when the configured throughput is lesser than or equal to 250 Mbps.

```
Device# show platform hardware throughput crypto
Current configured crypto throughput level: 10M
     Level is saved, reboot is not required
Configured crypto throughput level on rate limiter: 250M
Crypto Throughput will be rate limited at 250M
Default Crypto throughput level: 10M
Current boot level is network-essentials
```

The following is sample output of the **show platform hardware throughput crypto** command on a Cisco Catalyst 8300 Series Edge Platform (**C8300-1N1S-4T2X**). The software version running on the device is Cisco IOS XE Cupertino 17.9.3a. From the output you can derive these key conclusions:

- The throughput level that is effective is T3.
- On C8300-1N1S-4T2X, T3 is the equivalent of 2.5 Gbps.
- Configuration is saved in the startup configuration file; the configured value will therefore persist across reloads.
- On a C8300-1N1S-4T2X, when a throughput level of T3 (2.5 Gbps) is configured, the system lifts all throttling restrictions.

```
Device# show platform hardware throughput crypto
Current configured crypto throughput level: T3
     Level is saved, reboot is not required
Configured crypto throughput level on rate limiter: 2.5G
Crypto Throughput will not be rate limited
Default Crypto throughput level: 10M
Current boot level is network-premier
```

Related Commands

Command	Description
platform hardware throughput crypto	Configures a throughput value on a physical router.

show platform hardware throughput level

To display the current maximum throughput level for a virtual router, use the **show platform hardware throughput level** command in Privileged EXEC mode.

show platform hardware throughput level

Command Modes

Privileged EXEC

Command History

Release	Modification
Cisco IOS XE 3.9S	This command was introduced on the Cisco CSR 1000V Cloud Services Router.

Usage Guidelines

The maximum throughput level is determined by the installed license. Depending on the configuration and installed license, you can change the maximum throughput level. See the **platform hardware throughput level** command for more information.

Example

The following example displays the maximum throughput level on the router:

```
Router# show platform hardware throughput level
The current throughput level is 50000 kb/s
```

Related Commands

Command	Description
platform hardware throughput level	Changes the maximum throughput level on the virtual router.

show platform hardware subslot

To display information about a Cisco ASR 1000 Series shared port adapter (SPA), use the **showplatformhardwaresubslot**command in privileged EXEC or diagnostic mode.

show platform hardware subslot *slot/card* **plim** {**buffer** [**settings detail**] | **qos input bandwidth** | **spa settings** | **statistics** [**internal**]}

Syntax Description

slot /	Chassis slot where the Cisco ASR 1000 Series SPA interface processor (SIP) is installed.
card	Secondary slot number of the SIP where the SPA is installed.
plim	Provides Physical Line Interface Module (PLIM) information.
buffer	Provides PLIM buffer information (for Cisco Technical Support only).
settings detail	(Optional) Provides detailed PLIM buffer settings (for Cisco Technical Support only).
qos input bandwidth	Provides PLIM QoS input bandwidth information.
spa settings	Provides PLIM SPA settings (for Cisco Technical Support only).
statistics	Provides PLIM statistics.
internal	(Optional) Provides PLIM detailed statistics information (for Cisco Technical Support only).

Command Modes

Privileged EXEC (#) Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.
15.0(1)S	This command was modified. The minimum bandwidth and the proirity mode that cannot be configured in Strict Priority mode are not displayed in the output. The HP policer BW field was added to the output.

Examples

The following example displays ingress arbiter settings for all PLIM buffers that are in use for a SPA in chassis slot 1:

```
Router# show platform hardware subslot 1/0 plim qos input bandwidth
Ingress QOS Scheduling Mode: Strict Priority

0/0, SPA-3XOC3-ATM-V2
  Interface 0/0/0
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   100000 Kbps, HP Policer BW:
155520 Kbps
  Interface 0/0/1
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   155000 Kbps, HP Policer BW:
```

```
155520 Kbps
  Interface 0/0/2
    BW:   155520 Kbps, Min BW: N/A , Excessive Weight:   155000 Kbps, HP Policer BW:
155520 Kbps
```

The table below describes the significant fields shown in the display.

Table 211: show platform hardware subslot 1/0 plim qos input bandwidth Field Descriptions

Field	Description
Ingress QOS Scheduling Mode	Current scheduler operation mode.
BW	Interface bandwidth in kilobits per second (kb/s).
Min Bw	Guaranteed bandwidth assigned on this interface in kb/s.
Excessive Weight	Excessive bandwidth assigned on this interface in kb/s.
HP Policer BW	Bandwidth assigned for processing high priority traffic on this interface in kb/s.

The following example displays PLIM statistics for a SPA in chassis slot 1. Interprocess communication (IPC) packets are internal control packets. The first set of RX and TX packet counts includes both user packets and IPC packets. In this example, the RX/TX and RX IPC/TX IPC packet counts are the same because no user packets are being passed, only IPC packets.

```
Router# show platform hardware subslot 1/0 plim statistics
1/0, 2XOC3-POS, Online
  RX Pkts 739     Bytes 54564
  TX Pkts 739     Bytes 30752
  RX IPC Pkts 739     Bytes 54564
  TX IPC Pkts 739     Bytes 30752
```

The table below describes the significant fields shown in the display.

Table 212: show platform hardware subslot 1/0 plim statistics Field Descriptions

Field	Description
RX Pkts	Packets (user data and IPC data) received by the PLIM from the indicated SPA.
TX Pkts	Packets (user data and IPC data) transmitted from the PLIM to the indicated SPA.
RX IPC Pkts	IPC packets received by the PLIM from the indicated SPA.
TX IPC Pkts	IPC packets transmitted from the PLIM to the indicated SPA.

Related Commands

Command	Description
show platform hardware interface	Displays information about an interface.
show platform hardware port	Displays information about an interface port on a shared port adapter (SPA).
show platform hardware slot	Displays information about the processor in a chassis slot.

show platform hardware subslot (4400)

To display information on the network interface module, use the **show platform hardware subslot** command in privileged EXEC mode.

show platform hardware subslot *slot/bay* **module** [{ **firmware** | **status** | **device** *device-name* | **host-if** | [{**statistics** | **status** | **register**}]}]

Syntax Description

slot/ bay	Specifies the chassis slot and secondary slot number where the module is installed.
module	Specifies the module information.
firmware	Displays the firmware and bootloader version.
status	Displays information on the firmware operational status, CPU, and memory utilization.
device	Displays information for specific module devices.
device-name	Specifies the device.
host-if	Specifies the host interface.
statistics	(Optional) Displays the link statistics for the host interface.
status	(Optional) Displays the configuration, status, and interface ID for the host interface.
register	(Optional) Displays the register information for the host interface.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced.

Example

The following are sample outputs from the **show platform hardware subslot module** command.

```

show platform hardware transceiver

To see transceiver information on a port, use the show platform hardware transceiver command in EXEC mode.

show platform hardware transceiver {**brief** | **status** | **config** | **error** | **register**} [**port**]

Syntax Description

brief	Brief device information.
status	Device status.
config	Device configuration.
error	Device error information.
register	Device register contents.
port	Specifies the port. If you do not select a port, this command will iterate through all ports.

Command Default

No default behavior or values

Command Modes

EXEC (#)

Command History

Release	Modification
12.2(33)SRD	This command was introduced on the Cisco 7600 series routers. **Note** This command applies only to the Cisco 7600 Series Ethernet Services Plus (ES+) line card on the Cisco 7600 series router.

Usage Guidelines

Use this command with the remote command command in EXEC mode.

Examples

The following example shows brief information for port 1.

```
Router# remote command module 13 show platform hardware transceiver brief 1
Show brief info for port 1:
GigabitEthernet13/1:
        ID: SFP
        Extended ID: 4
        Xcvr Type: GE SX (13)
        Connector: LC
        Vendor name: CISCO-FINISAR
        Vendor part number: FTLF8519P2BCL-CS
        State: Enabled
```

The following example shows status information for port 1.

```
Router# remote command module 13 show platform hardware transceiver status 1
Show status info for port 1:
TenGigabitEthernet1/1:
        State: Enabled
        Environmental Information - raw values
```

```
            Temperature: 7616
            Tx voltage: 0 in units of 100uVolt
            Tx bias: 28722 uA
            Tx power: -2 dBm (5441 in units of 0.1 uW)
            Rx power: 0 dBm (7712 in units of 0.1 uW)
            (AUX1) Laser Temperature: 8704
            (AUX2) +3.3V Supply Voltage: 32928
    XFP TX is enabled.
    XFP TX is soft enabled.
    XFP is ready.
    XFP is not power down.
    XFP is not soft power down.
    XFP doesn't have interrupt(s).
    XFP is not LOS.
    XFP data is ready.
    XFP TX path is ready.
    XFP TX laser is not in fault condition.
    XFP TX path CDR is locked.
    XFP RX path is ready.
    XFP RX path CDR is locked.
    No active alarms
    No active warning
```

Related Commands

Command	Description
remote command {module num | standby-rp | switch} command	Executes a Cisco 7600 series router command directly on the switch console or a specified module without having to log into the Cisco 7600 series router first.

show platform isg memory

To display dynamically allocated memory usage information on the route processor (RP), use the **showplatformisgmemory**command in privileged EXEC mode.

show platform isg memory [**detail**]

Syntax Description

detail	(Optional) Displays detailed memory usage information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Examples

This is a sample output of the **showplatformisgmemory**command.

```
Router# show platform isg memory
Allocator-Name                  In-use/Allocated           Count

```

The table below describes the fields shown in the **showplatformisgmemory**command display.

Table 213: show platform isg memory Field Descriptions

Field	Description
Allocator-Name	Name of the memory allocating process.
In-use	Indicates the current memory usage.
Allocated	Total memory allocated by the process.
Count	Number of allocated memory blocks.

show platform mgf

To show the details of the multi-gigabit fabric, use the **show platform mgf** command in privileged EXEC mode.

show platform mgf [{**module** | **statistics cpu**}]

Syntax Description

module	Shows details of the modules registered to the backplane switch manager (BPSM).
statistics	Displays the multi-gigabit fabric's packet statistics.
cpu	Displays the multi-gigabit fabric's cpu port statistics.

Command Default

None

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced for the Cisco 3900 Series, 2900 Series, and 1900 Series Integrated Services Routers (ISRs).

Usage Guidelines

To show the details of the multi-gigabit fabric, use the **show platform mgf** command in privileged EXEC mode. Or, enter the **show platform mgf** command and press Enter to display VLAN and slot assignments on the router. An asterisk next to the slot indicates that the vlan is the slot's default VLAN. The following example displays output from a Cisco 3945 ISR.

Note Before Cisco IOS 15.1(3)T release, the Cisco Services Ready Engine (SRE) Service Module was managed by the platform backplane code. Therefore, when you entered the **show platform mgf** command, the Cisco SRE Service Module was displayed in the command output. But with Cisco IOS 15.1(3)T release, because the Cisco SRE Service Module is in the switchport managed module, it is no longer displayed in the **show platform mgf** command output.

Note VLAN1 is the default when no other VLAN are listed.

```
Router# show platform mgf
VLAN    Slots
------------------------------------------------------------
1       ISM*, EHWIC-0*, EHWIC-1*, EHWIC-2*, EHWIC-3*
        PVDM-0*, PVDM-1*, PVDM-2*, PVDM-3*, SM-1*
        SM-2*, SM-3*, SM-4*
```

Examples

The following example displays the output for the **show platform mgf module** command when entered on a Cisco 3945 ISR. The table below displays the information code that appears in the output.

```
Router# show platform mgf module
Registered Module Information
Code:   NR - Not Registered, TM - Trust Mode, SP - Scheduling Profile
        BL - Buffer Level, TR - Traffic Rate, PT - Pause Threshold
slot    vlan    type/ID         TM      SP      BL      TR      PT
----    ----    ----------      ------- ---     ------  -----   ----
ISM     NR
EHWIC-0 NR
EHWIC-1 NR
EHWIC-2 NR
EHWIC-3 NR
PVDM-0  NR
PVDM-1  NR
PVDM-2  NR
PVDM-3  NR
SM-1     1       SM/6            UP      1       high    1000    high
SM-2     1       SM/6            UP      1       high    1000    high
SM-3    NR
SM-4    NR
```

Table 214: Show Platform Backplane Module Information Code

Code	Description
NR	Not registered
TM	Trust mode
SP	Scheduling profile
BL	Buffer level
TR	Traffic rate
PT	Pause threshold

The following example displays output for the **show platform mgf statistics** command when entered on a Cisco 1941 ISR.

```
Router# show platform mgf statistics

Related Commands

Command	Description
show platform	To display platform information, use the show platform command in privileged EXEC mode.

show platform resources

To display information about the utilization of platform resources, such as the Control Processor (CP), Service Processor (SP), DRAM, bootflash, and harddisk, use the **show platform resources** command in privileged EXEC mode.

The command now reports Control Processor (CP) and Service Processor (SP) CPU utilization under the 'Control/Service Processor' entry.

show platform resources {R0 | R0 cpu | R0 memory | exmem | datapath | datpath oversubscription}

Syntax Description

Table 215: Syntax Description

R0	Shows the CPU summary from a BINOS perspective.
R0 cpu	Shows the CPU utilization.
R0 memory	Shows the memory utilization.
exmem	Shows the user allocation statistics.
datapath	Shows the quantum flow processor utilization.
datapath oversubscription	Shows the oversubscription of the quantum flow processor.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE release 3.14	This command was introduced.
Cisco IOS XE Gibraltar 16.11.1	The command output is enhanced to include bootflash and harddisk information for Route Processors.
Cisco IOS XE Amsterdam 17.3.1	This command was modified. The following keywords were added: **R0**, **R0 cpu**, **R0 memory**, **exmem**, **datapath**, and **datapath oversubscription**.

Examples

The following sample output from the **show platform resources** command displays resource utilization related to the Embedded Service Processor and the Route Processor.

```
Router# show platform resources
**State Acronym: H - Healthy, W - Warning, C - Critical

```

The output fields are self-explanatory.

Note On platforms where the harddisk is not present, only the bootflash information is displayed.

show platform slot r0 pcie status

To display information about all Peripheral Component Interconnect (PCI) buses on the Route Processor (RP) slot on the Cisco ASR 1000 Series Aggregation Services Router and devices connected to the PCI buses, use the **show platform slot r0 pcie status** command in user EXEC or privileged EXEC mode.

show platform slot r0 pcie status

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)
User EXEC (>)

Command History

Release	Modification
Cisco IOS XE Release 3.6	This command was introduced.

Examples

The following sample output from the **show platform slot r0 pcie status** command displays information about all PCI buses on the RP slot on the Cisco ASR 1000 Series Aggregation Services Router and the devices connected to them:

```
Router# show platform slot r0 pcie status

00:00.0 Class 0600: Device 8086:65c0 (rev 90)
00:02.0 Class 0604: Device 8086:65f7 (rev 90)
00:03.0 Class 0604: Device 8086:65e3 (rev 90)
00:04.0 Class 0604: Device 8086:65e4 (rev 90)
00:05.0 Class 0604: Device 8086:65e5 (rev 90)
00:06.0 Class 0604: Device 8086:65e6 (rev 90)
00:07.0 Class 0604: Device 8086:65e7 (rev 90)
00:08.0 Class 0880: Device 8086:65ff (rev 90)
00:10.0 Class 0600: Device 8086:65f0 (rev 90)
00:10.1 Class 0600: Device 8086:65f0 (rev 90)
00:10.2 Class 0600: Device 8086:65f0 (rev 90)
00:11.0 Class 0600: Device 8086:65f1 (rev 90)
00:13.0 Class 0600: Device 8086:65f3 (rev 90)
00:15.0 Class 0600: Device 8086:65f5 (rev 90)
00:16.0 Class 0600: Device 8086:65f6 (rev 90)
00:19.0 Class 0200: Device 8086:10e5 (rev 02)
00:1a.0 Class 0c03: Device 8086:2937 (rev 02)
00:1a.1 Class 0c03: Device 8086:2938 (rev 02)
00:1a.2 Class 0c03: Device 8086:2939 (rev 02)
00:1a.7 Class 0c03: Device 8086:293c (rev 02)
00:1b.0 Class 0403: Device 8086:293e (rev 02)
00:1d.0 Class 0c03: Device 8086:2934 (rev 02)
00:1d.1 Class 0c03: Device 8086:2935 (rev 02)
```

The output fields are self-explanatory.

show platform software agent iomd

To display the packets of High Priority and Low Priority queue in Over Subscription mode, use the **show platform software agent iomd** command in privileged EXEC mode.

show platform software agent iomd *im module* **dump fpga** *port number*

Syntax Description

im module	The name of the interface module.
port number	The port number used

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Everest 16.6.1	This command was introduced on Cisco ASR 900 Series Routers and Cisco NCS 4200 Routers.

Examples

```
#show platform software agent iomd 0/8 dump fpga 4
OS LP Drop Q Pkt Cnt :0x0
OS HP Drop Q Pkt Cnt :0x0
OS LP Q Pkt Cnt :0x22906bd0
OS HP Q Pkt Cnt :0x55fdd731
```

To clear the High Priority and Low Priority counters in Over Subscription mode, use the **show platform software agent iomd** command in privileged EXEC mode.

show platform software agent iomd *im module* **clear fpga** *port number*

Syntax Description

im module	The name of the interface module.
port number	The port number used

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Everest 16.6.1	This command was introduced on Cisco ASR 900 Series Routers and Cisco NCS 4200 Routers.

Examples

```
#show platform software agent iomd 0/8 clear fpga 4
OS LP Drop Q Pkt Cnt :0x0
OS HP Drop Q Pkt Cnt :0x0
```

```
OS LP Q Pkt Cnt :0x0
OS HP Q Pkt Cnt :0x0
```

show platform software audit

To display the SE Linux Audit logs, use the **show platform software audit** command in privileged EXEC mode.

show platform software audit { **all** | **summary** | **0** | **1** | **2** | **F0** | **R0** | **FP active** | **RP active**}

Syntax Description

all	Shows the audit log from all the slots.
summary	Shows the audit log summary count from all the slots.
0	Shows the audit log for the SM-Inter-Processor slot 0.
1	Shows the audit log for the SM-Inter-Processor slot 1.
2	Shows the audit log for the SM-Inter-Processor slot 2.
F0	Shows the audit log for the Embedded-Service-Processor slot 0.
R0	Shows the audit log for the Route-Processor slot 0.
FP active	Shows the audit log for the active Embedded-Service-Processor slot.
RP active	Shows the audit log for the active Route-Processor slot.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Gibraltar 16.11.1	This command was introduced on Cisco ISR 4000 series routers, Cisco CSR 1000V series routers, and Cisco 1000 ISR series routers running time-sensitive networking (TSN).

Usage Guidelines

This command was introduced in the Cisco IOS XE Gibraltar 16.11.1 as a part of the SELinux Permissive Mode feature. The **show platform software audit** command displays the system logs containing the access violation events.

In Cisco IOS XE Gibraltar 16.11.1, operation in a permissive mode is available - with the intent of confining specific components (process or application) of the IOS-XE platform. In the permissive mode, access violation events are detected and system logs are generated, but the event or operation itself is not blocked. The solution operates mainly in an access violation detection mode.

The following is a sample output of the `show software platform software audit summary` command:

```
Device# show platform software audit summary
===================================
AUDIT LOG ON ACTIVE
-----------------------------------
AVC Denial count: 7
```

The following is a sample output of the **show software platform software audit all** command. This command displays the information in the `audit.log` file.

```
Device#sh pla software audit all
===================================

```

show platform software memory

To display memory information for the specified process, use the **show platform software memory**command in privileged EXEC or diagnostic mode.

show platform software memory [{**database** | **messaging**}]{**chassis-manager** *slot* | **cpp-control-process** *process* | **cpp-driver** *process* | **cpp-ha-server** *process* | **cpp-service-process** *process* | **forwarding-manager** *slot* | **host-manager** *slot* | **interface-manager** *slot* | **ios** *slot* | **logger** *slot* | **pluggable-services** *slot* | **shell-manager** *slot*} [**brief**]

Syntax Description

database database	(Optional) Displays database memory information for the specified process.
messaging	(Optional) Displays messaging memory information for specified process. The information displayed is for internal debugging purposes only.
chassis-manager *slot*	Displays memory information for the Chassis Manager process in the specified *slot*. Possible *slot* values are: • **0** --Cisco ASR 1000 Series SPA Interface Processor (SIP) slot 0 • **1** --Cisco ASR 1000 Series SIP slot 1 • **2** --Cisco ASR 1000 Series SIP slot 2 • **f0** --Cisco ASR 1000 Series Embedded Services Processor (ESP) slot 0 • **f1** --Cisco ASR 1000 Series ESP slot 1 • **fp active** --Active Cisco ASR 1000 Series ESP • **fp standby** --Standby Cisco ASR 1000 Series ESP • **r0** --Cisco ASR 1000 Series Route Processor (RP) slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
cpp-control-process	Displays memory information for the specified Cisco Packet Processor (CPP) Client Control process. Possible *process* values are: • **cpp active** --Active CPP Client Control process • **cpp standby** --Standby CPP Client Control process The information displayed is for internal debugging purposes only.

cpp-driver	Displays memory information for the specified CPP Driver process. Possible *process* values are: • **cpp active** --Active CPPDriver process • **cpp standby** --Standby CPP Driver process The information displayed is for internal debugging purposes only.
cpp-ha-server	Displays memory information for the specified CPP High Availability (HA) Server process. Possible *process* values are: • **cpp active** --Active CPP HA Server process • **cpp standby** --Standby CPP HA Server process The information displayed is for internal debugging purposes only.
cpp-service-process	Displays memory information for the specified CPP Client Service process. Possible *process* values are: • **cpp active** --Active CPP Client Service process • **cpp standby** --Standby CPP Client Service process The information displayed is for internal debugging purposes only.
forwarding-manager *slot*	Displays memory information for the Forwarding Manager process in the specified *slot*. Possible *slot* values are: • **f0** --Cisco ASR 1000 Series ESP slot 0 • **f1** --Cisco ASR 1000 Series ESP slot 1 • **fp active** --Active Cisco ASR 1000 Series ESP • **fp standby** --Standby Cisco ASR 1000 Series ESP • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP

host-manager *slot*	Displays memory information for the Host Manager process in the specified *slot*. Possible *slot* values are: • **0** --Cisco ASR 1000 Series SIP slot 0 • **1** --Cisco ASR 1000 Series SIP slot 1 • **2** --Cisco ASR 1000 Series SIP slot 2 • **f0** --Cisco ASR 1000 Series ESP slot 0 • **f1** --Cisco ASR 1000 Series ESP slot 1 • **fp active** --Active Cisco ASR 1000 Series ESP • **fp standby** --Standby Cisco ASR 1000 Series ESP • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
interface-manager *slot*	Displays memory information for the Interface Manager process in the specified *slot*. Possible *slot* values are: • **0** --Cisco ASR 1000 Series SIP slot 0 • **1** --Cisco ASR 1000 Series SIP slot 1 • **2** -- Cisco ASR 1000 Series SIP slot 2 • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP

ios *slot*	Displays memory information for the IOS process in the specified *slot*. Possible *slot* values are: • **0/0** --Cisco ASR 1000 Series SIP slot 0, bay 0 • **0/1** --Cisco ASR 1000 Series SIP slot 0, bay 1 • **0/2** --Cisco ASR 1000 Series SIP slot 0, bay 2 • **0/3** --Cisco ASR 1000 Series SIP slot 0, bay 3 • **1/0** --Cisco ASR 1000 Series SIP slot 1, bay 0 • **1/1** --Cisco ASR 1000 Series SIP slot 1, bay 1 • **1/2** --Cisco ASR 1000 Series SIP slot 1, bay 2 • **1/3** --Cisco ASR 1000 Series SIP slot 1, bay 3 • **2/0** --Cisco ASR 1000 Series SIP slot 2, bay 0 • **2/1** --Cisco ASR 1000 Series SIP slot 2, bay 1 • **2/2** --Cisco ASR 1000 Series SIP slot 2, bay 2 • **2/3** --Cisco ASR 1000 Series SIP slot 2, bay 3 • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
logger *slot*	Displays memory information for the logger process in the specified *slot*. Possible *slot* values are: • **0** --Cisco ASR 1000 Series SIP slot 0 • **1** --Cisco ASR 1000 Series SIP slot 1 • **2** --Cisco ASR 1000 Series SIP slot 2 • **f0** --Cisco ASR 1000 Series ESP slot 0 • **f1** --Cisco ASR 1000 Series ESP slot 1 • **fp active** --Active Cisco ASR 1000 Series ESP • **fp standby** --Standby Cisco ASR 1000 Series ESP • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP

pluggable-services *slot*	Displays memory information for the pluggable-services process in the specified *slot*. Possible *slot* values are: • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
shell-manager *slot*	Displays memory information for the Shell Manager process in the specified slot. Possible *slot* values are: • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
brief	(Optional) Displays abbreviated memory information for the specified process.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The specification of the database and brief keywords are optional.

The specification of a process and slot are required.

Examples

The following example displays memory information for the Forwarding Manager process for Cisco ASR 1000 Series RP slot 0:

```
Router# show platform software memory forwarding-manager r0
Module: cdllib
  allocated: 900, requested: 892, overhead: 8
  Allocations: 2, failed: 0, frees: 1
Module: eventutil
  allocated: 117379, requested: 117059, overhead: 320
  Allocations: 46, failed: 0, frees: 6
Module: uipeer
  allocated: 9264, requested: 9248, overhead: 16
  Allocations: 3, failed: 0, frees: 1
Module: Summary
  allocated: 127543, requested: 127199, overhead: 344
  Allocations: 51, failed: 0, frees: 8
```

The table below describes the significant fields shown in the display.

Table 216: show platform software memory Field Descriptions

Field	Description
Module:	Name of submodule.
allocated:	Memory, allocated in bytes.
requested:	Number of bytes requested by application.
overhead:	Allocation overhead.
Allocations:	Number of discrete allocation event attempts.
failed:	Number of allocation attempts that were attempted, but failed.
frees:	Number of free events.

The following example displays abbreviated (brief keyword) memory information for the Chassis Manager process for Cisco ASR 1000 Series ESP slot 0:

```
Router# show platform software memory chassis-manager f0 brief

  module            allocated     requested     allocs        frees
  ------------------------------------------------------------------------
  CPP Features      692           668           3             0
  Summary           497816        495344        323           14
  chunk             419322        419290        4             0
  eventutil         68546         66146         312           12
  uipeer            9256          9240          4             2
```

The table below describes the significant fields shown in the **brief** keyword display.

Table 217: show platform software memory brief Field Descriptions

Field	Description
module	Name of submodule.
allocated	Memory, allocated in bytes.
requested	Number of bytes requested by application.
allocs	Number of discrete allocation event attempts.
frees	Number of free events.

show platform software mount

To display the mounted file systems, both physical and virtual, for a Cisco ASR 1000 Series SPA Interface Processor (SIP), Cisco ASR 1000 Series Embedded Services Processor (ESP), or Cisco ASR 1000 Series Route Processor (RP), use the **show platform software mount**command in privileged EXEC or diagnostic mode.

show platform software mount [*slot* [**brief**]]

Syntax Description

slot	(Optional) Displays mounted file systems for the specified *slot*. Possible *slot* values are: • **0** --Cisco ASR 1000 Series SIP slot 0 • **1** --Cisco ASR 1000 Series SIP slot 1 • **2** --Cisco ASR 1000 Series SIP slot 2 • **f0** --Cisco ASR 1000 Series ESP slot 0 • **f1** --Cisco ASR 1000 Series ESP slot 1 • **fp active** --Active Cisco ASR 1000 Series ESP • **fp standby** --Standby Cisco ASR 1000 Series ESP • **r0** --Cisco ASR 1000 Series RP slot 0 • **r1** --Cisco ASR 1000 Series RP slot 1 • **rp active** --Active Cisco ASR 1000 Series RP • **rp standby** --Standby Cisco ASR 1000 Series RP
brief	(Optional) Displays abbreviated mounted file system information.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

If no slot is specified, the command returns mounted file systems for the active RP.

This command allows you to ascertain the presence or absence of specific system mounts. For example, this command might be used to determine /tmp-related mounts, which are used to create many run-time directories and files.

Users may be requested to execute this command to collect information about the underlying configuration of the platform software.

The RP output can differ depending on how the router was booted, and whether there are USB devices inserted.

The SIP and ESP output can differ depending on whether the chassis is a dual or single RP.

Examples

The following example displays mounted file systems for the active RP:

```
Router# show platform software mount
Filesystem                         Used   Available  Use% Mounted on
rootfs                                0           0     - /
proc                                  0           0     - /proc
sysfs                                 0           0     - /sys
none                                524     1037640    1% /dev
/dev/bootflash1                  298263       42410   88% /bootflash
/dev/harddisk1                   609208     4025132   14% /misc/scratch
/dev/loop1                        28010           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop2                        26920           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop3                        48236           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop4                         6134           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop5                        43386           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop6                        30498           0  100% /tmp/sw/mount/2007-10-14_...
/dev/loop7                        14082           0  100% /tmp/sw/mount/2007-10-14_...
none                                524     1037640    1% /dev
/proc/bus/usb                         0           0     - /proc/bus/usb
/dev/mtdblock1                      460        1588   23% /obfl
automount(pid4165)                    0           0     - /vol
```

The following example displays mounted file systems for the Cisco ASR 1000 Series ESP in ESP slot 0:

```
Router# show platform software mount f0
Filesystem                         Used   Available Use% Mounted on
rootfs                                0           0     - /
proc                                  0           0     - /proc
sysfs                                 0           0     - /sys
none                              10864      507124    3% /dev
/dev/loop1                        41418           0  100% /tmp/sw/fp/0/0/fp/mount
none                              10864      507124    3% /dev
/proc/bus/usb                         0           0     - /proc/bus/usb

```

The table below describes the significant fields shown in the SIP slot (0, 1, or 2) displays.

Table 218: show platform software mount SIP slot Field Descriptions

Field	Description
Filesystem	Logical name of the file system device.
Used	Number of 1Kb blocks used.
Available	Number of free 1Kb blocks available.
Use%	Percentage of 1Kb blocks used of the total available.
Mounted on	Canonical path to the mounted file system.

The following example displays abbreviated (brief keyword) mounted file system information for Cisco ASR 1000 Series SIP slot 0:

```
Router# show platform software mount 0 brief
Mount point: rootfs
  Type     : rootfs
  Location : /
  Options  : rw
Mount point: proc
  Type     : proc
  Location : /proc
  Options  : rw
Mount point: sysfs
  Type     : sysfs
  Location : /sys
  Options  : rw
Mount point: none
  Type     : tmpfs
  Location : /dev
  Options  : rw
Mount point: /dev/loop1
  Type     : iso9660
  Location : /tmp/sw/cc/0/0/cc/mount
  Options  : ro

Mount point: none
  Type     : tmpfs
  Location : /dev
  Options  : rw

Mount point: /proc/bus/usb
  Type     : usbfs
  Location : /proc/bus/usb
  Options  : rw

Mount point: /dev/mtdblock1
  Type     : jffs2
  Location : /obfl
  Options  : rw,noatime,nodiratime

Mount point: automount(pid3199)
  Type     : autofs
```

```
Location : /misc1
Options  : rw,fd=5,pgrp=3199,timeout=60,minproto=2,maxproto=4,indirect
```

The tab le below describes the significant fields shown in the brief keyword display.

Table 219: show platform software mount brief Field Descriptions

Field	Description
Mount point:	Logical name of the file system device.
Type:	File system type.
Location:	Canonical path to the mounted file system.
Options:	Mount point type-specific flags and settings.

show platform software infrastructure punt-keepalive

To display information about the settings for the **platform punt-keepalive** command, use the **show platform software infrastructure punt-keepalive** command in the privileged EXEC mode.

show platform software infrastructure punt-keepalive

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.5S	This command was introduced.

Examples

The following is a sample output of the **show platform software infrastructure punt-keepalive** command when the punt-keepalive feature is enabled:

```
Router# show platform software infrastructure punt-keepalive

----- punt inject keepalive settings -----
punt keepalive interval (sec) = 2
punt keepalive warn count(miss) = 10
punt keepalive fatal (warn count) = 15

----- punt inject keepalive status -----
Last punt keepalive proc sched = 1.140 sec ago
Last punt keepalive sent = 1.140 sec ago
punt keepalive rx count = 1473
punt keepalive tx count = 1473
punt keepalive last keepalive received = yes

----- punt inject keepalive errors -----
punt keepalive failed to send no buffers = 0
punt keepalive tx fail count = 0

----- punt inject keepalive tweaks -----
ignore rx keepalive msg = no
ignore keepalive failover fault = yes
```

The following is a sample output of the **show platform software infrastructure punt-keepalive** command when the punt-keepalive feature is disabled:

```
Router# show platform software infrastructure punt-keepalive

----- punt inject keepalive settings -----
punt keepalive fatal (warn count) = 15
punt keepalive interval (sec) = 0(Stopped)
punt keepalive warning count (miss) = 10
Disable XE kernel core = No

----- punt inject keepalive status -----
```

```
Last punt keepalive proc sched = 8.005 sec ago
Last punt keepalive sent = 8.195 sec ago
punt keepalive rx count = 6695
punt keepalive tx count = 6695
punt keepalive last keepalive received = yes

----- punt inject keepalive errors -----
punt keepalive failed to send no buffers = 0
punt keepalive tx fail count = 0
```

Related Commands

Command	Description
platform punt-keepalive	Enables the Punt-Keepalive feature and monitors the status of the punt path between the forwarding processor (FP) and the route processor (RP).

show platform software interface summary

To display a summary of statistics for interfaces that are configured on a networking device, use the **show platform software interface summary** command in privileged EXEC mode.

show platform software interface summary [{[*name*][*queues*][*rates*]}]

Syntax Description

name	(Optional) Displays, for the named interface, a summary of the packets held and dropped in input/output queues and the transmission/reception rates.
queues	(Optional) Displays a summary of the packets held and dropped in input/output queues, for interfaces on the router..
rates	(Optional) Displays a summary of the transmission/reception rates, for interfaces on the router.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9	This command was introduced on Cisco 4400 Series Routers.

Usage Guidelines

Cisco ISR 4400 Series

On a Cisco ISR 4400 Series router you can use this command to show a summary of the packets held and dropped in input/output queues and the transmit/receive rates, for interfaces on the router.

Examples

The following example displays summary information for the interfaces of a Cisco 4400 Series router.

```
Router# show platform software interface summary
 Interface                  IHQ  IQD  OHQ  OQD  RXBS  RXPS  TXBS  TXPS  TRTL
-----------------------------------------------------------------------------
  GigabitEthernet0/0/0        0    0    0    0     0     0     0     0     0
  GigabitEthernet0/0/1        0    0    0    0     0     0     0     0     0
  GigabitEthernet0/0/2        0    0    0    0     0     0     0     0     0
  GigabitEthernet0/0/3        0    0    0    0     0     0     0     0     0
  Serial1/0/0                 0    0    0    0     0     0     0     0     0
* GigabitEthernet0            0    0    0    0 34000    60     0     0     0
```

Table 220: show platform software interface summary Field Descriptions

Field	Description
IHQ	Packets in input hold queue.
IQD	Packets dropped from input queue.
OHQ	Packets in output hold queue.

Field	Description
OQD	Packets dropped from output queue.
RXBS	Reception rate in bits per second.
RXPS	Reception rate in packets per second.
TXBS	Transmission rate in bits per second.
TXPS	Transmission rate in packets per second.
TRTL	Throttle count.

The following example displays summary (queues) information for interfaces of a Cisco 4400 Series router.

```
Router# show platform software interface summary queues

Interface                      IHQ           IQD           OHQ           OQD
----------------------------------------------------------------------------
GigabitEthernet0/0/0             0             0             0             0
GigabitEthernet0/0/1             0             0             0             0
GigabitEthernet0/0/2             0             0             0             0
GigabitEthernet0/0/3             0             0             0             0
Serial1/0/0                      0             0             0             0
GigabitEthernet0                 0             0             0             0
```

The table below describes the significant fields shown in the queues keyword display.

Table 221: show platform software interface summary queues Field Descriptions

Field	Description
IHQ	Packets in input hold queue.
IQD	Packets dropped from input queue.
OHQ	Packets in output hold queue.
OQD	Packets dropped from output queue.

Related Commands

Command	Description
show interfaces summary	Displays a summary of statistics for interfaces on a networking device.

show platform software l2pt statistics

Network devices maintain statistics counters for performance monitoring. Statistics counters in the Cisco routers collect Layer 2 Protocol Tunneling (L2PT) statistics, such as the number of packets that are enqueued and dequeued to an L2PT process, packets dropped, total number of outgoing tunneled packets, total number of outgoing L2 control packets, and unprocessed packets. Use the **show platform software l2pt statistics** command in previleged EXEC mode to collect L2PT statistics.

show platform software l2pt statistics

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Release	Modification
Cisco IOS XE Dublin 17.10.1	This command was introduced on Cisco NCS 520 Series Routers.

Examples

```
Router#show platform software l2pt statistics
Platform L2PT statistics:
 Number of packets enqueued to L2PT process  : 36
 Number of packets dequeued from L2PT process: 36
 Number of packets dropped                   : 0
 Total number of tunneled packets out        : 72
 Total number of L2 control packets out      : 0
 Number of packets failed to process         : 0
```

clear platform software l2pt counters

The **clear platform software l2pt counters** command clears the Layer 2 Protocol Tunneling (L2PT) statistics collected by the statistics counters.

clear platform software l2pt counters

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Release	Modification
Cisco IOS XE Dublin 17.10.1	This command was introduced on Cisco NCS 520 Series Routers.

Examples

```
Router#clear pla software l2pt counters
RTR1-Dom2#sh pla software l2pt statistics
Platform L2PT statistics:
 Number of packets enqueued to L2PT process  : 0
 Number of packets dequeued from L2PT process: 0
 Number of packets dropped                   : 0
 Total number of tunneled packets out        : 0
```

```
Total number of L2 control packets out      : 0
Number of packets failed to process         : 0
```

show platform software process list

To display a list of the processes running in a given slot, use the **show platform software process list**command in privileged EXEC or diagnostic mode.

show platform software process list *slot* [{**name** *process-name* | **process-id** *process-id* | **sort** *memory* | **summary**}]

Syntax Description

slot	Displays running process information for the specified *slot*. Possible *slot* values are: • **0**--Cisco ASR 1000 Series SPA Interface Processor (SIP) slot 0 • **1**--Cisco ASR 1000 Series SIP slot 1 • **2**--Cisco ASR 1000 Series SIP slot 2 • **f0**--Cisco ASR 1000 Series Embedded Services Processor (ESP) slot 0 • **f1**--Cisco ASR 1000 Series ESP slot 1 • **fp active**--Active Cisco ASR 1000 Series ESP • **fp standby**--Standby Cisco ASR 1000 Series ESP • **r0**--Cisco ASR 1000 Series Route Processor (RP) slot 0 • **r1**--Cisco ASR 1000 Series RP slot 1 • **rp active**--Active Cisco ASR 1000 Series RP • **rp standby**--Standby Cisco ASR 1000 Series RP
name *process-name*	(Optional) Displays information for the specified process name.
process-id process-id	(Optional) Displays information for the specified process ID.
sort *memory*	(Optional) Sorts the processes by memory.
summary	(Optional) Displays summary process information for the running host.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The name and process-id keywords can be used to narrow the process list display down to specific processes.

The **sort** keyword can be used to sort the process list by memory size.

The summary keyword can be used to display summary information about running processes.

Examples

The following example displays information about running processes for Cisco ASR 1000 Series SIP slot 0:

```
Router# show platform software process list 0

Name                     Pid    PPid  Group Id  Status    Priority  Size
------------------------------------------------------------------------------
init                       1       0         1  S               20  1974272

```

The table below describes the significant fields shown in the display.

Table 222: show platform software process list Field Descriptions

Field	Description
Name	Name of the process.

Field	Description
Pid	Process ID.
PPid	Parent Process ID.
Group Id	Process group ID.
Status	Process status.
Priority	Process priority.
Size	Virtual memory size (in bytes).

The following example displays information about a specific named process for Cisco ASR 1000 Series SIP slot 0:

```
Router# show platform software process list 0 name sleep
Name: sleep
  Process id       : 25938
  Parent process id: 3891
  Group id         : 3891
  Status           : S
  Session id       : 3816
  User time        : 0
  Kernel time      : 0
  Priority         : 20
  Virtual bytes    : 2482176
  Resident pages   : 119
  Resident limit   : 4294967295
  Minor page faults: 182
  Major page faults: 0
```

The following example displays information about a specific process identifier for Cisco ASR 1000 Series SIP slot 0:

```
Router# show platform software process list 0 process-id 1

Name: init
  Process id       : 1
  Parent process id: 0
  Group id         : 1
  Status           : S
  Session id       : 1
  User time        : 1
  Kernel time      : 741
  Priority         : 20
  Virtual bytes    : 1974272
  Resident pages   : 161
  Resident limit   : 4294967295
  Minor page faults: 756
  Major page faults: 0
```

The table below describes the significant fields shown in the **name** and **process-id keyword**displays.

Table 223: show platform software process list name and process-id Field Descriptions

Field	Description
Name	Name of the process.
Process id	Process ID.
Parent process id	Parent process ID.
Group id	Process group ID.
Status	Process status.
Session id	Process session ID.
User time	Time (in seconds) spent in user mode.
Kernel time	Time (in seconds) spent in kernel mode.
Priority	Process priority.
Virtual bytes	Virtual memory size (in bytes).
Resident pages	Resident page size.
Resident limit	Current limit on Resident pages.
Minor page faults	Number of minor page faults.
Major page faults	Number of major page faults.

The following example displays process summary information for Cisco ASR 1000 Series SIP slot 0:

```
Router# show platform software process list 0 summary
Total number of processes: 54
  Running          : 4
  Sleeping         : 50

```

The table below describes the significant fields shown in the **summary** keyword display.

Table 224: show platform software process list summary Field Descriptions

Field	Description
Total number of processes	Total number of processes in all possible states.
Running	Number of processes in the running state.
Sleeping	Number of processes in the sleeping state.
Disk sleeping	Number of processes in the disk-sleeping state.
Zombies	Number of processes in the zombie state.
Stopped	Number of processes in the stopped state.
Paging	Number of processes in the paging state.
Up time	System Up time (in seconds).
Idle time	System Idle time (in seconds).
User time	System time (in seconds) spent in user mode.
Kernel time	System time (in seconds) spent in kernel mode.
Virtual memory	Virtual memory size (in bytes).

Field	Description
Pages resident	Resident page size.
Major page faults	Number of major page faults.
Minor page faults	Number of minor page faults.
Architecture	System CPU architecture: PowerPC (ppc).
Memory (kB)	System memory heading.
Physical	Total physical memory (in kilobytes).
Total	Total available memory (in kilobytes). This value represents the physical memory available for kernel use.
Used	Used memory (in kilobytes).
Free	Free memory (in kilobytes).
Active	Most recently used memory (in kilobytes).
Inactive	Memory (in kilobytes) that has been less recently used. It is more eligible to be reclaimed for other purposes.
Inact-dirty	Memory (in kilobytes) that may need to be written to persistent store (cache or disk).
Inact-clean	Memory (in kilobytes) that is readily available for re-use.
Dirty	Memory (in kilobytes) that is waiting to get written back to the disk.
AnonPages	Memory (in kilobytes) that is allocated when a process requests memory from the kernel via the malloc() system call. This memory has no file backing on disk.
Bounce	Memory (in kilobytes) that is allocated to bounce buffers.
Cached	Amount of physical RAM (in kilobytes) used as cache memory.
Commit Limit	Total amount of memory (in kilobytes) currently available to be allocated on the system. This limit is only adhered to if strict overcommit accounting is enabled.
Committed As	Total amount of memory (in kilobytes) presently allocated on the system. The committed memory is a sum of all of the memory that has been allocated by processes, even if it has not been used by them as of yet.
High Total	Total amount of memory (in kilobytes) that is not directly mapped into kernel space. The High Total value can vary based on the type of kernel used.
High Free	Amount of free memory (in kilobytes) that is not directly mapped into kernel space. The High Free value can vary based on the type of kernel used.

Field	Description
Low Total	Total amount of memory (in kilobytes) that is directly mapped into kernel space. The Low Total value can vary based on the type of kernel used.
Low Free	Amount of free memory (in kilobytes) that is directly mapped into kernel space. The Low Free value can vary based on the type of kernel used.
Mapped	Total amount of memory (in kilobytes) that has been used to map devices, files, or libraries using the mmap command.
NFS Unstable	Total amount of memory (in kilobytes) used for unstable NFS pages. Unstable NFS pages are pages that have been written into the page cache on the server, but have not yet been synchronized to disk.
Page Tables	Total amount of memory (in kilobytes) dedicated to the lowest page table level.
Slab	Total amount of memory (in kilobytes) used by the kernel to cache data structures for its own use.
VMalloc Chunk	Largest contiguous block of available virtual address space (in kilobytes) that is free.
VMalloc Total	Total amount of memory (in kilobytes) of total allocated virtual address space.
VMalloc Used	Total amount of memory (in kilobytes) of used virtual address space.
Writeback	Memory (in kilobytes) that is actively being written back to the disk.
Swap (kB)	Swap memory heading.
Total	Total swap memory (in kilobytes).
Used	Used swap memory (in kilobytes).
Free	Free swap memory (in kilobytes).
Cached	Cached swap memory (in kilobytes).
Buffers (kB)	Buffers heading.
Load Average	Indicators of system load.
1-Min	Average number of processes running for the last minute.
5-Min	Average number of processes running for the last 5 minutes.
15-Min	Average number of processes running for the last 15 minutes.

The following example displays process summary information for Cisco ASR 1000 Series sorted by memory size:

```

show platform software process memory

To display the memory statistics of a platform software process, use the **show platform software process memory** command in privileged EXEC mode or diagnostic mode.

show platform software process memory *host* {**name** *process-name* {**maps** | **smaps**} | **process-id** *process-id* {**maps** | **smaps**} | **all** [{**sorted** | **virtual** [{**sorted**}] | **rss** [{**sorted**}]}]}

Syntax Description

host	Process information. Possible *host* values are: • **0**—Cisco ASR 1000 Series SPA Interface Processor (SIP) slot 0 • **1**—Cisco ASR 1000 Series SIP slot 1 • **f0**—Cisco ASR 1000 Series Embedded Services Processor (ESP) slot 0 • **fp**—Cisco ASR 1000 Series ESP • **r0**—Cisco ASR 1000 Series Route Processor (RP) slot 0 • **rp**—Cisco ASR 1000 Series RP
name *process-name*	Displays the name of the specified process.
maps	Displays the memory maps of the specified process.
smaps	Displays the smaps of the specified process.
process-id *process-id*	Displays the ID of the specified process.
all	Lists all the processes.
sorted	Sorts the output from the highest size to the lowest size.
virtual	Displays the virtual memory footprint of all the processes.
rss	Displays the physical memory footprint of all the processes.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 3.8S	This command was introduced.
Cisco IOS XE Release 3.9S	This command was modified. The **all**, **virtual**, and **rss** keywords were added.

Examples

The following is sample output of the **show platform software process memory** command on the host *r0* with the keywords **name** and **maps**:

```
Device# show platform software process memory r0 name smand maps

maps for process 29284:
address           perms offset   dev   inode      pathname

The following table describes the significant fields shown in the display.

Table 225: show platform software process memory Field Descriptions

Field	Description
Address	Address space that the memory occupies in the process.
Perms	Set of permissions, such as: • **r**—Read • **w**—Write • **x**—Execute • **s**—Shared • **p**—Private
Offset	Offset into the file.
Dev	Number of the device.
Inode Number	Number of the inode on the device.
PathName	Location of the file.
Name	Name of the process.
PID	Process ID.
VIRT	Virtual memory size (in KB).
RSS	Resident Set Size (in KB).
PSS	Proportional Set Size (in KB).
Heap	Heap memory (in KB).
Shared	Memory and libraries shared with other processes (in KB).
Private	Memory that is exclusive to the specified process (in KB).

Related Commands

Command	Description
show platform software process list	Displays the list of processes running in a given slot.

show platform software ptp foreign-master

To display the PTP foreign-master information, use the show platform software ptp foreign-master command in privileged EXEC mode.

show platform software ptp [{**foreign-master**}] **domain** *domain-number*

Syntax Description

domain	Filters output by domain.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
IOS-XE 3.18	This command was introduced.

Usage Guidelines

Use this command to verify a PTP foreign-master information.

Examples

The following examples show the output generated by this command:

```
Router# show platform software ptp foreign-master domain 24

PTPd Foreign Master Information:

Current Master: SLA

Port: SLA
  Clock Identity: 0x74:A2:E6:FF:FE:5D:CE:3F
  Clock Stream Id: 0
  Priority1: 128
  Priority2: 128
  Local Priority: 128
  Clock Quality:
    Class: 6
    Accuracy: Within 100ns
    Offset (Log Variance): 0x4E5D
  Steps Removed: 1
  Not-Slave: FALSE
```

The table below describes significant fields shown in the display.

Table 226: show ptp clock dataset Field Descriptions

Field	Description
Current Master	Indicates the type of foreign master.
Port	Indicates the type of port.
Clock Identity	Unique identifier for the clock.
Priority1	Priority1 preference value of the PTP clock; the priority1 clock is considered first during clock selection.

Field	Description
Priority2	Priority2 preference value of the PTP clock; the priority2 clock is considered after all other clock sources during clock selection.
Local Priority	Indicates the PTP clock local priority.
Clock quality	Summarizes the quality of the grandmaster clock.
Class	Displays the time and frequency traceability of the grandmaster clock
Accuracy	Field applies only when the Best Master Clock algorithm is in use; indicates the expected accuracy of the master clock were the grandmaster clock.
Offset (log variance)	Offset between the local clock and an ideal reference clock.
Steps removed	Number of hops from the local clock to the grandmaster clock.
Not-Slave	Indicates whether the foreign master is a slave.

show platform software status control-processor

To display status information about the control processors, use the **showplatformsoftwarestatuscontrol-processor**command in privileged EXEC or diagnostic mode.

show platform software status control-processor [**brief**]

Syntax Description

brief	(Optional) Displays summary status information for the control processors.

Command Modes

Privileged EXEC (#) Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.
Cisco IOS XE Release 2.2	This command was modified. The **brief** keyword was added.

Usage Guidelines

Control processors consist of Embedded Services Processors (ESPs), Route Processors (RPs), and SPA Interface Processors (SIPs).

Use the **showplatformsoftwarestatuscontrol-processor** command to provide a quick view of the health of the system concerning memory and CPU usage on each processor.

The CPU usage output reflects the relative percentage of CPU usage during the latest two seconds instead of the cumulative percent usage over the entire uptime.

All control processors should show a status of Healthy. Other possible status values are Warning and Critical. Warning indicates that the router is operational but that the operating level should be reviewed. Critical implies that the router is near failure.

If you see a status of Warning or Critical, take the following actions:

- Reduce static and dynamic loads on the system by reducing the number of elements in the configuration or by limiting the capacity for dynamic services.
- Reduce the number of routes and adjacencies, limit the number of ACLs and other rules, reduce the number of VLANs, and so on.

Examples

The following example displays status information about the control processors:

```
Router# show platform software status control-processor
RP0: online, statistics updated 7 seconds ago
Load Average: healthy
  1-Min: 0.16, status: healthy, under 5.00
  5-Min: 0.16, status: healthy, under 5.00
  15-Min: 0.12, status: healthy, under 5.00
Memory (kb): healthy
  Total: 3733016
  Used: 1320804 (31%)
  Free: 2412212 (58%)
  Committed: 1889524 (45%), status: healthy, under 90%
```

```
ESP0: online, statistics updated 7 seconds ago
Load Average: healthy
  1-Min: 0.00, status: healthy, under 5.00
  5-Min: 0.00, status: healthy, under 5.00
  15-Min: 0.00, status: healthy, under 5.00
Memory (kb): healthy
  Total: 984996
  Used: 532492 (50%)
  Free: 452504 (43%)
  Committed: 1724096 (164%), status: healthy, under 300%
SIP0: online, statistics updated 10 seconds ago
Load Average: healthy
  1-Min: 0.00, status: healthy, under 5.00
  5-Min: 0.00, status: healthy, under 5.00
  15-Min: 0.00, status: healthy, under 5.00
Memory (kb): warning
  Total: 479884
  Used: 434476 (82%)
  Free: 45408 (8%)
  Committed: 202508 (38%), status: healthy, under 90%
SIP1: online, statistics updated 10 seconds ago
Load Average: healthy
  1-Min: 0.00, status: healthy, under 5.00
  5-Min: 0.00, status: healthy, under 5.00
  15-Min: 0.00, status: healthy, under 5.00
Memory (kb): warning
  Total: 479884
  Used: 430384 (82%)
  Free: 49500 (9%)
  Committed: 202512 (38%), status: healthy, under 90%
```

The following example displays summary status information about the control processors with **brief** keyword:

```
Router# show platform software status control-processor brief
Load Average
 Slot  Status  1-Min  5-Min 15-Min
  RP0 Healthy   0.25   0.30   0.44
  RP1 Healthy   0.31   0.19   0.12
 ESP0 Healthy   0.01   0.05   0.02
 ESP1 Healthy   0.03   0.05   0.01

```

The table below describes the significant fields shown in the display.

Table 227: show platform software status control-processor Field Descriptions

Field	Description
processor-name : online	Name of the online control processor to which the statistics that follow apply.
statistics updated x seconds ago	Time (in seconds) when the statistics were last updated.
Load Average:	Summary status indicator of the overall control processor load average. This value is derived from the “5-Min” load average.
1-Min: / status:	One-minute load average on the control processor and status indicator.
5-Min: / status:	Five-minute load average on the control processor and status indicator.
15-Min: / status:	Fifteen-minute load average on the control processor and status indicator.
Memory (kb):	Summary status indicator of the overall control processor memory usage. This value signals if any of the individual memory values below are in critical or warning status.
Total:	Total memory (in kilobytes) on the control processor.
Used: xxxxxxx (pp%)	Total used memory (in kilobytes) on the control processor and the percentage of used memory on the control processor.
Free: xxxxxxx (pp%)	Total free memory (in kilobytes) on the control processor and the percentage of free memory on the control processor.
Committed: xxxxxxx (pp%) / status:	Total committed memory (in kilobytes) on the control processor, percentage of committed memory on the control processor, and status indicator.
CPU Utilization:	Percentage of time that the CPU is busy.
CPU:	Allocated processor.
User:	Non-Linux kernel processes.
System:	Linux kernel process.
Nice:	Low priority processes.
Idle:	Percentage of time that the CPU was inactive.
IRQ:	Interrupts.
SIRQ:	System interrupts.
IOwait:	Percentage of time that the CPU was waiting for I/O.

Related Commands

Command	Description
show platform software process list	Displays a list of the processes running in a given slot.

show platform software punt-policer

To display the VLAN packets that are sent to the IOS on a Cisco ASR 1000 Router, use the **show platform software punt-policer** command in privileged EXEC mode.

show platform software punt-policer

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE 3.2.0S	This command was introduced.
Cisco IOS XE 3.13.0S	This command was integrated into Cisco IOS XE Release 3.13.0S.

Example

The following is sample output of the **show platform software punt-policer** command:

```
Router# show platform software punt-policer

Punt                               Configured (pps)    Conform Packets     Dropped Packets
Cause      Description             Normal      High    Normal     High      Normal    High

-------------------------------------------------------------------------------------------
96       VLAN Auto Sense FSOL       2000       1000       0         0           0         0
```

The following table describes the significant fields shown in the display.

Table 228: show platform software punt-policer

Field	Description
Punt Cause	Indicates the punt cause number.
Description	Indicates the feature associated with a particular punt cause.
Configured (pps)	Indicates the number of packets the system handles for a particular VLAN. You can change the default maximum punt rate value 1000 by using the **platform punt-policer** *punt cause* command.
Conform Packets	Indicates the number of packets that conform to the rate limit.
Dropped Packets	Indicates the number of packets that are dropped.

show platform process slot

To monitor the software-running process in a given slot, use the **show platform software process slot**command in privileged EXEC or diagnostic mode.

show platform software process slot *slot* **monitor** [{**cycles** *cycles*}][{**interval** *delay*}][{**lines** *lines-of-output*}]

Syntax Description

slot	Specifies the Field Replace Unit (FRU) where the command is run.
slot	Slot information.
monitor	Monitors the running processes.
cycles	Checks the processes multiple times.
cycles	Number of times the command is run during a single invocation of the command. The range is from 1 to 4294967295. The default is 5.
interval	Sets delay interval after each command run.
delay	Delay between two successive runs of the command. The range is from 0 to 300. The default is 3.
lines	Sets the number of output lines that are displayed.
lines-of-output	Number of output lines displayed. The range is from 0 to 512. 0 displays all the lines. **Note** The number of lines is determined by the current terminal length.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.1.0S	This command was introduced in a release earlier than Release 3.1.0S on Cisco ASR 1000 Series Routers.

Examples

The following is a sample output of the show platform software process slot command. Only 23 lines are displayed because the lines-of-output argument is set to 23:

```
Router# show platform software process slot 0 monitor cycles 3 interval 2 lines 23
top - 19:29:32 up 1 day,  4:46,  0 users,  load average: 0.10, 0.11, 0.09

The table below describes the significant fields shown in the display.

Table 229: show platform software process slot Field Descriptions

Field	Description
%CPU	CPU Usage
%MEM	Memory Usage
COMMAND	Command name or command line
NI	Nice value
PID	Process ID
PR	Priority
RES	Resident memory size (in kb)
S	Process status
SHR	Shared memory size (in kb)
TIME+	Elapsed execution time
USER	User name
VIRT	Virtual memory size (in kb)

show platform software tech-support

To display system information or create a technical support information tar file for Cisco Technical Support, use the **show platform software tech-support**command in privileged EXEC or diagnostic mode.

show platform software tech-support [**file** {**bootflash:***filename***.tgz** | **fpd:***filename***.tgz** | **harddisk:***filename***.tgz** | **obfl:***filename***.tgz** | **stby-bootflash:***filename***.tgz** | **stby-harddisk:***filename***.tgz** | **stby-obfl:***filename***.tgz** | **stby-usb0:***filename***.tgz** | **stby-usb1:***filename***.tgz**}]

Syntax Description

file	(Optional) Creates a technical support information tar file for the specified destination file path.
bootflash: *filename* **.tgz**	Creates a technical support information tar file for the boot flash memory file system on the active RP.
fpd:*filename***.tgz**	Creates a technical support information tar file for the field-programmable device (FPD) image package on the active RP. The information displayed is for internal debugging puposes only.
harddisk:*filename* **.tgz**	Creates a technical support information tar file for the hard disk file system on the active RP.
obfl:*filename***.tgz**	Creates a technical support information tar file for the file system for Onboard Failure Logging (obfl) files. The information displayed is for internal debugging puposes only.
stby-bootflash: *filename* **.tgz**	Creates a technical support information tar file for the boot flash memory file system on the standby RP. The information displayed is for internal debugging puposes only.
stby-harddisk: *filename* **.tgz**	Creates a technical support information tar file for the hard disk file system on the standby RP. The information displayed is for internal debugging puposes only.
stby-obfl:*filename***.tgz**	Creates a technical support information tar file for the Onboard Failure Logging (obfl) files on the standby RP. The information displayed is for internal debugging puposes only.
stby-usb0:*filename***.tgz**	Creates a technical support information tar file for Universal Serial Bus (USB) memory. The information displayed is for internal debugging puposes only.
stby-usb1:*filename***.tgz**	Creates a technical support information tar file for Universal Serial Bus (USB) memory. The information displayed is for internal debugging puposes only.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Diagnostic (diag)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

If the file keyword is specified, the specification of the bootflash: or harddisk: keyword and filename is required.

The show platform software tech-support command without a destination file path specification returns a large volume of information in a short period of time. You should save the output of the show platform software tech-support command in a log file to send to Cisco Technical Support for analysis.

Examples

The following example displays system information for Cisco Technical Support:

```
Router# show platform software tech-support
---- show version installed -----
Type: provisioning file, Version: unknown
  Provisioned on: RP0, Status: active
  File: packages.conf.super
  Modified: 2007-11-07 15:06:12.212303000 +0000
  SHA1 (header): d929d995d5ba2d3dedf67137c3e0e321b1727d7b
  SHA1 (calculated): d929d995d5ba2d3dedf67137c3e0e321b1727d7b
  SHA1 (external): a16881b6a7e3a5593b63bf211f72b8af9c534063
instance address        : 0X890DE9B4
    fast failover address   : 00000000
    cpp interface handle  0
    instance address        : 0X890DE9B8
    fast failover address   : 00000000
    cpp interface handle  0
    instance address        : 0X890DE9BC
    fast failover address   : 00000000
...
```

Note The show platform software tech-support command returns a large volume of information in a short period of time. The example above has been abbreviated for the purposes of this description.

The following example creates a technical support information tar file for the boot flash memory file system on the active RP:

```
Router# show platform software tech-support file bootflash:tech_support_output.tgz
Running tech support command set; please wait...
Creating file 'bootflash:target_support_output.tgz.tgz' ...
File 'bootflash:target_support_output.tgz.tgz' created successfully
```

The following example creates a technical support information tar file for the hard disk file system on the active RP:

```
Router# show platform software tech-support file harddisk:tech_support_output.tgz
Running tech support command set; please wait...
Creating file 'harddisk:tech_support_ouput.tgz.tgz' ...
File 'harddisk:tech_support_ouput.tgz.tgz' created successfully
```

show platform software vnic-if interface-mapping

To display the mapping between the virtual Network Interface Cards (vNICs) on the virtual machine (VM) and the network interfaces on the virtual router, use the **show platform software vnic-if interface-mapping** command in Privileged EXEC mode.

show platform software vnic-if interface-mapping

Command Modes

Privilged EXEC

Command History

Release	Modification
Cisco IOS XE Release 3.8S (Controlled Availability)	This command was introduced on the Cisco CSR 1000V Cloud Services Router.
Cisco IOS XE Release 3.10S	The command display fields were changed. The Short Name field was removed, and the vNIC Name field was changed to Driver Name.

Usage Guidelines

The GigabitEthernet0 interface configured on the Cisco CSR 1000V automatically maps to the vNIC designated as “eth0” on the VM.

All subsequent interfaces configured on the router are sequentially mapped to the corresponding vNIC interface on the VM. For example, the GigabitEthernet1 interface is mapped to the eth1 vNIC on the VM, and the GigabitEthernet2 interface is mapped to the eth2 vNIC.

The display for this command was changed in Cisco IOS XE 3.10S.

Examples

The following example displays the vNIC-to-interface mapping for Cisco IOS XE Release 3.9S and earlier:

```
Router# show platform software vnic-if interface-mapping
-------------------------------------------------------------------------
Interface Name        Short Name     vNIC Name           Mac Addr
-------------------------------------------------------------------------
GigabitEthernet0       Gi0        eth0 (vmxnet3)      000c.2946.3f4d
GigabitEthernet2       Gi2        eth2 (vmxnet3)      0050.5689.0034
GigabitEthernet1       Gi1        eth1 (vmxnet3)      0050.5689.000b
-------------------------------------------------------------------------
```

The following example displays the vNIC-to-interface mapping for Cisco IOS XE Release 3.10S and later:

```
csr1000v# show platform software vnic-if interface-mapping
--------------------------------------------------------------------------
Interface Name             Driver Name          Mac Addr
--------------------------------------------------------------------------
GigabitEthernet0            vmxnet3           000c.2946.3f4d
GigabitEthernet2            vmxnet3           0050.5689.0034
GigabitEthernet1            vmxnet3           0050.5689.000b
--------------------------------------------------------------------------
```

The following table describes the significant fields shown in the display.

Table 230: show platform software vnic-if interface-mapping Field Descriptions

Field	Description
Interface Name	The virtual router interface name.
Short Name	(Cisco IOS XE 3.9S and earlier) The virtual router short interface name.
vNIC Name	(Cisco IOS XE 3.9S and earlier) The virtual network interface on the VM that the virtual router interface is mapped to.
Driver Name	(Cisco IOS XE 3.10S and later) The vNIC driver type for the interface on the VM that the virtual router interface is mapped to.
Mac Addr	The MAC address on the VM's physical host that the virtual network interface (vNIC) is mapped to.

Related Commands

Command	Description
clear platform software vnic-if-nvtable	Clears the virtual router's persistent interface database on the original VM and updates the interface mapping to the hypervisor.

show platform time-source

To display the platform time-source details configured, use the **showplatformtime-source** command in the Privileged Exec mode .

show platform time-source

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(2)S	This command was introduced on the Cisco 7600 series routers.

Usage Guidelines

The**showplatformtime-source** command displays the platform time source configuration.

Examples

This example displays the show platform time source output:

```
Router#show platform time-source
 Time Source mode     : PTP
 PTP State            : Synchronized
 Master IP Address    : 200.1.1.2
 Slave IP Address     : 60.60.60.60
 UDP Source Port      : 51966
 UDP Destination Port : 320
 Control packets sent : 21
 Internal Vlan        : 1035
```

Related Commands

Command	Description
platform time-source	Initiates the Time of Day (ToD) synchroniztion on a line card.

show plim fpga

To display details gathered from the registers of the internal FPGA (Field Programmable Gate Array) located in the PLIM (Physical Layer Interface Module) section of the line card, use the **show plim fpga** command in privileged EXEC mode.

show plim fpga

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(33)S4	This command was introduced.

Usage Guidelines

This command helps you to troubleshoot datapath failures and get the datapath counters on Shiver FPGA.

The following information is available:

- Rx packet counter
- Tx packet counter
- Rx Error Counter
- Status and control register
- Door bell register status
- FPGA Binary image revision number
- Whether loop back is enabled
- Whether Ingress and Egress paths are enabled

Examples

The following example shows how to display the Shiver FPGA details:

```
Router# show plim fpga
***Shiver FPGA Stats***
FPGA Doorbell Register   : 0x00
FGPA binary image Revsion : 0xDD
FPGA Datapath Ctrl Reg   : 0x000B
 FPGA is Enabled in Eggress Direction
 FGPA is Enabled in Ingress Direction
 FPGA Eggress is Empty
======== Output from Tofab755 =======
FPGA Control and Status Register  : 0x028104dd
FPGA Rx Packet Count    : 0x000000cc
FPGA Tx Packet Count    : 0x000000cb
FPGA Rx Packet Error Count   : 0x0008ffff
```

The table below describes significant fields shown in the display.

Table 231: show plim fpga Field Descriptions

Field	Description
FPGA Doorbell Register	Line card's version of mailbox doorbell register.
FGPA binary image Revision	FPGA image version.
FPGA Datapath Ctrl Reg	Indicates whether the ingress and eggress paths are enabled or disabled.
Control and Status Register	A 32-bit read-write register that provides the MPC8260 processor with interrupt mask control, interrupt status, Rx Error status, and the FPGA revision ID.
Rx Packet Count	The number of packets received from the FREEDM-336 in the receive direction. This 32-bit count value saturates at 0xFFFF_FFFF. The counter is cleared when a write cycle is detected.
Tx Packet Count	The number of packets transmitted to the FREEDM-336. This 32-bit count value saturates at 0xFFFF_FFFF. The counter is cleared when a write cycle is detected.
Rx Packet Error Count	The number of packets with errors received from the FREEDM-336 in the receive direction. In this 32-bit counter, the 16 bit MSB (Most Significant Bit) indicates the errors that saturate after the value reaches FFFF. The value of LSB (Least Significant Bit) 16 bits will always be FFFF.

show policy-map interface

To display the statistics and the configurations of the input and output policies that are attached to an interface, use the **show policy-map interface** command in user EXEC or privileged EXEC mode.

ATM Shared Port Adapters

show policy-map interface *slot/subslot/port* **.**[*subinterface*]

Cisco CMTS Routers

show policy-map interface *interface-type slot/subslot/port*

Cisco 3660, 3845, 7200, 7400, 7500, Cisco ASR 903 Series Routers, and Cisco ASR 1000 Series Routers

show policy-map interface *type type-parameter* [**vc** [*vpi*][/]*vci*] [**dlci** *dlci*] [{**input** | **output**}] [**class** *class-name*]

Cisco 6500 Series Switches

show policy-map interface [{*interface-type interface-number* | **vlan** *vlan-id*}] [**detailed**] [{**input** | **output**} [**class** *class-name*]]

show policy-map interface [**port-channel** *channel-number* [**class** *class-name*]]

Cisco 7600 Series Routers

show policy-map interface [{*interface-type interface-number* | **null 0** | **vlan** *vlan-id*}] [{**input** | **output**}]

Syntax Description

slot	(CMTS and ATM shared port adapter only) Chassis slot number. See the appropriate hardware manual for slot information. For SIPs, see the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
/subslot	(CMTS and ATM shared port adapter only) Secondary slot number on an SPA interface processor (SIP) where a SPA is installed. See the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on an SPA" topic in the platform-specific SPA software configuration guide for subslot information.
port	(CMTS and ATM shared port adapter only) Port or interface number. See the appropriate hardware manual for port information. For SPAs, see the corresponding "Specifying the Interface Address" topics in the platform-specific SPA software configuration guide.
.*subinterface*	(ATM shared port adapter only—Optional) Subinterface number. The number that precedes the period must match the number to which this subinterface belongs. The range is 1 to 4,294,967,293.
type	Type of interface or subinterface whose policy configuration is to be displayed.
type-parameter	Port, connector, interface card number, class-map name or other parameter associated with the interface or subinterface type.
vc	(Optional) For ATM interfaces only, shows the policy configuration for a specified PVC.

vpi /	(Optional) ATM network virtual path identifier (VPI) for this permanent virtual circuit (PVC). On the Cisco 7200 and 7500 series routers, this value ranges from 0 to 255. The *vpi* and *vci* arguments cannot both be set to 0; if one is 0, the other cannot be 0. The absence of both the forward slash (/) and a *vpi* value defaults the *vpi* value to 0. If this value is omitted, information for all virtual circuits (VCs) on the specified ATM interface or subinterface is displayed.
vci	(Optional) ATM network virtual channel identifier (VCI) for this PVC. This value ranges from 0 to 1 less than the maximum value set for this interface by the **atmvc-per-vp** command. Typically, the lower values 0 to 31 are reserved for specific traffic (F4 Operation, Administration, and Maintenance [OAM], switched virtual circuit [SVC] signaling, Integrated Local Management Interface [ILMI], and so on) and should not be used. The VCI is a 16-bit field in the header of the ATM cell. The VCI value is unique only on a single link, not throughout the ATM network, because it has local significance only. The *vpi* and *vci* arguments cannot both be set to 0; if one is 0, the other cannot be 0.
dlci	(Optional) Indicates a specific PVC for which policy configuration will be displayed.
dlci	(Optional) A specific data-link connection identifier (DLCI) number used on the interface. Policy configuration for the corresponding PVC will be displayed when a DLCI is specified.
input	(Optional) Indicates that the statistics for the attached input policy will be displayed.
output	(Optional) Indicates that the statistics for the attached output policy will be displayed.
class *class-name*	(Optional) Displays the QoS policy actions for the specified class.
interface-type	(Optional) Interface type; possible valid values are **atm**, **ethernet**, **fastethernet**, **ge-wan gigabitethernet**, **pos**, **pseudowire** and **tengigabitethernet**.
interface-number	(Optional) Module and port number; see the “Usage Guidelines” section for valid values.
vlan *vlan-id*	(Optional) Specifies the VLAN ID; valid values are from 1 to 4094.
detailed	(Optional) Displays additional statistics.
port-channel *channel-number*	(Optional) Displays the EtherChannel port-channel interface.
null 0	(Optional) Specifies the null interface; the only valid value is 0.

Command Default

This command displays the packet statistics of all classes that are configured for all service policies on the specified interface or subinterface or on a specific permanent virtual circuit (PVC) on the interface.

When used with the ATM shared port adapter, this command has no default behavior or values.

Command Modes

Privileged EXEC (#)

ATM Shared Port Adapter

User EXEC (>)

Privileged EXEC (#)

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.0(5)XE	This command was integrated into Cisco IOS Release 12.0(5)XE.
12.0(7)S	This command was integrated into Cisco IOS Release 12.0(7)S.
12.0(28)S	This command was modified for the QoS: Percentage-Based Policing feature to include milliseconds when calculating the committed (conform) burst (bc) and excess (peak) burst (be) sizes.
12.1(1)E	This command was integrated into Cisco IOS Release 12.1(1)E.
12.1(2)T	This command was modified to display information about the policy for all Frame Relay PVCs on the interface or, if a DLCI is specified, the policy for that specific PVC. This command was also modified to display the total number of packets marked by the quality of service (QoS) set action.
12.1(3)T	This command was modified to display per-class accounting statistics.
12.2(4)T	This command was modified for two-rate traffic policing and can display burst parameters and associated actions.
12.2(8)T	This command was modified for the Policer Enhancement—Multiple Actions feature and the WRED—Explicit Congestion Notification (ECN) feature. For the Policer Enhancement—Multiple Actions feature, the command was modified to display the multiple actions configured for packets conforming to, exceeding, or violating a specific rate. For the WRED—Explicit Congestion Notification (ECN) feature, the command displays ECN marking information.

Release	Modification
12.2(13)T	The following modifications were made: • This command was modified for the Percentage-Based Policing and Shaping feature. • This command was modified for the Class-Based RTP and TCP Header Compression feature. • This command was modified as part of the Modular QoS CLI (MQC) Unconditional Packet Discard feature. Traffic classes in policy maps can now be configured to discard packets belonging to a specified class. • This command was modified to display the Frame Relay DLCI number as a criterion for matching traffic inside a class map. • This command was modified to display Layer 3 packet length as a criterion for matching traffic inside a class map. • This command was modified for the Enhanced Packet Marking feature. A mapping table (table map) can now be used to convert and propagate packet-marking values.
12.2(14)SX	This command was modified. Support for this command was introduced on Cisco 7600 series routers.
12.2(15)T	This command was modified to display Frame Relay voice-adaptive traffic-shaping information.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2 and integrated into Cisco IOS Release 12.2(17d)SXB.
12.3(14)T	This command was modified to display bandwidth estimation parameters.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE. This command was modified to display aggregate WRED statistics for the ATM shared port adapter. Note that changes were made to the syntax, defaults, and command modes. These changes are labelled “ATM Shared Port Adapter.”
12.4(4)T	This command was modified. The **typeaccess-control** keywords were added to support flexible packet matching.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB, and the following modifications were made: • This command was modified to display either legacy (undistributed processing) QoS or hierarchical queueing framework (HQF) parameters on Frame Relay interfaces or PVCs. • This command was modified to display information about Layer 2 Tunnel Protocol Version 3 (L2TPv3) tunnel marking.

Release	Modification
12.2(31)SB2	The following modifications were made: • This command was enhanced to display statistical information for each level of priority service configured and information about bandwidth-remaining ratios, and this command was implemented on the Cisco 10000 series router for the PRE3. • This command was modified to display statistics for matching packets on the basis of VLAN identification numbers. As of Cisco IOS Release 12.2(31)SB2, matching packets on the basis of VLAN identification numbers is supported on Cisco 10000 series routers only.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
12.4(15)T2	This command was modified to display information about Generic Routing Encapsulation (GRE) tunnel marking. **Note** As of this release, GRE-tunnel marking is supported on the Cisco MGX Route Processor Module (RPM-XF) platform *only* .
12.2(33)SB	This command was modified to display information about GRE-tunnel marking, and support for the Cisco 7300 series router was added.
Cisco IOS XE 2.1	This command was integrated into Cisco IOS XE Release 2.1 and was implemented on the Cisco ASR 1000 series router.
12.4(20)T	This command was modified. Support was added for hierarchical queueing framework (HQF) using the Modular Quality of Service (QoS) Command-Line Interface (CLI) (MQC).
12.2(33)SXI	This command was implemented on the Catalyst 6500 series switch and modified to display the strict level in the priority feature and the counts per level.
12.2(33)SRE	This command was modified to automatically round off the bc and be values, in the MQC police policy map, to the interface's MTU size.
Cisco IOS XE Release 2.6	The command output was modified to display information about subscriber QoS statistics.
12.2(54)SG	This command was modified to display only the applicable count of policer statistics.
12.2(33)SCF	This command was integrated into Cisco IOS Release 12.2(33)SCF.
Cisco IOS XE Release 3.7S	This command was implemented on Cisco ASR 903 Series Routers.
Cisco IOS XE Release 3.8S	This command was modified. The *pseudowire* interface type was added.
Cisco IOS XE Release 3.8S	This command was modified. The *pseudowire* interface type was added on Cisco 1000 Series Routers.

Release	Modification
Cisco IOS Release 15.3(1)S	This command was modified. The *pseudowire* interface type was added.

Usage Guidelines

Cisco 3660, 3845, 7200, 7400, 7500, Cisco ASR 903 Series Routers, and Cisco ASR 1000 Series Routers

The **show policy-map interface** command displays the packet statistics for classes on the specified interface or the specified PVC only if a service policy has been attached to the interface or the PVC.

The counters displayed after the **show policy-map interface** command is entered are updated only if congestion is present on the interface.

The **show policy-map interface** command displays policy information about Frame Relay PVCs only if Frame Relay Traffic Shaping (FRTS) is enabled on the interface.

The **show policy-map interface** command displays ECN marking information only if ECN is enabled on the interface.

To determine if shaping is active with HQF, check the queue depth field of the "(queue depth/total drops/no-buffer drops)" line in the **show policy-map interface** command output.

In HQF images for Cisco IOS Releases 12.4(20)T and later, the packets delayed and the bytes delayed counters were removed for traffic shaping classes.

Cisco 7600 Series Routers and Catalyst 6500 Series Switches

The pos, atm, and ge-wan interfaces are not supported on Cisco 7600 series routers or Catalyst 6500 series switches that are configured with a Supervisor Engine 720

Cisco 7600 series routers and Catalyst 6500 series switches that are configured with a Supervisor Engine 2 display packet counters.

Cisco 7600 series routers and Catalyst 6500 series switches that are configured with a Supervisor Engine 720 display byte counters.

The output does not display policed-counter information; 0 is displayed in its place (for example, 0 packets, 0 bytes). To display dropped and forwarded policed-counter information, enter the **show mls qos** command.

On the Cisco 7600 series router, for OSM WAN interfaces only, if you configure policing within a policy map, the hardware counters are displayed and the class-default counters are not displayed. If you do not configure policing within a policy map, the class-default counters are displayed.

On the Catalyst 6500 series switch, the **show policy-map interface** command displays the strict level in the priority feature and the counts per level.

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

HQF

When you configure HQF, the **show policy-map interface** command displays additional fields that include the differentiated services code point (DSCP) value, WRED statistics in bytes, transmitted packets by WRED, and a counter that displays packets output/bytes output in each class.

Examples

This section provides sample output from typical **show policy-map interface** commands. Depending upon the interface or platform in use and the options enabled, the output you see may vary slightly from the ones shown below.

Weighted Fair Queueing (WFQ) on Serial Interface: Example

The following sample output of the **show policy-map interface** command displays the statistics for the serial 3/1 interface, to which a service policy called mypolicy (configured as shown below) is attached. Weighted fair queueing (WFQ) has been enabled on this interface. See the table below for an explanation of the significant fields that commonly appear in the command output.

```
policy-map mypolicy
 class voice
  priority 128
 class gold
  bandwidth 100
 class silver
  bandwidth 80
  random-detect
Router# show policy-map interface serial3/1 output

 Serial3/1
  Service-policy output: mypolicy
    Class-map: voice (match-all)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: ip precedence 5
      Weighted Fair Queueing
        Strict Priority
        Output Queue: Conversation 264
        Bandwidth 128 (kbps) Burst 3200 (Bytes)
        (pkts matched/bytes matched) 0/0
        (total drops/bytes drops) 0/0
    Class-map: gold (match-all)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: ip precedence 2
      Weighted Fair Queueing
        Output Queue: Conversation 265
        Bandwidth 100 (kbps) Max Threshold 64 (packets)
        (pkts matched/bytes matched) 0/0
        (depth/total drops/no-buffer drops) 0/0/0
    Class-map: silver (match-all)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: ip precedence 1
      Weighted Fair Queueing
        Output Queue: Conversation 266
        Bandwidth 80 (kbps)
        (pkts matched/bytes matched) 0/0
        (depth/total drops/no-buffer drops) 0/0/0
         exponential weight: 9
         mean queue depth: 0
class     Transmitted       Random drop      Tail drop    Minimum Maximum  Mark
          pkts/bytes        pkts/bytes       pkts/bytes    thresh  thresh  prob
0             0/0               0/0              0/0           20      40  1/10
1             0/0               0/0              0/0           22      40  1/10
2             0/0               0/0              0/0           24      40  1/10
3             0/0               0/0              0/0           26      40  1/10
```

```
4             0/0               0/0               0/0             28      40  1/10
5             0/0               0/0               0/0             30      40  1/10
6             0/0               0/0               0/0             32      40  1/10
7             0/0               0/0               0/0             34      40  1/10
rsvp          0/0               0/0               0/0             36      40  1/10
Class-map: class-default (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
```

Traffic Shaping on Serial Interface: Example

The following sample output from the **show policy-map interface** command displays the statistics for the serial 3/2 interface, to which a service policy called p1 (configured as shown below) is attached. Traffic shaping has been enabled on this interface. See the table below for an explanation of the significant fields that commonly appear in the command output.

Note In HQF images for Cisco IOS Releases 12.4(20)T and later, the packets delayed and bytes delayed counters were removed for traffic shaping classes.

```
policy-map p1
 class c1
  shape average 320000
Router# show policy-map interface serial3/2 output

 Serial3/2
  Service-policy output: p1
    Class-map: c1 (match-all)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: ip precedence 0
      Traffic Shaping
        Target    Byte   Sustain   Excess    Interval  Increment Adapt
        Rate      Limit  bits/int  bits/int  (ms)      (bytes)   Active
        320000    2000   8000      8000      25        1000      -
        Queue     Packets   Bytes     Packets   Bytes     Shaping
        Depth                         Delayed   Delayed   Active
        0         0         0         0         0         no
    Class-map: class-default (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
```

The table below describes significant fields commonly shown in the displays. The fields in the table are grouped according to the relevant QoS feature. A number in parentheses may appear next to the service-policy output name, class-map name, and match criteria information. The number is for Cisco internal use only and can be disregarded.

Table 232: show policy-map interface Field Descriptions

Field	Description
Fields Associated with Classes or Service Policies	

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets and bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.

Field	Description
Note In distributed architecture platforms (such as the Cisco 7500 series platform), the value of the transfer rate, calculated as the difference between the offered rate and the drop rate counters, can sporadically deviate from the average by up to 20 percent or more. This can occur while no corresponding burst is registered by independent traffic analyser equipment.	
Match	Match criteria specified for the class of traffic. Choices include criteria such as IP precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental (EXP) value, access groups, and QoS groups. For more information about the variety of match criteria that are available, see the "Classifying Network Traffic" module in the *Cisco IOS Quality of Service Solutions Configuration Guide* .
Fields Associated with Queueing (if Enabled)	
Output Queue	The weighted fair queueing (WFQ) conversation to which this class of traffic is allocated.
Bandwidth	Bandwidth, in either kbps or percentage, configured for this class and the burst size.
pkts matched/bytes matched	Number of packets (also shown in bytes) matching this class that were placed in the queue. This number reflects the total number of matching packets queued at any time. Packets matching this class are queued only when congestion exists. If packets match the class but are never queued because the network was not congested, those packets are not included in this total. However, if process switching is in use, the number of packets is always incremented even if the network is not congested.
depth/total drops/no-buffer drops	Number of packets discarded for this class. No-buffer indicates that no memory buffer exists to service the packet.

Field	Description
Fields Associated with Weighted Random Early Detection (WRED) (if Enabled)	
exponential weight	Exponent used in the average queue size calculation for a WRED parameter group.
mean queue depth	Average queue depth based on the actual queue depth on the interface and the exponential weighting constant. It is a fluctuating average. The minimum and maximum thresholds are compared against this value to determine drop decisions.
class	IP precedence level.
Transmitted pkts/bytes	Number of packets (also shown in bytes) passed through WRED and not dropped by WRED. **Note** If there is insufficient memory in the buffer to accommodate the packet, the packet can be dropped *after* the packet passes through WRED. Packets dropped because of insufficient memory in the buffer (sometimes referred to as “no-buffer drops”) are not taken into account by the WRED packet counter.
Random drop pkts/bytes	Number of packets (also shown in bytes) randomly dropped when the mean queue depth is between the minimum threshold value and the maximum threshold value for the specified IP precedence level.
Tail drop pkts/bytes	Number of packets dropped when the mean queue depth is greater than the maximum threshold value for the specified IP precedence level.
Minimum thresh	Minimum threshold. Minimum WRED threshold in number of packets.
Maximum thresh	Maximum threshold. Maximum WRED threshold in number of packets.
Mark prob	Mark probability. Fraction of packets dropped when the average queue depth is at the maximum threshold.
Fields Associated with Traffic Shaping (if Enabled)	
Target Rate	Rate used for shaping traffic.
Byte Limit	Maximum number of bytes that can be transmitted per interval. Calculated as follows: ((Bc+Be) /8) x 1
Sustain bits/int	Committed burst (Bc) rate.
Excess bits/int	Excess burst (Be) rate.
Interval (ms)	Time interval value in milliseconds (ms).

Field	Description
Increment (bytes)	Number of credits (in bytes) received in the token bucket of the traffic shaper during each time interval.
Queue Depth	Current queue depth of the traffic shaper.
Packets	Total number of packets that have entered the traffic shaper system.
Bytes	Total number of bytes that have entered the traffic shaper system.
Packets Delayed	Total number of packets delayed in the queue of the traffic shaper before being transmitted.
Bytes Delayed	Total number of bytes delayed in the queue of the traffic shaper before being transmitted.
Shaping Active	Indicates whether the traffic shaper is active. For example, if a traffic shaper is active, and the traffic being sent exceeds the traffic shaping rate, a "yes" appears in this field.

Precedence-Based Aggregate WRED on ATM Shared Port Adapter: Example

The following sample output of the **show policy-map interface** command displays the statistics for the ATM shared port adapter interface 4/1/0.10, to which a service policy called prec-aggr-wred (configured as shown below) is attached. Because aggregate WRED has been enabled on this interface, the classthrough Mark Prob statistics are aggregated by subclasses. See the table below for an explanation of the significant fields that commonly appear in the command output.

```
Router(config)# policy-map prec-aggr-wred
Router(config-pmap)# class class-default
Router(config-pmap-c)# random-detect aggregate
Router(config-pmap-c)# random-detect precedence values 0 1 2 3 minimum thresh 10
maximum-thresh 100 mark-prob 10
Router(config-pmap-c)# random-detect precedence values 4 5 minimum-thresh 40 maximum-thresh
 400 mark-prob 10
Router(config-pmap-c)# random-detect precedence values 6 minimum-thresh 60 maximum-thresh
600 mark-prob 10
Router(config-pmap-c)# random-detect precedence values 7 minimum-thresh 70 maximum-thresh
700 mark-prob 10
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface ATM4/1/0.10 point-to-point
Router(config-if)# ip address 10.0.0.2 255.255.255.0
Router(config-if)# pvc 10/110
Router(config-if)# service-policy output prec-aggr-wred
```

```
Router# show policy-map interface atm4/1/0.10

 ATM4/1/0.10: VC 10/110 -
  Service-policy output: prec-aggr-wred
    Class-map: class-default (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
```

```
        Exp-weight-constant: 9 (1/512)
        Mean queue depth: 0
        class       Transmitted     Random drop      Tail drop     Minimum   Maximum  Mark
 pkts/bytes pkts/bytes pkts/bytes thresh thresh prob

        0  1  2  3       0/0              0/0              0/0           10     100  1/10
        4  5             0/0              0/0              0/0           40     400  1/10
        6                0/0              0/0              0/0           60     600  1/10
        7                0/0              0/0              0/0           70     700  1/10
```

DSCP-Based Aggregate WRED on ATM Shared Port Adapter: Example

The following sample output of the **show policy-map interface** command displays the statistics for the ATM shared port adapter interface 4/1/0.11, to which a service policy called dscp-aggr-wred (configured as shown below) is attached. Because aggregate WRED has been enabled on this interface, the class through Mark Prob statistics are aggregated by subclasses. See the table below for an explanation of the significant fields that commonly appear in the command output.

```
Router(config)# policy-map dscp-aggr-wred
Router(config-pmap)# class class-default
Router(config-pmap-c)# random-detect dscp-based aggregate minimum-thresh 1 maximum-thresh
10 mark-prob 10
Router(config-pmap-c)# random-detect dscp values 0 1 2 3 4 5 6 7 minimum-thresh 10
maximum-thresh 20 mark-prob 10
Router(config-pmap-c)# random-detect dscp values 8 9 10 11 minimum-thresh 10 maximum-thresh
 40 mark-prob 10
Router(config-pmap-c)# exit
Router(config-pmap)# exit
Router(config)# interface ATM4/1/0.11 point-to-point
Router(config-subif)# ip address 10.0.0.2 255.255.255.0
Router(config-subif)# pvc 11/101
Router(config-subif)# service-policy output dscp-aggr-wred
Router# show policy-map interface atm4/1/0.11

 ATM4/1/0.11: VC 11/101 -
  Service-policy output: dscp-aggr-wred
    Class-map: class-default (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
        Exp-weight-constant: 0 (1/1)
        Mean queue depth: 0
        class       Transmitted     Random drop      Tail drop     Minimum   Maximum  Mark
                  pkts/bytes pkts/bytes pkts/bytes thresh thresh prob
        default          0/0              0/0              0/0            1      10  1/10
        0  1  2  3
        4  5  6  7       0/0              0/0              0/0           10      20  1/10
        8  9  10 11      0/0              0/0              0/0           10      40  1/10
```

The table below describes the significant fields shown in the display when aggregate WRED is configured for an ATM shared port adapter.

Table 233: show policy-map interface Field Descriptions—Configured for Aggregate WRED on ATM Shared Port Adapter

Field	Description
exponential weight	Exponent used in the average queue size calculation for a Weighted Random Early Detection (WRED) parameter group.

Field	Description
mean queue depth	Average queue depth based on the actual queue depth on the interface and the exponential weighting constant. It is a fluctuating average. The minimum and maximum thresholds are compared against this value to determine drop decisions.
Note When Aggregate Weighted Random Early Detection (WRED) is enabled, the following WRED statistics will be aggregated based on their subclass (either their IP precedence or differentiated services code point (DSCP) value).	
class	IP precedence level or differentiated services code point (DSCP) value.
Transmitted pkts/bytes	Number of packets (also shown in bytes) passed through WRED and not dropped by WRED. **Note** If there is insufficient memory in the buffer to accommodate the packet, the packet can be dropped *after* the packet passes through WRED. Packets dropped because of insufficient memory in the buffer (sometimes referred to as “no-buffer drops”) are not taken into account by the WRED packet counter.
Random drop pkts/bytes	Number of packets (also shown in bytes) randomly dropped when the mean queue depth is between the minimum threshold value and the maximum threshold value for the specified IP precedence level or DSCP value.
Tail drop pkts/bytes	Number of packets dropped when the mean queue depth is greater than the maximum threshold value for the specified IP precedence level or DSCP value.
Minimum thresh	Minimum threshold. Minimum WRED threshold in number of packets.
Maximum thresh	Maximum threshold. Maximum WRED threshold in number of packets.
Mark prob	Mark probability. Fraction of packets dropped when the average queue depth is at the maximum threshold.

Frame Relay Voice-Adaptive Traffic-Shaping: Example

The following sample output shows that Frame Relay voice-adaptive traffic shaping is currently active and has 29 seconds left on the deactivation timer. With traffic shaping active and the deactivation time set, this means that the current sending rate on DLCI 201 is minCIR, but if no voice packets are detected for 29 seconds, the sending rate will increase to CIR.

Note In HQF images for Cisco IOS Releases 12.4(20)T and later, the packets delayed and bytes delayed counters were removed for traffic shaping classes.

```
Router# show policy interface Serial3/1.1

 Serial3/1.1:DLCI 201 -
  Service-policy output:MQC-SHAPE-LLQ1

    Class-map:class-default (match-any)
      1434 packets, 148751 bytes
      30 second offered rate 14000 bps, drop rate 0 bps
      Match:any
      Traffic Shaping
           Target/Average   Byte   Sustain   Excess    Interval  Increment
             Rate           Limit  bits/int  bits/int  (ms)      (bytes)
            63000/63000     1890   7560      7560      120       945

        Adapt  Queue     Packets   Bytes     Packets   Bytes     Shaping
        Active Depth                         Delayed   Delayed   Active
        BECN   0         1434      162991    26        2704      yes
        Voice Adaptive Shaping active, time left 29 secs
```

The table below describes the significant fields shown in the display. Significant fields that are not described in the table below are described in the table above (for "show policy-map interface Field Descriptions").

Table 234: show policy-map interface Field Descriptions—Configured for Frame Relay Voice-Adaptive Traffic Shaping

Field	Description
Voice Adaptive Shaping active/inactive	Indicates whether Frame Relay voice-adaptive traffic shaping is active or inactive.
time left	Number of seconds left on the Frame Relay voice-adaptive traffic shaping deactivation timer.

Two-Rate Traffic Policing: Example

The following is sample output from the **show policy-map interface** command when two-rate traffic policing has been configured. In the example below, 1.25 Mbps of traffic is sent ("offered") to a policer class.

```
Router# show policy-map interface serial3/0
```

```
Serial3/0
 Service-policy output: policy1
  Class-map: police (match all)
   148803 packets, 36605538 bytes
   30 second offered rate 1249000 bps, drop rate 249000 bps
   Match: access-group 101
   police:
    cir 500000 bps, conform-burst 10000, pir 1000000, peak-burst 100000
    conformed 59538 packets, 14646348 bytes; action: transmit
    exceeded 59538 packets, 14646348 bytes; action: set-prec-transmit 2
    violated 29731 packets, 7313826 bytes; action: drop
    conformed 499000 bps, exceed 500000 bps violate 249000 bps
  Class-map: class-default (match-any)
   19 packets, 1990 bytes
   30 seconds offered rate 0 bps, drop rate 0 bps
   Match: any
```

The two-rate traffic policer marks 500 kbps of traffic as conforming, 500 kbps of traffic as exceeding, and 250 kbps of traffic as violating the specified rate. Packets marked as conforming will be sent as is, and packets marked as exceeding will be marked with IP Precedence 2 and then sent. Packets marked as violating the specified rate are dropped.

The table below describes the significant fields shown in the display.

Table 235: show policy-map interface Field Descriptions—Configured for Two-Rate Traffic Policing

Field	Description
police	Indicates that the **police** command has been configured to enable traffic policing. Also, displays the specified CIR, conform burst size, peak information rate (PIR), and peak burst size used for marking packets.
conformed	Displays the action to be taken on packets conforming to a specified rate. Displays the number of packets and bytes on which the action was taken.
exceeded	Displays the action to be taken on packets exceeding a specified rate. Displays the number of packets and bytes on which the action was taken.
violated	Displays the action to be taken on packets violating a specified rate. Displays the number of packets and bytes on which the action was taken.

Multiple Traffic Policing Actions: Example

The following is sample output from the **show policy-map** command when the Policer Enhancement—Multiple Actions feature has been configured. The sample output from the **show policy-map interface** command displays the statistics for the serial 3/2 interface, to which a service policy called “police” (configured as shown below) is attached.

```
policy-map police
 class class-default
  police cir 1000000 pir 2000000
   conform-action transmit
   exceed-action set-prec-transmit 4
   exceed-action set-frde-transmit
   violate-action set-prec-transmit 2
   violate-action set-frde-transmit
```

```
Router# show policy-map interface serial3/2

Serial3/2: DLCI 100 -
Service-policy output: police
    Class-map: class-default (match-any)
      172984 packets, 42553700 bytes
      5 minute offered rate 960000 bps, drop rate 277000 bps
      Match: any
     police:
         cir 1000000 bps, bc 31250 bytes, pir 2000000 bps, be 31250 bytes
       conformed 59679 packets, 14680670 bytes; actions:
         transmit
exceeded 59549 packets, 14649054 bytes; actions:
         set-prec-transmit 4
         set-frde-transmit
       violated 53758 packets, 13224468 bytes; actions:
         set-prec-transmit 2
         set-frde-transmit
       conformed 340000 bps, exceed 341000 bps, violate 314000 bps
```

The sample output from **show policy-map interface** command shows the following:

- 59679 packets were marked as conforming packets (that is, packets conforming to the CIR) and were transmitted unaltered.
- 59549 packets were marked as exceeding packets (that is, packets exceeding the CIR but not exceeding the PIR). Therefore, the IP Precedence value of these packets was changed to an IP Precedence level of 4, the discard eligibility (DE) bit was set to 1, and the packets were transmitted with these changes.
- 53758 packets were marked as violating packets (that is, exceeding the PIR). Therefore, the IP Precedence value of these packets was changed to an IP Precedence level of 2, the DE bit was set to 1, and the packets were transmitted with these changes.

Note Actions are specified by using the *action* argument of the **police** command. For more information about the available actions, see the **police** command reference page.

The table below describes the significant fields shown in the display.

Table 236: show policy-map interface Field Descriptions—Configured for Multiple Traffic Policing Actions

Field	Description
police	Indicates that the **police** command has been configured to enable traffic policing. Also, displays the specified CIR, conform burst size (BC), PIR, and peak burst size (BE) used for marking packets.
conformed, packets, bytes, actions	Displays the number of packets (also shown in bytes) marked as conforming to a specified rate and the actions taken on the packet. If there are multiple actions, each action is listed separately.
exceeded, packets, bytes, actions	Displays the number of packets (also shown in bytes) marked as exceeding a specified rate and the actions taken on the packet. If there are multiple actions, each action is listed separately.

Field	Description
violated, packets, bytes, actions	Displays the number of packets (also shown in bytes) marked as violating a specified rate and the actions taken on the packet. If there are multiple actions, each action is listed separately.

Explicit Congestion Notification: Example

The following is sample output from the **show policy-map interface** command when the WRED — Explicit Congestion Notification (ECN) feature has been configured. The words "explicit congestion notification" included in the output indicate that ECN has been enabled.

```
Router# show policy-map interface Serial4/1

 Serial4/1
  Service-policy output:policy_ecn
        Class-map:prec1 (match-all)
          1000 packets, 125000 bytes
          30 second offered rate 14000 bps, drop rate 5000 bps
          Match:ip precedence 1
          Weighted Fair Queueing
            Output Queue:Conversation 42
            Bandwidth 20 (%)
            Bandwidth 100 (kbps)
            (pkts matched/bytes matched) 989/123625
        (depth/total drops/no-buffer drops) 0/455/0
             exponential weight:9
             explicit congestion notification
             mean queue depth:0
     class   Transmitted  Random drop  Tail drop   Minimum     Maximum     Mark
             pkts/bytes   pkts/bytes    pkts/bytes threshold   threshold   probability
       0       0/0          0/0          0/0          20          40        1/10
       1     545/68125      0/0          0/0          22          40        1/10
       2       0/0          0/0          0/0          24          40        1/10
       3       0/0          0/0          0/0          26          40        1/10
       4       0/0          0/0          0/0          28          40        1/10
       5       0/0          0/0          0/0          30          40        1/10
       6       0/0          0/0          0/0          32          40        1/10
       7       0/0          0/0          0/0          34          40        1/10
     rsvp      0/0          0/0          0/0          36          40        1/10
     class   ECN Mark
            pkts/bytes
       0     0/0
       1    43/5375
       2     0/0
       3     0/0
       4     0/0
       5     0/0
       6     0/0
       7     0/0
     rsvp    0/0
```

The table below describes the significant fields shown in the display.

Table 237: show policy-map interface Field Descriptions—Configured for ECN

Field	Description
explicit congestion notification	Indication that Explicit Congestion Notification is enabled.
mean queue depth	Average queue depth based on the actual queue depth on the interface and the exponential weighting constant. It is a moving average. The minimum and maximum thresholds are compared against this value to determine drop decisions.
class	IP precedence value.
Transmitted pkts/bytes	Number of packets (also shown in bytes) passed through WRED and not dropped by WRED. **Note** If there is insufficient memory in the buffer to accommodate the packet, the packet can be dropped *after* the packet passes through WRED. Packets dropped because of insufficient memory in the buffer (sometimes referred to as “no-buffer drops”) are not taken into account by the WRED packet counter.
Random drop pkts/bytes	Number of packets (also shown in bytes) randomly dropped when the mean queue depth is between the minimum threshold value and the maximum threshold value for the specified IP precedence value.
Tail drop pkts/bytes	Number of packets dropped when the mean queue depth is greater than the maximum threshold value for the specified IP precedence value.
Minimum threshold	Minimum WRED threshold in number of packets.
Maximum threshold	Maximum WRED threshold in number of packets.
Mark probability	Fraction of packets dropped when the average queue depth is at the maximum threshold.
ECN Mark pkts/bytes	Number of packets (also shown in bytes) marked by ECN.

Class-Based RTP and TCP Header Compression: Example

The following sample output from the **show policy-map interface** command shows the RTP header compression has been configured for a class called “prec2” in the policy map called “p1”.

The **show policy-map interface** command output displays the type of header compression configured (RTP), the interface to which the policy map called “p1” is attached (Serial 4/1), the total number of packets, the number of packets compressed, the number of packets saved, the number of packets sent, and the rate at which the packets were compressed (in bits per second (bps)).

In this example, User Datagram Protocol (UDP)/RTP header compressions have been configured, and the compression statistics are included at the end of the display.

```
Router# show policy-map interface Serial4/1
```

```
Serial4/1
Service-policy output:p1
    Class-map:class-default (match-any)
      1005 packets, 64320 bytes
      30 second offered rate 16000 bps, drop rate 0 bps
      Match:any
compress:
          header ip rtp
          UDP/RTP Compression:
          Sent:1000 total, 999 compressed,
                41957 bytes saved, 17983 bytes sent
                3.33 efficiency improvement factor
                99% hit ratio, five minute miss rate 0 misses/sec, 0 max
                 rate 5000 bps
```

The table below describes the significant fields shown in the display.

Table 238: show policy-map interface Field Descriptions—Configured for Class-Based RTP and TCP Header Compression

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
UDP/RTP Compression	Indicates that RTP header compression has been configured for the class.
Sent total	Count of every packet sent, both compressed packets and full-header packets.
Sent compressed	Count of number of compressed packets sent.
bytes saved	Total number of bytes saved (that is, bytes not needing to be sent).
bytes sent	Total number of bytes sent for both compressed and full-header packets.

Field	Description
efficiency improvement factor	The percentage of increased bandwidth efficiency as a result of header compression. For example, with RTP streams, the efficiency improvement factor can be as much as 2.9 (or 290 percent).
hit ratio	Used mainly for troubleshooting purposes, this is the percentage of packets found in the context database. In most instances, this percentage should be high.
five minute miss rate	The number of new traffic flows found in the last five minutes.
misses/sec max	The average number of new traffic flows found per second, and the highest rate of new traffic flows to date.
rate	The actual traffic rate (in bits per second) after the packets are compressed.

Note A number in parentheses may appear next to the service-policy output name and the class-map name. The number is for Cisco internal use only and can be disregarded.

Modular QoS CLI (MQC) Unconditional Packet Discard: Example

The following sample output from the **show policy-map interface** command displays the statistics for the Serial2/0 interface, to which a policy map called "policy1" is attached. The discarding action has been specified for all the packets belonging to a class called "c1." In this example, 32000 bps of traffic is sent ("offered") to the class and all of them are dropped. Therefore, the drop rate shows 32000 bps.

```
Router# show policy-map interface

 Serial2/0
 Serial2/0
  Service-policy output: policy1
    Class-map: c1 (match-all)
       10184 packets, 1056436 bytes
       5 minute offered rate 32000 bps, drop rate 32000 bps
       Match: ip precedence 0
       drop
```

The table below describes the significant fields shown in the display.

Table 239: show policy-map interface Field Descriptions—Configured for MQC Unconditional Packet Discard

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.

Field	Description
packets, bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
Note In distributed architecture platforms (such as the Cisco 7500), the value of the transfer rate, calculated as the difference between the offered rate and the drop rate counters, can sporadically deviate from the average by up to 20 percent or more. This can occur while no corresponding burst is registered by independent traffic analyser equipment.	
Match	Match criteria specified for the class of traffic. Choices include criteria such as the Layer 3 packet length, IP precedence, IP DSCP value, MPLS experimental value, access groups, and QoS groups. For more information about the variety of match criteria that are available, see the “Classifying Network Traffic” module in the *Cisco IOS Quality of Service Solutions Configuration Guide* .

Field	Description
drop	Indicates that the packet discarding action for all the packets belonging to the specified class has been configured.

Note A number in parentheses may appear next to the service-policy output name and the class-map name. The number is for Cisco internal use only and can be disregarded.

Percentage-Based Policing and Shaping: Example

The following sample output from the **show policy-map interface** command shows traffic policing configured using a CIR based on a bandwidth of 20 percent. The CIR and committed burst (Bc) in milliseconds (ms) are included in the display.

```
Router# show policy-map interface Serial3/1

  Service-policy output: mypolicy
    Class-map: gold (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
      police:
          cir 20 % bc 10 ms
          cir 2000000 bps, bc 2500 bytes
          pir 40 % be 20 ms
          pir 4000000 bps, be 10000 bytes
     conformed 0 packets, 0 bytes; actions:
      transmit
     exceeded 0 packets, 0 bytes; actions:
       drop
      violated 0 packets, 0 bytes; actions:
       drop
      conformed 0 bps, exceed 0 bps, violate 0 bps
```

The table below describes the significant fields shown in the display. A number in parentheses may appear next to the service-policy output name and the class-map name. The number is for Cisco internal use only and can be disregarded.

Table 240: show policy-map interface Field Descriptions—Configured for Percentage-Based Policing and Shaping.

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.

Field	Description
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
police	Indicates that traffic policing based on a percentage of bandwidth has been enabled. Also, displays the bandwidth percentage, the CIR, and the committed burst (Bc) size in ms.
conformed, actions	Displays the number of packets and bytes marked as conforming to the specified rates, and the action to be taken on those packets.
exceeded, actions	Displays the number of packets and bytes marked as exceeding the specified rates, and the action to be taken on those packets.

Traffic Shaping: Example

The following sample output from the **show policy-map interface** command (shown below) displays the statistics for the serial 3/2 interface. Traffic shaping has been enabled on this interface, and an average rate of 20 percent of the bandwidth has been specified.

Note In HQF images for Cisco IOS Releases 12.4(20)T and later, the packets delayed and bytes delayed counters were removed for traffic shaping classes.

```
Router# show policy-map interface Serial3/2

Serial3/2
  Service-policy output: p1
    Class-map: c1 (match-all)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
      Traffic Shaping
        Target/Average      Byte   Sustain    Excess      Interval  Increment  Adapt
        Rate              Limit  bits/int  bits/int    (ms)      (bytes)    Active
         20 %                      10 (ms)    20 (ms)
        201500/201500       1952   7808       7808        38         976       -
        Queue     Packets   Bytes     Packets   Bytes     Shaping
        Depth                         Delayed   Delayed   Active
        0         0         0         0         0         no
```

The table below describes the significant fields shown in the display. A number in parentheses may appear next to the service-policy output name, class-map name, and match criteria information. The number is for Cisco internal use only and can be disregarded.

Table 241: show policy-map interface Field Descriptions—Configured for Percentage-Based Policing and Shaping (with Traffic Shaping Enabled).

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
Match	Match criteria specified for the class of traffic. Choices include criteria such as the Layer 3 packet length, IP precedence, IP DSCP value, MPLS experimental value, access groups, and quality of service (QoS) groups. For more information about the variety of match criteria that are available, see the “Classifying Network Traffic” module in the *Quality of Service Solutions Configuration Guide*.
Traffic Shaping	Indicates that traffic shaping based on a percentage of bandwidth has been enabled.
Target/Average Rate	Rate (percentage) used for shaping traffic and the number of packets meeting that rate.
Byte Limit	Maximum number of bytes that can be transmitted per interval. Calculated as follows: ((Bc+Be) /8) x 1
Sustain bits/int	Committed burst (Bc) rate.
Excess bits/int	Excess burst (Be) rate.
Interval (ms)	Time interval value in milliseconds (ms).

Field	Description
Increment (bytes)	Number of credits (in bytes) received in the token bucket of the traffic shaper during each time interval.
Adapt Active	Indicates whether adaptive shaping is enabled.
Queue Depth	Current queue depth of the traffic shaper.
Packets	Total number of packets that have entered the traffic shaper system.
Bytes	Total number of bytes that have entered the traffic shaper system.
Packets Delayed	Total number of packets delayed in the queue of the traffic shaper before being transmitted. **Note** In Cisco IOS Release 12.4(20)T, this counter was removed.
Bytes Delayed	Total number of bytes delayed in the queue of the traffic shaper before being transmitted. **Note** In Cisco IOS Release 12.4(20)T, this counter was removed.
Shaping Active	Indicates whether the traffic shaper is active. For example, if a traffic shaper is active, and the traffic being sent exceeds the traffic shaping rate, a “yes” appears in this field.

Packet Classification Based on Layer 3 Packet Length: Example

The following sample output from the **show policy-map interface** command displays the packet statistics for the Ethernet4/1 interface, to which a service policy called “mypolicy” is attached. The Layer 3 packet length has been specified as a match criterion for the traffic in the class called “class1”.

```
Router# show policy-map interface Ethernet4/1

  Ethernet4/1
  Service-policy input: mypolicy
    Class-map: class1 (match-all)
       500 packets, 125000 bytes
       5 minute offered rate 4000 bps, drop rate 0 bps
       Match: packet length min 100 max 300
       QoS Set
         qos-group 20
           Packets marked 500
```

The table below describes the significant fields shown in the display. A number in parentheses may appear next to the service-policy input name, class-map name, and match criteria information. The number is for Cisco internal use only and can be disregarded.

Table 242: show policy-map interface Field Descriptions—Configured for Packet Classification Based on Layer 3 Packet Length.

Field	Description
Service-policy input	Name of the input service policy applied to the specified interface or VC.

Field	Description
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class. **Note** If the packets are compressed over an outgoing interface, the improved packet rate achieved by packet compression is not reflected in the offered rate. Also, if the packets are classified *before* they enter a combination of tunnels (for example, a generic routing encapsulation (GRE) tunnel and an IP Security (IPSec) tunnel), the offered rate does not include all the extra overhead associated with tunnel encapsulation in general. Depending on the configuration, the offered rate may include no overhead, may include the overhead for only *one* tunnel encapsulation, or may include the overhead for *all* tunnel encapsulations. In most of the GRE and IPSec tunnel configurations, the offered rate includes the overhead for GRE tunnel encapsulation only.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
Match	Match criteria specified for the class of traffic. Choices include criteria such as the Layer 3 packet length, IP precedence, IP DSCP value, MPLS experimental value, access groups, and QoS groups.
QoS Set, qos-group, Packets marked	Indicates that class-based packet marking based on the QoS group has been configured. Includes the qos-group number and the number of packets marked.

Enhanced Packet Marking: Example

The following sample output of the **show policy-map interface** command shows the service policies attached to a FastEthernet subinterface. In this example, a service policy called "policy1" has been attached. In "policy1", a table map called "table-map1" has been configured. The values in "table-map1" will be used to map the precedence values to the corresponding class of service (CoS) values.

```
Router# show policy-map interface

 FastEthernet1/0.1
  Service-policy input: policy1
    Class-map: class-default (match-any)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any
      QoS Set
        precedence cos table table-map1
          Packets marked 0
```

The table below describes the fields shown in the display. A number in parentheses may appear next to the service-policy input name and the class-map name. The number is for Cisco internal use only and can be disregarded.

Table 243: show policy-map interface Field Descriptions—Configured for Enhanced Packet Marking.

Field	Description
Service-policy input	Name of the input service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of the packets coming into the class.
Match	Match criteria specified for the class of traffic. Choices include criteria such as Precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental value, access groups, and quality of service (QoS) group (set). For more information about the variety of match criteria that are available, see the "Classifying Network Traffic" module in the *Quality of Service Solutions Configuration Guide*.
QoS Set	Indicates that QoS group (set) has been configured for the particular class.
precedence cos table table-map1	Indicates that a table map (called "table-map1") has been used to determine the precedence value. The precedence value will be set according to the CoS value defined in the table map.
Packets marked	Total number of packets marked for the particular class.

Traffic Policing: Example

The following is sample output from the **show policy-map interface** command. This sample displays the statistics for the serial 2/0 interface on which traffic policing has been enabled. The committed (conform) burst (bc) and excess (peak) burst (be) are specified in milliseconds (ms).

```
Router# show policy-map interface serial2/0

 Serial2/0
  Service-policy output: policy1 (1050)
    Class-map: class1 (match-all) (1051/1)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: ip precedence 0  (1052)
      police:
          cir 20 % bc 300 ms
          cir 409500 bps, bc 15360 bytes
          pir 40 % be 400 ms
          pir 819000 bps, be 40960 bytes
        conformed 0 packets, 0 bytes; actions:
```

```
          transmit
        exceeded 0 packets, 0 bytes; actions:
          drop
        violated 0 packets, 0 bytes; actions:
          drop
        conformed 0 bps, exceed 0 bps, violate 0 bps
    Class-map: class-default (match-any) (1054/0)
      0 packets, 0 bytes
      5 minute offered rate 0 bps, drop rate 0 bps
      Match: any  (1055)
        0 packets, 0 bytes
        5 minute rate 0 bps
```

In this example, the CIR and PIR are displayed in bps, and both the committed burst (bc) and excess burst (be) are displayed in bits.

The CIR, PIR bc, and be are calculated on the basis of the formulas described below.

Formula for Calculating the CIR: Example

When calculating the CIR, the following formula is used:

- CIR percentage specified (as shown in the output from the **show policy-map** command) * bandwidth (BW) of the interface (as shown in the output from the**show interfaces** command) = total bits per second

According to the output from the **show interfaces** command for the serial 2/0 interface, the interface has a bandwidth (BW) of 2048 kbps.

```
Router# show interfaces serial2/0

Serial2/0 is administratively down, line protocol is down
  Hardware is M4T
  MTU 1500 bytes, BW 2048 Kbit, DLY 20000 usec, rely 255/255, load 1/255
```

The following values are used for calculating the CIR:

20 % * 2048 kbps = 409600 bps

Formula for Calculating the PIR: Example

When calculating the PIR, the following formula is used:

- PIR percentage specified (as shown in the output from the **show policy-map** command) * bandwidth (BW) of the interface (as shown in the output from the**show interfaces** command) = total bits per second

According to the output from the **show interfaces** command for the serial 2/0 interface, the interface has a bandwidth (BW) of 2048 kbps.

```
Router# show interfaces serial2/0

Serial2/0 is administratively down, line protocol is down
  Hardware is M4T
  MTU 1500 bytes, BW 2048 Kbit, DLY 20000 usec, rely 255/255, load 1/255
```

The following values are used for calculating the PIR:

40 % * 2048 kbps = 819200 bps

Note Discrepancies between this total and the total shown in the output from the **show policy-map interface** command can be attributed to a rounding calculation or to differences associated with the specific interface configuration.

Formula for Calculating the Committed Burst (bc): Example

When calculating the bc, the following formula is used:

- The bc in milliseconds (as shown in the **show policy-map** command) * the CIR in bits per seconds = total number bytes

The following values are used for calculating the bc:

300 ms * 409600 bps = 15360 bytes

Formula for Calculating the Excess Burst (be): Example

When calculating the bc and the be, the following formula is used:

- The be in milliseconds (as shown in the **show policy-map** command) * the PIR in bits per seconds = total number bytes

The following values are used for calculating the be:

400 ms * 819200 bps = 40960 bytes

The table below describes the significant fields shown in the display.

Table 244: show policy-map interface Field Descriptions

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets and bytes	Number of packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.

Field	Description
Match	Match criteria specified for the class of traffic. Choices include criteria such as the Layer 3 packet length, IP precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental value, access groups, and quality of service (QoS) groups. For more information about the variety of match criteria that are available, see the “Classifying Network Traffic” module in the *Quality of Service Solutions Configuration Guide* .
police	Indicates that traffic policing has been enabled. Display includes the CIR, PIR (in both a percentage of bandwidth and in bps) and the bc and be in bytes and milliseconds. Also displays the optional conform, exceed, and violate actions, if any, and the statistics associated with these optional actions.

Bandwidth Estimation: Example

The following sample output from the **show policy-map interface** command displays statistics for the Fast Ethernet 0/1 interface on which bandwidth estimates for quality of service (QoS) targets have been generated.

The Bandwidth Estimation section indicates that bandwidth estimates for QoS targets have been defined. These targets include the packet loss rate, the packet delay rate, and the timeframe in milliseconds. Confidence refers to the drop-one-in value (as a percentage) of the targets. Corvil Bandwidth means the bandwidth estimate in kilobits per second.

When no drop or delay targets are specified, “none specified, falling back to drop no more than one packet in 500” appears in the output.

```
Router# show policy-map interface FastEthernet0/1

 FastEthernet0/1
  Service-policy output: my-policy
    Class-map: icmp (match-all)
      199 packets, 22686 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: access-group 101
      Bandwidth Estimation:
        Quality-of-Service targets:
          drop no more than one packet in 1000 (Packet loss < 0.10%)
          delay no more than one packet in 100 by 40 (or more) milliseconds
            (Confidence: 99.0000%)
        Corvil Bandwidth: 1 kbits/sec
    Class-map: class-default (match-any)
      112 packets, 14227 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: any
      Bandwidth Estimation:
        Quality-of-Service targets:
          <none specified, falling back to drop no more than one packet in 500
        Corvil Bandwidth: 1 kbits/sec
```

Shaping with HQF Enabled: Example

The following sample output from the **show policy-mapinterface** command shows that shaping is active (as seen in the queue depth field) with HQF enabled on the serial 4/3 interface. All traffic is classified to the class-default queue.

Note In HQF images for Cisco IOS Releases 12.4(20)T and later, the packets delayed and bytes delayed counters were removed for traffic shaping classes.

```
Router# show policy-map interface serial4/3

 Serial4/3
  Service-policy output: shape
    Class-map: class-default (match-any)
      2203 packets, 404709 bytes
      30 second offered rate 74000 bps, drop rate 14000 bps
      Match: any
      Queueing
      queue limit 64 packets
      (queue depth/total drops/no-buffer drops) 64/354/0
      (pkts output/bytes output) 1836/337280
      shape (average) cir 128000, bc 1000, be 1000
      target shape rate 128000
        lower bound cir 0,  adapt to fecn 0
      Service-policy : LLQ
        queue stats for all priority classes:

          queue limit 64 packets
          (queue depth/total drops/no-buffer drops) 0/0/0
          (pkts output/bytes output) 0/0
        Class-map: c1 (match-all)
          0 packets, 0 bytes
          30 second offered rate 0 bps, drop rate 0 bps
          Match: ip precedence 1
          Priority: 32 kbps, burst bytes 1500, b/w exceed drops: 0
        Class-map: class-default (match-any)
          2190 packets, 404540 bytes
          30 second offered rate 74000 bps, drop rate 14000 bps
          Match: any
          queue limit 64 packets
          (queue depth/total drops/no-buffer drops) 63/417/0
          (pkts output/bytes output) 2094/386300
```

Packets Matched on the Basis of VLAN ID Number: Example

Note As of Cisco IOS Release 12.2(31)SB2, matching packets on the basis of VLAN ID numbers is supported on the Catalyst 1000 platform only.

The following is a sample configuration in which packets are matched and classified on the basis of the VLAN ID number. In this sample configuration, packets that match VLAN ID number 150 are placed in a class called “class1.”

```
Router# show class-map

Class Map match-all class1 (id 3)
Match vlan 150
```

Class1 is then configured as part of the policy map called “policy1.” The policy map is attached to Fast Ethernet subinterface 0/0.1.

The following sample output of the **show policy-map interface** command displays the packet statistics for the policy maps attached to Fast Ethernet subinterface 0/0.1. It displays the statistics for policy1, in which class1 has been configured.

```
Router# show policy-map interface

FastEthernet0/0.1
! Policy-map name.
Service-policy input: policy1
! Class configured in the policy map.
Class-map: class1 (match-all)
0 packets, 0 bytes
5 minute offered rate 0 bps, drop rate 0 bps
! VLAN ID 150 is the match criterion for the class.
Match: vlan 150
police:
cir 8000000 bps, bc 512000000 bytes
conformed 0 packets, 0 bytes; actions:
transmit
exceeded 0 packets, 0 bytes; actions:
drop
conformed 0 bps, exceed 0 bps
Class-map: class-default (match-any)
10 packets, 1140 bytes
5 minute offered rate 0 bps, drop rate 0 bps
Match: any
10 packets, 1140 bytes
5 minute rate 0 bps
```

The table below describes the significant fields shown in the display. A number in parentheses may appear next to the service-policy input name and the class-map name. The number is for Cisco internal use only and can be disregarded.

Table 245: show policy-map interface Field Descriptions—Packets Matched on the Basis of VLAN ID Number.

Field	Description
Service-policy input	Name of the input service policy applied to the specified interface or VC.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of the packets coming into the class.

Field	Description
Match	Match criteria specified for the class of traffic. Choices include criteria such as VLAN ID number, precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental value, access groups, and quality of service (QoS) group (set). For more information about the variety of match criteria that are available, see the “Classifying Network Traffic” module in the *Cisco IOS Quality of Service Solutions Configuration Guide* .

Cisco 7600 Series Routers: Example

The following example shows how to display the statistics and the configurations of all the input and output policies that are attached to an interface on a Cisco 7600 series router:

```
Router# show policy-map interface

 FastEthernet5/36
  service-policy input: max-pol-ipp5
    class-map: ipp5 (match-all)
      0 packets, 0 bytes
      5 minute rate 0 bps
      match: ip precedence 5
  class ipp5
    police 2000000000 2000000 conform-action set-prec-transmit 6 exceed-action p
policed-dscp-transmit
```

The following example shows how to display the input-policy statistics and the configurations for a specific interface on a Cisco 7600 series router:

```
Router# show policy-map interface fastethernet 5/36 input

 FastEthernet5/36
  service-policy input: max-pol-ipp5
    class-map: ipp5 (match-all)
      0 packets, 0 bytes
      5 minute rate 0 bps
      match: ip precedence 5
  class ipp5
    police 2000000000 2000000 conform-action set-prec-transmit 6 exceed-action p
policed-dscp-transmit
```

The table below describes the significant fields shown in the display.

Table 246: show policy-map interface Field Descriptions—Cisco 7600 Series Routers

Field	Description
service-policy input	Name of the input service policy applied to the specified interface.
class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.

Field	Description
minute rate	Rate, in kbps, of the packets coming into the class.
match	Match criteria specified for the class of traffic. Choices include criteria such as VLAN ID number, precedence, IP differentiated services code point (DSCP) value, Multiprotocol Label Switching (MPLS) experimental value, access groups, and quality of service (QoS) group (set). For more information about the variety of match criteria that are available, see the "Classifying Network Traffic" module in the *Cisco IOS Quality of Service Solutions Configuration Guide* .
class	Precedence value.
police	Indicates that the **police** command has been configured to enable traffic policing.

Cisco 7200 Series Routers: Example

The following example shows the automatic rounding-off of the **bc** and **be** values, in the MQC police policy-map, to the interface's MTU size in a Cisco 7200 series router. The rounding-off is done only when the bc and be values are lesser than the interface's MTU size.

```
Router# show policy-map interface

Service-policy output: p2
Service-policy output: p2
    Class-map: class-default (match-any)
      2 packets, 106 bytes
      30 second offered rate 0000 bps, drop rate 0000 bps
      Match: any
        2 packets, 106 bytes
        30 second rate 0 bps
      police:
          cir 10000 bps, bc 4470 bytes
          pir 20000 bps, be 4470 bytes
        conformed 0 packets, 0 bytes; actions:
          transmit
        exceeded 0 packets, 0 bytes; actions:
          drop
        violated 0 packets, 0 bytes; actions:
          drop
        conformed 0000 bps, exceed 0000 bps, violate 0000 bps
```

Multiple Priority Queues on Serial Interface: Example

The following sample output from the show policy-map interface command shows the types of statistical information that displays when multiple priority queues are configured. Depending upon the interface in use and the options enabled, the output that you see may vary slightly from the output shown below.

```
Router# show policy-map interface

Serial2/1/0
Service-policy output: P1
Queue statistics for all priority classes:
```

```
.
.
.
Class-map: Gold (match-all)
0 packets, 0 bytes   /*Updated for each priority level configured.*/
5 minute offered rate 0 bps, drop rate 0 bps
Match: ip precedence 2
Priority: 0 kbps, burst bytes 1500, b/w exceed drops: 0
Priority Level 4:
0 packets, 0 bytes
```

Bandwidth-Remaining Ratios: Example

The following sample output from the show policy-map interface command indicates that bandwidth-remaining ratios are configured for class queues. As shown in the example, the classes precedence_0, precedence_1, and precedence_2 have bandwidth-remaining ratios of 20, 40, and 60, respectively.

```
Router# show policy-map interface GigabitEthernet1/0/0.10

  Service-policy output: vlan10_policy
    Class-map: class-default (match-any)
      0 packets, 0 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: any
        0 packets, 0 bytes
        30 second rate 0 bps
      Queueing
      queue limit 250 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0
      shape (average) cir 1000000, bc 4000, be 4000
      target shape rate 1000000
      bandwidth remaining ratio 10
      Service-policy : child_policy
        Class-map: precedence_0 (match-all)
          0 packets, 0 bytes
          30 second offered rate 0 bps, drop rate 0 bps
          Match: ip precedence 0
          Queueing
          queue limit 62 packets
          (queue depth/total drops/no-buffer drops) 0/0/0
          (pkts output/bytes output) 0/0
          shape (average) cir 500000, bc 2000, be 2000
          target shape rate 500000
          bandwidth remaining ratio 20
        Class-map: precedence_1 (match-all)
          0 packets, 0 bytes
          30 second offered rate 0 bps, drop rate 0 bps
          Match: ip precedence 1
          Queueing
          queue limit 62 packets
          (queue depth/total drops/no-buffer drops) 0/0/0
          (pkts output/bytes output) 0/0
          shape (average) cir 500000, bc 2000, be 2000
          target shape rate 500000
          bandwidth remaining ratio 40
        Class-map: precedence_2 (match-all)
          0 packets, 0 bytes
          30 second offered rate 0 bps, drop rate 0 bps
          Match: ip precedence 2
```

```
    Queueing
    queue limit 62 packets
    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 0/0
    shape (average) cir 500000, bc 2000, be 2000
    target shape rate 500000
    bandwidth remaining ratio 60
  Class-map: class-default (match-any)
    0 packets, 0 bytes
    30 second offered rate 0 bps, drop rate 0 bps
    Match: any
      0 packets, 0 bytes
      30 second rate 0 bps

    queue limit 62 packets
    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 0/0
```

The table below describes the significant fields shown in the display.

Table 247: show policy-map interface Field Descriptions—Configured for Bandwidth-Remaining Ratios

Field	Description
Service-policy output	Name of the output service policy applied to the specified interface.
Class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
bandwidth remaining ratio	Indicates the ratio used to allocate excess bandwidth.

Tunnel Marking: Example

In this sample output of the **show policy-map interface** command, the character string “ip dscp tunnel 3” indicates that L2TPv3 tunnel marking has been configured to set the DSCP value to 3 in the header of a tunneled packet.

```
Router# show policy-map interface

 Serial0
  Service-policy input: tunnel
    Class-map: frde (match-all)
      0 packets, 0 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: fr-de
      QoS Set
        ip dscp tunnel 3
          Packets marked 0
    Class-map: class-default (match-any)
      13736 packets, 1714682 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: any
        13736 packets, 1714682 bytes
        30 second rate 0 bps
```

The table below describes the significant fields shown in the display.

Table 248: show policy-map interface Field Descriptions—Configured for Tunnel Marking

Field	Description
service-policy input	Name of the input service policy applied to the specified interface.
class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
match	Match criteria specified for the class of traffic. In this example, the Frame Relay Discard Eligible (DE) bit has been specified as the match criterion. For more information about the variety of match criteria that are available, see the "Classifying Network Traffic" module in the *Cisco IOS Quality of Service Solutions Configuration Guide*.
ip dscp tunnel	Indicates that tunnel marking has been configured to set the DSCP in the header of a tunneled packet to a value of 3.

Traffic Shaping Overhead Accounting for ATM: Example

The following output from the show policy-map interface command indicates that ATM overhead accounting is enabled for shaping and disabled for bandwidth:

```
Router# show policy-map interface

Service-policy output:unit-test
Class-map: class-default (match-any)
100 packets, 1000 bytes
30 second offered rate 800 bps, drop rate 0 bps
Match: any
shape (average) cir 154400, bc 7720, be 7720
target shape rate 154400
overhead accounting: enabled
bandwidth 30% (463 kbps)
overhead accounting: disabled
queue limit 64 packets
(queue depth/total drops/no-buffer drops) 0/0/0
(packets output/bytes output) 100/1000
```

The table below describes the significant fields shown in the display.

Table 249: show policy-map interface Field Descriptions—Configured for Traffic Shaping Overhead Accounting for ATM

Field	Description
service-policy output	Name of the output service policy applied to the specified interface.
class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
match	Match criteria specified for the class of traffic. In this example, the Frame Relay Discard Eligible (DE) bit has been specified as the match criterion. For more information about the variety of match criteria that are available, see the “Classifying Network Traffic” module in the *Cisco IOS Quality of Service Solutions Configuration Guide*.
target shape rate	Indicates that traffic shaping is enabled at the specified rate.
overhead accounting	Indicates whether overhead accounting is enabled or disabled for traffic shaping.
bandwidth	Indicates the percentage of bandwidth allocated for traffic queueing.
overhead accounting:	Indicates whether overhead accounting is enabled or disabled for traffic queueing.

HQF: Example

The following output from the show policy-map interface command displays the configuration for Fast Ethernet interface 0/0:

Note In HQF images for Cisco IOS Releases 12.4(20)T and later releases, the packets delayed and bytes delayed counters were removed for traffic shaping classes.

```
Router# show policy-map interface FastEthernet0/0
 FastEthernet0/0

  Service-policy output: test1

    Class-map: class-default (match-any)
      129 packets, 12562 bytes
      30 second offered rate 0 bps, drop rate 0 bps
      Match: any
      Queueing
      queue limit 64 packets
```

```
(queue depth/total drops/no-buffer drops) 0/0/0
(pkts output/bytes output) 129/12562
shape (average) cir 1536000, bc 6144, be 6144
target shape rate 1536000

Service-policy : test2

  queue stats for all priority classes:

    queue limit 64 packets
    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 0/0

  Class-map: RT (match-all)
    0 packets, 0 bytes
    30 second offered rate 0 bps, drop rate 0 bps
    Match: ip dscp ef (46)
    Priority: 20% (307 kbps), burst bytes 7650, b/w exceed drops: 0

  Class-map: BH (match-all)
    0 packets, 0 bytes
    30 second offered rate 0 bps, drop rate 0 bps
    Match: ip dscp af41 (34)
    Queueing
    queue limit 128 packets
    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 0/0
    bandwidth 40% (614 kbps)

  Class-map: BL (match-all)
    0 packets, 0 bytes
    30 second offered rate 0 bps, drop rate 0 bps
    Match: ip dscp af21 (18)
    Queueing
    queue limit 64 packets
    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 0/0
    bandwidth 35% (537 kbps)
      Exp-weight-constant: 9 (1/512)
      Mean queue depth: 0 packets
      dscp     Transmitted    Random drop    Tail drop   Minimum    Maximum    Mark
               pkts/bytes     pkts/bytes     pkts/bytes  thresh     thresh     prob

    (queue depth/total drops/no-buffer drops) 0/0/0
    (pkts output/bytes output) 129/12562
```

The table below describes the significant fields shown in the display.

Table 250: show policy-map interface Field Descriptions—Configured for HQF

Field	Description
FastEthernet	Name of the interface.

Field	Description
service-policy output	Name of the output service policy applied to the specified interface.
class-map	Class of traffic being displayed. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
offered rate	Rate, in kbps, of packets coming in to the class.
drop rate	Rate, in kbps, at which packets are dropped from the class. The drop rate is calculated by subtracting the number of successfully transmitted packets from the offered rate.
Match	Match criteria specified for the class of traffic. **Note** For more information about the variety of match criteria that are available, see the "Classifying Network Traffic" module in the *Cisco IOS Quality of Service Solutions Configuration Guide*.
Queueing	Indicates that queueing is enabled.
queue limit	Maximum number of packets that a queue can hold for a class policy configured in a policy map.
bandwidth	Indicates the percentage of bandwidth allocated for traffic queueing.
dscp	Differentiated services code point (DSCP). Values can be the following: • 0 to 63—Numerical DSCP values. The default value is 0. • af1 to af43—Assured forwarding (AF) DSCP values. • cs1 to cs7—Type of service (ToS) precedence values. • default—Default DSCP value. • ef—Expedited forwarding (EF) DSCP values.

Account QoS Statistics for the Cisco ASR 1000 Series Aggregation Services Routers: Example

The following example shows the new output fields associated with the QoS: Policies Aggregation Enhancements feature beginning in Cisco IOS XE Release 2.6 for subscriber statistics. The new output fields begin with the label "Account QoS Statistics."

```
Router# show policy-map interface port-channel 1.1

Port-channel1.1
   Service-policy input: input_policy
     Class-map: class-default (match-any)
       0 packets, 0 bytes
       5 minute offered rate 0000 bps, drop rate 0000 bps
```

```
      Match: any
      QoS Set
      dscp default
      No packet marking statistics available
  Service-policy output: Port-channel_1_subscriber
    Class-map: EF (match-any)
      105233 packets, 6734912 bytes
      5 minute offered rate 134000 bps, drop rate 0000 bps
      Match: dscp ef (46)
      Match: access-group name VLAN_REMARK_EF
      Match: qos-group 3
      Account QoS statistics
        Queueing
          Packets dropped 0 packets/0 bytes
      QoS Set
      cos 5
      No packet marking statistics available
      dscp ef
      No packet marking statistics available
    Class-map: AF4 (match-all)
      105234 packets, 6734976 bytes
      5 minute offered rate 134000 bps, drop rate 0000 bps
      Match: dscp cs4 (32)
      Account QoS statistics
        Queueing
          Packets dropped 0 packets/0 bytes
      QoS Set
      cos 4
      No packet marking statistics available
    Class-map: AF1 (match-any)
      315690 packets, 20204160 bytes
      5 minute offered rate 402000 bps, drop rate 0000 bps
      Match: dscp cs1 (8)
      Match: dscp af11 (10)
      Match: dscp af12 (12)
      Account QoS statistics
        Queueing
          Packets dropped 0 packets/0 bytes
      QoS Set
      cos 1
      No packet marking statistics available
    Class-map: class-default (match-any) fragment Port-channel_BE
      315677 packets, 20203328 bytes
      5 minute offered rate 402000 bps, drop rate 0000 bps
      Match: any
      Queueing
        queue limit 31250 bytes
        (queue depth/total drops/no-buffer drops) 0/0/0
        (pkts output/bytes output) 315679/20203482
        bandwidth remaining ratio 1
```

Cisco Catalyst 4000 Series Routers: Example

The following example shows how to display the policer statistics (the packet and byte count). The output displays only the applicable count (either packets or bytes) with the actual number.

```
Router# show policy-map interface GigabitEthernet 3/1 input

GigabitEthernet3/1
  Service-policy input: in1
    Class-map: p1 (match-all)
```

```
      0 packets
      Match:  precedence 1
           QoS Set
             ip precedence 7
      police:
          cir 20 %
          cir 200000000 bps, bc 6250000 bytes
        conformed 0 bytes; actions:
          transmit
        exceeded 0 bytes; actions:
          drop
        conformed 0000 bps, exceed 0000 bps
    Class-map: class-default (match-any)
      10000000 packets
      Match: any
      police:
          cir 20 %
          cir 200000000 bps, bc 6250000 bytes
        conformed 174304448 bytes; actions:
          transmit
        exceeded 465695552 bytes; actions:
          drop
        conformed 4287000 bps, exceed 11492000 bps
```

Cisco CMTS Routers: Example

The following example shows how to display the statistics and the configurations of the input and output service policies that are attached to an interface:

```
Router# show policy-map interface GigabitEthernet 1/2/0

Load for five secs: 1%/0%; one minute: 1%; five minutes: 1%
Time source is hardware calendar, *23:02:40.857 pst Thu Mar 3 2011

 GigabitEthernet1/2/0

  Service-policy input: policy-in

    Class-map: class-exp-0 (match-all)
      6647740 packets, 9304674796 bytes
      30 second offered rate 3234000 bps, drop rate 0 bps
      Match: mpls experimental topmost 0
      QoS Set
        precedence 3
          Packets marked 6647740

    Class-map: class-default (match-any)
      1386487 packets, 1903797872 bytes
      30 second offered rate 658000 bps, drop rate 0 bps
      Match: any

  Service-policy output: policy-out

    Class-map: class-pre-1 (match-all)
      2041355 packets, 2857897000 bytes
      30 second offered rate 986000 bps, drop rate 0 bps

      Match: ip precedence 1
      QoS Set
        mpls experimental topmost 1
          Packets marked 2041355
```

```
    Class-map: class-default (match-any)
      6129975 packets, 8575183331 bytes
      30 second offered rate 2960000 bps, drop rate 0 bps
      Match: any
```

The table below describes the significant fields shown in the display.

Table 251: show policy-map interface Field Descriptions—Cisco Catalyst 4000 Series Routers

Field	Description
class-map	Displays the class of traffic. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
conformed	Displays the action to be taken on packets conforming to a specified rate. Also displays the number of packets and bytes on which the action was taken.
drop	Indicates that the packet discarding action for all the packets belonging to the specified class has been configured.
exceeded	Displays the action to be taken on packets exceeding a specified rate. Displays the number of packets and bytes on which the action was taken.
match	Match criteria specified for the class of traffic.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
police	Indicates that the **police** command has been configured to enable traffic policing. Also displays the specified CIR, conform burst size, peak information rate (PIR), and peak burst size used for marking packets.
QoS Set	Indicates that QoS group (set) has been configured for the particular class.
service-policy input	Name of the input service policy applied to the specified interface.

Displaying Pseudowire Policy Map Information: Example

The following example shows how to display the class maps configured for a pseudowire interface:

```
Router# show policy-map interface pseudowire2
 pseudowire2
  Service-policy output: pw_brr

    Class-map: prec1 (match-all)
      0 packets, 0 bytes
      30 second offered rate 0000 bps, drop rate 0000 bps
      Match: ip precedence 1
      Queueing
      queue limit 4166 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0
      bandwidth remaining ratio 1
```

```
    Class-map: prec2 (match-all)
      0 packets, 0 bytes
      30 second offered rate 0000 bps, drop rate 0000 bps
      Match: ip precedence 2
      Queueing
      queue limit 4166 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0
      bandwidth remaining ratio 2

    Class-map: prec3 (match-all)
      0 packets, 0 bytes
      30 second offered rate 0000 bps, drop rate 0000 bps
      Match: ip precedence 3
      Queueing
      queue limit 4166 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0
      bandwidth remaining ratio 3

    Class-map: class-default (match-any)
      0 packets, 0 bytes
      30 second offered rate 0000 bps, drop rate 0000 bps
      Match: any
      Queueing
      queue limit 4166 packets
      (queue depth/total drops/no-buffer drops) 0/0/0
      (pkts output/bytes output) 0/0
      bandwidth remaining ratio 4
Device#
```

The table below describes the significant fields shown in the display.

Table 252: show policy-map interface Field Descriptions—Pseudowire Policy Map Information

Field	Description
bandwidth	Indicates the percentage of bandwidth allocated for traffic queueing.
Class-map	Displays the class of traffic. Output is displayed for each configured class in the policy. The choice for implementing class matches (for example, match-all or match-any) can also appear next to the traffic class.
Match	Match criteria specified for the class of traffic.
packets, bytes	Number of the packets (also shown in bytes) identified as belonging to the class of traffic being displayed.
Queueing	Indicates that queueing is enabled.
queue limit	Maximum number of packets that a queue can hold for a class policy configured in a policy map.
service-policy output	Name of the output service policy applied to the specified interface.

Related Commands

Command	Description
bandwidth remaining ratio	Specifies a bandwidth-remaining ratio for class queues and subinterface-level queues to determine the amount of unused (excess) bandwidth to allocate to the queue during congestion.
class-map	Creates a class map to be used for matching packets to a specified class.
compression header ip	Configures RTP or TCP IP header compression for a specific class.
drop	Configures a traffic class to discard packets belonging to a specific class.
match fr-dlci	Specifies the Frame Relay DLCI number as a match criterion in a class map.
match packet length (class-map)	Specifies the length of the Layer 3 packet in the IP header as a match criterion in a class map.
police	Configures traffic policing.
police (percent)	Configures traffic policing on the basis of a percentage of bandwidth available on an interface.
police (two rates)	Configures traffic policing using two rates, the CIR and the PIR.
policy-map	Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
priority	Specifies that low-latency behavior must be given to a traffic class and configures multiple priority queues.
random-detect ecn	Enables ECN.
shape (percent)	Specifies average or peak rate traffic shaping on the basis of a percentage of bandwidth available on an interface.
show class-map	Display all class maps and their matching criteria.
show frame-relay pvc	Displays statistics about PVCs for Frame Relay interfaces.
show interfaces	Displays statistics for all interfaces configured on a router or access server.
show mls qos	Displays MLS QoS information.
show policy-map	Displays the configuration of all classes for a specified service policy map or all classes for all existing policy maps.
show policy-map class	Displays the configuration for the specified class of the specified policy map.
show table-map	Displays the configuration of a specified table map or of all table maps.

Command	Description
table-map (value mapping)	Creates and configures a mapping table for mapping and converting one packet-marking value to another.

show power

To display information about the power status, use the **show power**command in user EXEC or privileged EXEC mode**.**

show power [{**available** | **inline** [{*interface number* | **module number**}] | **redundancy-mode** | **status** {**all** | **fan-tray** *fan-tray-number* | **module** *slot* | **power-supply** *pwr-supply-number*} | **total** | **used**}]

Syntax Description

available	(Optional) Displays the available system power (margin).
inline	(Optional) Displays the inline power status.
interface number	(Optional) Specifies the interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **null**, **port-channel**, and **vlan**. See the "Usage Guidelines" section for additional information.
module number	Displays the power status for a specific module.
redundancy-mode	(Optional) Displays the power-supply redundancy mode.
status	(Optional) Displays the power status.
all	Displays all the FRU types.
fan-tray *fan-tray-number*	Displays the power status for the fan tray .
module *slo* t	Displays the power status for a specific module.
power-supply *pwr-supply-number*	Displays the power status for a specific power supply; valid values are **1** and **2**
total	(Optional) Displays the total power that is available from the power supplies.
used	(Optional) Displays the total power that is budgeted for powered-on items.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17a)SX1	The output was changed to include the total system-power information.
12.2(17b)SXA	This command was changed to include information about the inline power status for a specific module.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.

Release	Modification
12.2(18)SXF	The output was changed to include information about the high-capacity power supplies.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

Valid values for *vlan-id* are from 1 to 4094.

The Inline power field in the **show power**output displays the inline power that is consumed by the modules. For example, this example shows that module 9 has consumed 0.300 A of inline power:

```
Inline power   #    current
module         9    0.300A
```

Examples

This example shows how to display the available system power:

```
Router>
show power
available
system power available = 20.470A
Router>
```

This example shows how to display power-supply redundancy mode:

```
Router#
show power
redundancy-mode
system power redundancy mode = redundant
Router#
```

This command shows how to display the system-power status:

```
Router> show power
system power redundancy mode = combined
system power total =     3984.12 Watts (94.86 Amps @ 42V)
system power used =      1104.18 Watts (26.29 Amps @ 42V)
system power available = 2879.94 Watts (68.57 Amps @ 42V)
                        Power-Capacity PS-Fan Output Oper
PS   Type               Watts   A @42V Status Status State
---- ------------------ ------- ------ ------ ------ -----
1    WS-CAC-3000W       2830.80 67.40  OK     OK     on
2    WS-CAC-1300W       1153.32 27.46  OK     OK     on
Note: PS2 capacity is limited to 2940.00 Watts (70.00 Amps @ 42V)
      when PS1 is not present
                        Pwr-Allocated  Oper
Fan  Type               Watts   A @42V State
---- ------------------ ------- ------ -----
1    FAN-MOD-9           241.50  5.75  OK
2                        241.50  5.75  failed
```

```
                         Pwr-Requested  Pwr-Allocated  Admin Oper
Slot Card-Type           Watts   A @42V Watts   A @42V State State
---- ------------------ ------- ------ ------- ------ ----- -----
1    WS-X6K-SUP2-2GE     145.32  3.46   145.32  3.46  on    on
2                          -      -     145.32  3.46  -     -
3    WS-X6516-GBIC       118.02  2.81   118.02  2.81  on    on
5    WS-C6500-SFM        117.18  2.79   117.18  2.79  on    on
7    WS-X6516A-GBIC      214.20  5.10     -      -    on    off (insuff cooling capacity)
8    WS-X6516-GE-TX      178.50  4.25   178.50  4.25  on    on
9    WS-X6816-GBIC       733.98 17.48     -      -    on    off (connector rating exceeded)
Router>
```

This example shows how to display the power status for all FRU types:

```
Router#
show power
status all
FRU-type       #    current   admin state oper
power-supply   1    27.460A   on          on
module         1    4.300A    on          on
module         2    4.300A    -           -   (reserved)
module         5    2.690A    on          on
Router#
```

This example shows how to display the power status for a specific module:

```
Router#
show power
status module 1
FRU-type       #    current   admin state oper
module         1    -4.300A   on          on
Router#
```

This example shows how to display the power status for a specific power supply:

```
Router#
show power
status power-supply 1
FRU-type       #    current   admin state oper
power-supply   1    27.460A   on          on
Router#
```

This example displays information about the high-capacity power supplies:

```
Router#
show power
status power-supply 2
                         Power-Capacity PS-Fan Output Oper
PS   Type                Watts   A @42V Status Status State
---- ------------------ ------- ------ ------ ------ -----
1    WS-CAC-6000W        2672.04  63.62 OK     OK     on
2    WS-CAC-9000W-E      2773.68  66.04 OK     OK     on
Router#
```

This example shows how to display the total power that is available from the power supplies:

```
Router#
show power
total
system power total = 27.460A
Router#
```

This example shows how to display the total power that is budgeted for powered-on items:

```
Router#
show power
used
system power used = -6.990A
Router#
```

This command shows how to display the inline power status on the interfaces:

```
Router#
show power
inline
Interface            Admin    Oper     Power ( mWatt )  Device
-------------------- ----- ---------- --------------- -----------
FastEthernet9/1      auto  on         6300            Cisco 6500 IP Phone
FastEthernet9/2      auto  on         6300            Cisco 6500 IP Phone
.
.
. <Output truncated>
```

This command shows how to display the inline power status for a specific module:

```
Router
# show power
inline mod 7

Interface  Admin    Oper     Power       Device         Class
                             (Watts)
---------- ----- ---------- ------- --------------  -----------
Gi7/1      auto   on            6.3  Cisco IP Phone 7960  n/a
Gi7/2      static power-deny      0  Ieee PD               3
.
.
. <Output truncated>
```

Related Commands

Command	Description
power enable	Turns on power for the modules.
power redundancy-mode	Sets the power-supply redundancy mode.

show power inline

To display the power status for a specified port or for all ports, use the **show power inline** command in privileged EXEC mode.

show power inline [*interface-type slot/port*] [{**actual** | **configured**}]

Syntax Description

interface -type	(Optional) Type of interface.
slot	(Optional) Slot number.
/ *port*	(Optional) Port number.
actual	(Optional) Displays the present power status, which might not be the same as the configured power.
configured	(Optional) Displays the configured power status.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(5)XU	This command was introduced.
12.2(2)XT	This command was introduced on the Cisco 2600 series, the Cisco 3600 series, and the Cisco 3700 series routers to support switchport creation.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support switchport creation on Cisco 2600 series, the Cisco 3600 series, and Cisco 3700 series routers.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE 3.9S	This command was integrated into Cisco IOS Release XE 3.9S.

Usage Guidelines

The **show power inline** command displays the amount of power used to operate a Cisco IP phone. To view the amount of power requested, use the **show cdp neighbors** command.

Use the **show power inline** *gigabitEthernet* **detail** command on a Cisco 4400 Series Integrated Services Router (ISR) to monitor the total available power budget on your router.

Examples

The following is sample output from the **show power inlinefa0**/**4actual** command asking for the actual status of each interface rather than what is configured for each:

```
Router#
show power inline fastethernet 0/4 actual
Interface            Power
-------------------- -----
FastEthernet0/4      no
```

Notice that the status shown for the FastEthernet interface 0/4, there is no power.

Cisco 4400 Series Integrated Services Router (ISR): Example

The following are sample outputs from the **show power inline** command and the **show power inline** *gigabitEthernet* **detail** commands

```
 Router# show power inline

Available:31.0(w)  Used:30.8(w)  Remaining:0.2(w)

```

Related Commands

Command	Description
power inline	Determines how inline power is applied to devices on the specified Fast Ethernet port.
show cdp neighbors	Displays detailed information about neighboring devices discovered using CDP.

show proc cpu platform

To display detailed CPU usage statistics for platform processes in relation to the Control Processor (CP), Service Processor (SP), or Data Processor (DP), use the **show proc cpu platform** command. This command now includes filtering options based on CP, SP, or DP, and can be sorted by time duration (1min, 5min, 5sec) to provide more specific output.

show process cpu platform [{ **control-plane** | **data-plane** | **service-plane** }]

Syntax Description

proc	Specifies process.
cpu	Specifies CPU.
platform	Specifies platform.
control-plane	(Optional) Specifies the control plane of the router. The control plane is responsible for routing operations and other control functions.
data-plane	(Optional) Specifies the data plane of the router. The data plane is responsible for processing and forwarding data packets.
service-plane	(Optional) Specifies the service plane of the router. The service plane handles services such as management and configuration interfaces.

Command Default

There is no default.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE 17.13.1a	The command was updated to include CP, SP, DP filters in the CLI. When these filters are specified by the user, the output is specific to the respective plane.

Usage Guidelines

The **show process cpu platform** command can provide detailed information on a core-by-core basis. This can be useful for getting a detailed view of your system's operation, but it might not always provide a clear picture of the overall system health.

For information about the overall system health, the recommended command is **show platform resources.**

The following example shows the detailed CPU usage statistics for platform processes related to the Control Processor

```
Router#show proc cpu plat sort
CPU utilization for five seconds:  8%, one minute:  7%, five minutes: 10%
Core 0: CPU utilization for five seconds: 12%, one minute:  4%, five minutes: 10%
Core 1: CPU utilization for five seconds: 12%, one minute:  3%, five minutes:  9%
Core 2: CPU utilization for five seconds:  0%, one minute:  0%, five minutes:  3%
Core 3: CPU utilization for five seconds:  0%, one minute:  0%, five minutes:  7%
Core 4: CPU utilization for five seconds:  0%, one minute:  0%, five minutes:  7%
Core 5: CPU utilization for five seconds:  0%, one minute:  0%, five minutes:  5%
Core 6: CPU utilization for five seconds: 10%, one minute:  6%, five minutes:  5%
```

```
Core 7: CPU utilization for five seconds:  6%, one minute:  3%, five minutes:  6%
Core 8: CPU utilization for five seconds: 28%, one minute: 15%, five minutes:  9%
Pid    PPid    5Sec    1Min    5Min  Status        Size  Name
--------------------------------------------------------------------------------
 17295   17288    166%    162%    116%  S           862100  ucode_pkt_PPE0
  8731    8722      3%      2%      8%  S           871892  linux_iosd-imag
 22924   22918      1%      0%      3%  S            14280  ngiolite
 17198   17187      1%      1%      1%  S           156380  fman_fp_image
 29497   29491      0%      0%      0%  S             2684  iox_restart.sh
 29491    8045      0%      0%      0%  S             2692  pman
```

Note The numbers reported are sourced from Linux and represent the specialized ways in which the CPU cores are being used from the kernel's perspective. The numbers can be high as the overall kernel CPU usage is typically high. The ucode_pkt_PPE0 process, which represents the sum of all threats, usually shows high utilization. It's important to note that this is not scaled to 100% and can exceed that number.

show process | include persis

To verify the validity of the process during alarm history configuration, use the **show process | include persis** command.

Syntax Description

Syntax Description

Command Default

There is no default.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Examples

The following example shows the detailed information about a particular circuit.:

```
Router#show process | include persis
292 Msi 13F0D4AC 0 49 010328/12000 0 mcprp_spa_persis
```

show protection-group

Use this command to verify the protection group configuration. It defines the status of the protection group.

show protection-group

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	Support for this command was introduced for the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

This command is used for configuring protection group parameters.

Examples

The following example shows how to configure protection group:

```
show protection-group
PGN Type Working I/f Protect I/f Active Status
--------------------------------------------------------------------------------
401 STS48C SONET0/3/6.1-48 SONET0/12/6.1-48 W A
--------------------------------------------------------------------------------
Status legend:D=Deleted FO=Force SF=SignalFailure SD=SignalDegrade
FL=Fail M=Manual L=Lockout C=Clear A=Auto
(W)=working, (P)=protect
```

Related Commands

Command	Description
controller protection-group	Configures protection group controller.
protection-group	Configures virtual protection group interface.
protection-group *group id* [**working** | **protect**]	Configures protection group roles.

show ptp clock dataset

To display a summary of the Precision Time Protocol clock status, use the show ptp clock dataset command in privileged EXEC mode.

show ptp clock dataset [{**default** | **current**}]

Cisco ASR 901 Series Aggregation Services Router

show ptp clock dataset {**default** | **current**}

Syntax Description

default	(Optional) Displays the default PTP clock dataset. **Note** **default** On the ASR 901 Series Aggregation Services Router, you must choose either the**default** keyword or the **current** keyword.
current	(Optional) Displays the current PTP clock dataset. **Note** On the ASR 901 Series Aggregation Services Router, you must choose either the**current** keyword or the **default** keyword.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

On the Cisco ASR 901 Series Aggregation Services Router, one of the keywords (**default** or **current**) must be used with the command.

Examples

The following examples show the output generated by this command:

```
Device# show ptp clock dataset default

CLOCK [Boundary Clock, domain 10]
  Two Step Flag: No
  Clock Identity: 0x2A:0:0:0:58:67:F3:4
  Number Of Ports: 1
  Priority1: 89
  Priority2: 90
  Domain Number: 10
  Slave Only: No
  Clock Quality:
    Class: 224
    Accuracy: Unknown
    Offset (log variance): 4252
```

```
Device# show ptp clock dataset current

CLOCK [Boundary Clock, domain 10]
  Steps Removed: 18522
  Offset From Master: 4661806827187470336
  Mean Path Delay: 314023819427708928
```

The table below describes significant fields shown in the display.

Table 253: show ptp clock dataset Field Descriptions

Field	Description
Two Step Flag	Indicates whether the clock is sending timestamp information using a FOLLOW_UP message (a 2-step handshake) or not (a 1-step handshake).
Clock Identity	Unique identifier for the clock.
Number of Ports	Number of ports assigned to the PTP clock.
Priority1	Priority1 preference value of the PTP clock; the priority1 clock is considered first during clock selection.
Priority2	Priority2 preference value of the PTP clock; the priority2 clock is considered after all other clock sources during clock selection.
Domain number	PTP clocking domain number.
Slave only	Specifies whether the PTP clock is a slave-only clock.
Clock quality	Summarizes the quality of the grandmaster clock.
Class	Displays the time and frequency traceability of the grandmaster clock
Accuracy	Field applies only when the Best Master Clock algorithm is in use; indicates the expected accuracy of the primary clock were the grandmaster clock.
Offset (log variance)	Offset between the local clock and an ideal reference clock.
Steps removed	Number of hops from the local clock to the grandmaster clock.
Offset From Master	Time offset between the subordinate and primary clocks.
Mean Path Delay	Mean propagation time between the primary and subordinate clocks.

show ptp clock dataset parent

To display a description of the Precision Time Protocol parent clock, use the show ptp dataset parent command in privileged EXEC mode.

show ptp clock dataset parent

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

Examples

The following example shows the output generated by this command:

```
Device# show ptp clock dataset parent

CLOCK [Boundary Clock, domain 10]
  Parent Stats: No
  Observed Parent Offset (log variance): 0
  Observed Parent Clock Phase Change Rate: 58087144
  Grandmaster Clock:
    Identity: 0x3E:D3:D0:0:0:0:0:0
    Priority1: 42
    Priority2: 0
    Clock Quality:
      Class: 176
      Accuracy: Unknown
      Offset (log variance): 4252
```

The table below describes significant fields shown in the display.

Table 254: show ptp clock dataset parent Field Descriptions

Field	Description
Parent Stats	Indicates the availability of parent statistics.
Observed Parent Offset (log variance)	The offset between the parent clock and the local clock.
Observed Parent Clock Phase Change Rate	This value indicates the parent clock speed relative to the subordinate clock. A positive value indicates that the parent clock is faster than the subordinate clock ; a negative value indicates that the parent clock is slower than the subordinate clock.
Grandmaster clock	Summarizes the Grandmaster clock configuration.

Field	Description
Identity	The hardware address of the Grandmaster clock.
Priority1	The priority1 preference value of the PTP clock; the priority1 clock is considered first during clock selection.
Priority2	The priority2 preference value of the PTP clock; the priority2 clock is considered after all other clock sources during clock selection.
Clock Quality	Summarizes the quality of the Grandmaster clock.
Class	Displays the time and frequency traceability of the grandmaster clock
Accuracy	This field applies only when the Best Master Clock algorithm is in use; indicates the expected accuracy of the primary clock were the grandmaster clock.
Offset (log variance)	The offset between the Grandmaster clock and the parent clock.

show ptp clock dataset time-properties

To display a summary of time properties for a Precision Time Protocol clock, use the show ptp dataset time-properties command in privileged EXEC mode.

show ptp clock dataset time-properties

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

Examples

The following example shows the output generated by this command:

```
Device# show ptp clock dataset time-properties

CLOCK [Boundary Clock, domain 10]
  Current UTC Offset Valid: TRUE
  Current UTC Offset: 10752
  Leap 59: FALSE
  Leap 61: TRUE
  Time Traceable: TRUE
  Frequency Traceable: TRUE
  PTP Timescale: TRUE
  Time Source: Unknown
```

The table below describes significant fields shown in the display.

Table 255: show ptp clock dataset time-properties Field Descriptions

Field	Description
Current UTC Offset Valid	Indicates whether the current UTC offset is valid.
Current UTC Offset	Offset between the TAI and UTC in seconds.
Leap 59	Indicates whether the last minute of the current UTC day contains 59 seconds.
Leap 61	Indicates whether the last minute of the current UTC day contains 61 seconds.
Time Traceable	Indicates whether the value of the current UTC offset is traceable to a primary reference.
Frequency Traceable	Indicates whether the frequency used to determine the time scale is traceable to a primary reference.

Field	Description
PTP Timescale	Indicates whether the PTP grandmaster clock uses a PTP clock time scale.
Time Source	Time source used by the grandmaster clock.

show ptp clock running

To display a summary of the Precision Time Protocol clock status, use the show ptp clock running command in privileged EXEC mode.

show ptp clock running [**domain**]

Syntax Description

domain	Filters output by domain.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

Examples

The following example shows the output generated by this command:

```
Device# show ptp clock running

PTP Boundary Clock [Domain 1]
         State          Ports          Pkts sent      Pkts rcvd
         FREERUN        3              1090           1023
                               PORT SUMMARY
Name               Tx Mode      Role         Transport    State         Sessions
MASTER-1           unicast      master       Et0/0        -             5
MASTER-2           mcast        master       Et0/0        -             5
SLAVE              unicast      slave        Et0/0        -             5
                      PTP Ordinary Clock [Domain 2]
         State          Ports          Pkts sent      Pkts rcvd
         HOLDOVER       1              2090           2023
                               PORT SUMMARY
Name               Tx Mode      Role         Transport    State         Sessions
MASTER             unicast      master       Et0/0        -             5
```

The table below describes significant fields shown in the display.

Table 256: show ptp clock running Field Descriptions

Field	Description
State	State of the PTP clock.
Ports	Number of ports assigned to the PTP clock.
Pkts sent	Number of packets sent by the PTP clock.
Pkts rcvd	Number of packets received by the PTP clock.

Field	Description
Name	Name of the PTP clock port.
Tx Mode	Transmission mode of the PTP clock port (unicast or multicast).
Role	PTP role of the clock port (primary or subordinate).
Transport	Physical port assigned to the clock port.
State	State of the clock port.
Sessions	Number of PTP sessions active on the clock port.

show ptp port dataset foreign-master

To display a summary of Precision Time Protocol foreign master records, use the **show ptp port dataset foreign-master-record** command in privileged EXEC mode.

show ptp port dataset foreign-master [**domain**]

Syntax Description

This command has no arguments or keywords.

domain	Filters output by domain.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

Examples

The following example shows the output generated by this command.

```
Device# show ptp dataset foreign-master

PTP FOREIGN MASTER RECORDS
Interface Vlan2
Number of foreign records 1, max foreign records 5
Best foreign record 0
RECORD #0
Foreign master port identity: clock id: 0x0:1E:4A:FF:FF:96:A2:A9
Foreign master port identity: port num: 1
Number of Announce messages: 8
Number of Current Announce messages: 6
Time stamps: 1233935406, 664274927
```

The table below describes significant fields shown in the display.

Table 257: show ptp port dataset foreign-master Field Descriptions

Field	Description
Interface	Currently foreign-master data is not displayed in the show command.
Number of foreign records	Number of foreign master records in device memory.
max foreign records	Maximum number of foreign records.
Best foreign record	Foreign record with the highest clock quality.
Foreign master port identity: clock id	Hardware address of the foreign master port.
Foreign master port identity: port number	Port number of the foreign master port.

Field	Description
Number of Announce messages	Number of Announce messages received from the foreign master clock.
Number of Current Announce messages	Number of current announcement messages.
Time stamps	Time stamps of current announcement messages.

show ptp port dataset port

To display a summary of Precision Time Protocol ports, use the **show ptp port dataset port** command in privileged EXEC mode.

show ptp dataset port

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

Use this command to verify a PTP clocking configuration.

Examples

The following example shows the output generated by this command.

```
Device# show ptp port dataset port

PORT [MASTER]
  Clock Identity: 0x49:BD:D1:0:0:0:0:0
  Port Number: 0
  Port State: Unknown
  Min Delay Req Interval (log base 2): 42
  Peer Mean Path Delay: 648518346341351424
  Announce interval (log base 2): 0
  Announce Receipt Timeout: 2
  Sync Interval (log base 2): 0
  Delay Mechanism: End to End
  Peer Delay Request Interval (log base 2): 0
  PTP version: 2
```

The table below describes significant fields shown in the display.

Table 258: show ptp port dataset port Field Descriptions

Field	Description
Clock Identity	Unique identifier for the clock.
Port Number	Port number on the PTP node.
Port State	State of the PTP port.
Min Delay Req Interval (log base 2)	Time interval permitted between Delay_Req messages.
Peer Mean Path Delay	One way propagation delay on the local port.
Announce interval (log base 2)	Mean interval between PTP announcement messages.
Announce Receipt Timeout	Number of intervals before a PTP announcement times out.

Field	Description
Sync Interval (log base 2)	Mean interval between PTP sync messages.
Delay Mechanism	Mechanism used for measuring propagation delay.
Peer Delay Request Interval (log base 2)	Interval permitted between Peer Delay Request messages.
PTP version	PTP version in use.

show pxf cpu access-lists

To display Parallel eXpress Forwarding (PXF) memory information for access control lists (ACLs), use the **show pxf cpu access-lists** command in privileged EXEC mode.

show pxf cpu access-lists [{**security** | **qos** | **pbr** | **compiled**}]

Cisco 10000 Series Router
show pxf cpu access-lists [{**security** [{[**tcam** *acl-name* [**detail**]] | **flex-sum** | **children**}] | **qos** | **pbr** | **compiled**}]

Syntax Description

security	(Optional) Displays information about the security ACLs defined in Cisco IOS and compiled to the PXF. Also displays information about split ACLs, such as how much memory has been used.
tcam *acl-name*	(Optional) Displays information about the specified security ACL stored in ternary content addressable memory (TCAM). This option is only available on the PRE3 for the Cisco 10000 series router.
detail	(Optional) Displays decoded information about the packet fields used for matching in the TCAM.
flex-sum	(Optional) Displays summary information describing the amount of memory allocated in the parallel express forwarding (PXF) engine for use by the flexible key construction microcode. This information is useful for design teams. This option is only available on the PRE3 for the Cisco 10000 series router.
children	(Optional) Displays information for child policies. If an ACL is a template child, the output typically does not display the child information. Specifying the **children** keyword displays data for child policies, too, and shows the children and the parent policy of each child. Use caution when using the **children** keyword as there might be thousands of child policies configured, which could have negative effects on the command output.
qos	(Optional) Displays information about the QoS ACLs defined in Cisco IOS and compiled to the PXF.
pbr	(Optional) Displays information about ACLs for policy-based routing (PBR).
compiled	(Optional) Displays information for all compiled Turbo-ACLs. The PRE2 supports Turbo-ACLs and the **compiled** option. The PRE3 accepts the PRE2 **compiled** option, but does not implement Turbo-ACLs.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2S	This command was introduced.
12.3(7)XI1	This command was introduced on the PRE2 for the Cisco 10000 series router.
12.2(31)SB2	This command was introduced on the PRE3 for the Cisco 10000 series router.

Usage Guidelines

Cisco 10000 Series Router (PRE2)

Because memory is shared between TurboACLs and MiniACLs, they can interfere with each other's capacities. The Mini-ACL is automatically set up with space for 8191 Mini-ACLs at router start. If more than 8191 Mini-ACLs are created, another block of MiniACLs (4096) is allocated. This process is repeated as necessary until the router is out of External Column Memory (XCM) in any one bank that the Mini-ACLs need.

Cisco 10000 Series router (PRE3)

The PRE3 implements only TCAM ACLs. Turbo-ACLs and Mini-ACLs are not supported.

Examples

The sample output from the **show pxf cpu access-lists security** command (see Sample Output) is based on the configuration of the access control list (ACL) called test_list (see ACL Configuration). The sample output is divided into several sections with a description of the type of information displayed in each.

ACL Configuration

```
Router# show pxf cpu access-lists test_list
Extended IP access list test_list (Compiled)
    10 permit ip any host 10.1.1.1
    20 permit ip any host 10.1.1.2
    30 permit ip any host 10.1.1.3
    40 permit ip any host 10.1.1.4
    50 permit ip any host 10.1.1.5
    60 permit ip any host 10.1.1.6
    70 permit ip any host 10.1.1.7
    80 permit ip any host 10.1.1.8
    90 permit ip any host 10.1.1.9
    100 permit ip any host 10.1.1.11
    110 permit ip any host 10.1.1.12
```

Sample Output

The following sample output describes the information displayed in the first section of the command output from the **show pxf cpu access-lists security** command:

```
Router# show pxf cpu access-lists security
PXF Security ACL statistics:
ACL            State      Tables  Entries  Config  Fragment  Redundant  Memory ACL_index
 1            Operational   1        -        -        -         -         0Kb     1
sl_def_acl    Operational   2        -        -        -         -         0Kb     2
test          Operational   3        -        -        -         -         0Kb     3
test_list     Operational   1        12       11       0         0         7Kb     1
```

The table below describes the significant fields shown in the display.

Table 259: show pxf cpu access-lists security Field Descriptions

Field	Description
ACL	Identifies the ACL by name or number.
State	Displays the current state of the ACL: • Copying--ACL is in the process of being created or compiled. • Operational--ACL is active and filtering packets. • Out of acl private mem--ACL has run out of the private memory that was allocated exclusively to it. • Out of shared mem--ACL has run out of the memory that it shares with other ACLs. • Unknown Failure--ACL has failed because of an uncategorized reason. • Unneeded--ACL was allocated but is not currently in use.
Tables	An indicator of whether the ACL has been split into more than one PXF pass. The first three ACLs in the output are MiniACLs, and have the ACL_index duplicated in the Tables column.
Entries	The count of ACL rules as seen by the Turbo compiler. This is the sum of the Config, Fragment, and Redundant columns plus 1.
Config	The count of rules for this ACL.
Fragment	The count of extra rules added to handle fragment handling, where Layer 4 information is needed but not available in a packet fragment.
Redundant	The count of rules that are not needed because they are covered by earlier rules.
Memory	The amount of PXF XCM in use for the ACL.
ACL_index	The index of the ACL in XCM.

The following sample output describes the information displayed in the next section of the command output from the **show pxf cpu access-lists security** command:

```
First level lookup tables:
Block      Use              Rows       Columns   Memory used
  0   TOS/Protocol            1/128     1/32      16384
  1   IP Source (MS)          1/128     1/32      16384
  2   IP Source (LS)          1/128     1/32      16384
  3   IP Dest (MS)            2/128     1/32      16384
  4   IP Dest (LS)           12/128     1/32      16384
  5   TCP/UDP Src Port        1/128     1/32      16384
  6   TCP/UDP Dest Port       1/128     1/32      16384
  7   TCP Flags/Fragment      1/128     1/32      16384
```

The table below describes the significant fields shown in the display.

Table 260: show pxf cpu access-lists security Field Descriptions

Field	Description
Block	Indicates the block number.
Use	Describes the IP packet field that is being matched.
Rows	An indication of where the largest variety of values are in use in the ACLs that are being applied. In the output, 12/128 means that there are 12 different values of significance in the field. If there are other rules added and the value exceeds 128, more memory will be needed to accommodate the new rules.
Columns	An indication of the number of TurboACLs in PXF memory. In the output, 1/32 means there is only one TurboACL in PXF memory. If there are more than 31 added, another chunk of memory is needed to accommodate the new ACLs.
Memory used	Displays the total amount of memory used for this particular lookup table.

The following sample output describes the information displayed in the next section of the command output from the **show pxf cpu access-lists security** command. There are 16 banks of XCM in each PXF column. This output section shows the usage level of each bank.

```
Banknum   Heapsize   Freesize  %Free
   0       4718592    4702208    99
   1       8126464    6012928    73
   2       8388608    6290432    74
   3       8388608    6290432    74
   4       5898240    5881856    99
   5       8126464    6012928    73
   6       8388608    6290432    74
   7       8126464    6012928    73
   8       4456448    4440064    99
   9       8126464    6012928    73
```

The table below describes the significant fields shown in the display.

Table 261: show pxf cpu access-lists security Field Descriptions

Field	Description
Banknum	The block of memory used for this particular lookup table.
Heapsize	The total amount of memory, in bytes, allocated for this block.
Freesize	The amount of memory, in bytes, that is currently available for use by this block of memory.
%Free	The percentage of memory that is free and available for use for this block of memory. When the %Free drops to 0, the router cannot hold any more ACLs in PXF memory, and any new ACL will not pass traffic.

This section of the sample command output indicates the memory usage of the MiniACLs in the router. All of the rows state about the same thing. To determine the actual number of MiniACLs in play, divide the memory used in any of blocks 1 to 10 by 256, or blocks 11 to 14 by 16.

```
MiniACL XCM Tables:
```

```
Block   Use               Memory Used   %Free
  0   IP Src 1              768        99
  1   IP Src 2              768        99
  2   IP Src 3              768        99
  3   IP Src 4              768        99
  4   IP Dest 1             768        99
  5   IP Dest 2             768        99
  6   IP Dest 3             768        99
  7   IP Dest 4             768        99
  8   ToS                   768        99
  9   Protocol              768        99
  10  TCP Flags/Fragment    768        99
  11  Source Port 1          48        99
  12  Source Port 2          48        99
  13  Destination Port 2     48        99
  14  Destination Port 2     48        99
```

The following describes the information displayed in the last section of the sample output from the **show pxf cpu access-lists security** command:

```
Available MiniACL count = 8191
Usable ranges(inclusive):
1->8191
```

The table below describes the significant fields shown in the display.

Table 262: show pxf cpu access-lists security Field Descriptions

Field	Description
Available MiniACL	The number of ACLs currently available for allocation in XCM.
Usable ranges	The ACL indexes that will be assigned to MiniACLs.

PRE2 and PRE3 Security ACLs Examples (Cisco 10000 Series Router)

This section compares the output from the **show pxf cpu access-lists security** command when issued on the PRE2 and PRE3.

For the PRE2, the following sample output displays VMR (value, plus a mask and result) data for the ACL named ICMP_IGMP_MATCH:

```
Router# show pxf cpu access-lists security tcam ICMP_IGMP_MATCH detail

-------------------------------------------------------------
VMR Format - handle: 524607B4
Format has 5 fields, refcount = 1
Field: Format, FIXED, start_bit = 69, end_bit = 71

```

Related Commands

Command	Description
show pxf cpu statistics	Displays PXF CPU statistics.
show pxf statistics	Displays a chassis-wide summary of PXF statistics.

show pxf cpu iedge

To display Parallel eXpress Forwarding (PXF) policy and template information, use the **show pxf cpu iedge**command in privileged EXEC mode.

show pxf cpu iedge[{ **detail** | **policy** *policy-name* | **template**}]

Syntax Description

detail	(Optional) Displays detailed information about policies and templates.
policy *policy-name*	(Optional) Displays summary policy information.
template	(Optional) Displays summary template information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2S	This command was introduced.

Examples

The following example shows PXF template information. The fields shown in the display are self-explanatory.

```
Router# show pxf cpu iedge template
Super ACL name                     OrigCRC   Class Count    CalcCRC
1sacl_2                           4EA94046   2             00000000
if_info 71BA3F20
```

Related Commands

Command	Description
show pxf statistics	Displays a summary of PXF statistics.

show pxf cpu qos

To display Parallel eXpress Forwarding (PXF) External Column Memory (XCM) contents related to a particular policy, use the **show pxf cpu qos** command in privileged EXEC mode.

show pxf cpu qos [{**policy-map** *policy-name* | **vcci-maps**}]

Cisco 10000 Series Router
show pxf cpu qos [{*vcci* | **classifiers** | **flex-sum** | **policy-map** *policy-name* | **vcci-maps**}]

Syntax Description

vcci	(Optional) Virtual Channel Circuit Identifier (VCCI). Information about this specified VCCI will be displayed.
classifiers	(Optional) Displays information about the criteria used to classify traffic.
flex-sum	(Optional) Displays summary information describing the amount of memory allocated in the PXF engine for use by the flexible key construction microcode. **Note** This option is only available on the Cisco 10000 series router for the PRE3.
policy-map *policy-name*	(Optional) Displays per-policy map information.
vcci-maps	(Optional) Displays VCCI map values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2S	This command was introduced.
12.3(7)XI1	This command was introduced on the Cisco 10000 series router for the PRE2.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(31)SB2	This command was introduced on the PRE3 for the Cisco 10000 series router.

Usage Guidelines

This command is useful in verifying the presence of a policy on interfaces and indexes programmed in the PXF.

Examples

The following example shows XCM contents related to a policy called police_test, which is defined as follows:

```
policy-map police_test
 class high-priority
 priority
 class low-priority
  set atm-clp
 class class-default
```

```
    queue-limit 512
Router# show pxf cpu qos police_test
Output Policymap: police_test
 Vcci: A05  Flags: 4  Policymap_index: 6  Policymap_data_index: 12
 OUT AT1/0/0.111 (0x71764660) ref_count 1
Output Action Table Contents for vcci 0xA05 - Policymap index: 6
 class-name: high-priority  class_index: 0  action_flags: 0x00
  srp_class_id: 0x01  prec/dscp: 0x00  cos: 0
  discard_class: 0x00  exp_value: 0
class-name: low-priority  class_index: 1  action_flags: 0x10
  srp_class_id: 0x00  prec/dscp: 0x00  cos: 0
  discard_class: 0x00  exp_value: 0
class-name: class-default  class_index: 2  action_flags: 0x00
  srp_class_id: 0x00  prec/dscp: 0x00  cos: 0
  discard_class: 0x00  exp_value: 0
```

Related Commands

Command	Description
show pxf cpu statistics qos	Displays match statistics for a service policy on an interface.

show pxf dma

To display the current state of direct memory access (DMA) buffers, error counters, and registers on the Parallel eXpress Forwarding (PXF), use the **show pxf dma**command in privileged EXEC mode.

show pxf dma [{**buffers** | **counters** | **reassembly** | **registers**}]

Cisco 10000 Series Router (PRE3 only)

show pxf dma [{**buffers** | **counters** | **reassembly** | **registers**}][{**brief** | **config** | **errors** | **status**}]

Syntax Description

buffers	(Optional) Displays PXF DMA buffers information.
counters	(Optional) Displays packet and error counters for the PXF DMA engine.
reassembly	(Optional) Displays PXF reassembly table usage information.
registers	(Optional) Displays PXF DMA registers information.
brief	(Optional) Displays PXF DMA information, including the initialization state of each block in the PXF API and any errors that occurred. **Note** This option is available on the PRE3 only.
config	(Optional) Displays a configuration summary of the registers in each of the PXF DMA blocks. **Note** This option is available on the PRE3 only.
errors	(Optional) Displays the errors that occurred in each of the PXF DMA blocks. **Note** This option is available on the PRE3 only.
status	(Optional) Displays the initialization state of each PXF DMA block. In normal operation, all blocks display the enabled state. **Note** This option is available on the PRE3 only.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2S	This command was introduced.
12.3(7)XI	This command was integrated into Cisco IOS Release 12.3(7)XI and implemented on the Cisco 10000 series router for the PRE2.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2 and implemented on the Cisco 10000 series router for the PRE3.

Examples

The following example shows PXF DMA buffers information:

```
Router# show pxf dma buffers
PXF To-RP DMA Ring Descriptors & Buffers:
     Descriptor       Buffer        Buffer      Descriptor

13   0x0CA06650       0x00000000        0       0x0000        Not set
14   0x0CA06660       0x00000000        0       0x0000        Not set
15   0x0CA06670       0x00000000        0       0x0001        Not set
```

The table below describes the fields shown in the display.

Table 263: show pxf dma Field Descriptions

Field	Description
Descriptor Address	Memory address pointing to the descriptor for this buffer.
Buffer Address	Address of this buffer in memory.
Buffer Length	Length, in bytes, of this particular buffer.
Descriptor Flags	Internal flags identifying this buffer's use and status.
Context Bit	State of the context bit which is set when the buffer is currently in use by a context (the basic unit of packet processing).

Related Commands

Command	Description
clear pxf	Clears PXF counters and statistics.
show pxf cpu	Displays PXF CPU statistics.
show pxf microcode	Displays the microcode version running on the PXF.

show pxf max-logical-interfaces

To display the configuration for the maximum number of classes permitted per QoS policy in PXF and the maximum number of PXF logical interfaces allowed on the router, use the **showpxfmax-logical-interfaces** command in privileged EXEC mode.

show pxf max-logical-interfaces

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S5	This command was introduced.

Usage Guidelines

The **showpxfmax-logical-interfaces** command is used to verify if the **pxfmax-logical-interfaces** configuration change was accepted by the router. The output from this command provides the settings for the maximum number of classes permitted per QoS policy in PXF and the number of PXF logical interfaces as set in both the running configuration file and the startup configuration file. The settings listed in the startup configuration file are the current settings on the router; the settings listed in the running configuration will be the settings on the router when the router is reloaded.

Examples

In the following example, the **pxfmax-logical-interfaces16k** command has been entered to change the setting from the previous setting of 4k. The router, however, has not been rebooted with the changes saved to the running configuration.

```
Router# show pxf max-logical-interfaces
Running configuration:
    PXF Max classes per interface: 23
    Max PXF interfaces:            16K
Startup configuration:
    PXF Max classes per interface: 64
    Max PXF interfaces:            4K
```

Related Commands

Command	Description
pxf max-logical-interfaces	Configures the maximum number of PXF logical interfaces permitted on the router.

show qm-sp port-data

To display information about the QoS-manager switch processor, use the **showqm-spport-data** command in privileged EXEC mode.

show **qm-sp** **port-data** *mod* *port*

Syntax Description

mod port	Module and port number; see the “Usage Guidelines” section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported by the supervisor engine only and can be entered only from theCisco 7600 series routers console (see the **remotelogin** command).

The *modport* arguments designate the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

Enter the **showqm-spport-data**command to verify the values that are programmed in the hardware.

Examples

This example shows how to display information about the QoS manager:

```
Router# show qm-sp port-data 1 2
-----------------------------------------------------------------------------
* Type: Tx[1p2q2t] Rx[1p1q4t]  [0] Pinnacle
* Per-Port: [Untrusted] Default COS[0] force[0] [VLAN based]
-----------------------------------------------------------------------------
* COSMAP(C[Q/T]) TX: 0[1/1] 1[1/1] 2[1/2] 3[1/2] 4[2/1] 5[3/1] 6[2/1] 7[2/2]
                 RX: 0[1/1] 1[1/1] 2[1/2] 3[1/2] 4[1/3] 5[2/1] 6[1/3] 7[1/4]
-----------------------------------------------------------------------------
* WRR bandwidth:        [7168 18432]
* TX queue limit(size): [311296 65536 65536]
* WRED queue[1]:        failed (0x82)
       queue[2]:        failed (0x82)
-----------------------------------------------------------------------------
* TX drop thr queue[1]: type[2 QOS_SCP_2_THR] dropThr[311104 311104]
              queue[2]: type[2 QOS_SCP_2_THR] dropThr[61504 61504]
* RX drop threshold:    type[4 QOS_SCP_4_THR] dropThr[62259 62259 62259 62259]
* RXOvr drop threshold: type[0 UNSUPPORTED] dropThr[16843009 131589 61504 61504]
* TXOvr drop threshold: type[0 UNSUPPORTED] dropThr[67174656 260 16843009 131589]
Switch-sp#
```

Related Commands

Command	Description
rcv-queue queue-limit	Sets the size ratio between the strict-priority and standard receive queues.
remote login	Accesses the Cisco 7600 series routers console or a specific module.
wrr-queue bandwidth	Allocates the bandwidth between the standard transmit queues.
wrr-queue queue-limit	Sets the transmit-queue size ratio on an interface.
wrr-queue threshold	Configures the drop-threshold percentages for the standard receive and transmit queues on 1q4t and 2q2t interfaces.

show rbscp

To display state and statistical information about Rate Based Satellite Control Protocol (RBSCP) tunnels, use the **showrbscp** command in user EXEC or privileged EXEC mode.

show rbscp {**all** | **inbound** | **state** | **statistics**} [**tunnel** *tunnel-number*]

Syntax Description

all	Displays both RBSCP state and RBSCP statistical information.
inbound	Displays all the RBSCP inbound queue dump information.
state	Displays the RBSCP state information.
statistics	Displays RBSCP statistical information.
tunnel *tunnel-number*	(Optional) Displays the RBSCP information for a specific tunnel interface in the range from 0 to 2147483647. If a tunnel interface is not specified, information for all RBSCP tunnels is displayed.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.4(22)T	This command was modified. The **inbound** keyword was added.
Cisco IOS 2.1 XE	This command was integrated into Cisco IOS XE Release 2.1.

Usage Guidelines

The output of this command is useful when you need to configure and monitor RBSCP tunnels. The output shows various state and statistical information about RBSCP tunnels.

Examples

The following is sample output from the **showrbscpall**command:

```
Router# show rbscp all
Tunnel0 is up, line protocol is up
RBSCP operational state:  IS OPENING
RBSCP operating mode: (264h) ack_split window_stuffing inorder SCTP_report
  window step: 1
  drop scale : 0
  ACK split size: 4
  input drop scale: 2
  initial TSN: 1h
  fuzz factor: 0
  next TSN: 1h
  next sequence: 1h
  current outstanding: 0
  max out per RTT: 68750
  packets since SACK: 0
  cumulative ack: 0h
  TSN at SACK: 1h
  last cumulative ack: 0h
```

```
  last delivered TSN: 0h
  next FWDTSN corr: 6h
  RTO: 704 ms
  RTT: 550 ms     srtt_sa: 0      srtt_sv: 4
  sentQ: num packets: 0, num bytes: 0
  tmitQ: num packets: 0, num bytes: 0
RBSCP protocol statistics:
  Init FWD-TSNs sent 0, received 0
  TUNNEL-UPs sent 0, received 0
  CLOSEDs sent 0, received 0
  TSNs sent 0, resent 0, lost by sender 0
  TSNs received 0 (duplicates 0)
  FWD-TSNs sent 63 (heartbeats 0)
  FWD-TSNs received 0 (ignored 0)
  FWD-TSNs caused 0 packet drops, 0 whole window drops
  SACKs sent 0, received 0 (ignored 0)
  Recovered with RTX 0
  Received with delay 0
  Most released at once 0
  Failed sends into the: tunnel 1, network 0
  Dropped due to: excess delay 0, tmit queue full 0
  Max on any queue: num packets: 0, num bytes: 0
  Max outstanding: 0
```

The table below describes the significant fields shown in the display.

Table 264: show rbscp all Field Descriptions

Field	Description
Tunnel*n* is {up | down}	Interface is currently active (up) or inactive (down).
line protocol is {up | down | administratively down}	Shows line protocol up if a valid route is available to the tunnel destination. Shows line protocol down if no route is available or if the route would be recursive.
RBSCP operational state	Indicates the current RBSCP state.
RBSCP operating mode	Indicates the RBSCP operating mode.
window step	Step size for the window scale.
drop scale	Scale factor for the number of bytes that can be queued before packets are dropped on the output side.
Ack split size	Number of TCP acknowledgements to send for every ack received.
input drop scale	Scale factor for the number of bytes that can be queued before packets are dropped on the input side.
initial TSN	Transport Sequence Number (TSN) of the first outgoing RBSCP/IP packet sent to a peer. RBSCP uses sequence numbers to ensure a reliable service. Peers will send the TSN back in the acknowledgment packet.
fuzz factor	Value added to the RBSCP delay clock to pad the delay when large round-trip time (RTT) fluctuations occur.
next TSN	TSN of the next outgoing RBSCP/IP packet.

Field	Description
next sequence	Next sequence number to use, in hexadecimal format.
current outstanding	Current number of bytes that are in transit or are unacknowledged.
max out per RTT	Maximum number of bytes allowed to be sent out per RTT.
packets sent since SACK	Number of packets sent since an RBSCP Selective Acknowledgement (SACK).
cumulative ack	Cumulative acknowledgement point that is the highest in sequence TSN that was received from a peer.
TSN at SACK	Value of highest TSN for the last SACK that was received from a peer.
last cumulative ack	Last cumulative acknowledgement point that was received from the peer.
last delivered TSN	Last TSN received that was subsequently delivered to an upper level protocol.
next FWDTSN corr	Next FWD_TSN correlation entry to use.
RTO	Retransmission timeout, in milliseconds.
RTT	Round-trip time estimate, in milliseconds.
srtt_sa	Smoothed round-trip time average.
srtt_sv	Smoothed round-trip time variance.
sentQ	Number of packets and bytes sent but not yet acknowledged.
tmitQ	Number of packets and bytes ready to be sent.
Init FWD-TSNs	Number of TSNs sent and received for initializing the RBSCP tunnel.
TUNNEL-UPs	Number of TUNNEL_UP messages sent and received.
CLOSEDs	Number of CLOSED messages sent and received.
heartbeats	Heartbeats are equivalent to keepalive messages.
Recovered with RTX	Number of packets recovered using a retransmitted message.
Received with delay	Number of packets that included a delay value.
Most released at once	Maximum burst of packets sent in one interval.
Failed sends	Number of packets that were sent but failed because of an internal error, such as no route or the underlying interface is down.

The following is sample output from the **showrbscpstate**command:

```
Router# show rbscp state
```

```
Tunnel0 is up, line protocol is up
RBSCP operational state:  IS OPENING
RBSCP operating mode: (264h) ack_split window_stuffing inorder SCTP_report
  window step: 1
  drop scale : 0
  ACK split size: 4
  input drop scale: 2
  initial TSN: 1h
  fuzz factor: 0
  next TSN: 1h
  next sequence: 1h
  current outstanding: 0
  max out per RTT: 68750
  packets since SACK: 0
  cumulative ack: 0h
  TSN at SACK: 1h
  last cumulative ack: 0h
  last delivered TSN: 0h
  next FWDTSN corr: 0h
  RTO: 704 ms
  RTT: 550 ms     srtt_sa: 0      srtt_sv: 4
  sentQ: num packets: 0, num bytes: 0
  tmitQ: num packets: 0, num bytes: 0
```

The following is sample output from the **showrbscpstatistics**command:

```
Router# show rbscp statistics tunnel 0
Tunnel0 is up, line protocol is up
RBSCP protocol statistics:
  Init FWD-TSNs sent 0, received 0
  TUNNEL-UPs sent 0, received 0
  CLOSEDs sent 0, received 0
  TSNs sent 0, resent 0, lost by sender 0
  TSNs received 0 (duplicates 0)
  FWD-TSNs sent 136 (heartbeats 0)
  FWD-TSNs received 0 (ignored 0)
  FWD-TSNs caused 0 packet drops, 0 whole window drops
  SACKs sent 0, received 0 (ignored 0)
  Recovered with RTX 0
  Received with delay 0
  Most released at once 0
  Failed sends into the: tunnel 1, network 0
  Dropped due to: excess delay 0, tmit queue full 0
  Max on any queue: num packets: 0, num bytes: 0
  Max outstanding: 0
```

Related Commands

Command	Description
clear rbscp	Resets and restarts RBSCP tunnels.

show redundancy

To display current or historical status and related information on planned or logged handovers, use the **show redundancy** command in user EXEC or privileged EXEC mode.

Privileged EXEC Mode
show redundancy [{**clients** | **counters** | **debug-log** | **handover** | **history** | **inter-device** | **states** | **switchover** | **switchover history**}]

User EXEC Mode
show redundancy {**clients** | **counters** | **history** | **states** | **switchover**}

Syntax Description

clients	(Optional) Displays the redundancy-aware client-application list.
counters	(Optional) Displays redundancy-related operational measurements.
debug-log	(Optional) Displays up to 256 redundancy-related debug entries.
handover	(Optional) Displays details of any pending scheduled handover.
history	(Optional) Displays past status and related information about logged handovers. This is the only keyword supported on the Cisco AS5800.
inter-device	(Optional) Displays redundancy interdevice operational state and statistics.
states	(Optional) Displays redundancy-related states: disabled, initialization, standby, active (various substates for the latter two), client ID and name, length of time since the client was sent the progression, and event history for the progression that was sent to the client.
switchover	(Optional) Displays the switchover counts, the uptime since active, and the total system uptime.
switchover history	(Optional) Displays redundancy switchover history.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
11.3(6)AA	This command was introduced in privileged EXEC mode.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T. Support for the Cisco AS5800 and Cisco AS5850 is not included in this release.
12.2(8)MC2	This command was modified. This command was made available in user EXEC mode.
12.2(11)T	The privileged EXEC mode form of this command was implemented on the Cisco AS5800 and Cisco AS5850.

Release	Modification
12.2(14)SX	The user EXEC mode form of this command was implemented on the Supervisor Engine 720.
12.2(18)S	This command was implemented on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(20)S	The **states**, **counters**, **clients**, **history**, and **switchover history** keywords were added.
12.2(17d)SXB	Support for the user EXEC mode form of this command was extended to the Supervisor Engine 2.
12.3(8)T	The **inter-device** keyword was added to the privileged EXEC form of the command.
12.3(11)T	The user EXEC form of this command was integrated into Cisco IOS Release 12.3(11)T.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SGA	This command was integrated into Cisco IOS Release 12.2(31)SGA.
12.2(33)SRB	The **clients** keyword was enhanced to provide information about the status of each client.
12.2(33)SRB1	ISSU is supported on the Cisco 7600 series routers in Cisco IOS Release 12.2(33)SRB1.
12.2(31)SXH	This command was integrated into Cisco IOS Release 12.2(31)SXH.
12.2(33)SRE	This command was integrated into Cisco IOS Release 12.2(33)SRE.
Cisco IOS XE Release 3.1S	More information regarding the **states** keyword was added.

Usage Guidelines

Cisco AS5800

Use this command from the router-shelf console to determine when failover is enabled. Use this command with the **history** keyword to log failover events.

Cisco AS5850

To use this command, the router must have two route-switch-controller (RSC) cards installed and must be connected to one of them.

Examples

The following example shows how to display information about the RF client:

```
Router# show redundancy clients
 clientID = 0       clientSeq = 0         RF_INTERNAL_MSG
 clientID = 25      clientSeq = 130       CHKPT RF
 clientID = 5026    clientSeq = 130       CHKPT RF
 clientID = 5029    clientSeq = 135       Redundancy Mode RF
```

```
 clientID = 5006    clientSeq = 170      RFS client
 clientID = 6       clientSeq = 180      Const OIR Client
 clientID = 7       clientSeq = 190      PF Client
 clientID = 5008    clientSeq = 190      PF Client
 clientID = 28      clientSeq = 330      Const Startup Config
 clientID = 29      clientSeq = 340      Const IDPROM Client
 clientID = 65000   clientSeq = 65000    RF_LAST_CLIENT
```

The output displays the following information:

- clientID displays the client's ID number.
- clientSeq displays the client's notification sequence number.
- Current RF state.

The following example shows how to display information about the RF counters:

```
Router# show redundancy counters
Redundancy Facility OMs
               comm link up = 0
        comm link down down = 0
          invalid client tx = 0
          null tx by client = 0
                tx failures = 0
      tx msg length invalid = 0
      client not rxing msgs = 0
 rx peer msg routing errors = 0
           null peer msg rx = 0
        errored peer msg rx = 0
                 buffers tx = 0
     tx buffers unavailable = 0
                 buffers rx = 0
      buffer release errors = 0
 duplicate client registers = 0
  failed to register client = 0
       Invalid client syncs = 0
```

The following example shows information about the RF history:

```
Router# show redundancy history
00:00:00 client added: RF_INTERNAL_MSG(0) seq=0
00:00:00 client added: RF_LAST_CLIENT(65000) seq=65000
00:00:02 client added: Const Startup Config Sync Clien(28) seq=330
00:00:02 client added: CHKPT RF(25) seq=130
00:00:02 client added: PF Client(7) seq=190
00:00:02 client added: Const OIR Client(6) seq=180
00:00:02 client added: Const IDPROM Client(29) seq=340
00:00:02 *my state = INITIALIZATION(2) *peer state = DISABLED(1)
00:00:02 RF_PROG_INITIALIZATION(100) RF_INTERNAL_MSG(0) op=0 rc=11
00:00:02 RF_PROG_INITIALIZATION(100) CHKPT RF(25) op=0 rc=11
00:00:02 RF_PROG_INITIALIZATION(100) Const OIR Client(6) op=0 rc=11
00:00:02 RF_PROG_INITIALIZATION(100) PF Client(7) op=0 rc=11
```

The following example shows information about the RF state:

```
Router# show redundancy states
       my state = 13 -ACTIVE
     peer state = 1  -DISABLED
           Mode = Simplex
           Unit = Primary
        Unit ID = 1
```

```
Redundancy Mode (Operational) = Route Processor Redundancy
Redundancy Mode (Configured)  = Route Processor Redundancy
     Split Mode = Disabled
   Manual Swact = Disabled  Reason: Simplex mode
 Communications = Down      Reason: Simplex mode
   client count = 11
 client_notification_TMR = 30000 milliseconds
          keep_alive TMR = 4000 milliseconds
        keep_alive count = 0
    keep_alive threshold = 7
           RF debug mask = 0x0
```

If you enter the **show redundancy states** command with stateful switchover (SSO) configured, the Redundancy Mode (Operational) and the Redundancy Mode (Configured) fields display stateful switchover.

The following example shows how to display the switchover counts, the uptime since active, and the total system uptime:

```
Router> show redundancy switchover
Switchovers this system has experienced          : 1
Uptime since this supervisor switched to active  : 1 minute
Total system uptime from reload                  : 2 hours, 47 minutes
```

Example: Setting the terminal length for the Cisco ASR 1006

The following example shows how to set the terminal length value to pause the multiple-screen output:

```
Router# terminal length 5
Router# show redundancy states
my state = 13 -ACTIVE
     peer state = 8  -STANDBY HOT
           Mode = Duplex
           Unit = Primary
        Unit ID = 48
```

Example: Cisco AS5850

The following is sample output from the **show redundancy handover** and **show redundancy states** commands on the Cisco AS5850:

```
Router# show redundancy handover

No busyout period specified
Handover pending at 23:00:00 PDT Wed May 9 2001
Router# show redundancy states

my state = 14 -ACTIVE_EXTRALOAD
peer state = 4 -STANDBY COLD
Mode = Duplex
Unit = Preferred Primary
Unit ID = 6
Redundancy Mode = Handover-split: If one RSC fails, the peer RSC will take over the
feature boards
Maintenance Mode = Disabled
Manual Swact = Disabled Reason: Progression in progress
```

```
Communications = Up
client count = 3
client_notification_TMR = 30000 milliseconds
keep_alive TMR = 4000 milliseconds
keep_alive count = 1
keep_alive threshold = 7
RF debug mask = 0x0
```

Example: Cisco AS5800

The following is sample output from the **show redundancy** command on the Cisco AS5800:

```
Router# show redundancy
DSC in slot 12:
Hub is in 'active' state.
Clock is in 'active' state.
DSC in slot 13:
Hub is in 'backup' state.
Clock is in 'backup' state.
```

Example: Cisco AS5800 with History

The following is sample output from the **show redundancy history** command on the Cisco AS5800:

```
Router# show redundancy history
DSC Redundancy Status Change History:
981130 18:56 Slot 12 DSC: Hub, becoming active - RS instruction
981130 19:03 Slot 12 DSC: Hub, becoming active - D13 order
```

Example: Cisco AS5800 Router Shelves as Failover Pair

The following is sample output from two Cisco AS5800 router shelves configured as a failover pair. The active router shelf is initially RouterA. The **show redundancy history** and **show redundancy** commands have been issued. The **show redundancy** command shows that failover is enabled, shows the configured group number, and shows that this router shelf is the active one of the pair. Compare this output with that from the backup router shelf (RouterB) that follows.

Note When RouterA is reloaded, thereby forcing a failover, new entries are shown on RouterB when the**show redundancy history** command is issued after failover has occurred.

Log from the First Router (RouterA)

```
RouterA# show redundancy history
DSC Redundancy Status Change History:
010215 18:17 Slot -1 DSC:Failover configured -> ACTIVE role by default.
010215 18:18 Slot -1 DSC:Failover -> BACKUP role.
010215 18:18 Slot 12 DSC:Failover -> ACTIVE role.
010215 18:18 Slot 12 DSC:Hub, becoming active - arb timeout
RouterA# show redundancy
```

```
failover mode enabled, failover group = 32
Currently ACTIVE role.
DSC in slot 12:
Hub is in 'active' state.
Clock is in 'active' state.
No connection to slot 13
RouterA# reload
Proceed with reload? [confirm] y

Related Commands

Command	Description
debug redundancy	Displays information used for troubleshooting dual (redundant) router shelves (Cisco AS5800) or RSCs (Cisco AS5850).
hw-module	Enables the router shelf to stop a DSC or to restart a stopped DSC.
mode	Sets the redundancy mode.
mode y-cable	Invokes y-cable mode.
redundancy	Enters redundancy configuration mode.
redundancy force-switchover	Forces a switchover from the active to the standby supervisor engine.
show chassis	Displays, for a router with two RSCs, information about the mode (handover-split or classic-split), RSC configuration, and slot ownership.
show standby	Displays the standby configuration.
standalone	Specifies whether the MWR 1941-DC router is used in a redundant or standalone configuration.
standby	Sets HSRP attributes.

show redundancy (HSA redundancy)

To display the current redundancy mode, use the **showredundancy**command in user EXEC or privileged EXEC mode.

show redundancy

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.2 GS	This command was introduced.
12.0(16)ST	This command was modified to display information about Route Processor Redundancy (RPR).
12.0(19)ST1	This command was modified to display information about RPR Plus (RPR+).
12.3(7)T	The command modifications to support RPR and RPR+ were integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

Use this command to display the redundancy mode of a Cisco 7500 series router. The default redundancy mode is High System Availability (HSA). Use the **redundancy**configuration command to enter redundancy configuration mode. Use the **moderpr**command in redundancy configuration mode to configure RPR as the high availability mode. HSA is the default high availability mode.

Examples

The following is sample output from the **showredundancy** command for a router with RPR configured:

```
Router# show redundancy
redundancy mode rpr
hw-module slot 2 image slot0:rsp-pv-mz
hw-module slot 3 image slot0:rsp-pv-mz
```

Related Commands

Command	Description
hw-module sec-cpu reset	Resets and reloads the standby RSP with the specified Cisco IOS image and executes the image.
hw-module slot image	Specifies a high availability Cisco IOS image to run on a standby RSP.
mode (HSA redundancy)	Configures the redundancy mode.
redundancy	Enters redundancy configuration mode.

show redundancy interchassis

To display information about interchassis redundancy group configuration, use the **show redundancy interchassis** command in privileged EXEC mode.

show redundancy interchassis *group-number*

Syntax Description

group-number	Interchassis redundancy group number.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS 15.2(1)S	This command was introduced.
Cisco IOS XE 3.11S	This command was integrated into Cisco IOS XE Release 3.11S.

The following is sample output from the **show redundancy interchassis** command when *group-number* is used to display information about an interchassis redundancy group:

```
Router# show redundancy interchassis 100

Redundancy Group 100 (0x64)
Applications connected: MR-APS with HSPW
Monitor mode: RW
member ip: 60.60.60.2 "R-222-2028", CONNECTED
Route-watch for 60.60.60.2 is UP
MR-APS with HSPW state: CONNECTED
backbone int GigabitEthernet0/4/0: UP (IP)
backbone int GigabitEthernet0/4/2: UP (IP)
ICRM fast-failure detection neighbor table
IP Address Status Type Next-hop IP Interface
========== ====== ==== =========== =========
60.60.60.2 UP RW
```

Related Commands

Command	Description
show hspw-aps-icrm	Displays information about HSPW.

show redundancy interlink

To display interlink utilization, use the **showredundancyinterlink**command in user EXEC or privileged EXEC mode.

show redundancy interlink [{**rx** | **tx** [{**pps** | **bps**}]}] [**histogram**]

Syntax Description

rx	(Optional) Receive interlink utilization histograms.
tx	(Optional) Transmit interlink utilization histograms.
pps	(Optional) Packets per second (pps) histograms.
bps	(Optional) Bytes per second (bps) histograms.
histogram	(Optional) Usage information.

Command Default

Interlink utilization information is not displayed.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(11)T	This command was introduced on the Cisco AS5850.
12.2(31)SB	This command was introduced on the Cisco 10000 series Internet routers. Support for the Cisco AS5850 is not included in this release.

Usage Guidelines

Use the **showredundancyinterlink** command to display the current or historical status on interlink utilization.

Examples

The following histogram displays receive BPS interlink information for the past minute, the past hour, and the past three days:

```
Router# show redundancy interlink rx bps histogram

```

show rpc

To display remote procedure call (RPC) information, use the **showrpc** command in user EXEC or privileged EXEC mode.

show rpc {**applications** | **counters** | **status**}

Syntax Description

applications	Displays information about the RPC application.
counters	Displays the RPC counters.
status	Displays the RPC status.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display RPC applications:

```
Router#
show rpc applications
  ID Dest Callback Application
   1 0011 <remote> rpc-master
   2 0011 <remote> cygnus-oir
   3 0021 60201708 rpc-slave-33
   4 0021 6022A514 idprom-MP
   5 0021 60204420 msfc-oir
   6 0011 <remote> Nipcon-SP
   7 0011 <remote> sw_vlan_sp
   8 0011 <remote> stp_switch_api
   9 0011 <remote> pagp_rpc
  10 0011 <remote> span_switch_rpc
  11 0011 <remote> pf_rp_rpc
  13 0011 <remote> mapping_sp
  14 0011 <remote> logger-sp
  17 0011 <remote> c6k_power_sp
  18 0011 <remote> c6k_sp_environmental
  19 0011 <remote> pagp_switch_rpc
  20 0011 <remote> pm-cp
  21 0021 602675B0 Nipcon-RP
  22 0021 602283B0 pm-mp
  23 0021 601F2538 sw_vlan_rp
  24 0021 601F77D0 span_switch_sp_rpc
  25 0021 601F7950 idbman_fec
  26 0021 601F7F30 logger-rp
  27 0021 601F80D8 pagp_switch_l3_split
```

```
  28 0021 601F81C0 pagp_switch_sp2mp
  29 0021 6026F190 c6k_rp_environmental
Router#
```

This example shows how to display information about the RPC counters:

```
Router#
show rpc counters
  ID Dest Rcv-req  Xmt-req  Q size   Application
   1 0011 0        26       0        rpc-master
   2 0011 0        6221     0        cygnus-oir
   4 0021 15       0        0        idprom-MP
   5 0021 6222     0        0        msfc-oir
   7 0011 0        2024     0        sw_vlan_sp
   8 0011 0        3        0        stp_switch_api
   9 0011 0        188      0        pagp_rpc
  11 0011 0        4        0        pf_rp_rpc
  13 0011 0        2        0        mapping_sp
  14 0011 0        3        0        logger-sp
  17 0011 0        2        0        c6k_power_sp
  18 0011 0        66       0        c6k_sp_environmental
  19 0011 0        109      0        pagp_switch_rpc
  20 0011 0        33       0        pm-cp
  22 0021 126      0        0        pm-mp
  23 0021 5        0        0        sw_vlan_rp
  24 0021 14       0        0        span_switch_sp_rpc
  25 0021 22       0        0        idbman_fec
  26 0021 8        0        0        logger-rp
  27 0021 3        0        0        pagp_switch_l3_split
  28 0021 3        0        0        pagp_switch_sp2mp
Router#
```

show running configuration | include mode

Use this command to configure hardware module of the chassis.

show running configuration | include mode

There are no keywords for this command.

Command Default

None

Command Modes

User EXEC Privileged EXEC

Examples

The following example shows how to configure configure 5G mode from 10G mode:

```
enable
configure terminal
platform hw-module configuration
hw-module slot / bay PID mode 5G_CEM
end
```

Related Commands

Command	Description
platform hw-module configuration	Configures the hardware module of the chassis
hw-module mode	Configures the IM from 10G to 5G mode.

show scp

To display Switch-Module Configuration Protocol (SCP) information, use the **show scp** in privileged EXEC mode on the Switch Processor.

show scp {**accounting** | **counters** | **linecards** [**details**] | **mcast** {**group** *group-id* | **inst**} | **process** *id* | **status**}

Syntax Description

accounting	Displays information about the SCP accounting.
counters	Displays information about the SCP counter.
linecards	Displays information about the Optical Services Module (OSM) wide area network (WAN) modules in the chassis.
details	(Optional) Displays detailed information about the OSM WAN module.
mcast	Displays information about the SCP multicast.
group *group-id*	(Optional) Displays information for a specific group and group ID; valid values are from 1 to 127.
inst	(Optional) Displays information for an instance.
process *id*	Displays all the processes that have registered an SAP with SCP.
status	Displays information about the local SCP server status.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC on the Switch Processor

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	The output of the **show scp process** command was changed to display all the processes that have registered an SAP with SCP on the Supervisor Engine 720 only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.0(1)S	The output of the **show scp status** command was changed to additionally display the Flow Control State (FC-State) and the Flow Control Count (FC-Count)

Examples

This example displays the SCP flow control status:

```
Router# show scp status
Rx 185,  Tx 181,  scp_my_addr 0x14
```

```
Id Sap   Channel name      current/peak/retry/dropped/totaltime(queue/process/ack) FC-state
  FC-count
-------------------------------------------------------------  --------- ---- -------
 0  18   SCP Unsolicited:18    801/    0/     0/      0/     0      0/   0/   0 off        0
 1  80   SCP Unsolicited:80      0/    0/     0/      0/     0      0/   0/   0 off        0
 2  23   SCP async: LCP#5        0/    0/     0/      0/     0      0/   0/   0 off        0
 3  0    SCP Unsolicited:0       0/    1/     0/      0/     5      0/   0/   0 off        0

------------------------------------------------------------------------------------------------------------------------
```

FC-state indicates the flow control state and FC-count indicates the number of times flow control has been turned on.

This example shows how to display all the processes that have registered an SAP with SCP:

```
Router# show module
Mod Ports Card Type                              Model              Serial No.

show service-module serial through standby port

show service-module serial

To display the performance report for an integrated CSU/DSU, use the **showservice-moduleserial** command in privileged EXEC mode.

show service-module serial *number* [**performance-statistics** [*interval-range*]]

Syntax Description

number	Interface number 0 or 1.
performance-statistics	(Optional) Displays the CSU/DSU performance statistics for the past 24 hours. This keyword applies only to the fractional T1/T1 module.
interval-range	(Optional) Specifies the number of 15-minute intervals displayed. You can choose a range from 1 to 96, where each value represents the CSU/DSU activity performed in that 15-minute interval. For example, a range of 2-3 displays the performance statistics for the intervals two and three.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to the 2- and 4-wire 56/64-kbps CSU/DSU module and FT1/T1 CSU/DSU module. The **performance-statistics** keyword applies only to the FT1/T1 CSU/DSU module.

Examples

The following sample output shows CSU/DSU performance statistics on a Cisco 2524 or Cisco 2525 router for intervals 30 to 32. Each interval is 15 minutes long. All the data is zero because no errors were discovered on the T1 line:

```
Router#
show service-module serial 1 performance-statistics 30-32
Total Data (last 58 15 minute intervals):
    0 Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in current interval (131 seconds elapsed):
    0 Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in Interval 30:
    0 Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in Interval 31:
    0 Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
```

```
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in Interval 32:
    0 Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

The following is sample output from the **showservice-moduleserial**command for a fractional T1 line:

```
Router1# show service-module serial 0
Module type is T1/fractional
    Hardware revision is B, Software revision is 1.1 ,
    Image checksum is 0x2160B7C, Protocol revision is 1.1
Receiver has AIS alarm,
Unit is currently in test mode:
    line loopback is in progress
Framing is ESF, Line Code is B8ZS, Current clock source is line,
Fraction has 24 timeslots (64 Kbits/sec each), Net bandwidth is 1536 Kbits/sec.
Last user loopback performed:
    remote loopback
    Failed to loopup remote
Last module self-test (done at startup): Passed
Last clearing of alarm counters 0:05:50
    loss of signal        :    1, last occurred 0:01:50
    loss of frame         :    0,
    AIS alarm             :    1, current duration 0:00:49
    Remote alarm          :    0,
    Module access errors  :    0,
Total Data (last 0 15 minute intervals):
Line Code Violations, 0 Path Code Violations
    0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
Data in current interval (351 seconds elapsed):
    1466 Line Code Violations, 0 Path Code Violations
    25 Slip Secs, 49 Fr Loss Secs, 40 Line Err Secs, 1 Degraded Mins
    0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 49 Unavail Secs
```

The following sample output from the **showservice-moduleserial**command displays the status of a switched 56-KB line:

```
Router1# show service-module serial 1
Module type is 4-wire Switched 56
    Hardware revision is B, Software revision is 1.00,
    Image checksum is 0x44453634, Protocol revision is 1.0
Connection state: active,
Receiver has loss of signal, loss of sealing current,
Unit is currently in test mode:
    line loopback is in progress
Current line rate is 56 Kbits/sec
Last user loopback performed:
    dte loopback
    duration 00:00:58
Last module self-test (done at startup): Passed
Last clearing of alarm counters 0:13:54
    oos/oof               :    3, last occurred 0:00:24
    loss of signal        :    3, current duration 0:00:24
    loss of sealing curren:    2, current duration 0:04:39
    loss of frame         :    0,
    rate adaption attempts:    0,
```

The following shows sample output from the **showservice-moduleserial**command issued on a Cisco 3640 modular access router:

```
Router# show service-module serial 0/1
Module type is 4-wire Switched 56
    Hardware revision is B, Software revision is 1.00,
    Image checksum is 0x42364436, Protocol revision is 1.0
Connection state: Idle
Receiver has no alarms.
CSU/DSU Alarm mask is 0
Current line rate is 56 Kbits/sec
Last module self-test (done at startup): Passed
Last clearing of alarm counters 4d02h
    oos/oof              :    0,
    loss of signal       :    0,
    loss of sealing curren:    0,
    loss of frame        :    0,
    rate adaptation attemp:    0,
```

The following shows sample output from the **showservice-moduleserial**command issued on a Cisco 1605 router:

```
Router# show service-module serial 0
Module type is 4-wire Switched 56
    Hardware revision is B, Software revision is 1.00,
    Image checksum is 0x42364436, Protocol revision is 1.0
Receiver has oos/oof, loss of signal,
CSU/DSU Alarm mask is 4
Current line rate is 56 Kbits/sec
Last module self-test (done at startup): Passed
Last clearing of alarm counters 1d02h
    oos/oof              :    1, current duration 1d02h
    loss of signal       :    1, current duration 1d02h
    loss of frame        :    0,
    rate adaptation attemp:    0,
```

The table below describes the fields displayed by the **showservice-moduleserial**command.

Table 265: show service-module serial Field Descriptions

Field	Description
Module type	CSU/DSU module installed in the router. The possible modules are T1/fractional, 2-wire switched 56-kbps, and 4-wire 56/64-kbps.

Field	Description		
Receiver has AIS alarm	Alarms detected by the FT1/T1 CSU/DSU module or 2- and 4-wire 56/64-kbps CSU/DSU modules. Possible T1 alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms. Possible switched 56k alarms are as follows: • Receiver has loss of signal. • Receiver has loss of sealing current. • Receiver has loss of frame. • Receiver has rate adaptation attempts.	Unit is currently in test mode	Loopback tests are in progress.
		Framing	Indicates frame type used on the line. Can be extended super frame or super frame.
		Line Code	Indicated line-code type configured. Can be alternate mark inversion (AMI) or binary 8-zero substitution (B8ZS).
		Current clock source	Clock source configured on the line, which can be supplied by the service provider (line) or the integrated CSU/DSU module (internal).
		Fraction	Number of time slots defined for the FT1/T1 module, which can range from 1 to 24.
		Net bandwidth	Total bandwidth of the line (for example, 24 time slots multiplied by 64 kbps equals a bandwidth of 1536 kbps).
		Last user loopback performed	Type and outcome of the last performed loopback.
		Last module self-test (done at startup): Passed	Status of the last self-test performed on an integrated CSU/DSU module.
Last clearing of alarm counters	List of network alarms that were detected and cleared on the CSU/DSU module.		
Total Data Data in current interval	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.		

Field	Description
Line Code Violations	Indicates the occurrence of either a bipolar violation or excessive zeroes error event.
Path Code Violations	Indicates a frame synchronization bit error in the D4 and E1-no cyclic redundancy checksum (CRC) formats or a CRC error in the extended super frame (ESF) and E1-CRC formats.
Slip Secs	Indicates the replication or detection of the payload bits of a DS1 frame. A slip may be performed when there is a difference between the timing of a synchronous receiving terminal and the received signal.
Fr Loss Secs	Indicates the number of seconds an Out-of-Frame error is detected.
Line Err Secs	Line errored seconds is a second in which one or more line code violation errors are detected.
Errored Secs	In ESF and E1-CRC links, an errored second is a second in which one of the following is detected: one or more path code violations; one or more Out-of-Frame defects; one or more controlled slip events; a detected AIS defect. For D4 and E1-no-CRC links, the presence of bipolar violation also triggers an errored second.
Bursty Err Secs	Second with fewer than 320 and more than 1 path coding violation errors. No severely errored frame defects or incoming AIS defects are detected. Controlled slips are not included in this parameter.
Severely Err Secs	For ESF signals, a second with one of the following errors: 320 or more path code violation errors; one or more Out-of-Frame defects; a detected AIS defect. For D4 signals, a count of 1-second intervals with framing errors, or an Out-of-Frame defect, or 1544 line code violations.
Unavail Secs	Total time the line was out of service.

Related Commands

Command	Description
clear service-module serial	Resets an integrated CSU/DSU.

show sip-disk

To display file information on the internal storage disk of the SPA interface processor (SIP), use the **showsip-disk** command in privileged EXEC configuration mode.

show sip *slot-disk0* [{**all** | **chips** | **filesys**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
all	(Optional) Displays all information on the Flash Disk.
chips	(Optional) Displays information for files on the Flash Disk. This is the default.
filesys	(Optional) Displays file system parameters for the Flash Disk.

Command Default

If no optional keyword is specified, information for files on the Flash Disk is the default display (same as using the **chips** keyword).

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Thiscommand was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

The following example shows information about eight files stored internally on the SIP located in slot 5 of the router:

```
Router# show sip5-disk0
-#- --length-- -----date/time------ path
 number of file 8
 inode path is 1 idprom-oc12-atm-superspa
 fullpath is disk0:/idprom-oc12-atm-superspa
1         1152 Jun 09 2004 13:03:38 idprom-oc12-atm-superspa
 inode path is 2 idprom-4oc3-atm-superspa
 fullpath is disk0:/idprom-4oc3-atm-superspa
2         1152 Jun 09 2004 05:51:34 idprom-4oc3-atm-superspa
 inode path is 3 bonham_brd_rev2_rev19.hex
 fullpath is disk0:/bonham_brd_rev2_rev19.hex
3      2626407 Aug 24 2004 11:04:42 bonham_brd_rev2_rev19.hex
 inode path is 4 sip2-dw-mz.b2-testt
 fullpath is disk0:/sip2-dw-mz.b2-testt
4      5895640 Aug 26 2004 05:09:08 sip2-dw-mz.b2-testt
 inode path is 5 sip2-dw-mz.hp-depth
 fullpath is disk0:/sip2-dw-mz.hp-depth
5      5897476 Aug 12 2004 04:40:38 sip2-dw-mz.hp-depth
 inode path is 6 viking1.jbc
 fullpath is disk0:/viking1.jbc
```

```
6      2678150 Jun 09 2004 12:48:32 viking1.jbc
 inode path is 7 sip2-dw-mz.hpd
 fullpath is disk0:/sip2-dw-mz.hpd
7      5916716 Aug 25 2004 10:25:14 sip2-dw-mz.hpd
 inode path is 8 sip2iofpga_promlatest_rev78.hex
 fullpath is disk0:/sip2iofpga_promlatest_rev78.hex
8       468975 Aug 24 2004 10:56:54 sip2iofpga_promlatest_rev78.hex
40606720 bytes available (23490560 bytes used)
```

The following example shows information about the SIP flash file system for the SIP located in slot 5 of the router:

```
Router# show sip3-disk0 filesys
******** ATA Flash Card Geometry/Format Info ********
ATA CARD GEOMETRY
   Number of Heads:       4
   Number of Cylinders    978
   Sectors per Cylinder   32
   Sector Size            512
   Total Sectors          125184
ATA CARD FORMAT
   Number of FAT Sectors  62
   Sectors Per Cluster    8
   Number of Clusters     15598
   Number of Data Sectors 125049
   Base Root Sector       227
   Base FAT Sector        103
   Base Data Sector       259
ATA MONLIB INFO
   Image Monlib size = 52216
   Disk monlib size = 52736

Highest version supported in Client : 0
```

show slot0:

To display information about the PCMCIA flash memory card's file system located in slot 0, use the **show slot0:**command in user EXEC or privileged EXEC mode.

show slot0:[{**all** | **chips** | **detailed** | **err** | **summary**}]

Syntax Description

all	(Optional) Displays all possible flash system information for all PCMCIA flash cards in the system.
chips	(Optional) Displays flash chip information.
detailed	(Optional) Displays the flash detailed directory.
err	(Optional) Displays the flash chip erase and write retries.
summary	(Optional) Displays the flash partition summary.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.0	This command was introduced.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **show slot0:** command to display details about the files in a particular linear PCMCIA flash memory card of less than 20 MB and some 32 MB linear PCMCIA cards.

Note Use the **show disk** command for ATA PCMCIA cards. Other forms of this commands are **show disk0:** and **show disk1:**.

For more information regarding file systems and flash cards, access the *PCMCIA Filesystem Compatibility Matrix and Filesystem Information* document at the following URL:

http://www.cisco.com/en/US/partner/products/hw/routers/ps341/products_tech_note09186a00800a7515.shtml

To see which flash cards are used in your router, use the **show version** command and look at the bottom portion of the output.

The following display indicates an ATA PCMCIA flash disk.

```
Router# show version
.
.
46976K bytes of ATA PCMCIA card at slot 0 (Sector size 512 bytes).
```

The following display indicates a linear PCMCIA flash card with 20480K bytes of flash memory in card at slot 1 with a sector size of 128K.

```
Router# show version
.
.
20480K bytes of Flash PCMCIA card at slot 1 (Sector size 128K).
```

Note In some cases the **show slot** command will not display the file systems, use **show slot0:** or **show slot1:**.

Examples

The following example displays information about slot 0. The output is self-explanatory.

```
Router# show slot0:
PCMCIA Slot0 flash directory:
File  Length   Name/status
  1   11081464  c3660-bin-mz.123-9.3.PI5b
[11081528 bytes used, 9627844 available, 20709372 total]
20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
Router# show slot0: all
Partition   Size    Used      Free      Bank-Size  State          Copy Mode

PCMCIA Slot0 flash directory:
File  Length   Name/status
        addr      fcksum  ccksum
  1   11081464  c3660-bin-mz.123-9.3.PI5b
        0x40      0x5EA3  0x5EA3
[11081528 bytes used, 9627844 available, 20709372 total]
20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
   Chip    Bank    Code      Size      Name
    1      1       89A0      2048KB    INTEL 28F016SA
    2      1       89A0      2048KB    INTEL 28F016SA
    1      2       89A0      2048KB    INTEL 28F016SA
    2      2       89A0      2048KB    INTEL 28F016SA
    1      3       89A0      2048KB    INTEL 28F016SA
    2      3       89A0      2048KB    INTEL 28F016SA
    1      4       89A0      2048KB    INTEL 28F016SA
    2      4       89A0      2048KB    INTEL 28F016SA
    1      5       89A0      2048KB    INTEL 28F016SA
    2      5       89A0      2048KB    INTEL 28F016SA
The following example shows flash chip information.
Router# show slot0: chips

20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
   Chip    Bank    Code      Size      Name
    1      1       89A0      2048KB    INTEL 28F016SA
    2      1       89A0      2048KB    INTEL 28F016SA
    1      2       89A0      2048KB    INTEL 28F016SA
    2      2       89A0      2048KB    INTEL 28F016SA
    1      3       89A0      2048KB    INTEL 28F016SA
    2      3       89A0      2048KB    INTEL 28F016SA
    1      4       89A0      2048KB    INTEL 28F016SA
    2      4       89A0      2048KB    INTEL 28F016SA
    1      5       89A0      2048KB    INTEL 28F016SA
    2      5       89A0      2048KB    INTEL 28F016SA
```

The following example show the flash detailed directory.

```
Router# show slot0: detailed
PCMCIA Slot0 flash directory:
File  Length   Name/status
```

```
        addr      fcksum  ccksum
  1   11081464  c3660-bin-mz.123-9.3.PI5b
        0x40      0x5EA3  0x5EA3
[11081528 bytes used, 9627844 available, 20709372 total]
20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
```

The following example shows the flash chip erase and write retries.

```
Router# show slot0: err

PCMCIA Slot0 flash directory:
File  Length   Name/status
  1   11081464  c3660-bin-mz.123-9.3.PI5b
[11081528 bytes used, 9627844 available, 20709372 total]
20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
   Chip    Bank    Code      Size      Name               erase  write
     1      1       89A0      2048KB    INTEL 28F016SA      0      0
     2      1       89A0      2048KB    INTEL 28F016SA      0      0
     1      2       89A0      2048KB    INTEL 28F016SA      0      0
     2      2       89A0      2048KB    INTEL 28F016SA      0      0
     1      3       89A0      2048KB    INTEL 28F016SA      0      0
     2      3       89A0      2048KB    INTEL 28F016SA      0      0
     1      4       89A0      2048KB    INTEL 28F016SA      0      0
     2      4       89A0      2048KB    INTEL 28F016SA      0      0
     1      5       89A0      2048KB    INTEL 28F016SA      0      0

```

The following example shows the flash partition summary.

```
Router# show
 slot0: summary

Partition   Size    Used      Free      Bank-Size  State          Copy Mode
  1        20223K  10821K     9402K     4096K      Read/Write     Direct
20480K bytes of processor board PCMCIA Slot0 flash (Read/Write)
```

Related Commands

Command	Description
dir slot0:	Directory listing of files on a PCMCIA Flash card located in slot0.
dir slot1:	Directory listing of files on a PCMCIA Flash card located in slot1.
show slot1:	Displays information about the PCMCIA flash memory card's file system located in slot 1.
show slot	Displays information about the PCMCIA flash memory cards.

show smf

To display the configured software MAC address filter (SMF) on various interfaces of a router, use the **showsmf**command in user EXEC or privileged EXEC mode.

show **smf** [*interface-name*]

Syntax Description

interface-name	(Optional) Displays information about the specified interface. Choices can include **atm**, **ethernet**, **fastethernet**, **null**, **serial**, **tokenring**, and **async**.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced in a release prior to 10.0.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The SMF is active whenever the router is doing bridging or Integrated Routing and Bridging (IRB). MAC address filtering can be used as a security feature in bridging or switching environments.

Examples

The following is sample output from the **showsmf** command:

```
Router# show smf fastethernet
 Software MAC address filter on FastEthernet0/0.2
  Hash Len    Address      Matches  Act      Type
  0x00:  0 ffff.ffff.ffff         0 RCV Physical broadcast
  0x0C:  0 0100.0c00.0000         0 RCV ISL vLAN Multicast
  0x2A:  0 0900.2b01.0001         0 RCV DEC spanning tree
  0xA6:  0 0010.a6ae.6000         0 RCV Interface MAC address

  0xC2:  2 0100.0ccd.cdce         0 RCV VLAN Bridge STP
```

The table below describes the fields shown in the display.

Table 266: show smf Field Descriptions

Field	Description
Hash	Position in the hash table for this entry.
Len	Length of the entry.
Address	MAC address for the interface.
Matches	Number of hits for the address.

Field	Description
Act	Action taken. Values can be receive (RCV), forward (FWD), or discard (DIS).
Type	Type of MAC address.

show srp

To display Spatial Reuse Protocol (SRP) information, use the **showsrp** command in user EXEC or privileged EXEC mode.

Cisco IOS SR, SX, and XE Trains
show srp [{**counters** | **failures** | **ips** | **source-counters** | **srr** | **topology** | **transit**}]

Cisco IOS T Train
show srp [{**counters** | **ips** | **source-counters** | **topology**}]

Syntax Description

counters	(Optional) Displays counters for the packets received and transmitted on both sides of an SRP node.
ips	(Optional) Displays Intrusion Prevention System (IPS) information.
source-counters	(Optional) Displays source counter information.
topology	(Optional) Displays topology map information.
failures	(Optional) Displays self-detected failures.
srr	(Optional) Displays Simple RSS Reader (SRR) information.
transit	(Optional) Displays information about traffic buffer delays.

Command Default

If no keyword is specified, generic information about SRP is displayed.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.4(24)T	This command was introduced in a release earlier than Cisco IOS Release 12.4(24)T.
12.2(33)SRC	This command was modified and integrated into a release earlier than Cisco IOS Release 12.2(33)SRC. The **failures**, **srr**, and **transit** keywords were added.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1.

Examples

The following is sample output from the **showsrptopology**command:

```
Router# show srp topology
 Topology Map for Interface: SRP2_3
  Topology pkt. sent every 60 sec.  (next pkt. after 13 sec.)
  Last received topology pkt. 00:03:45
  Last topology change was 01:20:21 ago
```

```
  Hops (outer ring)      MAC       IP Address   Wrapped SRR   Name
        0       0005.dd9b.0d05        0.0.0.0   No    found SRP4
        1       0005.dd9b.0105        0.0.0.0   No    found SRP5
RP/0/1/0:SRP4#   0005.dd9b.2505        0.0.0.0   No    found SRP1
```

The table below describes the significant fields shown in the display.

Table 267: show srp topology Field Descriptions

Field	Description
Hops (outer ring)	Total number of hops.
MAC	Displays the MAC address.
IP Address	Displays the IP address.
Wrapped	Indicates if the SRP ring is wrapped at a node or not: Yes or No. If yes, the packet is sent in the reverse direction.
SRR	Status of the SRR, found or not found.
Name	Displays the hostname of the router for the node.

The following is sample output from the **showsrpips**command:

```
Router# show srp ips
 IPS Information for Interface SRP2_3
 MAC Addresses
   Side A (Outer ring RX) neighbor 0005.dd9b.2505
   Side B (Inner ring RX) neighbor 0005.dd9b.0105
   Node MAC address 0005.dd9b.0d05
 IPS State
   Side A not wrapped
   Side B not wrapped
   Side A (Inner ring TX) IPS pkt. sent every 1 sec. (next pkt. after 1 sec.)
   Side B (Outer ring TX) IPS pkt. sent every 1 sec. (next pkt. after 1 sec.)
   IPS WTR period is 60 sec. (timer is inactive)
   Node IPS State: idle
 IPS Self Detected Requests           IPS Remote Requests
   Side A            IDLE               Side A IDLE
   Side B            IDLE               Side B IDLE
 IPS messages received
   Side A (Outer ring RX) { 0005.dd9b.2505,IDLE,SHORT}, TTL 255
   Side B (Inner ring RX) { 0005.dd9b.0105,IDLE,SHORT}, TTL 255
 IPS messages transmitted
   Side A (Inner ring TX) { 0005.dd9b.0d05,IDLE,SHORT}, TTL 255
   Side B (Outer ring TX) { 0005.dd9b.0d05,IDLE,SHORT}, TTL 255
```

The table below describes the significant fields shown in the display.

Table 268: show srp ips Field Descriptions

Field	Description
MAC Addresses	MAC address of the IPS interface.
IPS State	Information about the current IPS states.

Field	Description
IPS Self Detected Requests	Details about the IPS self-detected requests.
IPS Remote Requests	Details about the IPS remote requests.
IPS messages received	Details about the IPS messages received.
IPS messages transmitted	Details about the transmitted IPS messages.

Related Commands

Command	Description
clear counters srp	Clears SRP counters.
show interfaces srp	Displays the configuration on an SRP interface.
show srp counters	Displays counters for the packets received, transmitted, and transited on both sides of an SRP node.
show srp failures	Displays the IPS status.
show srp source-counters	Displays the total number of packets received by a node identified by its unique MAC address.
srp topology-timer	Specifies the frequency of the topology timer.

show storm-control

To display switchport characteristics, including storm-control levels set on the interface, use the **showstorm-control**command in user EXEC or privileged EXEC mode.

show storm-control [*interface-type interface-number*] [{**broadcast** | **multicast** | **unicast** | **history**}]

Syntax Description

interface-type interface-number	(Optional) Port for which information is to be displayed.
broadcast	(Optional) Displays broadcast storm information. This is the default.
multicast	(Optional) Displays multicast storm information.
unicast	(Optional) Displays unicast storm information.
history	(Optional) Displays storm history on a per-port basis.

Command Default

If the *interface-type* and *interface-number*values are omitted, the **showstorm-control** command displays storm-control settings for all ports on the switch.

You can display broadcast, multicast, or unicast packet-storm information by using the corresponding keyword. When no keyword option is specified, the default is to display broadcast storm-control information.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(2)XT	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support switchport creation on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(15)ZJ	This command was modified. The *interface-type* and *interface-number* arguments and the **broadcast**, **multicast**, **unicast**, and **history** keywords were added to support the Ethernet switch network module on the Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.

Examples

The following is partial sample output from the **showstorm-controlbroadcast**command:

```
Router# show storm-control broadcast
Interface  Filter State   Upper    Lower    Current
---------  -------------  -------  -------  -------
Fa0/1      <inactive>     100.00%  100.00%    0.00%
Fa0/2      <inactive>     100.00%  100.00%    0.00%
Fa0/3      <inactive>     100.00%  100.00%    0.00%
Fa0/4      Forwarding      30.00%   20.00%   20.32%
.
.
.
```

The table below describes the fields shown in the display.

Table 269: show storm-control broadcast Field Descriptions

Field	Description
Interface	Displays the ID of the interface.
Filter State	Displays the status of the filter: • Blocking--Storm control is enabled, a storm has occurred, and the action is filter. • Forwarding--Storm control is enabled, and a storm has not occurred. • Inactive--Storm control is disabled. • Shutdown--Storm control is enabled, a storm has occurred, and the action is to shut down. **Note** If an interface is disabled by a broadcast, multicast, or unicast storm, the filter state for all traffic types is *shutdown* .
Upper	Displays the rising suppression level as a percentage of total available bandwidth.
Lower	Displays the falling suppression level as a percentage of total available bandwidth.
Current	Displays the bandwidth utilization of a specific traffic type as a percentage of total available bandwidth. This field is valid only when storm control is enabled.

The following is sample output from the **showstorm-controlfastethernet0/4history** command, which displays the ten most recent storm events for an interface:

```
Router# show storm-control fastethernet 0/4 history
 Interface Fa0/4 Storm Event History
 Event Type          Event Start Time  Duration (seconds)
 ------------------  ----------------  ------------------
 Unicast             04:58:18          206
 Broadcast           05:01:54          n/a
 Multicast           05:01:54          n/a
 Unicast             05:01:54          108
 Broadcast           05:05:00          n/a
 Multicast           05:05:00          n/a
 Unicast             05:06:00          n/a
 Broadcast           05:09:39          n/a
 Multicast           05:09:39          n/a
 Broadcast           05:11:32          172
```

The table below describes the fields shown in the display.

Table 270: show storm-control history Field Descriptions

Field	Description
Interface	Displays the ID of the interface.

Field	Description
Event Type	Displays the type of storm event. The event type is one of the following: • Broadcast • Multicast • Unicast
Event Start Time	Time when the event started, in hours, minutes, seconds.
Duration (seconds)	Duration time of the event, in seconds. **Note** The duration field could be *n/a* when a storm is still present or when a new storm of a different type occurs before the current storm ends.

Related Commands

Command	Description
show interface counters	Displays the count of discarded packets.
storm control	Enables broadcast, multicast, or unicast storm control on a port.

show sup-bootflash

To display information about the sup-bootflash file system, use the **show sup-bootflash** command in privileged EXEC mode.

show **sup-bootflash** [{**all** | **chips** | **filesys**}]

Syntax Description

all	(Optional) Displays all possible Flash information.
chips	(Optional) Displays information about the Flash chip.
filesys	(Optional) Displays information about the file system.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.217d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display a summary of bootflash information:

```
Router#
show sup-bootflash
-#- ED --type-- --crc--- -seek-- nlen -length- -----date/time------ name
1   .. image    EBC8FC4D  A7487C    6 10700796 Nov 19 1999 07:07:37 halley

show syscon sdp

To display information about the Shelf Discovery Protocol (SDP), use the **showsysconsdp**command in privileged EXEC or user EXEC mode.

show syscon sdp

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC User EXEC

Command History

Release	Modification
11.3AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the**showsysconsdp** command:

```
Router# show syscon sdp
Current time 10:46:32 PST Jan 28 1998, system controller 172.23.66.100
Last hello packet received at 10:45:38 PST Jan 28 1998
11773 Total SDP packets
    0 packets with bad MD5 hash
    5884 Hello packets received
    5889 Hello packets sent
    0 Command packets received
    0 Command packets sent
```

The table below describes the fields shown in the sample display.

Table 271: show syscon sdp Field Descriptions

Field	Description
Current time	Current time and date.
system controller	IP address of the system controller.
Last hello packet received	Time and date when the last hello packet from the system controller was received by the shelf.
Total SDP packets	Total number of SDP packets sent or received by the shelf.
packets with bad MD5 hash	Number of packets with a bad MD5 hash.
Hello packets received	Number of hello packets received by the shelf from the system controller.
Hello packets sent	Number of hello packets sent from the shelf to the system controller.

Field	Description
Command packets received	Number of packets containing commands received by the shelf.
Command packets sent	Number of commands sent by the shelf.

Related Commands

Command	Description
syscon address	Specifies the system controller for a managed shelf.
syscon source-interface	Specifies the interface to use for the source address in SDP packets.

show system jumbomtu

To display the g lobal maximum transmission unit (MTU) setting, use the **show system jumbomtu** command in privileged EXEC mode.

show system jumbomtu

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to display the global MTU setting:

```
Router# show system jumbomtu
Global Ethernet MTU is 1550 bytes.
Router#
```

Related Commands

Command	Description
system jumbomtu	Sets the maximum size of the Layer 2 and Layer 3 packets.

show tcam counts

To display the Ternary Content Addressable Memory (TCAM) statistics, use the **showtcamcounts** command in privileged EXEC mode.

show tcam counts [**detail**] [{**arp** | **ip** | **ipv6** | **mpls** | **other**}] [**module** *number*]

Syntax Description

detail	Displays detailed TCAM statistics.
arp	Displays TCAM statistics for ARP traffic.
ip	Displays TCAM statistics for IP traffic
ipv6	Displays TCAM statistics for IPv6 traffic
mpls	Displays TCAM statistics for MPLS traffic
other	Displays TCAM statistics for other traffic
module *number*	(Optional) Specifies the module number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **module***number* keyword and argument designate the module and port number. Valid values for *number* depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 2 to 13 and valid values for the port number are from 1 to 48.

The display includes information about the per-bank TCAM utilization for the ACL/QoS TCAM for Cisco 7600 series routers that are configured with a Supervisor Engine 720 only.

Examples

This example shows how to display the TCAM statistics:

```
Router# show tcam counts
              Used        Free        Percent Used       Reserved
              ----        ----        ------------       --------
 Labels:         8         504             1
ACL_TCAM
--------
  Masks:         6        4090             0                    0
```

```
Entries:     37      32731           0                     0
QOS_TCAM
--------
  Masks:      3       4093           0                     0
Entries:     20      32748           0                     0
    LOU:      0        128           0
  ANDOR:      0         16           0
  ORAND:      0         16           0
    ADJ:      1       2047           0
Router#
```

The table below describes the fields that are shown in the example.

Table 272: show tcam counts Command Output Fields

Field	Description
Labels Used	Number of labels that are used (maximum of 512).
Labels Free	Number of free labels remaining.
Labels Percent Used	Percentage of labels that are used.
Masks Used	Number of masks that are used (maximum of 4096).
Masks Free	Number of free labels remaining.
Masks Percent Used	Percentage of masks that are used.
Entries Used	Number of labels that are used (maximum of 32767).
Entries Free	Number of free labels that are remaining.
Entries Percent Used	Percentage of entries that are used.

Related Commands

Command	Description
show tcam interfaces	Displays information about the interface-based Ternary Content Addressable Memory (TCAM).

show tcam interface

To display information about the interface-based Ternary Content Addressable Memory (TCAM), use the **showtcaminterface** command in privileged EXEC mode.

show tcam interface {*interface interface-number* | **null** *interface-number* | **vlan** *vlan-id* {**acl** {**in** | **out**} | **qos** {**type1** | **type2**} *type* [{**detail** | **module** *number*}]}}

Syntax Description

interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **pos**, **atm**, and **ge-wan**.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
null *interface-number*	(Optional) Specifies the null interface; the valid value is **0**.
vlan *vlan-id*	(Optional) Specifies the VLAN; see the "Usage Guidelines" section for valid values.
acl in	(Optional) Displays the ACL-based incoming packets.
acl out	(Optional) Displays the ACL-based outgoing packets.
qos type1	(Optional) Displays the QoS-based Type 1 packets.
qos type2	(Optional) Displays the QoS-based Type 2 packets.
type	Specifies the protocol type to display; valid values are **arp**, **ipv4**, **ipv6**, **mpls**, and **other**.
detail	(Optional) Displays detailed information.
module *number*	(Optional) Specifies the module number.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17a)SX	This command was changed to support the **ipv6** keyword.
12.2(17b)SXA	This command was changed as follows: • Support for the **detail** keyword was added to display detailed information. • The output (without the **detail** keyword) was changed to include the match count for supervisor engines and DFCs that support ACL counters.

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **pos**, **atm**, and **ge-wan**keywords are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2 only.

Use the clear mls acl counters command to clear the TCAM ACL match counters.

The match counts display is supported in PFC3BXL or PFC3B mode only.

Examples

This example shows how to display interface-based TCAM information:

```
Router# show tcam interface
 vlan 7 acl in ip
deny ip any any
permit ip 10.20.0.0 0.0.255.255 10.22.0.0 0.0.255.255

Related Commands

Command	Description
clear mls acl counters	Clears the MLS ACL counters.
show tcam counts	Displays the Ternary Content Addressable Memory (TCAM) statistics.

show tcam-mgr subslot

To display ternary content addressable memory (TCAM) manager information for a SPA, use the **showtcam-mgrsubslot**command in privileged EXEC configuration mode.

show tcam-mgr subslot *slot/subslot* **inst-info**
show tcam-mgr subslot *slot/subslot* **region** *region-number* [{**config** | **statistics**}]
show tcam-mgr subslot *slot/subslot* {**rx-dest-mac** | **rx-vlan**} {**alloc-mbus** [**summary**] | **table**}
show tcam-mgr subslot *slot/subslot* **statistics**

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
inst-info	Specifies the display of Instance Control Block information for the SPA.

region *region-number* **config** | **statistics**	Specifies the display of region-related TCAM manager information, with the following options:
	
	• **region** *region-number*-- Displays TCAM manager information, where:
	  • **region0**-- Specifies the destination MAC address TCAM region.
	  • **region1**-- Specifies the VLAN ID TCAM region.
	
	• **config** -- (Optional) Displays TCAM manager configuration information.
	
	• **statistics** -- (Optional) Displays TCAM manager statistical information.

rx-dest-mac | **rx-vlan** }{**alloc-mbussummary**] |**table**	Specifies the display of TCAM manager information related to the following areas: • **rx-dest-mac** --Destination MAC address filtering for received frames. • **rx-vlan** --VLAN filtering for received frames. • **alloc-mbus** **summary**]--Displays allocated Mask Block Unit (MBU) entry information related to the MAC or VLAN TCAM filters. There is no difference between the **alloc-mbus** and **alloc-mbussummary** form of the command. • **table** -- Displays table entries for the MAC or VLAN TCAM filters. **Note** The **label**and**free-mbussummary**] forms of the command are not supported on SPAs.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(19)S	This command was introduced.
12.2(20)S2	Thiscommand was integrated into Cisco IOS Release 12.2(20)S2 and support for the **subslot**, **rx-dest-mac**, and **rx-vlan** keywords were added for SPAs on the Cisco 7304 router.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **showtcam-mgrsubslot** command to display TCAM manager information for the destination MAC address and VLAN filter regions supported by the SPAs.

The TCAM manager allocates memory among the applications that it supports, in the form of regions. The SPAs support two TCAM regions, region 0 for destination MAC address filtering and region 1 for VLAN ID filtering of received frames.

Examples

The following examples provide sample output for several versions of the **showtcam-mgrsubslot** command for a 4-Port 10/100 Fast Ethernet SPA located in the top subslot (0) of the MSC that is installed in slot 4 on a Cisco 7304 router:

show tcam-mgr subslot inst-info Example

The following shows sample output from the **showtcam-mgrsubslotinst-info**command:

```
Router# show tcam-mgr subslot 4/0 inst-info
Instance Control Block Information :
CAM name                    =  SPA 4xFE/2xGE CAM2
Maximum key length          =  72 bits
TBU (TCAM Base Unit) length =  72 bits
V2M Ratio                   =  8
TCAM Size                   =  8192 TBUs
SRAM Size                   =  0 words
Start index of first VC     =  0
Label table size            =  0
```

show tcam-mgr subslot region Example

The following shows sample output from the **showtcam-mgrsubslotregion**command for the destination MAC address TCAM region (0) for the SPA:

```
Router# show tcam-mgr subslot 4/0 region 0
Region Configuration :
 Region ID                  =  0
 Region name                =  DA_FILTERING
 Fixed size                 =  no
```

```
 Region type (hash:mask    ) =  Partial_Order_Indep_Order_Dep_At_Bottom
 Application VMR V/M size    =  12
 Application VMR result size =  1
 Vc region size (percentage) =  50
Region Information :
 Region ID                  =   0
 Value cells size           =   4096
 Mask cells size            =   512
 MBUs size                  =   512
 Mask index start TBU       =   0
 Mask index end TBU         =   511
 First dynamic region       =   yes
 Last dynamic region        =   yes
 Size is fixed              =   yes
 Expansion unit MBUs        =   1
 Lower Limit, llimit_p      =   450A6CF0
 Upper Limit, ulimit_p      =   450AE4B4
 Lower limit pointer index  =   0
 Upper limit pointer index  =   511
 Lower next pointer index   =   0
 Upper next pointer index   =   4
 Lower free entries         =   1
 Upper free entries         =   507
 Bottom pointer index       =   510
 Free mask block units      =  508
 Region ID                   =  0
 Region expansion count      =  0
 Region Shifts             =  0
 Region expansion failures   =  0
 Invalid direction hits      =  0
 Invalid parameter hits      =  0
 No free entry failures      =  0
```

show tcam-mgr subslot region statistics Example

The following shows sample output from the **showtcam-mgrsubslotregionstatistics**command for the destination MAC address TCAM region (0) for the SPA:

```
Router# show tcam-mgr subslot 4/0 region 0 statistics
 Region ID                   =  0
 Region expansion count      =  0
 Region Shifts             =  0
 Region expansion failures   =  0
 Invalid direction hits      =  0
 Invalid parameter hits      =  0
 No free entry failures      =  0
```

show tcam-mgr subslot rx-dest-mac table Example

The following shows partial output from the **showtcam-mgrsubslotrx-dest-mactable**command:

```
Router# show tcam-mgr subslot 4/0 rx-dest-mac table
Dest mac filtering Table
-----------
 There are 15 entries in the table
 Entry# 1:
 Application ID              = 1

Related Commands

Command	Description
show controllers fastethernet	Displays Fast Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables.

show tdm backplane

To display modem and PRI channel assignments with streams and channels on the modem side as assigned to the unit and channels on the PRI side of the time-division multiplexing (TDM) assignment, use the **showtdmbackplane**command in privileged EXEC mode.

show tdm backplane stream [*stream-number*]

Syntax Description

stream	Backplane stream in the range 0 to 7. There are 8 backplane "streams" on the TDM backplane for the Cisco AS5300 access server. Each stream runs at 2 MHz and has 32 channels (running at 64 Hz) on the Cisco AS5300 access server backplane hardware.
stream-number	(Optional) Actual number entered (either 0 to 7 or 0 to 15).

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **showtdmbackplane**command shows the status of the TDM backplane, related data structure values, and TDM chip memory settings. This commands is generally used only by a Cisco technical support representative during troubleshooting of data continuity problems.

Examples

The following example shows sample output for the **showtdmbackplane**command. When the **debugtdmdetail** command is executed, more detail is shown. The following examples are run with the **debugtdmdetail** command executed:

```
Router# show tdm backplane
Show BackPlane Connections
TDM Backplane Connection for Stream 0
     Modem (St/Ch)<->PRI (Unit/Ch)   xx/xx:Not Used ??/??:Unknown State
0  :  xx/xx<->xx/xx,  xx/xx<->xx/xx,  00/02<->00/30,  00/03<->03/10

Related Commands

Command	Description
debug tdm detail	Displays debugging messages about TDM commands.
show tdm connections	Displays details about a specific TDM channel programmed on the Mitel chip.
show tdm data	Displays information about TDM bus connection memory on Cisco access servers.
show tdm detail	Displays information about the specified TDM device.
show tdm information	Displays TDM resources available for the specified TDM device.
show tdm pool	Displays information about the specified TDM pool.

show tdm connections

To display a snapshot of the time-division multiplexing (TDM) bus connection memory in a Cisco access server or to display information about the connection memory programmed on the Mitel TDM chip in a Cisco AS5800 access server, use the **showtdmconnections** command in privileged EXEC mode.

Standard Syntax

show tdm connections [{**motherboard** | **slot** *slot-nu mber*}]

Cisco AS5800 Access Server

show tdm connections {**motherboard stream** *stream-number* | **slot** *slot-number* **device** *device-number* **stream** *stream-number*}

Syntax Description

motherboard	(Optional) Displays connection memory for the TDM bus connections on the motherboard in the Cisco access server only. **Cisco AS5800 Access Server** The motherboard in the Cisco AS5800 access server has ethernet and serial interfaces, console port, and aux port. The motherboard has one TDM device (MT8980) for the Cisco 5300 access server.
slot *slot-number*	(Optional) Slot number. **Cisco AS5800 Access Server** There are three slots on the Cisco AS5800 access server. The range of the slots is from 0 to 2. A modem card or a trunk PRI card can be inserted into each slot. Each card in the slot has one or two TDM devices (either MT8980 or MT90820) on them.
stream	Device stream in the range 0 to 7. There are 8 backplane “streams” on the TDM backplane for the Cisco AS5800 access server. Each stream runs at 2 Mhz and has 32 channels (running at 64 Hz) on the Cisco AS5800 access server backplane hardware.
stream-number	Stream number (the range is from 0 to 7 or 0 to 15).
device	TDM device on the motherboard or slot cards. The range for the Cisco AS5800 access server is from 0 to 1. Each card has at least one TDM device (MT8980 or MT80920), and some of the slot cards have two devices (for example, the Octal PRI has two MT90820 TDM devices). The TDM device is also referred to as “TSI Chip Number” in the online help.
device-number	Valid range is from 0 to 1.

Usage Guidelines

Cisco AS5800 Access Server

The **showtdmconnections**command shows the status of the TDM chip memory settings. This command is generally used only by a Cisco technical support representative during troubleshooting of data continuity problems.

Examples

Cisco AS5800 Access Server

The following example shows sample output for the **showtdmconnections**command. When the **debugtdmdetail** command is executed, more detail is shown. The following examples are run with the **debugtdmdetail** executed.

```
Router# show tdm connections slot 0
Slot 0 MT8980 TDM Device 0, Control Register = 0x1E, ODE Register = 0x01
Connection Memory for ST0:

Related Commands

Command	Description
debug tdm detail	Displays debugging messages about TDM commands.
show tdm data	Displays information about TDM bus connection memory on Cisco access servers.

show tdm data

To display a snapshot of the time-division multiplexing (TDM) bus data memory in a Cisco access server or to display data memory that is programmed on the Mitel TDM chip in a Cisco 5800 access server, use the **showtdmdata**command in privilegedEXEC mode.

Standard Syntax
show tdm data [{**motherboard** | **slot** *slot-number*}]

Cisco AS5800 Access Server
show tdm data {**motherboard stream** *stream-number* | **slot** *slot-number* **device** *device-number* **stream** *stream-number*}

Syntax Description

motherboard	(Optional) Displays bus data memory for the TDM bus connections on the motherboard in the Cisco access server only. **Cisco AS5800 Access Server** The motherboard on the Cisco AS5300 access server has the ethernet I/Fs, serial I/Fs, console port, and aux port. The motherboard has one TDM device (MT8980) for the Cisco AS5300 access server.
slot *slot-number*	(Optional) Slot number. **Cisco AS5800 Access Server** In addition to the motherboard, there are three slots on the Cisco AS5300 access server. The range of the slots is 0 to 2. A modem card or a trunk PRI card can be inserted in each slot. Each card in the slot has one or two TDM devices (either MT8980 or MT90820) on them.
stream	TDM device stream in the range 0 to 15. There are up to 16 streams on a TDM device (Mitel 90820). The TDM device is also known as the TSI chip. The help on the command (by typing **?**) indicates whether the stream is “Stream number within the TSI chip” or “Backplane Stream.”
stream-number	Stream number within the range of either 0 to 7 or 0 to 15.
device	TDM device on the motherboard, or slot cards. Valid range for the Cisco AS5300 access server is 0 to 1. Each card has at least one TDM device (MT8980 or MT80920), and the Octal PRI has two MT90820 TDM devices. Also referred to as TSI Chip Number in the help pages.
device-number	Valid range is from 0 to 1.

12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The data memory for all TDM bus connections in the access server is displayed if you do not specify a motherboard or slot.

Cisco AS5800 Access Server

The **showtdmdata**command shows the status of the TDM data structure values. This command is generally used only by a Cisco technical support representative during troubleshooting of data continuity problems.

Examples

The following is sample output for the **showtdmdata**command on a Cisco AS5800 access server. When the **debugtdmdetail** command is executed, more detail is shown. The following example is run with the **debugtdmdetail** executed:

```
Router# show tdm data
Motherboard MT8980 TDM Device 0, Control Register = 0x1F, ODE Register = 0xE1
Data Memory for ST0:
Ch0:  0xFF, Ch1:  0xFF, Ch2:  0x98, Ch3:  0x61
Ch4:  0x0C, Ch5:  0xE1, Ch6:  0x8D, Ch7:  0x86
Ch8:  0xFF, Ch9:  0xF3, Ch10: 0xE4, Ch11: 0xFF
Ch12: 0x51, Ch13: 0x02, Ch14: 0x18, Ch15: 0x14

Related Commands

Command	Description
debug tdm detail	Displays debugging messages about TDM commands.
show tdm connections	Displays details about a specific TDM channel programmed on the Mitel chip.

show tdm detail

To display details about a specific time-division mulltiplexing (TDM) channel programmed on the Mitel chip, use the **showtdmdetail**command in privileged EXEC mode.

show tdm detail *slot-number*/*device-number* *source-stream-number*/*source-channel-number*

Syntax Description

slot-number	There are three slots on the Cisco AS5300 access server. A modem card or a trunk Primary Rate Interface (PRI) card can be inserted in each slot. Each card has one or two TDM devices (either MT8980 or MT90820) on it. The valid range is from 0 to 2.
device-number	TDM device on the motherboard or slot cards. Each card has at least one TDM device (MT8980 or MT80920), and the Octal PRI has two MT90820 TDM devices. Also referred to a TSI Chip Number in the online help. The valid values are 0 to 1.
source-stream-number	Source stream number from the TDM device. The valid range is from 0 to 15.
source-channel-number	Source channel from the TDM device stream. The valid range is from 0 to 31.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.

12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

The **showtdmdetail**command shows the status of the TDM backplane, related data structure values, and TDM chip memory settings. This command is generally used only by a Cisco technical support representative during troubleshooting of data continuity problems.

This command indicates connection memory and map, data memory, and whether the channel is enabled or disabled. Specify the slot, TDM device, TDM stream, and TDM channel to view the appropriate details.

Examples

The following is sample output from the **showtdmdetail**command. When the **debugtdmdetail**command is executed, more detail is shown. The following example was run with the **debugtdmdetail** command executed. The fields are self-explanatory.

```
Router# show tdm detail 0/0 1/2
Show Detail TDM device info: slot 0 unit 0
ODE Register: 0x0001
```

```
Connection Memory: 0x00ED, Output is Disable
Connection Map: STi7 CHi13 ----> STo1 CHo2
Data Memory: 0x00FF
```

       ptype: ipv4 [ipv4 dispatcher: punt]
       ptype: ipv6 [ipv6 dispatcher: punt]
       ptype: mpls [mpls dispatcher: drop]
There are 0 tunnels running over the EON IP protocol
There are 0 tunnels running over the IPinIP protocol
There are 0 tunnels running over the NOSIP protocol
There are 0 tunnels running over the IPv6inIP protocol
```

The table below describes the significant fields shown in the displays.

Table 273: show tunnel interface Field Descriptions

Field	Description
Mode	Tunnel encapsulation method. For example, GRE, IP in IP, IPv6 in IP.
Destination	Destination address of the tunnel packets. This field is relevant for point-to-point tunnels only.
Source	Source of packets in a tunnel.
IP transport	Destination of IP packets.
Application ID	Application that created the tunnel. For example,L3VPN, PIM, and generic applications that use a tunnel created using the CLI.
Tunnel Subblocks	Subset of tunnel information that is accessible through a Forwarding Information Base (FIB) Hardware Interface Descriptor Block (HWIDB) subblock.
src-track	Indicates the interface on which source tracking needs to be enabled in case an attack is suspected on a tunnel. Also indicates the number of tunnels associated with this interface.
Linestate	Indicates the state of the interface.
Tunnel Source Flags	Flag that indicates the set of sources for a tunnel. The value of this flag can be as follows: • Local—Indicates that the tunnel was created locally by an application. Tunnels on an active Route Processor (RP) have only a local source set. • Remote—Indicates that the tunnel was created on receipt of an External Data Representation (XDR) message. Tunnels on a standby RP always have a remote source set. The tunnels may also have a local source set if the application created a tunnel on the standby.

Field	Description
Corresponding hwidb	Corresponding HWIDB. This is the system-wide representation of an interface. There is one HWIDB per interface.
OCE	Output chain elements (OCEs) applied to tunnel packets after an adjacency. This is an object that is used to decapsulate traffic received on a tunnel and dispatch the payload. There is only one decapsulation OCE associated with a tunnel.
Provider	IP protocol type number of the tunneling protocol used. For example, GRE packets that are encapsulated within IP use IP protocol type 47.
ptype	Each tunnel endpoint can receive packets of different payload types. Each payload type has an adjacency associated with it. The payload type can include the Layer 2 next-hop address to which the tunnel packet has to be forwarded or special adjacency type information such as Drop (drop the packets) or Punt (forward the packets to a higher switching layer such as fast switching).
Switching statistics	Number of packets that have been received by the tunnel, forwarded through the tunnel, or dropped by the tunnel.
Subblocks	Subset of tunnel information that is accessible via a FIB HWIDB subblock.
Enable sequencing	Indicates whether sequencing of packets is enabled.
Carry ipso	Indicates whether IP Security Option (IPSO) or Commercial IP Security Option (CIPSO) labels are acquired from parent.
Fast capable	Indicates whether fast tunneling is possible.
Tableid	Indicates the table ID associated with the transport Virtual routing and forwarding (VRF).
Appid	Tunnel application identity.

Related Commands

Command	Description
show cef interface	Displays detailed Cisco Express Forwarding information for a specified interface or for all interfaces.

show tunnel keys-database tunnel

To display all transmit and receive generic routing encapsulation (GRE) key pairs associated with traffic flows in a tunnel, use the **show tunnel keys-database tunnel** command in privileged EXEC mode.

show tunnel keys-database tunnel *tunnel-number*

Syntax Description

tunnel-number	Tunnel number. The range is from 0 to 2147483647.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.8S	This command was introduced.

Usage Guidelines

A key can be optionally added to a GRE tunnel and used to identify a traffic flow within the tunnel, as defined in RFC 2890, *Key and Sequence Number Extensions to GRE*.

GRE keys can be used in various ways in a network, and one such use case is in the Proxy Mobile IPv6 (PMIPv6) application. To facilitate seamless movement of mobile users from one access network to another, PMIPv6 as described in RFC 5213, *Proxy Mobile IPv6*, defines network-based mobility protocols that allow mobile users to communicate without disruption while roaming. The solution requires IP tunneling of packets of mobile nodes from a Mobile Access Gateway (MAG) to a Local Mobility Anchor (LMA). A mobile node is an IP host or a device whose mobility is managed by the network. The LMA is the home agent for a mobile node in a PMIPv6 domain. The MAG is an access router function that manages mobility-related signaling for a mobile node, tracks the mobile node's movements, and signals the LMA. RFC 5845, *GRE Key Option for Proxy Mobile IPv6* further explains the scenario in which multiple GRE keys can be used to differentiate packets of a specific mobile session in a tunnel between an LMA and a MAG.

Tunnel endpoints are added by applications. For example, Next Hop Resolution Protocol (NHRP) adds the endpoint for Dynamic Multipoint Virtual Private Network (DMVPN) application. An endpoint is associated with a transport address and in many cases with an overlay address. The transport address corresponds to the egress point of a tunnel, which is where the tunnel terminates, and an overlay address can be any address reachable on or beyond the tunnel's egress point in the network.

Applications can add an endpoint with an overlay address and a corresponding transport address. In case applications do not need an overlay address or just need to forward packets to an endpoint based on a policy, they can add an endpoint with just a transport address.

In the context of PMIPv6, the overlay address corresponds to the mobile node address, and the transport address corresponds to either the Proxy Care-of Address (global address configured on the egress interface of the MAG) or the LMA address depending on where the endpoint is being added. When an endpoint is added on an LMA, the transport address is the Proxy Care-of Address of the MAG. When an endpoint is added on the MAG, the transport address is the LMA address.

The tunnel maintains a GRE key database, that is accessed by the forwarding plane using a receive GRE key that is unique for a tunnel. The receive GRE key database is populated on the request of an application when the application is associated with a tunnel. The receive key database also has other data such as the list of operations to be done before forwarding the payload. One of these operations is the setting of virtual routing and forwarding (VRF)-ID.

VRF-ID is an optional parameter that is used by applications to set the egress of the tunnel before forwarding packets. This can be used in case there are overlapping mobile node IP addresses belonging to different VRFs. At the egress of a tunnel, the forwarding plane can look up the GRE key database based on the received GRE Key and get the corresponding VRF-ID. If the VRF-ID is not set, the forwarding plane sets the VRF-ID based on the VRF of the tunnel interface.

Examples

The following is sample output from **show tunnel keys-database tunnel 0**, which shows all transmit and receive GRE key pairs associated with various traffic flows in a tunnel:

```
Device# show tunnel keys-database tunnel 0

Remote address 10.1.1.2, RefCount 2
Transmit Key 16, Receive Key 15, Association 1.1.1.2
Connection-ID 16, VRF-Override enabled, VRF-ID 65535
Transmit Key 161, Receive Key 151, Association 1.1.1.3
Connection-ID 161, VRF-Override enabled, VRF-ID 65535
```

The table below describes the significant fields shown in the display.

Table 274: show tunnel keys-database tunnel Field Descriptions

Field	Description
Remote address	Overlay address or a remote IPv4 or IPv6 address, reachable beyond the tunnel endpoint in the network.
RefCount	Reference count used for debugging.
Transmit Key	Transmit key associated with a flow.
Receive Key	Receive key associated with a flow.
Association	Associated flow identifier. For example, IP address in the payload.
Connection-ID	Locally stored connection identifier used for key insertion in a packet.
VRF-Override enabled	Flag that indicates which VRF to forward the received packets. If the flag is enabled, the received packets are forwarded to the VRF with a given VRF-ID. If the flag is disabled, the received packets are forwarded to the tunnel interface VRF.
VRF-ID	VRF identifier associated with a key.

show top counters interface report

To display TopN reports and information, use the **showtopcountersinterfacereport** command in user EXEC or privileged EXEC mode.

show top counters interface report [*number*]

Syntax Description

number	(Optional) Number of the report to be displayed; valid values are from 1 to 5.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Ethernet, Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet ports only. LAN ports on the OSMs are also supported.

When you enter a TopN request, a round of polling is performed, the counters for all the applicable ports in the Cisco 7600 series router are read, and the information is saved. The TopN process then sleeps for the specified interval. After wakeup, another round of polling is performed and the counter information from the ports is read. The difference between the two sets of data is stored. The ports are then sorted, the ports choose from one of the seven types of statistics information, and a TopN report is generated.

The port statistics will not be displayed in the following cases:

- If a port is not present during the first poll.
- If a port is not present during the second poll.
- If a port's speed or duplex changes during the polling interval.
- If a port's type changes from Layer 2 to Layer 3 or Layer 3 to Layer 2 during the polling interval.

Note For the report display format, due to the 80 characters per line limitation, only 10 spaces are reserved for the Tx/Rx-okts, Tx/Rx-bcst, and Tx/Rx-mcst columns. When these columns are larger than 10 digits, the display wraps around to the next line.

When you start the TopN processes from a Telnet session and the Telnet session is terminated before the TopN processes are completed, all the backgound TopN processes continue and generate the TopN reports, but the foreground TopN processes are terminated once the Telnet session is terminated.

When the TopN report is being generated against a large number of ports (for example, 13 slot x 96 ports/slot) in a very short interval (10 seconds), the actual interval time between the first and second polling may be longer than the specified interval time because polling takes time.

Examples

This example shows how to display TopN reports and information:

```
Router# show top counters interface report
Id Start Time                   Int N   Sort-By   Status  Owner
-- ---------------------------- --- --- --------- ------- ----------------------
1  08:18:25 UTC Tue Nov 23 2004 76  20  util      done    console
2  08:19:54 UTC Tue Nov 23 2004 76  20  util      done    console
3  08:21:34 UTC Tue Nov 23 2004 76  20  util      done    console
4  08:26:50 UTC Tue Nov 23 2004 90  20  util      done    bambam onvty0 (9.10.69.13)
Router#
```

This example shows how to display TopN reports and information for a specific report:

```
Router# show top counters interface report
 1
Started By        : console
Start Time        : 08:18:25 UTC Tue Nov 23 2004

Gi4/14  1000  0    0           0           0          0          0    0
Gi4/13  1000  0    0           0           0          0          0    0
Gi4/12  1000  0    0           0           0          0          0    0
Gi4/11  1000  0    0           0           0          0          0    0
Gi4/10  1000  0    0           0           0          0          0    0
Gi4/9   1000  0    0           0           0          0          0    0
Gi4/8   1000  0    776         2           0          2          0    0
Gi4/7   1000  0    0           0           0          0          0    0
Gi4/6   1000  0    0           0           0          0          0    0
Gi4/5   1000  0    0           0           0          0          0    0
Gi4/4   1000  0    0           0           0          0          0    0
Gi4/3   1000  0    776         2           0          2          0    0
Gi4/2   1000  0    0           0           0          0          0    0
Router#
```

This example shows the display if you request a TopN report that is still in pending status:

```
Router# show top counters interface report
 4
Id   Start time          Int N   Sort-by     Status   Owner (type/machine/user)
---  ------------------- --- --- ---------- -------- -------------------------
  4  1/24/2004,11:34:26  30  20  In-Errors  pending  Console//
Router#
```

Related Commands

Command	Description
clear top counters interface report	Clears the TopN reports.
collect top counters interface	Lists the TopN processes and specific TopN reports.

show ucse imc download progress

To display the status of the CIMC firmware download, use the **show ucse imc download progress** command in EXEC mode.

show ucse *slot* **imc download progress**

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

When the CIMC firmware is downloading, this command displays the percentage complete. After the download is complete, this command displays the last known download status.

Examples

The following examples show how to display the status of the CIMC firmware download:

```
Router# show ucse 2 imc download progress

Download is in progress (1% - 9894k/679M - 1kB/s)
Router# show ucse 2 imc download progress

No Download is not currently in process
Last download status: Downloaded successfully : ubuntu-server.iso
```

show ucse imc files

To display the CIMC installable images that are available on the local file system, use the **show ucse imc files** command in EXEC mode.

show ucse *slot* **imc files**

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command to determine which images can be used to boot the server, or which files can be deleted to free up space.

Examples

The following example shows how to display the CIMC firmware files:

```
Router# show ucse 2 imc files

Directory of UCSE slot 2 imc filesystem
 -rw-  1697952   May 5 2010 16:55:04 +00.00 debian.iso
```

show ucse server boot

To display the device types from which the Cisco E-Series Server can boot, the order in which the boot is attempted, or the progress of boot initialization, use the **show ucse server boot** command from EXEC mode.

show ucse *slot* **server boot** [{**devices** | **order** | **progress**}]

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
devices	The device types available to the module from which the Cisco E-Series Server can boot. It can be one of the following: • HDD—Hard disk drive • FDD—Floppy disk drive • CDROM—Bootable CD-ROM • PXE—PXE boot • EFI—Extensible Firmware Interface
order	The current order in which the boot configuration will be attempted.
progress	The status of the image boot and image download.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use the output of this command to see the boot options.

Examples

The following example displays the list of all devices that can be used to boot the module:

```
Router# show ucse 1 server boot devices

PXE
FDD
HDD:HDD3
HDD:RAID-MD0
HDD:USB-FF5D6CC3DAA67F12-1
CDROM:USB-CD
```

The following example shows how to display the boot order:

```
Router# show ucse 1 server boot order

Currently booted from CDROM:USB-CD
Boot order:
```

```
1) PXE
2) CDROM:USB-CD
3) FDD
4) HDD:RAID-MD0
```

show ucse server erase device status

To display the status of devices that have been erased, use the **show ucs server erase device status** command in EXEC mode.

show ucse *slot* **server erase device status**

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command after you have erased HDDs using the **ucse** *slot* **server erase device hh [all | use***device_list***]**command.

Examples

The following example shows how to display the details after erasing HDDs:

```
Router# ucse 2 server erase device hdd use hdd2

You are about to erase all data on the selected hard drives.
Proceed with drive erasure? y

Erasing HDD2 started
Router#
Router# show ucse 2 server erase device status

HDD2 erased 0%
```

show ucse server raid level

To display the current RAID configuration, use the **show ucse server raid level** command in EXEC mode.

show ucse *slot* **server raid level**

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command after you have configured the RAID levels by using the **ucse** *slot* **server raid level** {**0** | **1** | **5** | **NONE**} [**use** *HDD_list*] command.

Examples

The following example shows how to display RAID details:

```
Router# ucse 2 server raid level 1

You are about to change RAID configuration.
It will destroy all data on the hard drives.

Are you sure [y/n] y
RAID reconfigured
Router# show ucse 2 server raid level

RAID 0 (Ctrl:SLOT-5 ID:0 Size:1905440 MB State:Optimal)
        HDD1 :              953869 MB online (0 errors)
      HDD255 :              953869 MB online (0 errors)
HDDs not in the RAID:
        HDD2 :              286102 MB system (0 errors)
```

show upgrade file

The show upgrade file command is replaced by the **show upgrade fpd file** command. See the **show upgrade fpd file** command for more information.

show upgrade fpd file

To display the contents of an FPD image package file, enter the **showupgradefpdfile** command in privileged EXEC mode.

show upgrade fpd file *file-url* [**detail**]

Syntax Description

file-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include **disk0**, **slot0**, **tftp**, or **ftp**) and followed by the path to the FPD image package file.
detail	(Optional) Displays detailed information about the contents of the FPD image package file. This option is intended for use by Cisco customer support personnel only.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(20)S6	This command was introduced and replaced the **showupgradefile** command on the Cisco 7304 router.
12.2(25)S3	The output of the **showupgradefpdfile***file-url* command was changed to display only brief versioning information. The output generated from this command in previous Cisco IOS releases can still be generated in this release by entering the **showupgradefpd***file-url***detail** command. The **detail** option is also new in this release.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD	This command was integrated into Cisco IOS Release 12.4(4)XD.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

This command provides information related to the FPD image package file. Most of the information in this command output is useful for Cisco customer support purposes only.

In Cisco IOS Releases 12.2(20)S2 through 12.2(20)S5, the output generated by entering this command can be generated by entering the **showupgradefile** command.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

Cisco 7200 VXR

The following example shows that the router is able to generate FPD image package information for the FPD image package on the TFTP server:

```
Router# show upgrade fpd file tftp://mytftpserver/myname/myfpdpkg/c7200-fpd-pkg.124-4.XD.pkg
Loading /auto/tftpboot-users/jsmith/c7200-fpd-pkg.124-4.XD.pkg from 223.255.254.254 (via
GigabitEthernet0/1):

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatibility is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.

Command	Description
upgrade hw-module slot	Manually upgrades the current FPD image package on a SIP or any FPD-capable cards.
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.

show upgrade fpd package default

To display which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards for the running Cisco IOS release, enter the **showupgradefpdpackagedefault** command in privileged EXEC mode.

show upgrade fpd package default

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(20)S6	This command was introduced and replaced the **showupgradepackagedefault**command on the Cisco 7304 router.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD	This command was integrated into Cisco IOS Release 12.4(4)XD.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

It is important to note that the output from this command is generated from the Cisco IOS image and provides information regarding the default FPD image package file that is needed for your particular Cisco IOS release. This command output also lists the SPAs or other cards supported by the default FPD image package file for the running Cisco IOS image.

In Cisco IOS Releases 12.2(20)S2 through 12.2(20)S5, the output generated by entering this command can be generated by entering the **showupgradepackagedefault**command.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

Cisco 7200 VXR

The following example shows which cards are supported with your current Cisco IOS release and which FPD image package you need:

```
Router# show upgrade fpd package default
```

```
***********************************************************************
This IOS release requires the following default FPD Image Package for
the automatic upgrade of FPD images:
***********************************************************************
Version: 12.4(4)XD
Package Filename: c7200-fpd-pkg.124-4.XD.pkg
        List of card type supported in this package:
                                        Minimal
                 No. Card Type          HW Ver.
                ---- ------------------ -------
                  1) VSA                  0.0
                  2) NPE-G2               0.0
                ---- ------------------ -------
***********************************************************************
```

Cisco 7304

In the following example, the **showupgradefpdpackagedefault** command output shows that the spa_fpd.122-20-S6.pkg FPD image package file is required if you install the SPA-4FE-7304 or the SPA-2GE-7304 on this particular router with this particular Cisco IOS software release:

```
Router# show upgrade fpd package default
***********************************************************************
This IOS release supports the following default FPD Image Package(s) for
automatic upgrade:
***********************************************************************
SPA FPD Image Package:spa_fpd.122-20.S6.pkg
        List of SPAs supported in this package:
                                        Minimal
                 No. SPA Name           HW Ver.
                ---- ------------------ -------
                  1) SPA-4FE-7304         0.0
                  2) SPA-2GE-7304         0.0
                ---- ------------------ -------
```

Cisco uBR10012 Universal Broadband Router

In the following example, the **showupgradefpdpackagedefault** command output shows that the ubr10k-fpd-pkg.122-122_33_SCB_20081123.pkg FPD image package file is required for the SPAs on this particular router with this particular Cisco IOS software release:

```
Router# show upgrade fpd package default
****************************************************************************
This Cisco IOS software image requires the following default FPD Image
Package for the automatic upgrade of FPD images (the package is available
from Cisco.com and is accessible from the Cisco Software Center page where
this IOS software image can be downloaded):
****************************************************************************

Version: 12.2(20080919:205903)

Package Filename: ubr10k-fpd-pkg.122-122_33_SCB_20081123.pkg

        List of card type supported in this package:

                                                              Minimal
                 No. Card Type                                HW Ver.

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatibility is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module slot	Manually upgrades the current FPD image package on a SIP or any FPD-capable cards.
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.

show upgrade fpd progress

To view the progress of an FPD upgrade while an FPD upgrade is taking place, enter the **showupgradefpdprogress** command in privileged EXEC mode.

show upgrade fpd progress

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(20)S6	This command was introduced and replaced the **showupgradeprogress** command on the Cisco 7304 router.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD	This command was integrated into Cisco IOS Release 12.4(4)XD.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

In Cisco IOS Releases 12.2(20)S2 through 12.2(20)S5, the output generated by entering this command can be generated by entering the **showupgradeprogress**command.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), refer to the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

Cisco 7200 VXR

The following example shows that the FPD image is being updated, the approximate amount of time needed to perform the update, and the amount of time the FPD update has taken so far:

```
Router# show upgrade fpd progress
FPD Image Upgrade Progress Table:
 ==== =================== ====================================================
                                                     Approx.
                          Field Programmable   Time      Elapsed
 Slot Card Type           Device : "ID-Name"   Needed      Time    State
 ==== =================== ================== ========== ========== ===========
```

```
  npe NPE-G2 IOFPGA       1-NPEG2 I/O FPGA    00:01:00   00:00:23  Updating...
 ==== =================== ====================================================
```

Cisco 7304

The following example shows the status of FPD updates on the SPAs located in subslots 0 and 1:

```
Router# show upgrade fpd progress
FPD Image Upgrade Progress Table:
 ==== =================== ====================================================
                          Field Programmable    Time
 Slot Card Description    Device :"ID-Name"    Needed   Time Left  State
 ==== =================== ================== ========== ========== ===========
  2/0 SPA-2GE-7304        1-4FE/2GE FPGA      00:06:00   00:05:17  Updating...
 ---- ------------------- ------------------ ----------- --------- -----------
  2/1 SPA-4FE-7304        1-4FE/2GE FPGA      --:--:--   --:--:--  Waiting...
 ==== =================== ====================================================
```

Cisco uBR10012 Universal Broadband Router

The following example shows the status of FPD updates on a Cisco uBR10012 router:

```
Router# show upgrade fpd progress
FPD Image Upgrade Progress Table:
==== =================== ====================================================
                                               Approx.
                          Field Programmable    Time     Elapsed
 Slot Card Type           Device : "ID-Name"   Needed      Time    State
 ==== =================== ================== ========== ========== ===========
  3/2 SPA-24XDS-SFP       1-Modena BLAZE FPG  00:10:00   00:05:07  Updating...
 ==== =================== ====================================================
```

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatibility is detected.

Command	Description
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module slot	Manually upgrades the current FPD image package on a SIP or any FPD-capable cards.
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.

show upgrade fpd table

To view various information used by the Cisco IOS software to manage the FPD image package file, use the **showupgradefpdtable** command in privileged EXEC mode.

show upgrade fpd table

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S6	This command was introduced and replaced the **showupgradetable**command on the Cisco 7304 router.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

This command provides version information used by the Cisco IOS image to manage the FPD image package file and to locate the correct FPD image within the FPD image package file to perform an FPD upgrade. Most of the information provided by this command is useful for customer support purposes.

In Cisco IOS Releases 12.2(20)S2 through 12.2(20)S5, the output generated by entering this command can be generated by entering the **showupgradetable**command.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), refer to the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

The following example displays various FPD information for Cisco IOS Release 12.2(20)S5:

```
Router# show upgrade fpd table

Field Programmable Devices (FPD) Bundle Information Table:

```

Related Commands

Command	Description
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatability is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
show hw-module slot fpd	Displays the current versions of FPD image files for all of the active SIPs on a router.
show hw-module subslot fpd	Displays the FPD version on each SPA in the router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.

show upgrade fpga progress

To display the progress of an FPGA upgrade on a Cisco 7304 router, use the **showupgradefpgaprogress**command in privileged EXEC mode.

show upgrade fpga progress

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S6	This command was introduced.

Usage Guidelines

This command will only provide useful output during an FPGA upgrade.

This command provides information regarding FPGA upgrades, including the approximate amount of time a particular FPGA upgrade would take and the amount of time the in-progress FPGA upgrade has taken.

Because the console where you began the FPGA upgrade becomes unusable during the FPGA upgrade, this command can only be entered from a connection that was not used to initiate the FPGA upgrade.

Examples

The following example displays information about an in-progress FPGA update. Note that the example shows the FPGA mismatch and provides the user with the approximate time needed to complete the upgrade and the amount of time the current upgrade has taken.

```
Router# show upgrade fpga progress
FPGA image update progress information:
  Slot 0, FPGA name = NPEG100
  Hardware version = 01.00
  Current FPGA version = 02.04
  New FPGA version = 02.05
  Time needed to update = 00:12:00 (approximate)
  Actual time taken so far = 00:01:47
```

Related Commands

Command	Description
show c7300	Displays the types of hardware installed in a Cisco 7304 router, including the current FPGA version and the bundled FPGA version.
show diag	Displays hardware information for any slot or the chassis.
upgrade fpga	Specifies router response when an FPGA mismatch is detected.
upgrade fpga all	Manually upgrades all of the FPGAs for all of the installed hardware on the Cisco 7304 router.

show upgrade hw-programmable file

To display the names and versions of individual files in the hw-programmable package file in a Cisco ASR 1000 Series Router, use the **showupgradehw-programmablefile**command in Privileged EXEC configuration mode.

show upgrade hw-programmable file filename

Syntax Description

filename	Specifies the hw-programmable upgrade package file and its file system location. For filename, specify one of the following system locations and a package file name: • bootflash: RP-relative HW programmable package name • flash: RP-relative HW programmable package name • harddisk: RP-relative HW programmable package name This is the hw-programmable upgrade package file that contains a new version of the CPLD and FPGA code, used for performing the CPLD on a Cisco ASR 1013 Router or FPGA upgade on a Cisco ASR 1000 Series Router. The package file name is typically named asr1000-hw-programmables.<release_name>.pkg

Command Default

The names and versions of individual files in the hw-programmable package file is not displayed.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced in Cisco IOS XE Release 3.1S.

Usage Guidelines

For procedures on performing a CPLD upgrade, see the Upgrading Field Programmable Hardware Devices for Cisco ASR 1000 Series Routers document.

Examples

The following example displays the names of the card types and version numbers in the package file:

```
Router# show upgrade hw-programmable file harddisk:asr1000-hw-programmables.xe31.100616.pkg

  List of card type, hw-programmable device and version in this package:
  No.  Card Type           hw-programmable device  Version
--------------------------------------------------------------
   0   ASR1000-SIP10       CPLD                    09111601
   1   ASR1000-RP2         CPLD                    10021901
```

Related Commands

Command	Description
upgrade hw-programmable	Performs a Complex Programmable Logic Device (CPLD) or Field-Programmable Gate Array (FPGA) upgrade on a Cisco ASR 1000 Series Router.
show hw-programmable	Displays the current CPLD and FPGA versions on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable progress	Displays the upgrade progress of the line card-field upgradeable device (LC-FPD) on a Cisco ASR 1000 Series Router.

show upgrade hw-programmable progress

To display the upgrade progress of the line card-field upgradeable device (LC-FPD) on a Cisco ASR 1000 Series Router, use the **showupgradehw-programmableprogress**command in Privileged EXEC configuration mode.

show upgrade hw-programmable progress

Syntax Description

This command has no arguments or keywords.

Command Default

The upgrade progress of the line card-field upgradeable device is not displayed.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced in Cisco IOS XE Release 3.1S.

Usage Guidelines

The line card may be an RP, ESP, or SIP card.

This command only displays the hardware programmable upgrades that are in progress.

For procedures on performing a CPLD upgrade, see the Upgrading Field Programmable Hardware Devices for Cisco ASR 1000 Series Routers document.

Examples

The following example displays the upgrade progress of the CPLD upgrade in the RP slot 1:

```
Router# show upgrade hw-programmable progress

Upgrade hw-programmable progress

Slot              Hw-programmable device    Upgrade status
------------------------------------------------------------
R1                CPLD                      in progress
```

Related Commands

Command	Description
upgrade hw-programmable	Performs a Complex Programmable Logic Device (CPLD) or Field-Programmable Gate Array (FPGA) upgrade on a Cisco ASR 1000 Series Router.
show hw-programmable	Displays the current CPLD and FPGA version on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable	Displays the names and versions of individual files in the hw_programmable package file.

show upgrade package default

The show upgrade package default command is replaced by the **show upgrade fpd package default** command. See the **show upgrade fpd package default** command for more information.

show upgrade progress

The show upgrade progress command is replaced by the **show upgrade fpd progress** command. See the **show upgrade fpd progress** command for more information.

show upgrade table

The show upgrade table command is replaced by the **show upgrade fpd table** command. See the **show upgrade fpd table** command for more information.

show vmi neighbors

To display information about neighbor connections to the Virtual Multipoint Interface (VMI), use the **showvmineighbors** command in User EXEC mode.

show vmi neighbors [**detail**] [*vmi-interface*]

Syntax Description

detail	(Optional) Displays details about the VMI neighbors.
vmi-interface	(Optional) Number of the VMI interface

Command Default

If no arguments are specified, information about all neighbors for all VMI interfaces is displayed.

Command Modes

User EXEC

Command History

Release	Modification
12.4(15)XF	This command was introduced.
12.3(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

If no arguments are specified, information about all neighbors for all VMI interfaces is displayed.

The **showvmineighbors**command provides a list of devices that have been dynamically discovered by the connected radio devices in a router-to-radio network, and for which connectivity has been achieved through PPPoE and the radio network.

Examples

The following is sample output from the **showvmineighbors** command used to display dynamically created neighbors on a VMI interface.

```
Router# show vmi neighbors vmi1
1 vmi1 Neighbors
           IPV6       IPV4                          Transmit    Receive
Interface  Address    Address        Uptime       Packets     Packets
vmi1       ::         10.3.3.2       00:02:11     0000000008  0000000073
```

The table below describes the significant fields shown in the **showvmineighbors** command display.

Table 275: show vmi neighbors Field Descriptions

Field	Description
Interface	The interface number.
IPv6 Address	IPv6 address of the neighbor.
IPv4 Address	IPv4 address of the neighbor.
Uptime	How long the interface has been up. Time shown in hh:mm:ss format.
Transmit Packets	Number of packets transmitted from the interface during the monitored up time.

Field	Description
Received Packets	Number of packets received on the interface during the monitored up time.

show vmi neighbors command with detail keyword: Example

The following example shows the details about the known VMI neighbors.

```
Router# show vmi neighbors detail

1 vmi1 Neighbors
vmi1   IPV6 Address=::
       IPV4 Address=10.3.3.2, Uptime=00:02:16
       Output pkts=8, Input pkts=75
       No Session Metrics have been received for this neighbor.
       Transport PPPoE, Session ID=79
       INTERFACE STATS:
          VMI Interface=vmi1,
             Input qcount=0, drops=0, Output qcount=0, drops=0

```

The table below describes the significant fields shown in the **showvmineighborsdetail**command display.

Table 276: show vmi neighbors detail Field Descriptions

Field	Description
Interface	The interface number.
IPv6 Address	IPv6 address of the neighbor.
IPv4 Address	IPv4 address of the neighbor.
Uptime	How long the interface has been up. Time shown in hh:mm:ss format.
Output pkts	Number of outgoing packets during the recorded up time.
Input pkts	Number of incoming packets during the recorded up time.
Transmitted packets	Number of packets transmitted from the interface.
Received Packets	Number of packets received on the interface.

Field	Description
Transport	The routing protocol, in this case-PPPoE.
Session ID	The identifier of the VMI session.
INTERFACE STATS	A series of statistics collected on the interface and shows for each of the VMI interface, virtual access interface, and the physical interface. For each interface, statistics are displayed indicating the number of packets in the input and output queues and the number of packets dropped from each queue.
PPPoE Flow Control Stats	The statistics collected for PPPoE credit flow. **Local Credits** : The amount of credits belonging to this node.**PeerCredits**: The amount of credits belonging to the peer.**CreditGrantThreshold**: The number of credits below which the peer needs to dip before this node sends an inband or out-of-band grant.**MaxCreditspergrant**: 65534**PADGSeqNum**: 133 **PADGTimerindex**: 0**PADGlastrcvdSeqNum**: 133**PADGlastnonzeroSeqNum**: 0**PADGlastnonzerorcvdamount**: 0**PADGTimers**: [0]-1000 [1]-2000 [2]-3000 [3]-4000**PADGxmit**:*numberic***rcvd**: *numeric* **PADCxmit**:**133rcvd:133** **PADQxmit**:**0rcvd**: 0

Command	Description
debug vmi	Displays debugging output for virtual multipoint interfaces (VMIs)
interface vmi	Creates a virtual multipoint interface (VMI) that can be configured and applied dynamically.

show wedged-interfaces

To display input and output queue wedged interfaces, use the **showwedged-interfaces** command in user EXEC or privileged EXEC mode.

show wedged-interfaces {**input** | **output**}

Syntax Description

input	Displays input the queue wedged interface list.
output	Displays output the queue wedged interface list.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M on the Cisco AS 5400 series routers.

Usage Guidelines

Interface queue wedged monitoring is disabled by default. You can use the **interface-monitorenable** command to enable the queue wedged monitoring. Once the monitoring is switched on, a background process is created, which monitors all the existing input and output queue wedged interfaces.

Examples

The following is sample output from the **showwedged-interfaces** command:

```
Router# show wedged-interfaces output
Interface Name             Time Since Wedge
Async4/00                  00:23:33
Async4/01                  00:23:26
Async4/02                  00:23:21
Async4/03                  00:23:15
FastEthernet0/0            00:24:35
FastEthernet0/1            00:24:50
Virtual-Access2            00:38:19
Virtual-Access3            00:38:19
```

The table below describes the fields shown in the display.

Table 277: show wedged-interfaces output Field Descriptions

Field	Description
Interface Name	Lists the name of the interface.
Time Since Wedge	Time since a problem was detected in the interface.

Related Commands

Command	Description
interface-monitor enable	Enables interface queue wedge monitoring.

shutdown (controller)

To disable the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 or Cisco 10000 series routers, use the **shutdown**command in controller configuration mode. To restart a disabled CT3IP, use the **no** form of this command.

shutdown
no shutdown

Syntax Description

This command has no arguments or keywords.

Command Default

Using this command assumes that the controller is already enabled. By default, if this command is not issued, the controller remains enabled.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Cisco 7500 Series Routers

Shutting down the CT3IP disables all functions on the interface and sends a blue alarm to the network. The **shutdown** command marks the interface as unavailable. To check if the CT3IP is disabled, use the **showcontrollerst3** command.

Cisco 10000 Series Router

Alarms are cleared automatically 10 seconds after a no shutdown command is issued on a T3 port. Shutting down a controller causes a T3 port to transmit:

- A blue alarm for m13 framing
- An idle signal for c-bit framing

There is no delay for alarms to clear after issuing a no shutdown command on an E3 port.

Examples

Cisco 7500 Series Router

The following example shuts down the CT3IP:

```
Router(config
)
# controller t3 9/0/0
```

```
Router(config
-controller)
# shutdown
```

Cisco 10000 Series Router

The following example shuts down the controller on port 0:

```
Router(config
)
# dsx3 1/0/0
Router(config
-controller)
# shutdown
```

Related Commands

Command	Description
show controllers j1	Displays information about the J1 link.
show controllers t1	Displays the total number of calls and call durations on a T1 controller.
show controllers t3	Displays the hardware and software driver information for a T3 controller.

shutdown (dwdm)

To disable DWDM controller processing, use the **shutdown** command in controller configuration mode. To bring a DWDM controller back up and enable DWDM controller processing, use the**no** form of this command.

shutdown
no shutdown

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled by default.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Usage Guidelines

The DWDM controller is enabled by default. You must use the shutdown command to disable the controller.

Examples

The following example disables the DWDM controller :

```
Router(config)# controller dwdm 1/1
Router(config-controller)# shutdown
```

Related Commands

Command	Description
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.

shutdown (hub)

To shut down a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router, use the **shutdown**command in hub configuration mode. To restart the disabled hub, use the **no** form of this command.

shutdown
no shutdown

Syntax Description

This command has no arguments or keywords.

Command Default

Using this command assumes that the hub is already enabled. By default, if this command is not issued, the hub remains enabled.

Command Modes

Hub configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shuts down hub 0, ports 1 through 3:

```
Router(config)#
 hub ethernet 0 1 3
Router(config-hub)#
 shutdown
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

shutdown (interface)

To disable an interface, use the **shutdown** command in interface configuration mode. To restart a disabled interface, use the **no**form of this command.

shutdown
no shutdown

Syntax Description

This command has no arguments or keywords.

Command Default

Using this command assumes that the interface is already enabled. By default, if this command is not issued, the interface remains enabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **shutdown** command disables all functions on the specified interface. On serial interfaces, this command causes the data terminal ready (DTR) signal to be dropped. On Token Ring interfaces, this command causes the interface to be removed from the ring. On FDDI interfaces, this command causes the optical bypass switch, if present, to go into bypass mode.

This command also marks the interface as unavailable. To check whether an interface is disabled, use the **showinterfaces** user EXEC command; an interface that has been shut down is shown as administratively down in the display from this command.

Examples

The following example turns off Ethernet interface 0:

```
Router(config
)
# interface ethernet 0
Router(config-if
)
# shutdown
08:32:03:%LINK-5-CHANGED:Interface Ethernet 0, changed state to administratively down
```

The following example turns the interface back on:

```
Router(config
)
# interface ethernet 0
Router(config
-if)
```

```
# no shutdown
08:32:16:%LINK-3-UPDOWN:Interface Ethernet 0, changed state to up
08:32:17:%LINEPROTO-5-UPDOWN:Line protocol on Interface Ethernet 0, changed state to up
```

Related Commands

Command	Description
interface	Configures an interface type and enters interface configuration mode.
show interfaces	Displays the statistical information specific to a serial interface.

signaling

To enable channel-associated signaling (CAS), use the **signaling**command in CEM configuration mode. To disable signaling, use the **no** form of this command.

signaling [*on-hook-pattern*] [*off-hook-pattern*] [*msec*]
no signaling [*on-hook-pattern*] [*off-hook-pattern*] [*msec*]

Syntax Description

on-hook-pattern	(Optional) Specifies the ABCD signaling bits sent to the attached device (typically a PBX) to simulate the remote PBX sending notification that any call in progress has been terminated or is on-hook. The T1 default is 5 hex. The E1 default is D hex.
off-hook-pattern	(Optional) Specifies the ABCD signaling bits sent to the attached device (typically a PBX) to simulate the remote PBX sending notification that a channel is already in use, or is off-hook. The T1 default is F hex. The E1 default is 5 hex.
msec	(Optional) Specifies the time, in milliseconds, between the onhook and offhook patterns. Values are in the range from 50 to 5000. Default is 2000. Any value entered is rounded up to the next multiple of 50 milliseconds.

Command Default

CAS is disabled.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.3(7)T1	The *on-hook-pattern*, *off-hook-pattern*, and *msec* arguments were added.

Usage Guidelines

When a T1/E1 channel with signaling enabled is placed in the failed state, the on-hook pattern is sent to the attached device for a duration specified by the *msec* attribute. After the time specified by the *msec*attribute, the off-hook pattern is sent to the attached device for as long as the CEM connection remains failed.

The on-hook pattern parameter specifies, as a single hexadecimal character, the ABCD signaling bits sent to the attached device (typically a PBX) to simulate the remote PBX sending notification that any call in progress has been terminated or is on-hook. This provides a forced disconnect of any calls when the CEM connection fails.

The off-hook pattern parameter specifies, as a single hexadecimal character, the ABCD signaling bits sent to the attached device (typically a PBX) to simulate the remote PBX sending notification that a channel is already in use, or is off-hook. This prevents the attached PBX from trying to use the failed channel to place a new call while the CEM connection remains failed.

Examples

The following example shows how to enable signaling.

```
Router(config-cem)# signaling
```

The following example shows how to enable signaling with onhook and offhook parameters:

```
Router(config-cem)# signalling 0x0 0x1 101
Delay will be set to 150 ms
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
failure	Specifies a time period before a CEM connection enters, or recovers from, a failed state.
show cem	Displays CEM channel statistics.

smt-queue-threshold

To set the maximum number of unprocessed FDDI station management (SMT) frames that will be held for processing, use the **smt-queue-threshold** command in global configuration mode. To restore the queue to the default, use the **no** form of this command.

smt-queue-threshold *number*
no smt-queue-threshold

Syntax Description

number	Number of buffers used to store unprocessed SMT messages that are to be queued for processing. Acceptable values are positive integers. The default value is equal to the number of FDDI interfaces installed in the router.

Command Default

The default threshold value is equal to the number of FDDI interfaces installed in the router.

Command Modes

Global configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command helps ensure that routers keep track of FDDI *upstream* and *downstream* neighbors, particularly when a router includes more than one FDDI interface.

In FDDI, upstream and downstream neighbors are determined by transmitting and receiving SMT Neighbor Information Frames (NIFs). The router can appear to lose track of neighbors when it receives an SMT frame and the queue currently contains an unprocessed frame. This occurs because the router discards incoming SMT frames if the queue is full. Discarding SMT NIF frames can cause the router to lose its upstream or downstream neighbor.

Caution Use this command carefully because the SMT buffer is charged to the inbound interface (input hold queue) until the frame is completely processed by the system. Setting this value to a high limit can impact buffer usage and the ability of the router to receive routable packets or routing updates.

Examples

The following example specifies that the SMT queue can hold ten messages. As SMT frames are processed by the system, the queue is decreased by one:

```
Router(config)# smt-queue-threshold 10
```

snmp ifmib ifindex persist

To globally enable ifIndex values to persist , which will remain constant across reboots, for use by the Simple Network Management Protocol (SNMP), use the **snmpifmibifindexpersist**command in global configuration mode. To globally disable ifIndex persistence, use the **no** form of this command.

snmp ifmib ifindex persist
no snmp ifmib ifindex persist

Syntax Description

This command has no arguments or keywords.

Command Default

The ifIndex persistence on a router is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SRA	This command was introduced. This command replaces the **snmp-serverifindexpersist**command.
12.2(31)SG	This command was integrated into Cisco IOS Release 12.2(31)SG.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

The **snmpifmibifindexpersist** command does not override an interface-specific configuration. The interface-specific configuration of ifIndex persistence is configured with the **snmpifindexpersist** and **snmpifindexclear** commands in interface configuration mode.

The **snmpifmibifindexpersist** command enables ifIndex persistence for all interfaces on a routing device by using the ifDescr and ifIndex entries in the ifIndex table of interface MIB (IF-MIB).

ifIndex persistence means that the ifIndex values in the IF-MIB persist across reboots, allowing for the consistent identification of specific interfaces that use SNMP.

If ifIndex persistence was previously disabled for a specific interface by using the **nosnmpifindexpersist** command, ifIndex persistence will remain disabled for that interface.

Examples

The following example shows how to enable ifIndex persistence for all interfaces:

```
Router(config)# snmp ifmib ifindex persist
```

Related Commands

Command	Description
snmp ifindex clear	Clears any previously configured **snmpifIndex** commands issued in interface configuration mode for a specific interface.
snmp ifindex persist	Enables ifIndex values that persist across reboots (ifIndex persistence) in the IF-MIB.

snmp ifindex clear

To clear previously configured Simple Network Management Protocol (SNMP) ifIndex commands issued for a specific interface or a specific service instance, use the **snmpifindexclear** command in either interface configuration mode or service instance configuration mode. This command does not have a **no** form.

snmp ifindex clear

Syntax Description

This command has no arguments or keywords.

Command Default

ifIndex values are not cleared.

Command Modes

Interface configuration (config-if) Service instance configuration (config-if-srv)

Command History

Release	Modification
12.0(11)S	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command was introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRD1	Support for this command was extended to service instance configuration mode in Cisco IOS Release 12.2(33)SRD1.

Usage Guidelines

Interface Index Persistence means that ifIndex values in the IF-MIB persist across reboots, allowing for consistent identification of specific interfaces using SNMP.

Use the**snmpifindexclear** command on a specific interface when you want that interface to use the global configuration setting for ifIndex persistence. This command clears all ifIndex configuration commands previously entered for that specific interface.

When you clear the ifIndex configuration, the ifIndex persistence is enabled for all interfaces as specified by the **snmp-serverifindexpersist** command in global configuration mode.

Examples

The following example shows how to enable ifIndex persistence for all interfaces:

```
Router(config)# snmp-server ifindex persist
```

The following example shows how to disable IfIndex persistence for Ethernet interface 0/1:

```
Router(config)# interface ethernet 0/1
Router(config-if)# no snmp ifindex persist
Router(config-if)# exit
```

The following example shows how to clear ifIndex persistence for service instance 100 on Ethernet interface 0/1:

```
Router(config)# interface ethernet 0/1
Router(config-if)# service instance 100 ethernet

Router(config-if-srv)# snmp ifindex clear
```

Router(config-if-srv)# **exit**

The following example shows how to clear the ifIndex configuration from Ethernet interface 0/1:

```
Router(config)# interface ethernet 0/1
Router(config-if)# snmp ifindex clear
Router(config-if)# exit
```

The ifIndex persistence configuration is now enabled for all interfaces, as specified by the **snmp-serverifindexpersist** global configuration command.

Related Commands

Command	Description
snmp ifindex persist	Enables ifIndex values in the Interfaces MIB (IF-MIB) that persist across reboots (ifIndex persistence) only on a specific interface.
snmp-server ifindex persist	Enables ifIndex values that will remain constant across reboots for use by SNMP.

snmp-server enable traps netsync

To configure the Simple Network Management Protocol (SNMP) SyncE trap, use the**snmp-serverenabletrapsnetsync**command in global configuration mode. To disable the SNMP SyncE trap, use the **no** form of this command.

snmp-server enable traps netsync
no snmp-server enable traps netsync

Syntax Description

This command has no arguments or keywords.

Command Default

SNMP traps are not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(2)S	This command was introduced.
Cisco IOS XE Release 3.8S	This command was integrated into Cisco IOS XE Release 3.8S.

Usage Guidelines

The **showrunning-config**command when used with the **trap** keyword displays the SNMP traps that are enabled on a device.

Examples

The following example shows how to enable the SNMP traps on the SyncE event:

```
Device# configure terminal
Device(config)# snmp-server enable traps netsync
Device(config)# end
```

Related Commands

Command	Description
show running-config	Displays the running configuration of the device.

snmp ifindex persist

To enable ifIndex values in the Interfaces MIB (IF-MIB) that persist across reboots (ifIndex persistence) on a specific interface or service instance, use the **snmpifindexpersist**command in either interface configuration mode or service instance configuration mode. To disable ifIndex persistence on a specific interface or service instance, use the **no** form of this command.

snmp ifindex persist
no snmp ifindex persist

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled.

Command Modes

Interface configuration (config-if) Service instance configuration (config-if-srv)

Command History

Release	Modification
12.0(11)S	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRD1	Support for this command was extended to service instance configuration mode in Cisco IOS Release 12.2(33)SRD1.

Usage Guidelines

Interface Index Persistence means that ifIndex values in the IF-MIB persist across reboots, allowing for consistent identification of specific interfaces using Simple Network Management Protocol (SNMP).

The **snmpifindexpersist** command in interface configuration mode enables and disables ifIndex persistence for individual entries (corresponding to individual interfaces) in the ifIndex table of the IF-MIB.

The **snmpifindexpersist** command in service instance configuration mode enables and disables ifIndex persistence for individual service instances (Layer 2 VLAN interfaces) in the ifIndex table of the IF-MIB.

The **snmp-serverifindexpersist** command in global configuration mode enables and disables ifIndex persistence for all interfaces on the routing device that have ifDescr and ifIndex entries in the ifIndex table of the IF-MIB.

IfIndex commands configured for an interface apply to all subinterfaces on that interface.

Examples

In the following example, ifIndex persistence is enabled for Ethernet interface 0/1 only:

```
Router(config)# interface ethernet 0/1
Router(config-if)# snmp ifindex persist
Router(config-if)# exit
```

In the following example, ifIndex persistence is enabled for all interfaces and then disabled for Ethernet interface 0/1 only:

```
Router(config)# snmp-server ifindex persist
Router(config)# interface ethernet 0/1
Router(config-if)# no snmp ifindex persist
Router(config-if)# exit
```

In the following example, ifIndex persistence is enabled for service instance 100 on Ethernet interface 0/1:

```
Router(config)# interface ethernet 0/1
Router(config-if)# service instance 100 ethernet
Router(config-if-srv)# snmp ifindex persist
```

Router(config-if-srv)# **exit**

Related Commands

Command	Description
snmp ifindex clear	Clears previously configured SNMP ifIndex commands for a specific interface or service instance.
snmp-server ifindex persist	Enables ifIndex values that will remain constant across reboots for use by SNMP.

snmp trap illegal-address

To issue a Simple Network Management Protocol (SNMP) trap when a MAC address violation is detected on an Ethernet hub port of a Cisco 2505, Cisco 2507, or Cisco 2516 router, use the **snmptrapillegal-address** command in hub configuration mode. To disable this function, use the **no** form of this command.

snmp trap illegal-address
no snmp trap illegal-address

Syntax Description

This command has no arguments or keywords.

Command Default

No SNMP trap is issued.

Command Modes

Hub configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In addition to setting the **snmptrapillegal-address**command on the Ethernet hub, you can set the frequency that the trap is sent to the network management station (NMS). This is done on the NMS via the Cisco Repeater MIB. The frequency of the trap can be configured for once only or at a decaying rate (the default). If the decaying rate is used, the first trap is sent immediately, the second trap is sent after one minute, the third trap is sent after two minutes, and so on until 32 minutes, at which time the trap is sent every 32 minutes. If you use a decaying rate, you can also set the trap acknowledgment so that the trap will be acknowledged after it is received and will no longer be sent to the network management station.

Because traps are not reliable, additional information on a port basis is provided by the Cisco Repeater MIB. The network management function can query the following information: the last illegal MAC source address, the illegal address trap acknowledgment, the illegal address trap enabled, the illegal address first heard (timestamp), the illegal address last heard (timestamp), the last illegal address trap count for the port, and the illegal address trap total count for the port.

In addition to issuing a trap when a MAC address violation is detected, the port is also disabled as long as the MAC address is invalid. The port is enabled and the trap is no longer sent when the MAC address is valid (that is, either the address was configured correctly or learned).

Examples

The following example enables an SNMP trap to be issued when a MAC address violation is detected on hub ports 2, 3, or 4. SNMP support must already be configured on the router.

```
Router(config)#
 hub ethernet 0 2 4
Router(config-hub)#
 snmp trap illegal-address
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

snmp-server ifindex persist

Note This command is not supported in Cisco IOS Release 12.2SR. For Cisco IOS Release 12.2SR, use the **snmpifmibifindexpersist** command.

To globally enable ifIndex values that will remain constant across reboots for use by Simple Network Management Protocol (SNMP), use the **snmp-serverifindexpersist** command in global configuration mode. To globally disable ifIndex persistence, use the **no** form of this command.

snmp-server ifindex persist
no snmp-server ifindex persist

Syntax Description

This command has no arguments or keywords.

Command Default

This command is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.0(11)S	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was integrated into Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was replaced by the **snmpifmibifindexpersist**command in Cisco IOS Release 12.2SR.

Usage Guidelines

Interface Index Persistence means that ifIndex values in the IF-MIB persist across reboots, allowing for consistent identification of specific interfaces using SNMP.

The **snmp-serverifindexpersist** global configuration command will not override interface-specific configuration. Interface-specific configuration of ifIndex persistence is performed with the **[no]snmpifindexpersist** and **snmpifindexclear** interface configuration commands.

The **[no]snmp-serverifindexpersist** global configuration command enables and disables ifIndex persistence for all interfaces on the routing device using ifDescr and ifIndex entries in the ifIndex table of the IF-MIB.

Examples

In the following example, ifIndex persistence is enabled for all interfaces:

```
Router(config)# snmp-server ifindex persist
```

Note that in this example if ifIndex persistence was previously disabled for a specific interface using the **nosnmpifindexpersist** interface configuration command, ifIndex persistence will remain disabled for that interface. The global ifIndex command does not override the interface-specific commands.

Related Commands

Command	Description
snmp ifindex clear	Clears any previously configured snmp ifIndex commands issued in interface configuration mode for a specific interface.
snmp ifindex persist	Enables ifIndex values in the Interfaces MIB (IF-MIB) that persist across reboots (ifIndex persistence) only on a specific interface.

snr margin

To set the signal-to-noise ratio (SNR) on the controller to improve the line stability, use the **snrmargin** command in controller configuration mode. To reset the SNR to default settings, use the **no** form of this command.

snr margin {**current** [{*snr-value* | **disable**}] | **snext** [{*snr-value* | **disable**}]}
no snr margin {**current** | **snext**}

Syntax Description

current	Sets the current signal-to-noise ratio on the controller. To disable the current SNR, set **current** to **disable**.
snext	Sets the Self Near End Cross Talk (SNEXT) signal-to-noise ratio. To disable the SNEXT, set **snext** to **disable**.
snr-value	(Optional) Value, in decibels (dB), for the signal-to-noise ratio on the controller or the SNEXT. Range is from -10 to 10 . The default value is 0.
disable	(Optional) Disables the **snrmargin** command.

Command Default

The default value for both **current** and **snext** is 0.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on the Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.3(4)XG	This command was integrated into Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series, Cisco 3631, and Cisco 3700 series routers.
12.3(11)T	This command was integrated into Cisco IOS Release 12.3(11)T on Cisco 2800 series and Cisco 3800 series routers.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T on Cisco 1800 series routers.

Usage Guidelines

The **snrmargincurrent**command can create a more stable line by making the line train more than the current noise margin plus signal-to-noise ratio threshold during training time. If any external noise is applied that is less than the set SNR margin, the line will be stable.

The **snrmarginsnext**command can create a more stable line by making the line train more than the Self Near End Cross Talk (SNEXT) threshold during training time. If any external noise is applied that is less than the set SNEXT margin, the line will be stable.

Examples

SNR with SNEXT Disabled

The following example configures the signal-to-noise ratio to 5 dB on the DSL controller in slot 3 and port 0 and disables the SNEXT signal-to-ratio.

```
Router(config)# controller
 dsl
 3/0
Router(config-controller)# snr margin
current

5
Router(config)# controller
 dsl
 3/0
Router(config-controller)# snr margin
snext

disable
```

SNR Margin set on CPE Router

The following example shows the **snrmarginsnext5** command issued on the customer premises equipment (CPE) router.

```
Router_CPE(config)# controller dsl
 1/0
Router_CPE(config-controller)# snr margin
 snext
 5
Router_CPE(config-controller)#
*Jun 15 18:29:38.511: %CONTROLLER-5-UPDOWN: Controller DSL 1/0, changed state tn
*Jun 15 18:29:40.511: %LINK-3-UPDOWN: Interface ATM1/0, changed state to down
*Jun 15 18:29:41.511: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM1/0, cn
*Jun 15 18:30:04.579:  DSL 1/0 controller Link up! line rate: 4608 Kbps
*Jun 15 18:30:04.579: %CONTROLLER-5-UPDOWN: Controller DSL 1/0, changed state tp
*Jun 15 18:30:12.351: %LINK-3-UPDOWN: Interface ATM1/0, changed state to up
*Jun 15 18:30:13.351: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM1/0, cp
```

Status on CO Side with SNR Margin set on CPE Router

The following example is the resulting output on the router that is configured as the central office (CO) side after the **snrmarginsnext5** command is entered on the CPE side.

```
Router_CO#
Jun 15 18:29:42.781: %CONTROLLER-5-UPDOWN: Controller DSL 0/0, changed state ton
Jun 15 18:29:44.784: %LINK-3-UPDOWN: Interface ATM0/0, changed state to down
Jun 15 18:29:45.786: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/0, chn
Jun 15 18:30:03.122:  DSL 0/0 controller Link up! line rate: 4608 Kbps
Jun 15 18:30:03.122: %CONTROLLER-5-UPDOWN: Controller DSL 0/0, changed state top
Jun 15 18:30:11.456: %LINK-3-UPDOWN: Interface ATM0/0, changed state to up
Jun 15 18:30:12.458: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/0, chp
```

source-address

To configure source address control on a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router, use the **source-address** command in hub configuration mode. To remove a previously defined source address, use the **no** form of this command.

source-address [*mac-address*]
no source-address

Syntax Description

mac-address	(Optional) MAC address in the packets that the hub will allow to access the network.

Command Default

Source address control is disabled.

Command Modes

Hub configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you omit the MAC address, the hub uses the value in the last source address register, and if the address register is invalid, it will remember the first MAC address it receives on the previously specified port and allow only packets from that MAC address onto that port.

Examples

The following example configures the hub to allow only packets from MAC address 1111.2222.3333 on port 2 of hub 0:

```
Router(config)#
 hub ethernet 0 2
Router(config-hub)#
 source-address 1111.2222.3333
```

The following example configures the hub to use the value of the last source address register. If the address register is invalid, it will remember the first MAC address it receives on port 2 and allow only packets from the learned MAC address on port 2:

```
Router(config)#
 hub ethernet 0 2
Router(config-hub)#
 source-address
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

speed

To configure the speed for a Fast Ethernet or Gigabit Ethernet interface, use the **speed** command in interface configuration mode. To return to the default configuration, use the **no** form of this command.

speed {**10** | **100** | **1000** [**negotiate**] | **auto** [*speed-list*]}
no speed

Syntax Description

10	Configures the interface to transmit at 10 Mbps.
100	Configures the interface to transmit at 100 Mbps.
1000	Configures the interface to transmit at 1000 Mbps. This keyword is valid only for interfaces that support Gigabit Ethernet.
auto	Enables Fast Ethernet autonegotiation. The interface automatically operates at 10 Mbps or 100 Mbps depending on environmental factors, such as the type of media and transmission speeds for the peer routers, hubs, and switches used in the network configuration. Autonegotiation is the default.
negotiate	(Optional) Enables or disables the link-negotiation protocol on Gigabit Ethernet ports.
speed-list	(Optional) Speed autonegotiation capability for a specific speed; see the "Usage Guidelines" section for valid values.

Command Default

Autonegotiation is enabled. The command is set to **auto**.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.2(10)P	This command was introduced.
12.1(7)E	This command was modified. The **1000** keyword was added for Gigabit Ethernet interfaces.
12.2S	This command was integrated into Cisco IOS Release 12.2 S.
12.2(20)S2	This command was implemented on the 4-port 10/100 Fast Ethernet SPA and the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router.
12.2(14)SX	This command was implemented on the Supervisor Engine 720.
12.2(17a)SX	This command was modified. The *speed-list* argument was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Release	Modification
15.2(02)SA	This command was implemented on the Cisco ME 2600X Series Ethernet Access Switches.

Usage Guidelines

Use the **speed** {**10** | **100**} command for 10/100 ports, the **speed auto 10 100 1000** command for 10/100/1000 ports, and the **speed 1000** [**negotiate**] command for Gigabit Ethernet ports.

Cisco Cloud Services Router 1000V Series

Cisco Cloud Services Router 1000V Series does not support the **speed** command.

Cisco 7600 Series Routers

Cisco 7600 Series Routers cannot automatically negotiate interface speed and duplex mode if either of the connecting interfaces is configured to a value other than **auto**.

Ethernet Interfaces

If you set the Ethernet interface speed to **auto** on a 10/100-Mbps or 10/100/1000-Mbps Ethernet interface, both duplex operation and speed are autonegotiated.

Gigabit Ethernet Interfaces

The Gigabit Ethernet interfaces are full duplex only. You cannot change the duplex mode on Gigabit Ethernet interfaces or on a 10/100/1000-Mbps interface that is configured for Gigabit Ethernet.

SPA Interfaces

The **speed** command applies to Shared Port Adapter (SPA) interfaces that use RJ-45 media. Gigabit Ethernet interfaces using fiber media support 1000-Mbps speed only and use the **negotiation** command to enable and disable autonegotiation.

See also “Flow Control” in the “Usage Guidelines” section.

Speed Command Syntax Combinations

The table below lists the supported command options by interface.

Table 278: Supported speed Command Options

Interface Type	Supported Syntax	Default Settings	Usage Guidelines
10/100-Mbps module	**speed** {**10** | **100**} **speed auto 10 100**	**auto**	If the speed is set to **auto**, you cannot set **duplex**. If the speed is set to **10** or **100**, without configuring the duplex setting, the duplex is set to **half** by default.

Interface Type	Supported Syntax	Default Settings	Usage Guidelines
10/100/1000-Mbps interface	**speed auto 10 100 1000**	**auto**	If the speed is set to **auto**, you cannot set **duplex**. If the speed is set to **10** or **100**, without configuring the duplex setting, the duplex is set to **half** by default. If the speed is set to **10** or **100**, the interface is not forced to half duplex by default.
100-Mbps fiber modules	Factory set	Not applicable.	
Gigabit Ethernet module	**speed 1000** [**negotiate**]	Speed is 1000 or negotiation is enabled.	Speed, duplex, flow control, and clocking negotiations are enabled.
10-Mbps ports	Factory set	Not applicable.	

Autonegotiation

To enable the autonegotiation capability on an RJ-45 interface, you must set either the **speed** command or the **duplex** command to **auto**. The default configuration is that both commands are set to **auto**.

If you need to force an interface port to operate with certain settings and, therefore, disable autonegotiation, you must be sure that the remote link is configured for compatible link settings for proper transmission including support of flow control on the link.

When you enable link negotiation, the speed, duplex, flow control, and clocking negotiations between two Gigabit Ethernet ports are automatically enabled.

Flow Control

Flow control support is always advertised when autonegotiation is enabled.

Every interface on a 4-port 10/100 Fast Ethernet SPA supports transmission of pause frames to stop packet flow when the Modular Services Card (MSC) is full. You cannot disable flow control for an interface on the 4-port 10/100 Fast Ethernet SPA. Therefore, flow control support is not configurable, but it is advertised during autonegotiation.

If you disable autonegotiation, then you must be sure that the remote device is configured to support flow control because flow control is automatically enabled for all interfaces on the 4-port 10/100 Fast Ethernet SPA.

Speed Settings

Separate the *speed-list* entries with a space.

When manually configuring the interface speed to either 10 or 100 Mbps, the switch prompts you to configure duplex mode on the interface.

The following *speed-list* configurations are supported:

- **speed auto**—Negotiate all speeds.
- **speed auto 10 100**—Negotiate 10 and 100 speeds only.
- **speed auto 10 100 1000**—Negotiate all speeds.

Speed and Duplex Combinations

The table below describes the interface behavior for various combinations of the **duplex** and **speed** command settings. The specified **duplex** command configured with the specified **speed** command produces the resulting system action.

If you decide to configure the interface speed and duplex commands manually, and enter a value other than **speed auto** (for example, 10 or 100 Mbps), ensure that you configure a connected interface with a matching speed using the speed command without using the **auto** keyword.

If you specify both a **duplex** and **speed** setting other than **auto** on an RJ-45 interface, then autonegotiation is disabled for the interface.

You cannot set the duplex mode to **half** when the port speed is set to **1000**, and similarly, you cannot set the port speed to **1000** when the mode is set to **half duplex**. In addition, if the port speed is set to **auto**, the **duplex** command is rejected.

Caution Changing the interface speed and duplex mode might shut down and reenable the interface during reconfiguration.

Table 279: Relationship Between duplex and speed Commands

duplex Command	speed Command	Resulting System Action
duplex auto	**speed auto**	Autonegotiates both speed and duplex settings. The interface advertises the capability for the following link settings: • 10 Mbps and half duplex • 10 Mbps and full duplex • 100 Mbps and half duplex • 100 Mbps and full duplex • 1000 Mbps and half duplex (Gigabit Ethernet only) • 1000 Mbps and full duplex (Gigabit Ethernet only)

duplex Command	speed Command	Resulting System Action
duplex auto	**speed 10** or **speed 100** or **speed 1000**	Autonegotiates the duplex mode. The interface advertises the capability for both half-duplex and full-duplex modes at the configured speed. For example, if the **speed 100** command is configured with **duplex auto**, then the interface advertises the following capability: • 100 Mbps and half duplex • 100 Mbps and full duplex
duplex half or **duplex full**	**speed auto**	Autonegotiates the speed. The interface advertises the capability for duplex mode for Fast Ethernet interfaces at a speed of 10-Mbps and 100-Mbps, and Gigabit interfaces at 10-Mbps, 100-Mbps, and 1000-Mbps. For example, if the **duplex full** command is configured with the **speed auto** command, then the interface advertises the following capability: • 10 Mbps and full duplex • 100 Mbps and full duplex • 1000 Mbps and full duplex (Gigabit Ethernet interfaces only)
duplex half	**speed 10**	Forces a speed of 10-Mbps and the half-duplex operation, and disables autonegotiation on the interface.
duplex full	**speed 10**	Forces a speed of10-Mbps and the full-duplex operation, and disables autonegotiation on the interface.
duplex half	**speed 100**	Forces a speed of 100-Mbps and the half-duplex operation, and disables autonegotiation on the interface.
duplex full	**speed 100**	Forces a speed of 100-Mbps and the full-duplex operation, and disables autonegotiation on the interface.
duplex half	**speed 1000**	Forces a speed of 1000-Mbps and the half-duplex operation, and disables autonegotiation on the interface (Gigabit Ethernet only).
duplex full	**speed 1000**	Forces a speed of 1000-Mbps and the full-duplex operation, and disables autonegotiation on the interface (Gigabit Ethernet only).

Examples

The following example specifies the advertisement of only the 10 Mbps operation and either the full-duplex or half-duplex capability during autonegotiation for the second interface (port 1) on the SPA located in the bottom subslot (1) of the MSC that is installed in slot 2 of the Cisco 7304 router:

```
Device# configure terminal
Device(config)# interface fastethernet 2/1/1
Device(config-if)# speed 10
Device(config-if)# duplex auto
```

With this configuration, the interface advertises the following capabilities during autonegotiation:

- 10 Mbps and half duplex
- 10 Mbps and full duplex

Related Commands

Command	Description
duplex	Configures the duplex operation on an interface.
interface fastethernet	Selects a particular Fast Ethernet interface for configuration.
interface gigabitethernet	Selects a particular Gigabit Ethernet interface for configuration.
show controllers fastethernet	Displays Fast Ethernet interface information, transmission statistics and errors, and the applicable MAC destination address and VLAN filtering tables.
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics and errors, and the applicable MAC destination address and VLAN filtering tables.
show interfaces fastethernet	Displays information about the Fast Ethernet interfaces.
show interfaces gigabitethernet	Displays information about the Gigabit Ethernet interfaces.

squelch

To extend the Ethernet twisted-pair 10BASE-T capability beyond the standard 100 meters on the Cisco 4000 platform, use the **squelch** command in interface configuration mode. To restore the default, use the **no** form of this command.

squelch {**normal** | **reduced**}
no squelch

Syntax Description

normal	Allows normal capability. This is the default.
reduced	Allows extended 10BASE-T capability.

Command Default

Normal range

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example extends the twisted-pair 10BASE-T capability on the cable attached to Ethernet interface 2:

```
Router(config
)
# interface ethernet 2
Router(config
-if)
# squelch reduced
```

sra line

To accommodate changes to the total link capacity with the least amount of disruption to communications, use the **sra line** command in controller configuration mode. To disable seamless rate adaptation, use the **no** form of this command.

sra [line *line-number***]**
no sra [line *line-number***]**

Syntax Description

line-number	Line number. Valid values are either 0 or 1.

Command Default

Seamless rate adaptation is disabled.

Command Modes

Controller configuration (config-controller)#

Command History

Release	Modification
15.4(4)T	This command was introduced.

Usage Guidelines

If you specify the line-number, seamless rate adaptation will be enabled only on that line. If you do not specify the line-number, SRA will be enabled on both the lines.

Examples

The following example shows how to enable seamless rate adaptation on line 0:

```
Router(config-controller)# sra line 0
```

The following example shows how to disable seamless rate adaptation:

```
Router(config-controller)# no sra
```

Related Commands

Command	Description
bitswap line	Diverts the data of a disturbed transmission channel to other channels.

standby port

To defer the activation of a port on the standby chassis during standby recovery, use the **standbyport** virtual switching system (VSS) mode command. To disable port deferral activation, use the **no** form of this command.

standby port {**bringup** *num duration* | **delay** *seconds*}

Syntax Description

bringup	Configures the number of ports to be activated per cycle and the waiting time between cycles. Note: You must configure the standby port delay time before you can configure the standby port bringup time.
num	Number of ports to be activated per cycle. Range: 1 to 100. Default: 1.
duration	Period of time in seconds between cycles. Range: 1 to 10. Default: 1.
delay *seconds*	Specifies the period in seconds before port activation is performed. Range: 30 to 3600. Default: 0.

Command Default

Port deferral activation is disabled if standby port delay is not configured. If port deferral activation is enabled, the default number of ports activated in one cycle is one and the duration of the cycle is one second.

Command Modes

Virtual switch configuration submode (config-vs-domain)

Command History

Release	Modification
12.2(33)SXH2	Support for this command was introduced.

Usage Guidelines

Note We recommend that enter you this command under TAC supervision.

Note You must configure the standby port delay command before you can configure the standby port bringup command.

If the you configure the standby port bringup without configuring the standby port delay, a message is displayed asking you to configure the standby port delay first and then the standby port bringup. If you remove the standby port delay configuration, the standby port bringup is automatically removed.

In default configuration, all ports are activated simultaneously when a failed chassis is restarted as the standby chassis. You can enter the **standbyport** command to defer the activation of ports that are not virtual switch link (VSL) ports and then activate the ports in groups over a period of time.

You can enter the **standbyport** command to defer the activation of ports that are not virtual switch link (VSL) ports and then activate the ports in groups over a period of time. This can help in reducing traffic loss on the standby ports and alleviate the high CPU utilization on the active switch and route processors during system initialization of the standby chassis.

Examples

The following example shows how to configure the period in seconds before port activation is performed:

```
Router(config)# switch virtual domain 22
Router (config-vs-domain)# standby port delay 400
Router (config-vs-domain)#
```

The following example shows how to configure the bringup delay for a port’s activation during a standby recovery:

```
Router(config)# switch virtual domain 22
Router (config-vs-domain)# standby port bringup 2 30
Router (config-vs-domain)#
```

Related Commands

Command	Description
switch virtual domain	Assigns a switch number and enters virtual switch domain configuration submode.

sts-1

To configure the Synchronous Transport Signal (STS) (level)-1 in the SONET hierarchy, use the **sts-1** command in controller configuration mode.

sts-1 *number*

Syntax Description

number	Specifies the sts-1 number. The range is 1 to 3.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
15.1(01)S	This command was introduced on the Cisco 7600 routers.
Cisco IOS XE Everest 16.5.1	This command was introduced on the Cisco ASR 920 Routers and Cisco NCS 4200 Series.

Examples

This example shows how to configure the (STS) (level)-1:

```
Router(config)# controller sonet-acr 1
Router(config-controller)#
sts-1 2
```

Related Commands

Command	Description
vtg	Configures the (CESoPSN) CEM group.
mode vt-15	Configures the path operation mode.
controller sonet-acr	Configures the SONET Access Circuit Redundancy (ACR) virtual controller.

squelch through system jumbomtu

squelch

To extend the Ethernet twisted-pair 10BASE-T capability beyond the standard 100 meters on the Cisco 4000 platform, use the **squelch** command in interface configuration mode. To restore the default, use the **no** form of this command.

squelch {**normal** | **reduced**}
no squelch

Syntax Description

normal	Allows normal capability. This is the default.
reduced	Allows extended 10BASE-T capability.

Command Default

Normal range

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example extends the twisted-pair 10BASE-T capability on the cable attached to Ethernet interface 2:

```
Router(config
)
# interface ethernet 2
Router(config
-if)
# squelch reduced
```

srp buffer-size

To make adjustments to buffer settings on the receive side for different priority traffic, use the **srpbuffer-size**command in interface configuration mode. To disable buffer size configurations, use the **no** form of this command.

srp buffer-size receive [{**low** *buffer* | **medium** *buffer* | **high** *buffer*}]
no srp buffer-size receive [{**low** *buffer* | **medium** *buffer* | **high** *buffer*}]

Syntax Description

receive	Allocates SDRAM buffer for incoming packets.
low *buffer*	(Optional) Specifies buffer size, in kilobytes, for low-priority packets. Any number from 16 to 8192. The default is 8192.
medium *buffer*	(Optional) Specifies buffer size, in kilobytes, for medium-priority packets. Any number from 16 to 8192. The default is 4096.
high *buffer*	(Optional) Specifies buffer size, in kilobytes, for high-priority packets. Any number from 16 to 8192. The default is 4096.

Command Default

low = 8192 kilobytes, medium = 4096 kilobytes, high = 4096 kilobytes

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was implemented on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example sets the buffer size for the receive side at the high setting of 17 kilobytes:

```
Router(config-if)# srp buffer-size receive high 17
```

Related Commands

Command	Description
mtu	Adjusts the maximum packet size MTU size.
srp deficit-round-robin	Transfers packets from the internal receive buffer to Cisco IOS software.

srp deficit-round-robin

To transfer packets from the internal receive buffer to Cisco IOS software, use the **srpdeficit-round-robin** command in interface configuration mode. To disable the packet transfer, use the **no** form of this command.

srp deficit-round-robin [{**input** | **output**}] [{**low** | **medium** | **high**}] [{**quantum** *number* | **deficit** *number*}]
no srp deficit-round-robin

Syntax Description

input	(Optional) Specifies input buffer.
output	(Optional) Specifies output buffer.
low	(Optional) Specifies low-priority queue level.
medium	(Optional) Specifies medium-priority queue level.
high	(Optional) Specifies high-priority queue level.
quantum *number*	(Optional) Specifies the Deficit Round Robin (DRR) quantum value. Any number from 9216 to 32767. The default is 9216.
deficit *number*	(Optional) Specifies the DRR deficit value. Any number from 0 to 65535. The default is 16384.

Command Default

quantum : 9216**deficit**: 16384

Command Modes

12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to configure packets for the medium-priority input queue:

```
Router(config)# srp deficit-round-robin input medium deficit 15000
```

Related Commands

Command	Description
srp buffer-size	Makes adjustments to buffer settings on the receive side for different priority traffic.

Command	Description
srp priority-map	Sets priority mapping for transmitting and receiving packets.
srp random-detect	Configures WRED parameters on packets received through an SRP interface.

srp loopback

To loop the spatial reuse protocol (SRP) interface on an OC-12c DPTIP, use the **srploopback**command in interfaceconfiguration mode. To remove the loopback, use the **no** form of this command.

srp loopback {**internal** | **line**} {**a** | **b**}
no srp loopback

Syntax Description

internal	Sets the loopback toward the network before going through the framer
line	Loops the payload data toward the network.
a	Loops back the A side of the interface (inner tx, outer rx).
b	Loops back the B side of the interface (outer tx, inner rx).

Command Default

No loops are configured.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was introduced on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command for troubleshooting purposes.

Examples

The following example configures the loopback test on the A side of the SRP interface:

```
Router(config-if)# srp loopback line a
```

srp priority-map

To set priority mapping for transmitting and receiving packets, use the**srppriority-map**command in interface configuration mode. To disable priority mapping u se the **no** form of this command .

srp priority-map receive {**low** *priority* | **medium** *priority* | **high** *priority* | **transmit** {**medium** *priority* | **high** *priority*}}
no srp priority-map

Syntax Description

receive	Specifies priority mapping for receiving packets.
transmit	Specifies priority mapping for transmitting packets.
low *priority*	(Optional) Specifies mapping for low-priority packets. Any number from 1 to 8. The default is 1.
medium *buffer*	(Optional) Specifies mapping for medium-priority packets. Any number from 1 to 8. The default is 3.
high *buffer*	(Optional) Specifies mapping for high-priority packets. Any number from 1 to 8. The default is 5 for receiving packets, and default is 7 for transmitting packets.

Command Default

receive low : 1**receivemedium**: 3 **receivehigh**: 5 **transmithigh**: 7

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was implemented on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The spatial reuse protocol (SRP) interface provides commands to enforce quality of service (QoS) functionality on the transmit side and receive side of Cisco routers. SRP uses the IP type of service (ToS) field values to determine packet priority.

The SRP interface classifies traffic on the transmit side into high- and low-priority traffic. High-priority traffic is rate shaped and has higher priority than low-priority traffic. You have the option to configure high- or low-priority traffic and can rate limit the high-priority traffic.

The **srppriority-maptransmit** command enables the user to specify IP packets with values equal to or greater than the ToS value to be considered as high-priority traffic.

On the receive side, when WRED is enabled, SRP hardware classifies packets into high-, medium-, and low-priority packets on the basis of the IP ToS value. After classification, it stores the packet into the internal receive buffer. The receive buffer is partitioned for each priority packet. Cisco routers can employ WRED on the basis of the IP ToS value. Routers also employ the Deficit Round Robin (DRR) algorithm to transfer packets from the internal receive buffer to Cisco IOS software.

The **srppriority-mapreceive** command enables the user to classify packets as high, medium, or low based on the IP ToS value.

Examples

The following example configures Cisco 7500 series routers to transmit packets with priority greater than 5 as high-priority packets:

```
Router(config-if)# srp priority-map transmit high 6
```

Related Commands

Command	Description
srp random-detect	Configures WRED parameters on packets received through an SRP interface.

srp random-detect

To configure weighted RED (WRED) parameters on packets received through an spatial reuse protocol (SRP) interface, use the **srprandom-detect**command in interfaceconfiguration mode. To return the value to the default, use the **no** form of this command.

srp random-detect {**compute-interval** *interval* | **enable** | **input** [{**low** | **medium** | **high**}] | [{**exponential-weight** *weight* | **precedence** *precedence*}]}
no srp random-detect

Syntax Description

compute-interval *compute-interval*	Specifies the queue depth compute interval, in nanoseconds. Number in the range from 1 to 128. Default is 128.
enable	Enables WRED.
input	Specifies WRED on packet input path.
low	(Optional) Specifies low-priority queue level.
medium	(Optional) Specifies medium-priority queue level.
high	(Optional) Specifies high-priority queue level.
exponential-weight *weight*	(Optional) Specifies the queue weight, in bits. Number in the range from 0 to 6. The default is 6.
precedence *number*	(Optional) Specifies the input queue precedence. Number in the range from 0 to 7. The default is 7.

Command Default

compute-interval: 128 weight: 6 precedence: 7

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was implemented on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example configures WRED parameters on packets received through an SRP interface with a weight factor of 5:

```
Router(config-if)# srp random-detect input high exponential-weight 5
```

srp shutdown

To disable the spatial reuse protocol (SRP) interface, use the **srpshutdown** command in interface configuration mode. To restart a disabled interface, use the **no** form of this command.

srp shutdown [{**a** | **b**}]
no srp shutdown [{**a** | **b**}]

Syntax Description

a	(Optional) Specifies side A of the SRP interface.
b	(Optional) Specifies side B of the SRP interface.

Command Default

The SRP interface continues to be enabled until this command is issued.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was introduced on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **srpshutdown** command disables all functions on the specified side.

Examples

The following example turns off side A of the SRP interface:

```
Router(config-if)# srp shutdown a
```

srp tx-traffic-rate

To limit the amount of high-priority traffic that the spatial reuse protocol (SRP) interface can handle, use the**srptx-traffic-rate** command in interface configuration mode. Use the **no** form of this command to disable transmitted traffic rate .

srp **tx-traffic-rate** *number*
no **srp** **tx-traffic-rate** *number*

Syntax Description

number	Transmission speed, in kilobits per second. The range is from 1 to 65535. Default is 10.

Command Default

number : 10

Command Modes

Interface configuration

Command History

Release	Modification
12.0(6)S	This command was introduced.
12.0(7)XE1	This command was implemented on Cisco 7500 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example configures SRP traffic to transmit at 1000 kilobits per second:

```
Router(config-if)# srp tx-traffic-rate 1000
```

stack-mib portname

To specify a name string for a port, use the **stack-mib portname**command in interface configuration mode.

stack-mib portname *portname*

Syntax Description

portname	Name for a port.

Command Default

This command has no default settings.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2917d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Using the **stack-mib** command to set a name string to a port corresponds to the portName MIB object in the portTable of CISCO-STACK-MIB. portName is the MIB object in the portTable of CISCO-STACK-MIB. You can set this object to be descriptive text describing the function of the interface.

Examples

This example shows how to set a name to a port:

```
Router(config-if)#
stack-mib portname portall
Router(config-if)#
```

storm-control

To enable broadcast, multicast, or unicast storm control on a port or to specify the action when a storm occurs on a port, use the **storm-control** command in interface configuration mode. To disable storm control for broadcast, multicast, or unicast traffic or to disable the specified storm-control action, use the **no** form of this command.

storm-control {{**broadcast** | **multicast** | **unicast**} **level** *level* | **action** {**shutdown** | **trap**}}
no storm-control {{**broadcast** | **multicast** | **unicast**} **level** | **action** {**shutdown** | **trap**}}

Cisco ME 2600X Series Ethernet Access Switch
storm-control {{**broadcast** | **multicast**} **cir** *cir-value* | **action shutdown**}
no storm-control {{**broadcast** | **multicast**} **cir** *cir-value* | **action shutdown**}

Syntax Description

broadcast	Enables broadcast storm control on the port.
multicast	Enables multicast storm control on the port.
unicast	Enables unicast storm control on the port.
level *level*	Defines the rising and falling suppression levels. • *level* —Rising suppression level as a percent of the total bandwidth (up to two decimal places). The valid values are from 0 to 100. When the value specified for a level is reached, the flooding of storm packets is blocked.
action	Specifies the action to take when a storm occurs on a port. The default action is to filter traffic.
shutdown	Disables the port during a storm.
trap	Sends a Simple Network Management Protocol (SNMP) trap.
cir *cir-value*	Defines the Committed Information Rate (cir). • *cir-value*—The acceptable range is 10000000 -1000000000 for a gigabit ethernet interface, and 100000000-10000000000 for a ten gigabit interface. The recommended maximum value is up to 98 percent.

Command Default

Broadcast, multicast, and unicast storm control is disabled. The default action is to filter traffic.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(2)XT	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support switchport creation.

Release	Modification
12.2(15)ZJ	This command was integrated into Cisco IOS Release 12.2(15)ZJ. The **level** *level* keyword-argument pair, and the **action** and **shutdown** keywords were added.
15.0(1)S	This command was modified. The **trap** keyword was added.
15.1(1)SY	This command was integrated into Cisco IOS Release 15.1(1)SY.
15.2(02)SA	This command was implemented on the Cisco ME 2600X Series Ethernet Access Switches.

Usage Guidelines

Use the **storm-control** command to enable or disable broadcast, multicast, or unicast storm control on a port. After a port is disabled during a storm, use the **no shutdown** interface configuration command to enable the port.

The suppression levels are entered as a percentage of total bandwidth. A suppression value of 100 percent means that no limit is placed on the specified traffic type. This command is enabled only when the rising suppression level is less than 100 percent. If no other storm-control configuration is specified, the default action is to filter the traffic that is causing the storm.

When a storm occurs and the action is to filter traffic, and the falling suppression level is not specified, the networking device blocks all traffic until the traffic rate drops below the rising suppression level. If the falling suppression level is specified, the networking device blocks traffic until the traffic rate drops below this level.

When a multicast or unicast storm occurs and the action is to filter traffic, the networking device blocks all traffic (broadcast, multicast, and unicast traffic) and sends only Spanning Tree Protocol (STP) packets.

When a broadcast storm occurs and the action is to filter traffic, the networking device blocks only broadcast traffic.

The trap action is used to send an SNMP trap when a broadcast storm occurs.

Note Adding or removing of storm control configuration under the member link of LACP is not supported.

Note On Cisco Catalyst 3750 Series Switches, when the **storm-control** command is applied, it is rejected and the port is not put into a suspended state.

Examples

The following example shows how to enable broadcast storm control on a port with a 75.67-percent rising suppression level:

```
Device(config-if)# storm-control broadcast level 75.67
```

The following example shows how to enable multicast storm control on a port with an 87-percent rising suppression level:

```
Device(config-if)# storm-control multicast level 87
```

The following example shows how to enable the shutdown action on a port:

```
Device(config-if)# storm-control action shutdown
```

The following example shows how to disable the shutdown action on a port:

```
Device(config-if)# no storm-control action shutdown
```

The following example shows how to enable the trap action on a port:

```
Device(config-if)# storm-control action trap
```

The following example shows how to disable the trap action on a port:

```
Device(config-if)# no storm-control action trap
```

Related Commands

Command	Description
no shutdown	Enables a port.
show storm-control	Displays the packet-storm control information.
shutdown (interface)	Disables an interface.

storm-control level

To set the suppression level, use the **storm-control level** command in interface configuration mode. To turn off the suppression mode, use the **no** form of this command.

storm-control {**broadcast** | **multicast** | **unicast**} **level** *level* [**.** *level*]
no storm-control {**broadcast** | **multicast** | **unicast**} **level**

Syntax Description

broadcast	Specifies the broadcast traffic.
multicast	Specifies the multicast traffic.
unicast	Specifies the unicast traffic.
level	Integer-suppression level; valid values are from 0 to 100 percent.
. *level*	(Optional) Fractional-suppression level; valid va lues are from 0 to 99.

Command Default

All packets are passed.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can enter this command on switch ports and router ports.

Enter the **storm-control level** command to enable traffic storm control on the interface, configure the traffic storm-control level, and apply the traffic storm-control level to all traffic storm-control modes that are enabled on the interface.

Only one suppression level is shared by all three suppression modes. For example, if you set the broadcast level to 30 and set the multicast level to 40, both levels are enabled and set to 40.

The Cisco 7600 series router supports storm control for multicast and unicast traffic only on Gigabit Ethernet LAN ports. The switch supports storm control for broadcast traffic on all LAN ports.

The **multicast** and **unicast** keywords are supported on Gigabit Ethernet LAN ports only. These keywords are not supported on 10 Mbps, 10/100 Mbps, 100 Mbps, or 10-Gigabit Ethernet modules.

The period is required when you enter the fractional-suppression level.

The suppression level is entered as a percentage of the total bandwidth. A threshold value of 100 percent means that no limit is placed on traffic. A threshold value of 0 or 0.0 (fractional) percent means that all specified traffic is blocked on a port, with the following guidelines:

- A fractional level value of 0.33 or lower is the same as 0.0 on the following modules:

- WS-X6704-10GE
- WS-X6748-SFP
- WS-X6724-SFP
- WS-X6748-GE-TX

- A fractional level value of 0.29 or lower is the same as 0.0 on the WS-X6716-10G-3C / 3CXL in Oversubscription Mode.
- Enter 0 on all other modules to block all specified traffic on a port.

Enter the **show interfaces counters broadcast** command to display the discard count.

Enter the **show running-config** command to display the enabled suppression mode and level setting.

To turn off suppression for the specified traffic type, you can do one of the following:

- Set the *level* to 100 percent for the specified traffic type.
- Use the **no** form of this command.

Examples

This example shows how to enable and set the suppression level:

```
Router(config-if)#
storm-control broadcast level 30
```

This example shows how to disable the suppression mode:

```
Router(config-if)#
no storm-control multicast level
```

Related Commands

Command	Description
show interfaces counters	Displays the traffic that the physical interface sees.
show running-config	Displays the status and configuration of the module or Layer 2 VLAN.

subslot

To add an IPSec VPN SPA to a Blade Failure Group, use the **subslot** command in redundancy-linecard configuration mode.

subslot *slot* *subslot*

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on the SIP where the SPA is installed.

Command Default

No default behavior or values.

Command Modes

Redundancy-linecard configuration

Command History

Release	Modification
12.2(18)SXE2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

To complete the configuration of a Blade Failure Group, you must repeat the **subslot** command for each IPSec VPN SPA in the group.

Examples

The following example configures a Blade Failure Group that has a group ID of 1 and consists of two IPSec VPN SPAs--one IPSec VPN SPA is in slot 5, subslot 1 and one IPSec VPN SPA is in slot 6, subslot 1:

```
Router(config)# redundancy
Router
(config-red)# linecard-group 1 feature-card
Router(config-r-lc)# subslot 5/1
Router(config-r-lc)# subslot 6/1
```

Related Commands

Command	Description
linecard-group feature card	Assigns a group ID to a Blade Failure Group.
redundancy	Enters redundancy configuration mode.
show redundancy linecard-group	Displays the components of a Blade Failure Group.

switchport

Cisco 3550, 4000, and 4500 Series Switches

To put an interface that is in Layer 3 mode into Layer 2 mode for Layer 2 configuration, use the **switchport** command in interface configuration mode. To put an interface into Layer 3 mode, use the **no** form of this command.

switchport
no switchport

Cisco Catalyst 6500 and 6000 Series Switches and Cisco 7600 Series Routers

To modify the switching characteristics of the Layer 2-switched interface, use the **switchport** command (without keywords). Use the **no** form of this command (without keywords) to return the interface to the routed-interface status and cause all further Layer 2 configuration to be erased. Use the **switchport** commands (with keywords) to configure the switching characteristics.

switchport
switchport {**host** | **nonegotiate**}
no switchport
no switchport nonegotiate

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

To configure the server module to communicate with the router over a high-speed Multi Gigabit Fabric (MGF) backplane switch port, use the **switchport** command (with keywords) in interface configuration mode.

switchport {**access** | **mode** | **trunk**}

Cisco 1000 Series Integrated Services Routers with 4 or 8 Front-Panel Switch Ports

To configure the flex Layer 2 and Layer 3 ports to Layer 2 interface, use the **switchport** command (without keywords). To configure to Layer 3 interface, use the **no switchport** command (without keywords).

switchport
no switchport

Syntax Description

Cisco 3550, 4000, and 4500 Series Switches

This command has no arguments or keywords.

Cisco Catalyst 6500 and 6000 Series Switches and Cisco 7600 Series Routers

Table 280: Syntax Description for Cisco Catalyst 6500 and 6000 Series Switches and Cisco 7600 Series Routers

host	Optimizes the port configuration for a host connection.
nonegotiate	Specifies that the device will not engage in negotiation protocol on this interface.

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

Table 281: Syntax Description for Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

access	Sets the access mode characteristics of the interface.
mode	Sets the interface type: Access or Trunk.
trunk	Sets trunk characteristics when the interface is in Trunk mode. This is the default mode.

Cisco 1000 Series Integrated Services Routers with 4 or 8 Front-Panel Switch Ports

This command has no arguments or keywords.

Command Default

Cisco 3550, 4000, and 4500 Series Switches

All interfaces are in Layer 2 mode.

Catalyst 6500/6000 Series Switches and 7600 Series Routers

The default access VLAN and trunk-interface native VLAN are default VLANs that correspond to the platform or interface hardware.

Cisco 1000 Series Integrated Services Routers with 4 or 8 Front-Panel Switch Ports

The last two ports of the front-panel switch ports (flex ports) are set to Layer 2 interface by default.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.1(4)EA1	This command was introduced.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(15)ZJ	This command was implemented on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T on the following platforms: Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
15.1(2)T	Support for IPv6 was added.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Routers (ISR).
Cisco IOS XE Release 17.11.1a	This command was implemented to provide flex support on the last two Layer 2 switch ports of the Cisco 1000 Series ISRs with 4 or 8 Front-Panel Switch Ports.

Usage Guidelines

Cisco 3550, 4000, and 4500 Series Switches

Use the **no switchport** command to put the interface into the routed-interface status and to erase all Layer 2 configurations. You must use this command before assigning an IP address to a routed port. Entering the **no switchport** command shuts down the port and then reenables it, which might generate messages on the device to which the port is connected.

You can verify the switchport status of an interface by entering the **show running-config** privileged EXEC command.

Cisco Catalyst 6500 and 6000 Series Switches and Cisco 7600 Series Routers

You must enter the **switchport** command without any keywords to configure the LAN interface as a Layer 2 interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

Entering the **no switchport** command shuts down the port and then reenables it. This action may generate messages on the device to which the port is connected.

To optimize the port configuration, entering the **switchport host** command sets the switch port mode to access, enables spanning tree PortFast, and disables channel grouping. Only an end station can accept this configuration.

Because spanning-tree PortFast is enabled, you should enter the **switchport host** command only on ports that are connected to a single host. Connecting other Cisco 7600 series routers, hubs, concentrators, switches, and bridges to a fast-start port can cause temporary spanning-tree loops.

Enable the **switchport host** command to decrease the time that it takes to start up packet forwarding.

The no form of the **switchport** nonegotiate command removes nonegotiate status.

When using the **nonegotiate** keyword, Dynamic Inter-Switch Link Protocol and Dynamic Trunking Protocol (DISL/DTP)-negotiation packets are not sent on the interface. The device trunks or does not trunk according to the mode parameter given: access or trunk. This command returns an error if you attempt to execute it in dynamic (auto or desirable) mode.

You must force a port to trunk before you can configure it as a SPAN-destination port. Use the **switchport nonegotiate** command to force the port to trunk.

Examples

Cisco 3550, 4000, and 4500 Series Switches

The following example shows how to cause an interface to cease operating as a Layer 2 port and become a Cisco-routed (Layer 3) port:

```
Router(config-if)#no switchport
```

Cisco Catalyst 6500 and 6000 Series Switches and Cisco 7600 Series Routers

The following example shows how to cause the port interface to stop operating as a Cisco-routed port and convert to a Layer 2-switched interface:

```
Router(config-if)#
switchport
Router(config-if)#
```

Note The **switchport** command is not used on platforms that do not support Cisco-routed ports. All physical ports on such platforms are assumed to be Layer 2-switched interfaces.

The following example shows how to optimize the port configuration for a host connection:

```
Router(config-if)# switchport host
switchport mode will be set to access
spanning-tree portfast will be enabled
channel group will be disabled
Router(config-if)#
```

This example shows how to cause a port interface that has already been configured as a switched interface to refrain from negotiating trunking mode and act as a trunk or access port (depending on the mode set):

```
Router(config-if)#
switchport nonegotiate
Router(config-if)#
```

The following example shows how to cause an interface to cease operating as a Cisco-routed port and to convert it into a Layer 2 switched interface:

```
Router(config-if)#
switchport
```

Note The **switchport** command is not used on platforms that do not support Cisco-routed (Layer 3) ports. All physical ports on such platforms are assumed to be Layer 2 switched interfaces.

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

The following example shows how to set the interface to **access** mode:

```
Router#configure terminal
Router(config)# interface ucse 1/0/0
Router(config-if)# switchport mode access
```

The following example shows how to set the interface to **trunk** mode:

```
Router#configure terminal
Router(config)# interface ucse 1/0/0
Router(config-if)# switchport mode trunk
```

Cisco 1000 Series Integrated Services Routers with 4 or 8 Front-Panel Switch Ports

The following example shows how to convert a flex port to a Layer 3 port:

```
Device# configure terminal
Device(config)# interface GigabitEthernet 0/1/6
```

```
Device(config-if)# no switchport
Device(config-if)# ip address 10.10.0.1 255.255.255.0
Device(config-if)# exit
```

The following example shows how to convert a flex port to a Layer 2 port:

```
Device# configure terminal
Device(config)# interface GigabitEthernet 0/1/6
Device(config-if)# switchport
Device(config-if)# switchport mode access
Device(config-if)# exit
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port, including port blocking and port protection settings.
show running-config	Displays the current operating configuration.
switchport access vlan	Sets the VLAN when the interface is in Access mode.
switchport mode	Sets the interface type: Access or Trunk
switchport trunk	Sets trunk characteristics when the interface is in Trunk mode.

switchport access vlan

To set the VLAN when the interface is in access mode, use the **switchport access vlan** command in interface configuration or template configuration mode. To reset the access-mode VLAN to the appropriate default VLAN for the device, use the **no** form of this command.

switchport access vlan *vlan-id*
no switchport access vlan

Syntax Description

vlan-id	VLAN to set when the interface is in access mode; valid values are from 1 to 4094. Valid values for Cisco UCS E-Series Servers installed in Cisco 4400 Integrated Services Routers are: • 1-2349—VLAN ID Range 1 • 2450-4095—VLAN ID Range 2

Command Default

The defaults are as follows:

- Access VLAN and trunk-interface native VLAN are default VLANs that correspond to the platform or interface hardware.
- All VLAN lists include all VLANs.

Command Modes

Interface configuration (config-if)

Template configuration (config-template)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Routers (ISR).
Cisco IOS XE Release 3.6E	This command was integrated into Cisco IOS XE Release 3.6E. This command is supported in template configuration mode.

Usage Guidelines

You must enter the **switchport** command without any keywords to configure the LAN interface as a Layer 2 interface before you can enter the **switchport access vlan** command. This action is required only if you have not entered the **switchport** command for the interface.

Entering the **no switchport** command shuts down the port and then reenables it. This action may generate messages on the device to which the port is connected.

The no form of the **switchport access vlan** command resets the access-mode VLAN to the appropriate default VLAN for the device.

Examples

The following example shows how to stop the port interface from operating as a Cisco-routed port and convert to a Layer 2 switched interface:

```
Device(config-if)# switchport
```

Note The **switchport** command is not used on platforms that do not support Cisco-routed ports. All physical ports on such platforms are assumed to be Layer 2-switched interfaces.

The following example shows how to make a port interface that has already been configured as a switched interface to operate in VLAN 2 instead of the platform's default VLAN in interface configuration mode:

```
Device(config-if)# switchport access vlan 2
```

The following example shows how to make a port interface that has already been configured as a switched interface to operate in VLAN 2 instead of the platform's default VLAN, using an interface template in template configuration mode:

```
Device# configure terminal
Device(config)# template user-template1
Device(config-template)# switchport access vlan 2
Device(config-template)# end
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.
switchport	Configures a LAN interface as a Layer 2 interface.

switchport autostate exclude

To exclude a port from the VLAN interface link-up calculation, use the **switchportautostateexclude**command in interface configuration mode. To return to the default settings, use the **no** form of this command.

switchport autostate exclude
no switchport autostate exclude

Syntax Description

This command has no keywords or arguments.

Command Default

All ports are included in the VLAN interface link-up calculation.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17b)SXA	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command was introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You must enter the **switchport** command without any keywords to configure the LAN interface as a Layer 2 interface before you can enter the **switchportautostateexclude** command. This action is required only if you have not entered the **switchport** command for the interface.

Note The **switchport**command is not used on platforms that do not support Cisco-routed ports. All physical ports on such platforms are assumed to be Layer 2 switched interfaces.

A VLAN interface configured on the MSFC is considered up if there are ports forwarding in the associated VLAN. When all ports on a VLAN are down or blocking, the VLAN interface on the MSFC is considered down. For the VLAN interface to be considered up, all the ports in the VLAN need to be up and forwarding. You can enter the switchport autostate **exclude**command to exclude a port from the VLAN interface link-up calculation.

The switchport autostate **exclude** command marks the port to be excluded from the interface VLAN up calculation when there are multiple ports in the VLAN.

The **showinterface***interface***switchport** command displays the autostate mode if the mode has been set. If the mode has not been set, the autostate mode is not displayed.

Examples

This example shows how to exclude a port from the VLAN interface link-up calculation:

```
Router(config-if)#
switchport autostate exclude
```

This example shows how to include a port in the VLAN interface link-up calculation:

```
Router(config-if)#
no switchport autostate exclude
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.
switchport	Configures a LAN interface as a Layer 2 interface.

switchport backup

To configure an interface as a Flexlink backup interface, use the **switchport backup** command in interface configuration mode. To disable this configuration, use the **no** form of this command.

switchport backup interface *type number*[{**preemption** {**delay** *delay* | **mode** {**bandwidth** | **forced** | **off**}}}]
no switchport backup [{**interface** *type number* [{**preemption** {**delay** | **mode**}}]}]

Syntax Description

interface *type number*	Specifies the interface type and the module and port number to be configured as a Flexlink backup interface.
preemption delay *delay*	Specifies the preemption delay in seconds. The range is from 0 to 300 seconds.
preemption mode bandwidth	Specifies that a higher bandwidth interface is preferred for preemption.
preemption mode forced	Specifies that an active interface is preferred for preemption.
preemption mode off	Specifies that preemption is turned off.

Command Default

Interfaces are not configured as Flexilink backup interfaces.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(18)SXF	This command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.1(1)SY	This command was modified. The **no** form was modified so that specific backup configurations can be disabled.

Usage Guidelines

When you enable Flexlink, both the active and standby links are up physically, and mutual backup is provided.

Flexlink is supported on Layer 2 interfaces only and does not support routed ports.

The *number* arguement designates the module and port number. Valid values depend on the chassis and module that are used. For example, if you have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the slot number are from 1 to 13, and valid values for the port number are from 1 to 48.

Flexlink is designed for simple access topologies (two uplinks from a leaf node). You must ensure that there are no loops from the wiring closet to the distribution/core network to enable Flexlink to perform correctly.

Flexlink converges faster for directly connected link failures. Flexlink fast convergence does not impact any other type of network failure.

You must enter the **switchport** command without any keywords to configure a LAN interface as a Layer 2 interface before you can enter the **switchport backup** command.

You can remove all Flexilink configurations on an interface by using the **no switchport backup** command. You can remove specific backup configurations by using the optional keywords in the **no** form of this command.

Note The **switchport** command is used only on platforms that support Cisco-routed ports. All physical ports on such platforms are assumed to be Layer 2 switched interfaces.

Examples

The following example shows how to enable Flexlink on an interface. This example also shows how to configure a preemption delay of 100 seconds on an interface.

```
Device(config)# interface GigabitEthernet1/1
Device(config-if)# switchport
Device(config-if)# switchport backup interface GigabitEthernet1/2
Device(config-if)# switchport backup interface GigabitEthernet1/2 preemption delay 100
Device(config-if)# end
Device# show running interface GigabitEthernet1/1

Building configuration...

Current configuration : 219 bytes
!
interface GigabitEthernet1/1
 switchport
 switchport backup interface Gi1/2
 switchport backup interface Gi1/2 preemption delay 100
end

Device# show interfaces switchport backup

Switch Backup Interface Pairs:

Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi1/1                   Gi1/2                   Active Up/Backup Down
```

The following example shows how to disable specific backup configurations on an interface:

```
Device(config)# interface GigabitEthernet1/1
Device(config-if)# no switchport backup interface GigabitEthernet1/2 preemption delay
Device(config-if)# end
Device# show running-config interface GigabitEthernet1/1

Building configuration...

Current configuration : 219 bytes
!
interface GigabitEthernet1/1
 switchport
 switchport backup interface Gi1/2
end
```

The following example shows how to disable Flexlink and remove all Flexlink configurations on an interface:

```
Device(config)# interface GigabitEthernet1/1
Device(config-if)# no switchport backup interface GigabitEthernet1/2
Device(config-if)# end
```

```
Device# show running-config interface GigabitEthernet1/1

Building configuration...

Current configuration : 219 bytes
!
interface GigabitEthernet1/1
 switchport
end
```

Related Commands

Command	Description
show interfaces switchport backup	Displays Flexlink pairs.
show running-config	Displays the contents of the current running configuration file or the configuration for a specific module, Layer 2 VLAN, class map, interface, map class, policy map, or VC class.
switchport	Configures a LAN interface as a Layer 2 interface.
switchport autostate exclude	Excludes a port from the VLAN interface link-up calculation.

switchport block unicast

To prevent the unknown unicast packets from being forwarded, use the **switchportblockunicast**command in interface configuration mode. To allow the unknown unicast packets to be forwarded, use the **no** form of this command.

switchport block unicast
no switchport block unicast

Syntax Description

This command has no arguments or keywords.

Command Default

The default settings are as follows:

- Unknown unicast traffic is not blocked.
- All traffic with unknown MAC addresses is sent to all ports.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can block the unknown unicast traffic on the switch ports.

Blocking the unknown unicast traffic is not automatically enabled on the switch ports; you must explicitly configure it.

Note For more information about blocking the packets, refer to the Cisco 7600 Series Router Cisco IOS Software Configuration Guide.

You can verify your setting by entering the **showinterfaces** *interface-id***switchport** command.

Examples

This example shows how to block the unknown unicast traffic on an interface:

```
Router(config-if)# switchport block unicast
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.

switchport capture

To configure the port to capture VACL-filtered traffic, use the **switchportcapture**command in interface configuration mode. To disable the capture mode on the port, use the **no** form of this command.

switchport capture
no switchport capture

Syntax Description

This command has no keywords or arguments.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You must enter the **switchport** command without any keywords to configure the LAN interface as a Layer 2 switched interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

The VACL capture function for the NAM is supported on the Supervisor Engine 720 but is not supported with the IDSM-2.

The **switchportcapture** command applies only to Layer 2 switched interfaces.

WAN interfaces support only the capture functionality of VACLs.

Entering the **noswitchport** command shuts down the port and then reenables it. This action may generate messages on the device to which the port is connected.

Entering the **switchportcapture** command sets the capture function on the interface so that the packets with the capture bit set are received by the interface.

There is no restriction on the order that you enter the **switchportcapture** and **switchportcaptureallowedvlan**commands. The port does not become a capture port until you enter the **switchportcapture** (with no arguments) command.

The capture port must allow the destination VLANs of the captured packets. Once you enable a capture port, the packets are allowed from all VLANs by default, the capture port is on longer in the originally configured mode, and the capture mode enters monitor mode. In monitor mode, the capture port does the following:

- Does not belong to any VLANs that it was in previously.
- Does not allow incoming traffic.
- Preserves the encapsulation on the capture port if you enable the capture port from a trunk port and the trunking encapsulation was ISL or 802.1Q. The captured packets are encapsulated with the corresponding

encapsulation type. If you enable the capture port from an access port, the captured packets are not encapsulated.

- When you enter the **noswitchportcapture** command to disable the capture function, the port returns to the previously configured mode (access or trunk).
- Packets are captured only if the destination VLAN is allowed on the capture port.

Examples

This example shows how to configure an interface to capture VACL-filtered traffic:

```
Router(config-if)# switchport capture
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.
switchport capture allowed vlan	Specifies the destination VLANs of the VACL-filtered traffic.
switchport	Configures the LAN interface as a Layer 2 switched interface.

switchport capture allowed vlan

To specify the destination VLANs of the VACL-filtered traffic, use the **switchport** capture allowed vlancommand in interface configuration mode. To clear the configured-destination VLAN list and return to the default settings, use the **no** form of this co mmand.

switchport capture allowed vlan {**add** | **all** | **except** | **remove**} *vlanid* [,*vlanid* [,*vlanid*]] [, . . .]
no switchport capture allowed vlan

Syntax Description

add	Adds the specified VLANs to the current list.
all	Adds all VLANs to the current list.
except	Adds all VLANs except the ones that are specified.
remove	Removes the specified VLANs from the current list.
vlan-id	VLAN IDs of the allowed VLANs when this port is in capture mode; valid values are from 1 to 4094.

Command Default

all

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You must enter the **switchport** command without any keywords to configure the LAN interface as a Layer 2-switched interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

The switchport capture allowed vlan command applies only to Layer 2-switched interfaces.

Entering the **noswitchport** command shuts down the port and then reenables it. This action may generate messages on the device to which the port is connected.

You can enter the *vlan-id* as a single VLAN, a group of VLANs, or both. For example, you would enter **switchportcaptureallowedvlan1-1000,2000,3000-3100**.

There is no restriction on the order in which you enter the **switchportcapture** and **switchportcaptureallowedvlan**commands. The port does not become a capture port until you enter the **switchportcapture** (with no arguments) command.

WAN interfaces support only the capture functionality of VACLs.

Examples

This example shows how to add the specified VLAN to capture VACL-filtered traffic:

```
Router(config-if)# switchport capture
 allowed vlan add 100
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.
switchport	Configures the LAN interface as a Layer 2 switched interface.
switchport capture	Configures the port to capture VACL-filtered traffic.

switchport dot1q ethertype

To specify the EtherType value to be programmed on the interface, use the **switchportdot1qethertype** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

switchport dot1q ethertype *value*
no switchport dot1q ethertype *value*

Syntax Description

value	EtherType value for 802.1Q encapsulation; valid values are from 0x600 to 0xFFFF.

Command Default

The *value* is 0x8100.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can configure a custom EtherType-field value on trunk ports and on access ports.

Each port supports only one EtherType-field value. A port that is configured with a custom EtherType-field value does not recognize frames that have any other EtherType-field value as tagged frames.

Caution A port that is configured with a custom EtherType-field value considers frames that have any other EtherType-field value to be untagged frames. A trunk port that is configured with a custom EtherType-field value puts frames that are tagged with any other EtherType-field value into the native VLAN. An access port or tunnel port that is configured with a custom EtherType-field value puts frames that are tagged with any other EtherType-field value into the access VLAN.

You can configure a custom EtherType-field value on the following modules:

- Supervisor engines
- WS-X6516A-GBIC
- WS-X6516-GBIC

Note The WS-X6516A-GBIC and WS-X6516-GBIC modules apply a configured custom EtherType-field value to all ports that are supported by each port ASIC (1 through 8 and 9 through 16).

- WS-X6516-GE-TX
- WS-X6748-GE-TX

- WS-X6724-SFP
- WS-X6704-10GE
- WS-X6816-GBIC

You cannot configure a custom EtherType-field value on the ports in an EtherChannel.

You cannot form an EtherChannel from ports that are configured with custom EtherType-field values.

Examples

This example shows how to set the EtherType value to be programmed on the interface:

```
Router (config-if)# switchport dot1q ethertype 1234
```

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port.

switchport mode

To set the interface type, use the **switchport mode** command in interface configuration mode. Use the appropriate **no** form of this command to reset the mode to the appropriate default mode for the device.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers
switchport mode {**access** | **trunk**}
no switchport mode

Cisco Catalyst 6500/6000 Series Switches
switchport mode {**access** | **dot1q-tunnel** | **dynamic** {**auto** | **desirable**} | **trunk**}
no switchport mode

Cisco 7600 Series Routers
switchport mode {**access** | **dot1q-tunnel** | **dynamic** {**auto** | **desirable**} | **private-vlan** | **trunk**}
no switchport mode
switchport mode private-vlan {**host** | **promiscuous**}
no switchport mode private-vlan

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers
switchport mode {**access** | **trunk**}
no switchport mode {**access** | **trunk**}

Syntax Description

access	Sets a nontrunking, nontagged single VLAN Layer 2 interface.
trunk	Specifies a trunking VLAN Layer 2 interface.
dot1q-tunnel	Sets the trunking mode to TUNNEL unconditionally.
dynamic auto	Sets the interface to convert the link to a trunk link.
dynamic desirable	Sets the interface to actively attempt to convert the link to a trunk link.
private vlan host	Specifies that the ports with a valid private VLAN (PVLAN) association become active host private VLAN ports.
private vlan promiscuous	Specifies that the ports with a valid PVLAN mapping become active promiscuous ports.

Table 282: Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

access	Sets a nontrunking, nontagged single VLAN Layer 2 interface.
trunk	Specifies a trunking VLAN Layer 2 interface.

Command Default

The default is **access** mode.

The default mode is dependent on the platform; it should be either **dynamic auto** for platforms that are intended as wiring closets or **dynamic desirable** for platforms that are intended as backbone switches. The default for PVLAN ports is that no mode is set.

The defaults are as follows:

- The mode is dependent on the platform; it should either be **dynamic auto** for platforms that are intended for wiring closets or **dynamic desirable** for platforms that are intended as backbone switches.
- No mode is set for PVLAN ports.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.0(7)XE	This command was introduced on the Cisco Catalyst 6000 family switches.
12.1(1)E	This command was integrated on the Cisco Catalyst 6000 family switches.
12.1(8a)EX	The switchport mode **private-vlan** {**host** | **promiscuous**} syntax was added.
12.2(2)XT	Creation of switchports became available on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T for creation of switchports on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Routers (ISR).

Usage Guidelines

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

If you enter a forced mode, the interface does not negotiate the link to the neighboring interface. Ensure that the interface ends match.

The **no** form of the command is not supported on the Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.

Cisco Catalyst 6500/6000 Switches and Cisco 7600 Series Routers

If you enter **access** mode, the interface goes into permanent nontrunking mode and negotiates to convert the link into a nontrunk link even if the neighboring interface does not agree to the change.

If you enter **trunk** mode, the interface goes into permanent trunking mode and negotiates to convert the link into a trunk link even if the neighboring interface does not agree to the change.

If you enter **dynamic auto** mode, the interface converts the link to a trunk link if the neighboring interface is set to **trunk** or **desirable** mode.

If you enter **dynamic desirable** mode, the interface becomes a trunk interface if the neighboring interface is set to **trunk**, **desirable**, or **auto** mode.

If you configure a port as a promiscuous or host-PVLAN port and one of the following applies, the port becomes inactive:

- The port does not have a valid PVLAN association or mapping configured.
- The port is a SPAN destination.

If you delete a private-port PVLAN association or mapping, or if you configure a private port as a SPAN destination, the deleted private-port PVLAN association or mapping or the private port that is configured as a SPAN destination becomes inactive.

If you enter **dot1q-tunnel** mode, PortFast Bridge Protocol Data Unit (BPDU) filtering is enabled and Cisco Discovery Protocol (CDP) is disabled on protocol-tunneled interfaces.

Examples

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

The following example shows how to set the interface to **access** mode:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)#switchport mode access
```

The following example shows how to set the interface to **trunk** mode:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)#switchport mode trunk
```

Cisco Catalyst 6500/6000 Switches and Cisco 7600 Series Routers

The following example shows how to set the interface to dynamic desirable mode:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)# switchport mode dynamic desirable
```

The following example shows how to set a port to PVLAN-host mode:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)# switchport mode private-vlan host
```

The following example shows how to set a port to PVLAN-promiscuous mode:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)# switchport mode private-vlan promiscuous
```

Integrated Series Routers Generation 2 (ISR G2) Platforms with EHWIC-4/8ESG

The following example shows how to configure tunneling on port 4/1 and verify the configuration:

```
Router#configure terminal
Router(config)# interface fastethernet 4/1
Router(config-if)# switchport mode dot1q-tunnel
Router(config-if)# end
```

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

The following example shows how to set the interface to **access** mode:

```
Router#configure terminal
Router(config)# interface ucse 1/0/0
Router(config-if)# switchport mode access
```

The following example shows how to set the interface to **trunk** mode:

```
Router#configure terminal
Router(config)# interface ucse 1/0/0
Router(config-if)# switchport mode trunk
```

Related Commands

Command	Description
show dot1q-tunnel	Displays a list of 802.1Q tunnel-enabled ports.
show interfaces switchport	Displays administrative and operational status of a switching (nonrouting) port.
show interfaces trunk	Displays trunk information.
switchport	Modifies the switching characteristics of the Layer 2-switched interface.
switchport private vlan host association	Defines a PVLAN association for an isolated or community port.
switchport private vlan mapping	Defines the PVLAN mapping for a promiscuous port.
switchport trunk	Sets trunk characteristics when the interface is in trunking mode.

switchport port-security

To enable port security on an interface, use the **switchportport-security** command in i nterface configuration mode . To disable port security, use the **no** form of this command.

switchport port-security
no switchport port-security

Syntax Description

This command has no keywords or arguments.

Command Default

D isabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed as follows on the Supervisor Engine 720: • With Release 12.2(18)SXE and later releases, port security is supported on trunks. • With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Follow these guidelines when configuring port security:

- With Release 12.2(18)SXE and later releases, port security is supported on trunks.
- With releases earlier than Release 12.2(18)SXE, port security is not supported on trunks.
- With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports.
- With releases earlier than Release 12.2(18)SXE, port security is not supported on 802.1Q tunnel ports.
- A secure port cannot be a destination port for a Switch Port Analyzer (SPAN).
- A secure port cannot belong to an EtherChannel.
- A secure port cannot be a trunk port.
- A secure port cannot be an 802.1X port. If you try to enable 802.1X on a secure port, an error message appears, and 802.1X is not enabled. If you try to change an 802.1X-enabled port to a secure port, an error message appears, and the security settings are not changed.

Examples

This example shows how to enable port security:

```
Router(config-if)#
switchport port-security
```

This example shows how to disable port security:

Related Commands

Command	Description
show port-security	Displays information about the port-security setting.

switchport port-security aging

To configure the port security aging , use the **switchport** port-security aging time command in interface configuration mode . To disable aging, use the **no** form of this command.

switchport port-security aging {**time** *time* | **type** {**absolute** | **inactivity**}}
no switchport port-security aging

Syntax Description

time *time*	Sets the duration for which all addresses are secured; valid values are from 1 to 1440 minutes.
type	Specifies the type of aging.
absolute	Specifies absolute aging; see the "Usage Guidelines" section for more information.
inactivity	Specifies that the timer starts to run only when there is no traffic; see the "Usage Guidelines" section for more information.

Command Default

The defaults are as follows:

- Disabled.
- If enabled, t he defaults are as follows:
  - *time* is 0.
  - **type** is **absolute**

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed as follows on the Supervisor Engine 720: • With Release 12.2(18)SXE and later releases, port security is supported on trunks. • With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports. • The **type**, **absolute**, and **inactivity** keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Follow these guidelines when configuring port security:

- With Release 12.2(18)SXE and later releases, port security is supported on trunks. With releases earlier than Release 12.2(18)SXE, port security is not supported on trunks.
- With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports. With releases earlier than Release 12.2(18)SXE, port security is not supported on 802.1Q tunnel ports.

You can apply one of two types of aging for automatically learned addresses on a secure port:

- Absolute aging times out the MAC address after the age-time has been exceeded, regardless of the traffic pattern. This default is for any secured port, and the age-time is set to 0.
- Inactivity aging times out the MAC address only after the age_time of inactivity from the corresponding host has been exceeded.

Examples

This example shows how to set the aging time as 2 hours:

```
Router(config-if)# switchport port-security aging time 120
```

This example shows how to set the aging time as 2 minutes:

```
Router(config-if)# switchport port-security aging time 2
```

This example shows how to set the aging type on a port to absolute aging:

```
Router(config-if) switchport port-security aging type absolute
```

This example shows how to set the aging type on a port to inactivity aging:

```
Router(config-if) switchport port-security aging type
 inactivity
```

Related Commands

Command	Description
show port-security	Displays information about the port-security setting.

switchport port-security mac-address

To add a MAC address to the list of secure MAC addresses, use the **switchportport-securitymac-address** command. To remove a MAC address from the list of secure MAC addresses, use the **no** form of this command.

switchport port-security mac-address {*mac-addr* | **sticky** [*mac-addr*] [{**vlan** *vlan* [**voice**]*vlan-list*}]}
no switchport port-security mac-address {*mac-addr* | **sticky** [*mac-addr*] [{**vlan** *vlan* [**voice**]*vlan-list*}]}

Syntax Description

mac-addr	MAC addresses for the interface; valid values are from 1 to 1024.
sticky	Configures the dynamic MAC addresses as sticky on an interface.
vlan *vlan* | *vlan-list*	(Optional) Specifies a VLAN or range of VLANs; see the "Usage Guidelines" section for additional information.

Command Default

MAC-addresses are not classified as secured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed as follows on the Supervisor Engine 720: • With Release 12.2(18)SXE and later releases, port security is supported on trunks. • With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports. • The **vlan***vlan* | *vlan-list*keyword and arguments were added. • The **sticky** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you configure fewer secure MAC addresses than the maximum number of secure MAC addresses on all interfaces, the remaining MAC addresses are dynamically learned.

To clear multiple MAC addresses, you must enter the **no** form of this command once for each MAC address to be cleared.

The *vlan-list* argument is visible only if the port has been configured and is operational as a trunk. Enter the **switchportmodetrunk** command and then enter the **switchportnonegotiate** command.

The **sticky** keyword configures the dynamic MAC addresses as sticky on an interface. Sticky MAC addresses configure the static Layer 2 entry to stay sticky to a particular interface. This feature can prevent MAC moves or prevent the entry from being learned on a different interface.

You can configure the sticky feature even when the port security feature is not enabled on the interface. It becomes operational once port security is enabled on the interface.

Note You can enter the **switchportport-securitymac-addresssticky** command only if sticky is enabled on the interface.

When port security is enabled, disabling the sticky feature causes all configured and learned sticky addresses to be deleted from the configuration and converted into dynamic secure addresses.

When port security is disabled, disabling the sticky feature causes all configured and learned sticky addresses to be deleted from the configuration.

For trunk ports, if you enter the **noswitchportport-securitymac-addresssticky** command, a search is conducted for the MAC address in the native VLAN. An error message is displayed if the MAC address is not found in the native VLAN. You must specify the VLAN in the **no** form of the **switchportport-securitymac-addresssticky** command to remove the MAC address.

For voice ports, you must specify the **vlanvoice** keywords in the **no** form of the command.

Examples

This example shows how to configure a secure MAC address:

```
Router(config-if)# switchport port-security mac-address 1000.2000.3000
```

This example shows how to delete a secure MAC address from the address table:

```
Router(config-if)# no switchport port-security mac-address 1000.2000.3000
```

This example shows how to enable the sticky feature on an interface:

```
Router(config-if)# switchport port-security mac-address sticky
```

This example shows how to disable the sticky feature on an interface:

```
Router(config-if)# no switchport port-security mac-address sticky
```

This example shows how to make a specific MAC address as a sticky address:

```
Router(config-if)# switchport port-security mac-address sticky 0000.0000.0001
```

This example shows how to delete a specific sticky address:

```
Router(config-if)# no switchport port-security mac-address sticky 0000.0000.0001
```

This example shows how to delete all sticky and static addresses that are configured on an interface:

```
Router(config-if)# no switchport port-security mac-address
```

The following example shows how to configure a VLAN in the voice port:

```
Router(config-if)# switch port-security mac-address 0.0.1 vlan voice
```

To remove the MAC address 0.0.1 from the voice port, use the following command:

```
Router(config-if)# no switchport port-security mac-address 0.0.1 vlan voice
```

Related Commands

Command	Description
clear port-security	Deletes configured secure MAC addresses and sticky MAC addresses from the MAC address table.
show port-security	Displays information about the port-security setting.
switchport mode trunk	Configures the port as a trunk member.
switchport nonegotiate	Configures the LAN port into permanent trunking mode.

switchport port-security maximum

To set the maximum number of secure MAC addresses on a port, use the **switchportport-securitymaximum**command in interface configuration mode. To return to the default settings, use the **no** form of this command.

switchport port-security maximum *maximum* [{**vlan** *vlanvlan-list*}]
no switchport port-security maximum

Syntax Description

maximum	M aximum number of secure MAC addresses for the interface; valid values are from 1 to 4097.
vlan *vlan* | *vlan-list*	(Optional) Specifies a VLAN or range of VLANs; see the "Usage Guidelines" section for additional information.

Command Default

This command has no default setings .

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to the Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed as follows on the Supervisor Engine 720 only: • The maximum number of secure MAC addresses was changed from 1024 to 4097. • The **vlan***vlan* | *vlan-list*keyword and arguments were added. • With Release 12.2(18)SXE and later releases, port security is supported on trunks. • With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you enter this command more than once, subsequent use of this command overrides the previous value of *maximum*. If the new *maximum*argument is larger than the current number of the secured addresses on this port, there is no effect except to increase the value of the *maximum*.

If the new *maximum* is smaller than the old *maximum* and there are more secure addresses on the old *maximum*, the command is rejected.

If you configure fewer secure MAC addresses than the maximum number of secure MAC addresses on the port, the remaining MAC addresses are dynamically learned.

Once the maximum number of secure MAC addresses for the port is reached, no more addresses are learned on that port even if the per-VLAN port maximum is different from the aggregate maximum number.

You can override the maximum number of secure MAC addresses for the port for a specific VLAN or VLANs by entering the **switchportport-securitymaximum***maximum***vlan***vlan*|*vlan-list*command.

The *vlan-list* argument allows you to enter ranges, commas, and delimited entries such as 1,7,9-15,17.

The *vlan-list* argument is visible only if the port has been configured and is operational as a trunk. Enter the **switchportmodetrunk** command and then enter the **switchportnonegotiate** command.

Examples

This example shows how to set the maximum number of secure MAC addresses that are allowed on this port:

```
Router(config-if)# switchport port-security maximum 5
```

This command shows how to override the maximum set for a specific VLAN:

```
Router(config-if)# switchport port-security maximum 3 vlan 102
```

Related Commands

Command	Description
show port-security	Display information about the port-security setting.
switchport nonegotiate	Configures the LAN port into permanent trunking mode.

switchport port-security violation

To set the action to be taken when a security violation is detected, use the **switchportport-securityviolation** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

switchport port-security violation {**shutdown** | **restrict** | **protect**}
no switchport port-security violation {**shutdown** | **restrict** | **protect**}

Syntax Description

shutdown	Shuts down the port if there is a security violation.
restrict	Drops all the packets from the insecure hosts at the port-security process level and increments the security-violation count.
protect	Drops all the packets from the insecure hosts at the port-security process level but does not increment the security-violation count.

Command Default

The port security violation is shutdown.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed as follows on the Supervisor Engine 720: • With Release 12.2(18)SXE and later releases, port security is supported on trunks. • With Release 12.2(18)SXE and later releases, port security is supported on 802.1Q tunnel ports.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(14)SXH	**Platform port-security disable traps** was introduced as part of protect violation mode.

Usage Guidelines

When a security violation is detected, one of the following actions occurs:

- Protect--When the number of port-secure MAC addresses reaches the maximum limit that is allowed on the port, the packets with unknown source addresses are dropped until you remove a sufficient number of secure MAC addresses. Platform port-security disable traps is configurable only when the violation mode is set to **protect**. When this option is configured, drop entries will not be installed into hardware for violating addresses, thus allowing traffic to continue to flow to violating address from legitimate ports. To protect switch CPU against overload when this option is enabled, we recommend that you configure the port-security rate-limiter to 2000 packets per second with a burst rate of 10.

Note This feature also permits traffic to legitimate ports from insecure MAC addresses.

- Restrict--A port-security violation restricts data and causes the security-violation counter to increment.
- Shutdown--The interface is error disabled when a security violation occurs.

Note When a secure port is in the error-disabled state, you can bring it out of this state by entering the **errdisablerecoverycausepsecure-violation** global configuration command or you can manually reenable it by entering the **shutdown** and **noshutdown** commands in interface-configuration mode.

Examples

This example shows how to set the action to be taken when a security violation is detected:

```
Router(config-if)# switchport port-security violation restrict
```

This example allows the traffic to a secured MAC address on one port to flow even in the presence of violations on other ports while in protect mode.

```
Router(config-if)# switchport port-security violation protect
Router(config-if)# platform port-security disable traps
```

Related Commands

Command	Description
show port-security	Displays information about the port-security setting.
errdisable recovery cause psecure-violation (global configuration)	Removes a secure port from an error-disabled state.
platform port-security disable traps	Modifies the behavior of protect violation mode.

switchport private-vlan host-association

To define a PVLAN association for an isolated or community port, use the **switchportprivate-vlanhost-association**command in i nterface configuration mode . To remove the PVLAN mapping from the port, use the **no** form of this command.

switchport private-vlan host-association *primary-vlan-id secondary-vlan-id*
no switchport private-vlan host-association

Syntax Description

primary-vlan-id	Number of the primary VLAN of the PVLAN relationship; valid values are from 1 to 4094.
secondary-vlan-id	Number of the secondary VLAN of the private VLAN relationship; valid values are from 1 to 4094.

Command Default

No PVLAN is configured.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to t Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

There is no run-time effect on the port unless it is in PVLAN-host mode. If the port is in PVLAN-host mode but neither of the VLANs exist, the command is allowed but the port is made inactive.

The secondary VLAN may be an isolated or community VLAN.

Examples

This example shows how to configure a port with a primary VLAN (VLAN 18) and secondary VLAN (VLAN 20):

```
Router(config-if)#
switchport private-vlan host-association 18 20
```

This example shows how to remove the PVLAN association from the port:

```
Router(config-if)#
no switchport private-vlan host-association
```

Related Commands

Command	Description
switchport mode	Displays the administrative and operational status of a switching (nonrouting) port.

switchport private-vlan mapping

To define the PVLAN mapping for a promiscuous port, use the **switchportprivate-vlanmapping** command in interface configuration mode. To clear all mappings from the primary VLAN, use the **no** form of this command.

{**switchport private-vlan mapping primary-vlan-id secondary-vlan-list | add secondary-vlan-list | remove secondary-vlan-list**}
no switchport private-vlan mapping

Syntax Description

primary-vlan-id	Number of the primary VLAN of the PVLAN relationship; valid values are from 1 to 4094.
secondary-vlan- list	Number of the secondary VLAN of the private VLAN relationship; valid values are from 1 to 4094.
add	Maps the secondary VLANs to the primary VLAN.
remove	Clears mapping between the secondary VLANs and the primary VLAN.

Command Default

No PVLAN mappings are configured.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

There is no run-time effect on the port unless it is in PVLAN-promiscuous mode. If the port is in PVLAN-promiscuous mode but the VLANs do not exist, the command is allowed but the port is made inactive.

The secondary VLAN may be an isolated or community VLAN.

Examples

This example shows how to configure the mapping of primary VLAN 18 to secondary isolated VLAN 20 on a port:

```
Router(config-if)#
switchport private-vlan mapping 18 20
```

This example shows how to add a VLAN to the mapping:

```
Router(config-if)#
switchport private-vlan mapping 18 add 21
```

This example shows how to remove the PVLAN mapping from the port:

```
Router(config-if)#
no switchport private-vlan mapping
```

Related Commands

Command	Description
show interfaces private-vlan mapping	Displays the information about the PVLAN mapping for VLAN SVIs.

switchport protected

Use the switch**portprotected**command to isolate unicast, multicast, and broadcast traffic at Layer 2 from other protected ports on the same switch in interface configuration mode. To disable protection on the port, use the **no** form of the command.

switchport protected
no switchport protected

Syntax Description

This command has no arguments or keywords.

Command Default

No protected port is defined. All ports are nonprotected.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.1(4)EA1	This command was first introduced.
12.4(15)T	This command was implemented on the following platforms: the Cisco 1841 Integrated Services Router (ISR), Cisco 2800 series ISRs, and Cisco 3800 series ISRs.

Usage Guidelines

The switchport protection feature is local to the switch; communication between protected ports on the same switch is possible only through a Layer 3 device. To prevent communication between protected ports on different switches, you must configure the protected ports for unique VLANs on each switch and configure a trunk link between the switches.

Beginning with Cisco IOS Release 12.4(15)T, the following Cisco ISRs support port protection when an appropriate high-speed WAN interface card (HWIC) is installed:

- Cisco 1841 ISR
- Cisco 2800 Series ISRs, including models 2801, 2811, 2821, and 2851
- Cisco 3800 Series ISRs, including models 3825 and 3845

To support port protection, the Cisco routers listed above must be equipped with one of the following HWICs:

- HWIC-4ESW
- HWIC-D-9ESW

Note Only the ports attached to the HWICs can be configured with port protection.

A protected port does not forward any unicast, multicast, or broadcast traffic to any other protected port. A protected port continues to forward unicast, multicast, and broadcast traffic to unprotected ports and vice versa.

Port monitoring does not work if both the monitor and monitored ports are protected ports.

A protected port is different from a secure port.

Examples

The following example shows how to enable a protected port on an interface:

```
Switch(config)# interface gigabitethernet0/3
Switch(config-if)# switchport protected
```

You can verify the previous command by entering the**showinterfacesswitchport**privileged EXEC command.

Related Commands

Command	Description
show interfaces switchport	Displays the administrative and operational status of a switching (nonrouting) port, including port blocking and port protection settings.
switchport block	Prevents unknown multicast or unicast traffic on the interface.

switchport trunk

To set the trunk characteristics when the interface is in trunking mode, use the **switchport trunk** command in interface configuration mode. To reset all of the trunking characteristics back to the original defaults, use the **no** form of this command.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers
switchport trunk {**encapsulation dot1q** | **native vlan** | **allowed vlan**}
no switchport trunk {**encapsulation dot1q** | **native vlan** | **allowed vlan**}

Cisco 7600 Series Routers and Catalyst 6500 Series Switches
{**switchport trunk encapsulation** {**isl** | **dot1q** [**ethertype** *value*] | **negotiate**} | **native vlan** {**tag***vlan-id*} | **allowed vlan** *vlan-list* | **pruning vlan** *vlan-list*}
no switchport trunk {**encapsulation** {**isl** | **dot1q** [**ethertype** *value*] | **negotiate**} | **native vlan** [**tag**] | **allowed vlan** | **pruning vlan**}

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers
switchport trunk {**native vlan** *vlan-id* | **allowed vlan** *vlan-list*}
no switchport trunk {**native vlan** *vlan-id* | **allowed vlan** *vlan-list*}

Syntax Description

encapsulation isl	Sets the trunk encapsulation format to Inter-Switch Link (ISL).
encapsulation dot1q	Sets the trunk encapsulation format to 802.1Q.
native vlan	Sets the native VLAN for the trunk in 802.1Q trunking mode.
allowed vlan *vlan list*	Sets the list of allowed VLANs that transmit traffic from this interface in tagged format when in trunking mode.
ethertype *value*	(Optional) Sets the EtherType value; valid values are from 0x0 to 0x5EF-0xFFFF.
encapsulation negotiate	Specifies that if the Dynamic Inter-Switch Link (DISL) protocol and Dynamic Trunking Protocol (DTP) negotiation do not resolve the encapsulation format, ISL is the selected format.
native vlan tag	Enables the native VLAN tagging state on the interface.
native vlan *vlan id*	The particular native VLAN.
pruning vlan *vlan list*	Sets the list of VLANs that are enabled for VLAN Trunking Protocol (VTP) pruning when the interface is in trunking mode. See the “Usage Guidelines” section for the *vlanlist*argument formatting guidelines.

Table 283: Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

native vlan *vlan-id*	The particular native VLAN. Valid values are: • 1-2349—VLAN ID Range 1 • 2450-4095—VLAN ID Range 2

allowed vlan *vlan-list*	Sets the list of allowed VLANs that transmit traffic from this interface in tagged format when in trunking mode. **Note** For *vlan-list* format, see **Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers** section under **Usage Guidelines**.

Command Default

- The default encapsulation type is dot1q.
- The default access VLAN and trunk interface native VLAN are default VLANs that correspond to the platform or interface hardware.
- The default for all VLAN lists is to include all VLANs.

- The encapsulation type is dependent on the platform or interface hardware.
- The access VLAN and trunk interface native VLAN are default VLANs that correspond to the platform or interface hardware.
- The default for all VLAN lists is to include all VLANs.
- **ethertype** *value* for 802.1Q encapsulation is 0x8100.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.0(7)XE	This command was introduced on the Catalyst 6500 series switches.
12.1(1)E	Switchport creation on Catalyst 6500 series switches was added.
12.2(2)XT	This command was introduced to support switchport creation on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support switch port creation on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(14)SX	This command was integrated into Cisco IOS Release 12.2(14)SX to support the Supervisor Engine 720 on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.2(17a)SX	This command was modified to include the following: • Restriction of ISL trunk-encapsulation. • Addition of the **dot1q** keyword and **ethertype***value* keyword and argument.
12.2(17d)SXB	Support for the Supervisor Engine 2 on the Cisco 7600 series routers and Catalyst 6500 series switches was added.
12.2(18)SXD	This command was modified to allow the **switchport trunk allowed vlan**command to be entered on interfaces where the span destination port is either a trunk or an access port.

Release	Modification
12.2(18)SXE	This command added a restriction that Gigabit Ethernet (GE) Optimized Layer 2 WAN ports are not supported on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(15)T	This command was modified to extend the range of valid VLAN IDs from 1 to 4094 for specified platforms.
12.2(33)SXH	This command was changed as follows: • Allowed the tagging of native VLAN traffic on a per-port basis. • Introduced on the Supervisor Engine 720-10GE.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Routers (ISR).

Usage Guidelines

802.1Q Trunks

- When you connect Cisco switches through an 802.1Q trunk, make sure that the native VLAN for an 802.1Q trunk is the same on both ends of the trunk link. If the native VLAN on one end of the trunk is different from the native VLAN on the other end, spanning-tree loops might result.
- Disabling spanning tree on the native VLAN of an 802.1Q trunk without disabling spanning tree on every VLAN in the network can cause spanning-tree loops. Cisco recommends that you leave spanning tree enabled on the native VLAN of an 802.1Q trunk. If this is not possible, disable spanning tree on every VLAN in the network. Make sure that your network is free of physical loops before disabling spanning tree.
- When you connect two Cisco switches through 802.1Q trunks, the switches exchange spanning-tree bridge protocol data units (BPDUs) on each VLAN allowed on the trunks. The BPDUs on the native VLAN of the trunk are sent untagged to the reserved IEEE 802.1d spanning-tree multicast MAC address (01-80-C2-00-00-00). The BPDUs on all other VLANs on the trunk are sent tagged to the reserved Shared Spanning Tree Protocol (SSTP) multicast MAC address (01-00-0c-cc-cc-cd).
- The 802.1Q switches that are not Cisco switches maintain only a single instance of spanning-tree (Mono Spanning Tree [MST]) that defines the spanning-tree topology for all VLANs. When you connect a Cisco switch to a switch through an 802.1Q trunk without a Cisco switch, the MST of the switch and the native VLAN spanning tree of the Cisco switch combine to form a single spanning-tree topology known as the Common Spanning Tree (CST).
- Because Cisco switches transmit BPDUs to the SSTP multicast MAC address on VLANs other than the native VLAN of the trunk, switches that are not Cisco switches do not recognize these frames as BPDUs and flood them on all ports in the corresponding VLAN. Other Cisco switches connected to the 802.1Q cloud receive these flooded BPDUs. This condition allows Cisco switches to maintain a per-VLAN spanning-tree topology across a cloud of 802.1Q switches that are not Cisco switches. The 802.1Q cloud of switches separating the Cisco switches is treated as a single broadcast segment among all switches connected to the 802.1Q cloud of switches that are not Cisco switches through 802.1Q trunks.
- Make sure that the native VLAN is the same on *all* of the 802.1Q trunks that connect the Cisco switches to the 802.1Q cloud of switches that are not Cisco switches.

- If you are connecting multiple Cisco switches to a 802.1Q cloud of switches that are not Cisco switches, all of the connections must be through 802.1Q trunks. You cannot connect Cisco switches to an 802.1Q cloud of switches that are not Cisco switches through ISL trunks or through access ports. Doing so will cause the switch to place the ISL trunk port or access port into the spanning-tree “port inconsistent” state and no traffic will pass through the port.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

The **switchport trunk encapsulation** command is supported only for platforms and interface hardware that can support 802.1Q formats.

The *vlanlist* format is **all | none | add | remove | except***vlanlist*[,*vlanlist*...] where:

- **all** --Specifies all VLANs from 1 to 1005. Beginning with Cisco IOS Release 12.4(15)T, the valid VLAN ID range is from 1 to 4094.
- **none** --Indicates an empty list. This keyword is not supported in the **switchport trunk allowed vlan** form of the command.
- **add** --Adds the defined list of VLANs to those currently set instead of replacing the list.
- **remove** --Removes the defined list of VLANs from those currently set instead of replacing the list.
- **except** --Lists the VLANs that should be calculated by inverting the defined list of VLANs.
- *vlan list*-- Is either a single VLAN number from 1 to 1005 or a continuous range of VLANs described by two VLAN numbers, the lesser one first, separated by a hyphen that represents the VLAN IDs of the allowed VLANs when this port is in trunking mode. Beginning with Cisco IOS Release 12.4(15)T, the valid VLAN ID range is from 1 to 4094.

Cisco 7600 Series Routers and Catalyst 6500 Series Switches

This command is not supported on GE Layer 2 WAN ports.

You can enter the **switchport trunk** command only on the PO. If you enter the **switchport trunk** command on a port member the following message is displayed:

```
Configuration is not allowed on Port members. Remove the interface from the Port Channel
to modify its config
```

The **switchport trunk encapsulation dot1q**command is supported only for platforms and interface hardware that can support both ISL and 802.1Q formats. Only 802.1Q encapsulation is supported by shared port adapters (SPAs).

If you enter the **switchport trunk encapsulation isl** command on a port channel containing an interface that does not support ISL-trunk encapsulation, the command is rejected.

You can enter the **switchport trunk allowed vlan** command on interfaces where the span destination port is either a trunk or an access port.

You can enter the **switchport trunk native vlan tag** command to enable the tagging of native VLAN traffic on a per-port basis. When tagging is enabled, all the packets on the native VLAN are tagged and all incoming untagged data packets are dropped, but untagged control packets are accepted. When tagging is disabled, the native VLAN packets going out on trunk ports are not tagged and the incoming untagged packets are allowed and assigned to the native VLAN. The **no switchport trunknative vlan tag** command overrides the **vlan dot1q tag native** command for global tagging.

Note The **switchport trunk native vlan tag** interface configuration mode command does not enable native VLAN tagging unless you first configure the switch to tag native VLAN traffic globally. To enable native VLAN tagging globally, use the **vlan dot1q tag native** command in global configuration mode.

Note The **switchport trunk pruning vlan** *vlan-list* command does not support extended-range VLANs; valid *vlan-list* values are from 1 to 1005.

The **dot1q ethertype** *value* keyword and argument are not supported on port-channel interfaces. You can enter the command on the individual port interface only. Also, you can configure the ports in a channel group to have different EtherType configurations.

Caution Be careful when configuring the custom EtherType value on a port. If you enter the **negotiate** keyword and DISL and Dynamic Trunking Protocol (DTP) negotiation do not resolve the encapsulation format, then ISL is the selected format and may pose as a security risk. The **no** form of this command resets the trunk-encapsulation format to the default.

- The **no** form of the **switchport trunk native vlan** command resets the native mode VLAN to the appropriate default VLAN for the device.
- The **no** form of the **switchport trunk native vlan tag** command configures the Layer 2 port not to tag native VLAN traffic.
- The **no** form of the **switchport trunk allowed vlan** command resets the list to the default list, which allows all VLANs.
- The **no** form of the **switchport trunk pruning vlan**command resets the list to the default list, which enables all VLANs for VTP pruning.
- The **no** form of the **switchport trunk encapsulation dot1qethertype***value* command resets the list to the default value.

The *vlan-list* format is **all** | **none** | **add** | **remove** | **except** [*vlan-list*[**,***vlan-list*...]] where:

- **all** --Specifies all the appropriate VLANs. This keyword is not supported in the **switchporttrunkpruningvlan** command.
- **none** --Indicates an empty list. This keyword is not supported in the **switchporttrunkallowedvlan** command.
- **add** *vlan-list* **,** *vlan-list...*]-- Adds the defined list of VLANs to those currently set instead of replacing the list.
- **remove** *vlan-list* **,** *vlan-list...*]-- Removes the defined list of VLANs from those currently set instead of replacing the list. You can remove VLAN 1. If you remove VLAN 1 from a trunk, the trunk interface continues to send and receive management traffic (for example, Cisco Discovery Protocol, version 3; VTP; Port Aggregation Protocol, version 4 (PAgP4); and DTP) in VLAN 1.

Note You can remove any of the default VLANs (1002 to 1005) from a trunk; this action is not allowed in earlier releases.

- **except** *vlan-list* **,** *vlan-list...*] --Excludes the specified list of VLANs from those currently set instead of replacing the list.
- *vlan-list* **,** *vlan-list...* -- Specifies a single VLAN number from 1 to 4094 or a continuous range of VLANs that are described by two VLAN numbers from 1 to 4094. You can specify multiple VLAN numbers or ranges of numbers using a comma-separated list.

To specify a range of VLANs, enter the smaller VLAN number first, separated by a hyphen and the larger VLAN number at the end of the range.

Do not enable the reserved VLAN range (1006 to 1024) on trunks when connecting a Cisco 7600 series router running the Cisco IOS software on both the supervisor engine and the Multilayer Switch Feature Card (MSFC) to a Cisco 7600 series router running the Catalyst operating system. These VLANs are reserved in Cisco 7600 series routers running the Catalyst operating system. If enabled, Cisco 7600 series routers running the Catalyst operating system may disable the ports if a trunking channel is between these systems.

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

Note To set trunk characteristics, the interface must be in trunk mode.

The *vlan-list* format is **all** | **none** | **add** | **remove** | **except** | **WORD**, where:

- **all**—Specifies all VLANs: 1-2349—VLAN IDs in range 1; and 2450-4095—VLAN IDs in range 2.
- **none**—Indicates an empty list.
- **add**—Adds the defined list of VLANs to those currently set instead of replacing the list.
- **remove**—Removes the defined list of VLANs from those currently set instead of replacing the list.
- **except**—Lists the VLANs that should be calculated by inverting the defined list of VLANs.
- **WORD**—Is either a single VLAN number from 1 to 4095 or a continuous range of VLANs described by two VLAN numbers, the lesser one first, separated by a hyphen that represents the VLAN IDs of the allowed VLANs when this port is in trunking mode.

Examples

The following example shows how to cause a port interface configured as a switched interface to encapsulate in 802.1Q trunking format regardless of its default trunking format in trunking mode:

Router(config-if)# switchport trunk encapsulation dot1q

The following example shows how to configure the Layer 2 port to tag native VLAN traffic:

```
Router(config-if)#
switchport trunk native vlan tag
```

Cisco UCS E-Series Server Installed in Cisco 4400 Integrated Services Routers

Note To set trunk characteristics, the interface must be in trunk mode.

The following example shows how to allow trunking on specified VLANs:

```
Router(config)# interface ucse 1/0/0
Router(config-if)# switchport mode trunk
Router(config-if)# switchport trunk allowed vlan 1-2,40,60,1002-1005
```

Related Commands

Command	Description
show interfaces switchport	Displays administrative and operational status of a switching (nonrouting) port.
vlan dot1q tag native	Enables dot1q tagging for all VLANs in a trunk.

switchport vlan mapping

To map the traffic arriving on the VLAN original-vlan-id to the VLAN translated-vlan-id and the traffic that is internally tagged with the VLAN translated-vlan-id with the VLAN original-vlan-id before leaving the port, use the **switchportvlanmapping** command in interface configuration mode. To clear the mapping between a pair of VLANs or clear all the mappings that are configured on the switch port, use the **no** form of this command.

switchport vlan mapping *original-vlan-id translated-vlan-id*
no switchport vlan mapping {*original-vlan-id translated-vlan-id* | **all**}

Syntax Description

original-vlan-id	Original VLAN number; valid values are from 1 to 4094.
translated-vlan-id	Translated VLAN number; valid values are from 1 to 4094.
all	Clears all the mappings that are configured on the switch port.

Command Default

No mappings are configured on any switch port.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17b)SXA	Support for this command was introduced on the Supervisor Engine 720.
12.2(18)SXE	This command is not supported on GE Layer 2 WAN ports.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

This command is not supported on GE Layer 2 WAN ports.

You must enable VLAN translation on the port where you want VLAN translation to work. Use the **switchportvlanmappingenable** command to enable VLAN translation.

Do not remove the VLAN that you are translating from the trunk. When you map VLANs, make sure that both VLANs are allowed on the trunk that carries the traffic.

The table below lists the VLAN translation, the type of VLAN translation support, the number of ports that you can configure per port group, and the trunk type for each module that supports VLAN translation.

Table 284: Modules That Support VLAN Translation

Product Number	VLAN Translation Support Type	Number of Port Groups	Port Ranges per Port Group	Translations per Port Group	VLAN Translation Trunk-Type Support
WS-SUP720	Per port group	1	1-2	32	802.1Q
WS-X6704-10GE	Per port	4	1 port in each group	128	ISL and 802.1Q
WS-X6501-10GEX4	Per port	1	1 port in 1 group	32	802.1Q

Product Number	VLAN Translation Support Type	Number of Port Groups	Port Ranges per Port Group	Translations per Port Group	VLAN Translation Trunk-Type Support
WS-X6502-10GE	Per port	1	1 port in 1 group	32	802.1Q
WS-X6724-SFP	Per port group	2	1-12, 13-24	128	ISL and 802.1Q
WS-X6816-GBIC	Per port group	4	1-8, 9-16	32	802.1Q
WS-X6516A-GBIC	Per port group	2	1-8, 9-16	32	802.1Q
WS-X6516-GBIC	Per port group	2	1-8, 9-16	32	802.1Q
WS-X6748-GE-TX	Per port group	4	1-12, 13-24, 25-36, 37-48	128	ISL and 802.1Q
WS-X6516-GE-TX	Per port group	2	1-8, 9-16	32	802.1Q
WS-X6524-100FX-MM	Per port group	1	1-24	32	ISL and 802.1Q
WS-X6548-RJ-45	Per port group	1	1-48	32	ISL and 802.1Q
WS-X6548-RJ-21	Per port group	1	1-48	32	ISL and 802.1Q

The mapping that you configured using the **switchportvlanmapping** command does not become effective until the switch port becomes an operational trunk port.

The VLAN mapping that is configured on a port may apply to all the other ports on the same ASIC. In some cases, a mapping that is configured on one of the ports on an ASIC can overwrite a mapping that is already configured on another port on the same ASIC.

The port VLAN mapping is applied to all the ports on a port ASIC if that ASIC does not support per-port VLAN mapping.

If you configure VLAN mapping on the port ASIC that is a router port, the port-VLAN mapping does not take effect until the port becomes a switch port.

You can map any two VLANs regardless of the trunk types carrying the VLANs.

Examples

This example shows how to map the original VLAN to the translated VLAN:

```
Router(config-if)#
 switchport vlan mapping 100 201
```

This example shows how to clear the mappings that are between a pair of VLANs:

```
Router(config-if)#
 no switchport vlan mapping 100 201
```

This example shows how to clear all the mappings that are configured on the switch port:

```
Router(config-if)#
 no switchport vlan mapping all
```

Related Commands

Command	Description
show interfaces vlan mapping	Display the status of a VLAN mapping on a port.
show vlan mapping	Registers a mapping of an 802.1Q VLAN to an ISL VLAN.
switchport vlan mapping enable	Enables VLAN mapping per switch port.

switchport vlan mapping enable

To enable VLAN mapping per switch port, use the **switchportvlanmappingenable** command in interface configuration mode. To disable VLAN mapping per switch port, use the **no** form of this command.

switchport vlan mapping enable
no switchport vlan mapping enable

Syntax Description

This command has no arguments or keywords.

Command Default

VLAN mapping is disabled on all switch ports.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17b)SXA	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

Note You must enter the **switchportvlanmappingenable** command on the port where you want the mapping to take place.

The switchport vlan mapping enable command enables or disables VLAN-mapping lookup in the hardware regardless of whether the mapping is configured by the global VLAN mapping command or the switchport VLAN mapping command.

This command is useful on the hardware that supports VLAN mapping per ASIC only because you can turn on or off VLAN translation selectively on ports that are connected to the same port ASIC.

Examples

This example shows how to enable VLAN mapping per switch port:

```
Router(config-if)#
 switchport vlan mapping enable
```

This example shows how to disable VLAN mapping per switch port:

```
Router(config-if)#
 no switchport vlan mapping enable
```

Related Commands

Command	Description
show interfaces vlan mapping	Displays the status of a VLAN mapping on a port.
show vlan mapping	Registers a mapping of an 802.1Q VLAN to an ISL VLAN.

Command	Description
switchport vlan mapping	Maps the traffic arriving on the VLAN original-vlan-id to the VLAN translated-vlan-id and the traffic that is internally tagged with the VLAN translated-vlan-id with the VLAN original-vlan-id before leaving the port.

switchport voice vlan

To configure a voice VLAN on a multiple-VLAN access port, use the **switchportvoicevlan** command in interface configuration mode. To remove the voice VLAN from the switch port, use the **no** form of the command.

switchport voice vlan {*vlan-id* | **dot1p** | **none** | **untagged**}
no switchport voice vlan

Syntax Description

vlan id	Voice VLAN identifier (VVID) of the VLAN used for voice traffic. Valid IDs are from 1 to 1005 (IDs 1006 to 4096 are not supported). Do not enter leading zeros. The switch port is an 802.1Q trunk port.
dot1p	The telephone uses priority tagging and uses VLAN 0. The switch port is an 802.1Q trunk port.
none	The telephone is not instructed through the command line interface (CLI) about the voice VLAN. The telephone uses its own configuration from the telephone keypad and transmits untagged voice traffic in the default VLAN.
untagged	The telephone does not tag frames; it uses VLAN 4095. The switch port can be an access port or an 802.1Q trunk port.

Command Default

The switch default is to not automatically configure the telephone (**none**).

The Cisco IP 7960 telephone default is to generate an 802.1Q/802.1P frame.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(2)XT	This command was introduced.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support creation of switchports .
12.2(14)SX	This command was integrated into Cisco IOS Release 12.2(14)SX and introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was integrated into Cisco IOS Release 12.2(17d)SXB and introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	This command was integrated into Cisco IOS Release 12.2(33)SXI.

Usage Guidelines

This command does not create a voice VLAN. You can create a voice VLAN in VLAN-configuration mode by entering the **vlan(globalconfigurationmode)** command. If you configure both the native VLAN and the voice VLAN in the VLAN database and set the switch port to multiple-VLAN access mode, this command brings up the switch port as operational.

If you enter a voice VLAN identifier, the switch port sends CDP packets that configure the IP phone to transmit voice traffic in the voice VLAN in 802.1Q frames that are tagged with a Layer 2 CoS value . The default Layer 2 CoS is 5. The default Layer 3 IP-precedence value is 5.

If you enter dot1p, the switch port sends CDP packets that configure the IP phone to transmit voice traffic in the default VLAN in 802.1p frames that are tagged with a Layer 2 CoS value.

If you enter none, the switch port does not send CDP packets with VVID TLVs.

If you enter **untagged**, the switch port is enabled to receive untagged packets only.

Examples

This example shows how to create an operational multiple-VLAN access port with VLAN 101 as the voice VLAN:

```
Router(config-if)# switchport
Router(config-if)# switchport mode access
Router(config-if)# switchport access vlan 100
Router(config-if)# switchport voice vlan 101
Router(config-if)
```

This example shows how to change the multiple-VLAN access port to a normal access port:

```
Router(config-if)# interface fastethernet5/1
Router(config-if)# no switchport voice vlan
Router(config-if)
```

Related Commands

Command	Description
switchport access vlan	Sets the VLAN when the interface is in access mode.
switchport mode	Sets the interface type.

sync interval

To specify an interval for the device to exchange Precision Time Protocol synchronization messages, use the **sync interval** command in PTP port configuration mode. To disable a sync interval configuration, use the **no** form of this command.

sync interval *interval-value*
no sync interval *interval-value*

Syntax Description

interval-value	Value of the interval at which the device sends sync packets. The intervals are set using log base 2 values, as follows: • 4—1 packet every 16 seconds • 3—1 packet every 8 seconds • 2—1 packet every 4 seconds • 1—1 packet every 2 seconds • 0—1 packet every second • -1—1 packet every 1/2 second, or 2 packets per second • -2—1 packet every 1/4 second, or 4 packets per second • -3—1 packet every 1/8 second, or 8 packets per second • -4—1 packet every 1/16 seconds, or 16 packets per second • -5—1 packet every 1/32 seconds, or 32 packets per second • -6—1 packet every 1/64 seconds, or 64 packets per second The recommended value is -6.

Command Default

The default value is 1.

Command Modes

PTP port configuration (config-ptp-port)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Examples

The following example shows how to configure the PTP sync interval:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# clock-port slave slaveport
Device(config-ptp-port)# sync interval -4
Device(config-ptp-port)# end
```

Related Commands

Command	Description
clock-port	Specifies the mode of a PTP clock port.

sync-restart-delay

To set the synchronization-restart delay timer to ensure accurate status reporting, use the **sync-restart-delay** command in interface configuration mode. To disable the synchronization-restart delay timer, use the **no** form of this command.

sync-restart-delay *timer*
no sync-restart-delay *timer*

Syntax Description

timer	Interval between status-register resets; valid values are from 200 to 60000 milliseconds.

Command Default

timer is **210** milliseconds.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Gigabit Ethernet fiber ports only.

The status register records the current status of the link partner.

Examples

This example shows how to set the Gigabit Ethernet synchronization-restart delay timer:

```
Router(config-if)# sync-restart-delay 2000
```

Related Commands

Command	Description
show running-config	Displays the status and configuration of the module or Layer 2 VLAN.

syscon address

To specify the system controller for a managed shelf, use the **sysconaddress** command in global configuration mode. To stop the management of the shelf by the system controller, use the **no** form of this command.

syscon address *ip-address password*
no syscon address

Syntax Description

ip-address	IP address of the system controller.
password	Password string.

Command Default

No system controller is specified.

Command Modes

Global configuration

Command History

Release	Modification
11.3AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is required in order for the shelf to be managed by the system controller.

Examples

The following example configures a shelf to be managed by a system controller at 10.2.3.4 using the password green:

```
Router# syscon address 10.2.3.4 green
```

Related Commands

Command	Description
show syscon sdp	Displays information about the Shelf Discovery Protocol.
syscon source-interface	Specifies the interface to use for the source address in SDP packets.

syscon shelf-id

To specify a shelf ID for a managed shelf, use the **sysconshelf-id**command in global configuration mode. To remove the shelf ID, use the **no** form of this command.

syscon shelf-id *number*
no syscon shelf-id

Syntax Description

number	Shelf ID. The value ranges from 0 to 9999.

Command Default

No shelf ID is specified.

Command Modes

Global configuration

Command History

Release	Modification
11.3AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to specify a shelf ID for a managed shelf. Some platforms, such as the Cisco AS5800, use other commands to assign a shelf ID. In these situations, do not specify a shelf ID with the **sysconshelf-id** command. Use the platform-specific command instead.

Examples

The following example configures a shelf ID of 5 for the managed shelf:

```
Router# syscon shelf-id 5
```

Related Commands

Command	Description
show syscon sdp	Displays information about the Shelf Discovery Protocol.
syscon address	Specifies the system controller for a managed shelf.

syscon source-interface

To specify the interface to use for the source address in Shelf Discovery Protocol (SDP) packets, use the **sysconsource-interface**command in global configuration mode. To return to the default source interface for a packet (the interface that sent the packet from the shelf), use the **no** form of this command.

syscon source-interface *type number*
no syscon source-interface

Syntax Description

type number	Type and number of the interface to use for the source IP address.

Command Default

SDP packets use the IP address of the output interface.

Command Modes

Global configuration

Command History

Release	Modification
11.3AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to ensure that all SDP packets sent by the managed shelf have the same source IP address.

Examples

The following example configures a shelf to use the IP address of Ethernet interface 99/1/0:

```
Router# syscon source-address Ethernet99/1/0
```

Related Commands

Command	Description
show syscon sdp	Displays information about the Shelf Discovery Protocol.
syscon shelf-id	Specifies a shelf ID for a managed shelf.

system flowcontrol bus

To set the FIFO overflow error count, use the **system flowcontrol bus** command in global configuration mode. To return to the original FIFO threshold settings, use the **no** form of this command.

[**default**] **system flowcontrol bus** {**auto** | **on**}
no system flowcontrol bus

Syntax Description

default	(Optional) Specifies the default settings.
auto	Monitors the FIFO overflow error count and sends a warning message if the FIFO overflow error count exceeds a configured error threshold in 5-second intervals.
on	Specifies the original FIFO threshold settings.

Command Default

auto

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720 and the Supervisor Engine 32.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Note We recommend that you leave the system flow control in auto mode and use the other modes under the advice of Cisco TAC only.

Examples

This example shows how to monitor the FIFO overflow error count and send a warning message if the FIFO overflow error count exceeds a configured error threshold in 5-second intervals:

```
Router(config)# system flowcontrol bus auto
```

This example shows how to specify the original FIFO threshold settings:

```
Router(config)# system flowcontrol bus on
```

system jumbomtu

To set the maximum size of the Layer 2 and Layer 3 packets, use the system **jumbo**mtu command in global configuration mode. To revert to the default MTU setting, use the **no** form of this command.

system jumbomtu mtu-size
no system jumbomtu

Syntax Description

mtu-size	Maximum size of the Layer 2 and Layer 3 packet s; valid values are from 1500 to 9216 bytes.

Command Default

mtu-size is **9216** bytes.

Command Modes

Global configuration

Command History

Release	Modification
1.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *mtu-size* parameter specifies the Ethernet packet size, not the total Ethernet frame size. The Layer 3 MTU is changed as a result of entering the **system jumbo**mtucommand.

The **system jumbo**mtucommand enables the global MTU for port ASICs. On a port ASIC after jumbo frames are enabled, the port ASIC accepts any size packet on the ingress side and checks the outgoing packets on the egress side. The packets on the egress side that exceed the global MTU are dropped by the port ASIC.

For example, if you have port A in VLAN 1 and Port B in VLAN 2, and if VLAN 1 and VLAN 2 are configured for **mtu 9216** and you enter the **system jumbomtu 4000** command, the packets that are larger than 4000 bytes are not transmitted out because Ports B and A drop anything larger than 4000 bytes.

Examples

This example shows how to set the global MTU size to 1550 bytes:

```
Router(config)# system jumbomtu 1550
```

This example shows how to revert to the default MTU setting:

```
Router(config)# no system jumbomtu
```

Related Commands

Command	Description
mtu	Adjusts the maximum packet size or MTU size.
show interfaces	Displays traffic that is seen by a specific interface.
show system jumbomtu	Displays the g lobal MTU setting.

t1 through tug-2 e1 unframed

t1

To create a logical T1 controller from each of the specified time slots of the T3 line, use the **t1**command in controller configuration mode. To delete the defined logical controller, use the **no** form of this command.

t1 *ds1* **controller**
no t1 *ds1* **controller**

Syntax Description

ds1	Time slot within the T3 line. The valid time-slot range is from 1 to 28.

Command Default

No default behavior or values.

Command Modes

Controller configuration

Command History

Release	Modification
11.3AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The purpose of this command is to convert the collection of the 28 T1 controllers comprising the T3 controller into individual T1 controllers that the system can use. In other words, the Cisco AS5800 access server cannot pass data until a T1 controller is configured (using the **controller** command), and you cannot configure a T1 controller until it has been created using the **t1** command.

Examples

The following example shows how to configure a logical T1 controller at T1 time slot 1 for the T3 controller located in shelf 1, slot 4, port 0. Note that you have to enter the command from controller configuration mode.

```
Router(config)# controller
 t3 1/4/0
Router(config-controller)# t1 1 controller
Router(config-controller)# end
```

Related Commands

Command	Description
controller	Configures a T1 and other types of controller and enters controller configuration mode.
controller t3	Configures a T3 controller.

t1 bert

To enable or disable a bit error rate tester (BERT) test pattern for a T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1bert**command in controller configuration mode. To disable a BERT test pattern, use the **no** form of this command.

t1 *channel* **bert pattern** {**0s** | **1s** | **2^15** | **2^20** | **2^23**} **interval** *minutes* [**unframed**]
no t1 *channel* **bert pattern** {**0s** | **1s** | **2^15** | **2^20** | **2^23**} **interval** *minutes* [**unframed**]

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
pattern	Specifies the length of the repeating BERT test pattern.
0s	0s--Repeating pattern of zeros (...000...).
1s	1s--Repeating pattern of ones (...111...).
2^15	215--Pseudorandom repeating pattern that is 32,767 bits in length.
2^20	220--Pseudorandom repeating pattern that is 1,048,575 bits in length.
2^23	223--Pseudorandom repeating pattern that is 8,388,607 bits in length.
interval *minutes*	Specifies the duration of the BERT test, in minutes. The interval can be a value from 1 to 14400.
unframed	(Optional) Specifies T1 unframed BERT.

Command Default

No BERT test is performed.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2S	The **unframed** keyword was added to this command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The BERT test patterns from the CT3IP are framed test patterns (that is, the test patterns are inserted into the payload of the framed T1 signal).

To view the BERT results, use the **showcontrollert3** or **showcontrollert3brief** EXEC commands. The BERT results include the following information:

- Type of test pattern selected
- Status of the test

- Interval selected
- Time remaining on the BERT test
- Total bit errors
- Total bits received

When the T1 channel has a BERT test running, the line state is DOWN. Also, when the BERT test is running and the Status field is Not Sync, the information in the total bit errors field is not valid. When the BERT test is done, the Status field is not relevant.

The**t1bert**command is not written to NVRAM because it is only used for testing the T1 channel for a short predefined interval and for avoiding accidentally saving the command, which could cause the interface not to come up the next time the router reboots.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Examples

The following example shows how to run a BERT test pattern of all zeros for 30 minutes on T1 channel 6 on the CT3IP in slot 9:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 6 bert pattern 0s interval 30
```

Related Commands

Command	Description
show controllers t3	Displays the hardware and software driver information for a T3 controller.

t1/e1 cem-group

To create a circuit emulation (CEM) channel from one or more time slots of a T1/E1 ports on the Channelized T3/E3 Interface Module, use the **t1/e1cem-group** command in controller configuration mode.

t1/e1 *channel* **cem-group***cem-group-id***unframed**

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
cem-group-id	Specifies the cem circuit number to be used for the cem circuit. This number must be unique across all cem-circuits.
unframed	Specifies that a single CEM channel is being created including all time slots and the framing structure of the line. This unframed keyword is used to create an SAToP circuit.

Command Default

No CEM groups are defined.

Command Modes

Controller configuration

Command History

Command History

Release	Modification
XE 3.18SP	This command was introduced.
XE Everest 16.5.1	This command was introduced on the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

Use this command to configure cem-group for channelized T1/E1 under T3/E3 controller.

Examples

The following example shows how to create cem-group on the Channelized T3 Interface Module:

```
Router(config-controller)# t1 1 cem-group 0 unframed
```

Examples

The following example shows how to create cem-group on the Channelized E3 Interface Module:

```
Router(config-controller)# e1 1 cem-group 0 unframed
```

t1 clock source

To specify where the clock source is obtained for use by each T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1clocksource** command in controller configuration mode.

t1 *channel* **clock source** {**internal** | **line**}

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
internal	Specifies that the internal clock source is used. This is the default.
line	Specifies that the network clock source is used.

Command Default

Internal

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not specify the **t1clocksource**command, the default clock source of **internal** is used by all the T1s on the CT3IP.

You can also set the clock source for the CT3IP by using the **clocksource**(CT3IP)controller configuration command.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

This command does not have a **no** form.

Examples

The following example shows how to set the clock source to line T1 6 and T1 8 on the CT3IP:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 6 clock source line
Router(config
```

```
-controller)
# t1 8 clock source line
```

Related Commands

Command	Description
clock source (CT3IP)	Specifies where the clock source is obtained for use by the CT3IP in Cisco 7500 series routers.

t1 external

To specify that a T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers is used as an external port so that the T1 channel can be further multiplexed on the Multichannel Interface Processor (MIP) or other multiplexing equipment, use the **t1external**command in controller configuration mode. To remove a T1 as an external port, use the **no** form of this command.

t1 external *channel* [**cablelength** *feet*] [**linecode** [{**ami** | **b8zs**}]]
no t1 external *channel*

Syntax Description

channel	Number 1, 2, or 3 that indicates the T1 channel.
cablelength *feet*	(Optional) Specifies the cable length, in feet, from the T1 channel to the external CSU or MIP. Values are from 0 to 655. Default is 133.
linecode ami | **b8zs**	(Optional) Specifies the line coding used by the T1. Values are alternate mark inversion (AMI) or bipolar 8 zero suppression (B8ZS). Default is B8ZS.

Command Default

No external T1 is specified. The default cable length is 133 feet. The default line coding is B8ZS.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The first three T1 channels (1, 2, and 3) of the CT3IP can be broken out to the DSUP-15 connectors on the CPT3IP so that the T1 channel can be further demultiplexed by the MIP on the same router or on another router.

After you configure the external T1 channel, you can continue configuring it as a channelized T1 (also referred to as a *fractional* T1) from the MIP. All channelized T1 commands might not be applicable to the T1 interface. After you configure the channelized T1 on the MIP, you can continue configuring it as you would a normal serial interface. All serial interface commands might not be applicable to the T1 interface.

The line coding on the T1 channel and the MIP must be the same. Because the default line coding format on the T1 channel is B8ZS and the default line coding on the MIP is AMI, you must change the line coding on the MIP or on the T1 so that they match.

To determine if the external device connected to the external T1 port is configured and cabled correctly before configuring an external port, use the **showcontrollerst3** command and locate the line Ext1... in the display output. The line status can be one of the following:

- LOS--Loss of signal indicates that the port is not receiving a valid signal. This is the expected state if nothing is connected to the port.

- AIS--Alarm indication signal indicates that the port is receiving an all-ones signal.
- OK--A valid signal is being received and the signal is not an all-ones signal.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Note Although you can specify a cable length from 0 to 655 feet, the hardware only recognizes the following ranges: 0 to 133, 134 to 266, 267 to 399, 400 to 533, and 534 to 655. For example, entering 150 feet uses the 134 to 266 range. If you later change the cable length to 200 feet, there is no change because 200 is within the 134 to 266 range. However, if you change the cable length to 399, the 267 to 399 range is used. The actual number you enter is stored in the configuration file.

Examples

The following example shows how to configure T1 1 on the CT3IP as an external port using AMI line coding and a cable length of 300 feet:

```
Router(config
)
# controllers t3 9/0/0
Router(config
-controller)
# t1 external 1 cablelength 300 linecode ami
```

Related Commands

Command	Description
show controllers t3	Displays the hardware and software driver information for a T3 controller.

t1 fdl ansi

To enable the 1-second transmission of the remote performance reports via the Facility Data Link (FDL) per ANSI T1.403 for a T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1fdlansi** command in controller configuration mode. To disable the performance report, use the **no** form of this command.

t1 *channel* **fdl** **ansi**
no **t1** *channel* **fdl** **ansi**

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.

Command Default

Disabled

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The**t1fdlansi** command can be used only if the T1 framing type is Extended Super Frame (ESF).

To display the remote performance report information, use the**showcontrollerst3remoteperformance** command.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Examples

The following example shows how to generate the performance reports for T1 channel 8 on the CT3IP:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 8 fdl ansi
```

Related Commands

Command	Description
show controllers t3	Displays the hardware and software driver information for a T3 controller.

t1 framing

To specify the type of framing used by T1 channels, use the**t1framing** command in controller configuration mode.

Cisco 7500 Series Routers with Channelized T3 Interface Processor
t1 *channel* **framing** {**esf** | **sf**}

Channelized T3 Shared Port Adapters
t1 channel framing {**esf** | **sf** [**hdlc-idle** {**0x7e** | **0xff**}] [**mode j1**]}
no t1 channel framing {**esf** | **sf** [**hdlc-idle** {**0x7e** | **0xff**}] [**mode j1**]}

Syntax Description

channel	Number indicating the T1 channel. • On the CT3IP--1 to 28 • On the 2-Port and 4-Port Channelized T3 SPA --0 to 23
esf	Specifies that Extended Super Frame (ESF) is used as the T1 framing type. This is the default for the CT3IP.
sf	Specifies that Super Frame (SF) is used as the T1 framing type. This is the default for the 2-Port and 4-Port Channelized T3 SPA.
hdlc-idle {**0x7e** | **0xff**}	(Optional) Sets the idle pattern for the T1 interface to either **0x7e** (the default) or **0xff**.
mode {**j1**}	(Optional) Specifies the JT-G704 Japanese frame type. The mode keyword is not supported on Cisco 7304 routers with the 2-Port and 4-Port Channelized T3 SPA.

Command Default

esf (for C3TIP)

sf (for 2-Port and 4-Port Channelized T3 SPA)

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.0(14)S	This command was integrated into Cisco IOS Release 12.0(14)S. The **hdlc-idle** keyword option was added.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 series routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series router and Catalyst 6500 series switch. The **mode** keyword option was added.

Release	Modification
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you do not specify the **t1framing**command, the default ESF is used.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

To return to the default mode, use the no form of this command. This command does not have a **no** form on the Cisco 7500 series router with the CT3IP.

The mode keyword is not supported on Cisco 7304 routers with the 2-Port and 4-Port Channelized T3 SPA.

Examples

The following example shows how to set the framing for the T1 6 and T1 8 on the CT3IP to Super Frame:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 6 framing sf
Router(config
-controller)
# t1 8 framing sf
```

Related Commands

Command	Description
controller	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller	Displays controller configuration.

t1 linecode

To specify the type of line coding used by the T1 channels on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1linecode**command in controller configuration mode.

t1 *channel* **linecode** [{**ami** | **b8zs**}]

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
ami	Specifies that alternate mark inversion (AMI) line coding is used by the T1 channel.
b8zs	Specifies that bipolar 8 zero suppression (B8ZS) line coding is used by the T1 channel. This is the default.

Command Default

B8ZS

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not specify the **t1linecode**command, the default B8ZS is used.

AMI Line Coding

If you select **ami** line coding for the T1 channel, you must also invert the data on the T1 channel by using the **invertdata** interface command. This is required because the T1 channel is bundled into the T3 signal, so there are no local T1 line drivers and receivers associated with it. Therefore, the **t1***channel***linecodeami** command does not modify local line driver settings. Rather, it advises the CT3IP what line code the remote T1 is using. The CT3IP uses this information solely for the purpose of determining whether or not to enable the pulse density enforcer for that T1 channel.

B8ZS Line Coding

When you select **b8zs** line coding, the pulse density enforcer is disabled. When you select **ami** line coding, the pulse density enforcer is enabled. To avoid having the pulse density enforcer corrupt data, the T1 channel should be configured for inverted data.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Examples

The following example shows how to set the line coding for T1 channel 16 on the CT3IP to AMI:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 16 linecode ami
Router(config
-controller)
# exit
Router(config
)
# interface serial 9/0/0:16
Router(config
-if)
# invert data
```

Related Commands

Command	Description
invert data	Inverts the data stream.
loopback remote (interface)	Loops packets through a CSU/DSU, over a DS3 link or a channelized T1 link, to the remote CSU/DSU and back.

t1 logging-events

To print typical T1 controller Up and Down messages on a channelized T3 port adapterin T3 controller, use the t1 **logging-eventscommand**configuration mode**.TodisableprintingoftheT1controllerUpandDownmessages,usethenoformofthiscommand.**

t1 t1 logging-events [**detail**]
[**no**] **t1 t1 logging-events**

Syntax Description

t1	Number between 1 and 28 that represents the T1 channel for the Channelized T3 Interface Processor (CT3IP) on Cisco 7500 series and Cisco 7200 series routers.
detail	(Optional) Enables printing the reason code when a T1 controller of a T3 controller changes from the Up state to the Down state.

Command Default

The **t1logging-eventscommandisthedefault.**

Command Modes

T3 controller configuration mode.

Command History

Release	Modification
12.2(19c)	This command was introduced.

Usage Guidelines

This command refers to the T1 controller as part of a T3 controller.

The no t1 logging-events command disables printing of the controller Up and Down messages. These messages will appear neither on the console nor in the logs.

Examples

The following example uses the **t1logging-events**command to print normal controller Up and Down messages, without indicating the reason code for a changed state. The T1 1 controller is part of the T3 controller with a bay/port of 4/1.

```
Router(config-controller)# t1 1 logging-events
*Jun 20 00:29:39: %CONTROLLER-5-UPDOWN: Controller T3 4/1 T1 1, changed state to UP
*Jun 20 00:30:09: %CONTROLLER-5-UPDOWN: Controller T3 4/1 T1 1, changed state to DOWN
```

The following example uses the **t1logging-eventsdetail**command to show the Out-of-Frame (OOF) reason code when the T1 1 controller of a T3 controller with a bay/port of 4/1 changes from an Up state to a Down state:

```
Router(config-controller)# t1 1 logging-events detail
*Jun 19 17:47:50: %CONTROLLER-5-DOWNDETAIL: Controller T3 4/1 T1 1, changed state to down
due to OOF
```

Related Commands

Command	Description
logging-events	**Prints typical T3 controller Up and Down messages** on a channelized T3 port adapter**.**

t1/e1 loopback

To set the loopback method for testing T1, E1, T3 or E3 interface module, use the **t1loopback** command in controller configuration mode. To remove the existing loopback, use the no form of this command.

t1 *t1 number* **loopback** { *local* | *network* { *line* | *payload* } }

e1 *e1 number* **loopback** { *local* | *network* { *line* | *payload* } }

Syntax Description

t1 number	Displays the T1 channel number. It ranges from 1-28.
e1 number	Displays the E1 channel number. It ranges from 1-16.
local	Places the interface into local loopback mode and creates a loopback wherein information received from the locally-attached customer premises equipment (CPE) is transmitted back to the locally-attached CPE.
network	Creates a loopback wherein data received over the network from the remote CPE is transmitted back to the remote CPE. • payload: Creates a loopback of only the data in individual time slots. In this mode, framing bits are terminated and then regenerated instead of being looped back. This mode is not available if the port is configured for framing unframed. • line: Creates a full physical layer loopback of all bits, including data and framing bits.

Command Default

No loopback is configured

Command Modes

Controller configuration

Command History

Command History

Release	Modification
XE 3.18SP	This command was introduced on the Cisco NCS 4200 series.
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Examples

The following example shows how to create the local loopback on the controller :

```
Router(config-controller)# t1 1 loopback local
```

The following example shows how to create a network line loopback on a controller.

```
Router(config-controller)# t1 1 loopback network line
```

Examples

The following example shows how to create the local loopback on the controller :

```
Router(config-controller)# e1 1 loopback local
```

Related Commands

Command	Description
controller	Enters controller configuration mode.

t1 t1-line-number cem-group

To create a single Structure-Agnostic TDM over Packet (SAToP) CEM group, use the **t1** *t1-line-number* **cem-group** command in controller configuration mode.

t1 *t1-line-number* **cem-group** *cem-group-number* **unframed**

Syntax Description

t1-line-number	Specifies the T1 line number. The range is 1 to 4.
cem-group-number	The **cem-group-number** keyword identifies the channel number to be used for this channel. For T1 ports, the range is 0 to 23. For E1 ports, the range is 0 to 30.
unframed	Use the **unframed** keyword to specify that a single CEM channel is being created including all time slots and the framing structure of the line. It assigns all the T1 timeslots to the CEM channel.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

The command is used to configure t1 channels under CT3 mode. You can configure 28 T1 channels with CT3 mode.

Examples

The following example shows how to configure DS1 CT3 SAToP mode :

```
enable
configure terminal
controller Mediatype 0/5/0
mode sonet
controller sonet 0/5/0
rate oc12
sts-1 1
mode ct3
t1 1 cem-group 100 unframed
interface cem 0/5/0
no ip address
cem 100
xconnect 2.2.2.2 10 encapsulation mpls
exit
```

Related Commands

Command	Description
controller sonet	Displays information about Synchronous Optical Network (SONET) controllers.
show controller sonet	Displays SONET controller configuration.

t1 t1-line-number clock source

To specify where the clock source is obtained for use by each T1 channel, use the **t1** *t1-line-number* **clock source** command in controller configuration mode.

t1 *t1-line-number* **clock source** {*internal* | *line*}

Syntax Description

Syntax Description

t1-line-number	Specifies the T1 line number. The range is 1 to 4.
internal	Specifies that the internal clock source is used. This is the default.
line	Specifies that the network clock source is used.

Command Default

The default mode is internal.

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

If you do not specify the **t1 clock source** command, the default clock source of internal is used by all the T1s. The no form of this command is available for clock source line mode.

Examples

The following example shows how to configure DS1 CT3 SAToP mode:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
rate oc12
sts-1 1
mode ct3
t1 1 cem-group 100 unframed
t1 1 framing unframed
t1 1 clock source internal
end
```

Related Commands

Command	Description
controller sonet	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller sonet	Displays controller configuration.

t1 t1 line-number framing

To specify the type of framing used by T1 channels, use the **t1** *t1-line-number* **framing** command in controller configuration mode.

t1 *t1-line-number* **framing** {*esf* | *sf* | *unframed*}

Syntax Description

Syntax Description

t1-line-number	The name of a CEM interface parameters class.
esf	Specifies that Extended Super Frame (ESF) is used as the T1 framing type.
sf	Specifies that Super Frame (SF) is used as the T1 framing type.
unframed	Creates an unframed (clear channel) logical channel group on a T1 line.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

If you do not specify the **t1** *t1-line-number* **framing** command, the default ESF is used.

Examples

The following example shows how to configure DS1 CT3 SAToP mode:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
rate oc12
sts-1 1
mode ct3
t1 1 cem-group 100 unframed
t1 1 framing unframed
exit
```

Related Commands

Command	Description
controller sonet	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller sonet	Displays controller configuration.

t1 span

To enable link noise monitoring on a clear channel T1 link on Cisco 10000 series routers, use the **t1span** command in controller configuration mode. To disable link noise monitoring, use the **no** form of this command.

t1 *channel* **span** {**minor-warn** | **remove** | **major-warn**} [{**duration** *seconds* | **lcv** *threshold* [**pcv** *threshold*] [{**set** | **clear**}]}]
no t1 *channel* **span** {**minor-warn** | **remove** | **major-warn**} [{**duration** *seconds* | **lcv** *threshold* [**pcv** *threshold*] [{**set** | **clear**}]}]

Syntax Description

channel	Number that indicates the T1 channel. The range is from 1 to 28.
minor-warn	Enables minor warning messages for noisy T1 links.
major-warn	Enables major warning messages for noisy T1 links.
remove	Enables removal of noisy T1 links from a multilink bundle.
lcv *threshold*	Specifies the line code violation (LCV) threshold value in bit error per second. The valid range on a T1 link is 5 to 1544 seconds. The valid range on an E1 link is 7 to 2048 seconds. • The default LCV value for minor-warn on a T1 link is 154 seconds and on E1 link is 205 seconds. • The default LCV value for major-warn or removal on a TI link is 1544 seconds and on E1 link is 2048 seconds.
duration *seconds*	Specifies the number of consecutive seconds that a threshold is exceeded or improved for a condition to occur. The valid range on a T1/E1 link is 4 to 600 seconds. The default value for T1 and E1 links is 10 seconds.
pcv *threshold*	Specifies the number of timeslots in error per second. The valid range on a T1 link is 3 to 320 seconds and on an E1 link is 8 to 832 seconds. **Note** A T1 link has 24 timeslots and an E1 link has 32 timeslots. • The default path code violation (PCV) value for minor-warn on a T1 link is 145 seconds and on E1 link is 205 seconds. • The default PCV value for major-warn or removal on a TI link is 320 seconds and on E1 link is 832 seconds.
set	(Optional) Specifies the set condition. Set is used as the default when no conditions are given.
clear	(Optional) Specifies the clear condition.

Command Default

Link Noise Monitoring on any T1 or E1 link is disabled by default. If enabled without specifying any thresholds, the default values are used as mentioned in the Syntax Description.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)XNE	This command was introduced.

Usage Guidelines

Note the following when configuring link noise monitoring on T1 and E1 links:

- The **major-warn** and **remove** keywords cannot be used at the same time; disable one to use the other.
- If the **warn** and **remove** keywords are specified without any other options, the LCV and PCV thresholds and duration defaults are used to determine set (**set**) and clear (**clear**) conditions.
- If the **span** command is issued with the **set** keyword and the command is not issued again with the **clear** keyword, or vice versa, the values configured for the threshold and duration is used for both keywords.
- If the **span** command is issued without the **set** or **clear** keywords specified, **set** is the default keyword.
- The **set** and **clear** keywords can be specified only if the threshold values for the LCV and/or duration is specified.
- The threshold for a clear condition must be less than the threshold for a set condition.
- The threshold for a warn event must be less than the threshold for a remove event.
- The duration is calculated in seconds and is the number of consecutive seconds by which either of the thresholds (exceed or improve) must be surpassed for a condition to occur.
- For events, the BER on a line should be greater than or equal to (>=) the thresholds for exceed condition. For improve condition, BER has to be less than (<) the threshold.
- If the PCV threshold is not configured (using the **pcv** keyword and value), this threshold is calculated by the linear extrapolation of the Gaussian probability that is representative of most noise environments based on the configured LCV threshold. If the LCV threshold is specified, it is not mandatory to specify the PCV threshold.

Examples

The following example shows how to generate an exceed event for a minor warning, if the number of LCVs on the T1 line remain above or equal to 20, or the number of PCVs remains above or equal to 10 for 10 continuous seconds.

```
Router(config-controller)# t1 1 span minor-warn lcv 20 pcv 10 duration 10 set
```

The following example shows how to generate an improve event for a minor warning, if the number of LCVs on the T1 line remain below 15 or the number of PCVs remain below 8 for 20 continuous seconds.

```
Router(config-controller)# t1 1 span minor-warn lcv 15 pcv 8 duration 20 clear
```

The following example shows the same threshold value being used by the **set** and **clear** conditions, when both keywords are not specified. In this example, the threshold value is 80 for both conditions.

```
Router(config-controller)# t1 1 span major-warn lcv 150 pcv 100 duration 80
Router(config-controller)# end
Router# show running-config | section controller sonet 7/0/0
controller SONET 7/0/0
```

```
 framing SONET
 path 1 controller t3
 clock source internal
controller T3 7/0/0.1
 t1 1 channel-group 0 timeslots 1-24
 t1 1 span minor-warn lcv 150 pcv 100 duration 80 set
t1 1 span minor-warn lcv 150 pcv 100 duration 80 clear
```

The following example shows how the threshold value specified for the clear condition is used by the set condition when set condition is not specified. In this example, the threshold value of 100 specified for the clear condition is used for the set condition.

```
Router(config-controller)# t1 1 span major-warn lcv 100 pcv 70 duration 100 clear
Router(config-controller)# end
Router# show running-config | section controller sonet 7/0/0
controller SONET 7/0/0
 framing SONET
 path 1 controller t3
 clock source internal
controller T3 7/0/0.1
t1 1 channel-group 0 timeslots 1-24
 t1 1 span minor-warn lcv 100 pcv 70 duration 100 set
 t1 1 span minor-warn lcv 100 pcv 70 duration 100 clear
```

The following is a sample output showing the details of the calculated PCV threshold value. The calculated PCV value is 141:

```
Router# debug c10k lnm
Router(config-controller)# t1 1 span major-warn lcv 150
Router(config-controller)# end
*Sep 10 20:34:43.923:  T1 extrapolation: pcv_delta=130 lcv_delta=139 factor=140 pcv_const=14

 computed pcv_threshold = 141
*Sep 10 20:34:43.923: CMD for minor-warn set
*Sep 10 20:34:43.923: clear taking set thresholds
*Sep 10 20:34:43.923: T3 7/0/0.1#1 setting values to be sent to LC for WARN ENABLE 3
*Sep 10 20:34:43.923:
 3, 150, 150, 141, 141, 10, 10, 0, 0, 0, 0, 0, 0
Router# show running-config | section controller sonet 7/0/0
controller SONET 7/0/0
 framing SONET
 path 1 controller t3
 clock source internal
controller T3 7/0/0.1
 t1 1 channel-group 0 timeslots 1-24
 t1 1 span minor-warn lcv 150 pcv 141 duration 10 set
 t1 1 span minor-warn lcv 150 pcv 141 duration 10 clear
```

Related Commands

Command	Description
t1 clock source	Specifies where the clock source is obtained for use by each T1 channel on the channelized T3 interface.
show controllers t3	Displays the hardware and software driver information for a T3 controller.
t1 span syslog	Generates syslog messages for spans that are enabled with the link noise monitoring feature.

t1 span syslog

To generate syslog messages for all the spans on which the link noise monitoring feature is enabled, use the **t1spansyslog**command in controller configuration mode. To disable the generation of syslog messages, use the **no** form of this command.

t1 *channel* **span syslog**
no t1 *channel* **span syslog**

Syntax Description

channel	Number that indicates the T1 channel. The range is from 1 to 28.
syslog	Generates syslog messages for T1 links that are enabled with the Link Noise Monitoring feature.

Command Default

Syslog messages are disabled by default.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)XNE	This command was introduced.

Usage Guidelines

The Cisco 10000 series router is a scalable platform and supports up to 4000 T1 links on one chassis. When enabled, syslog messages are generated for all T1 links on which link noise monitoring is configured. A syslog event is reported as a message. The syslog report stores the last five events.

When an ‘exceed’ event is reported, a syslog message is generated. Such syslog messages from all links clog up the logging buffer. When enabling syslog messages, a message prompts you to confirm whether to generate syslog messages or not.

To view the events for a line card, use the **showcontroller***typenumber***lnmevent**command in the privileged EXEC mode. To view the events for a SPA, use the **showplatformspa***slot/subslot***lnmevent**command.

Examples

The following example shows the message displayed when the minor warning threshold has exceeded:

```
LNM-3- MINWARNEXCEED: Interface Serial7/0/0.1/1:0, noise exceeded above minor warning
threshold
```

The following example shows the sample output of the **showcontroller** command, when executed for a specified T1 channel:

```
Router# show controllers t3 7/0/0.1 /5 lnm

Channel    Monitoring type                Thresholds (lcv/pcv/duration)
--------------------------------------------------------------------------------
  5     minor-warn (syslog disabled)   Set(154 /145 /10  ) Clear(154 /145 /10  )
Router#
```

The following example shows the sample output of the last five stored messages:

```
Router# show controller t3 7/0/0.1 lnm events
Channel          Last five events
```

```
--------------------------------------------------------------------------------
 1     MINWARNEXCEED : Noise exceeded minor-warn thresholds at Jun 11 1995 13:42:01
        MAJWARNEXCEED : Noise exceeded major-warn thresholds at Jun 11 1995 13:42:01
     MINWARNIMPROVE: Noise improved minor-warn thresholds at Jun 11 1995 13:42:01
        MAJWARNIMPROVE: Noise improved major-warn thresholds at Jun 11 1995 13:42:01
 2      Channel not configured for E1/T1
 3     Channel not configured for E1/T1
 4     No events
 5       Channel not configured for E1/T1
```

Related Commands

Command	Description
t1 clock source	Specifies where the clock source is obtained for use by each T1 channel on the channelized T3 interface.
show controllers t3	Displays the hardware and software driver information for a T3 controller.
t1 span	Enables link noise monitoring on T1 links.

t1 test

To break out a T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers to the test port for testing, use the **t1test**command in controller configuration mode. To remove the T1 channel from the test port, use the **no** form of this command.

t1 test *channel* [**cablelength** *feet*] [**linecode** [{**ami** | **b8zs**}]]
no t1 test *channel*

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
cablelength *feet*	(Optional) Specifies the cable length, in feet, from the T1 channel to the external CSU or Multi-Channel Interface Processor (MIP). Values are from 0 to 655. Default is 133.
linecode {**ami** | **b8zs**	(Optional) Specifies the line coding format used by the T1 channel. Values are alternate mark inversion (AMI) or bipolar 8 zero suppression (B8ZS). Default is B8ZS.

Command Default

No test port is configured. The default cable length is 133 feet. The default line coding is B8ZS.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can use the T1 test port available on the CT3IP to break out any of the 28 T1 channels for testing (for example, 24-hour bit error-rate tester (BERT) testing as is commonly done by telephone companies before a line is brought into service).

The T1 test port is also available as an external port. For more information on configuring an external port, see the **t1external**controller configuration command.

To determine if the external device connected to the T1 test port is configured and cabled correctly before configuring a test port, use the **showcontrollerst3** command and locate the line Ext1... in the display output. The line status can be one of the following:

- LOS--Loss of signal indicates that the port is not receiving a valid signal. This is the expected state if nothing is connected to the port.
- AIS--Alarm indication signal indicates that the port is receiving an all-ones signal.
- OK--A valid signal is being received and the signal is not an all-ones signal.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Note Although you can specify a cable length from 0 to 655 feet, the hardware only recognizes the following ranges: 0 to 133, 134 to 266, 267 to 399, 400 to 533, and 534 to 655. For example, entering 150 feet uses the 134 to 266 range. If you later change the cable length to 200 feet, there is no change because 200 is within the 134 to 266 range. However, if you change the cable length to 399, the 267 to 399 range is used. The actual number you enter is stored in the configuration file.

Examples

The following example shows how to configure T1 6 on the CT3IP as a test port using the default cable length and line coding:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 test 6
```

Related Commands

Command	Description
show controllers t3	Displays the hardware and software driver information for a T3 controller.
t1 external	Specifies that a T1 channel on the CT3IP in Cisco 7500 series routers is used as an external port so the T1 channel can be further multiplexed on the MIP or other multiplexing equipment.

t1 timeslot

To specify the time slots and data rate used on each T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1timeslot**command in controller configuration mode. To remove the configured T1 channel, use the **no** form of this command.

t1 *channel* **timeslot** *range* [**speed** {**56** | **64**}]
no t1 *channel* **timeslot**

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
range	Specifies the time slots assigned to the T1 channel. The range can be from 1 to 24. A dash represents a range of time slots, and a comma separates time slots. For example, 1-10,15-18 assigns time slots 1 through 10 and 15 through 18.
speed {**56** | **64**}	(Optional) Specifies the data rate for the T1 channel, in kbps. Values are 56 or 64. The default is 64. The 56-kbps speed is valid only for T1 channels 21 through 28.

Command Default

No time slots are specified for the T1 channel. The default data rate is 64 kbps.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You must specify the time slots used by each T1 channel.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Examples

The following example shows how to assign time slots 1 through 24 to T1 1 for full T1 bandwidth usage:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 1 timeslot 1-24
```

The following example shows how to assign time slots 21 to 23 and 26 to 28 and a data rate of 56 kbps to T1 6 for fractional T1 bandwidth usage:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 6 timeslot 21-23,26-28 speed 56
```

t1 yellow

To enable detection and generation of yellow alarms for a T1 channel on the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **t1yellow**command in controller configuration mode. To disable the detection and generation of yellow alarms, use the **no** form of this command.

t1 *channel* **yellow** {**detection** | **generation**}
no t1 *channel* **yellow** {**detection** | **generation**}

Syntax Description

channel	Number between 1 and 28 that indicates the T1 channel.
detection	Detects yellow alarms. This is the default, along with **generation**.
generation	Generates yellow alarms. This is the default, along with **detection**.

Command Default

Yellow alarms are detected and generated on the T1 channel.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the T1 framing type is super frame (SF), you should consider disabling yellow alarm detection because the yellow alarm can be incorrectly detected with SF framing.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with Telco numbering schemes for T1 channels within channelized T3 equipment.

Examples

The following example shows how to disable the yellow alarm detection on T1 channel 6 on the CT3IP:

```
Router(config
)
# controller t3 9/0/0
Router(config
-controller)
# t1 6 framing sf
Router(config
-controller)
# no t1 6 yellow detection
```

tcam priority

To prioritize the interfaces for forwarding to software in the event of Ternary Content Addressable Memory (TCAM) entry or label exhaustion, use the **tcampriority** command interface configuration mode. To revert to the default setting, use the **no** form of this command.

tcam priority [{**high** | **low**}]
no tcam priority

Syntax Description

high	Sets priority to high.
low	Sets priority to low.

Command Default

normal

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The interfaces are chosen in the following order:

1. Low-priority interfaces without Vlan Access Control Lists (VACLs) and without multicast
2. Low-priority interfaces without VACLs and approved by multicast
3. Low-priority interfaces with VACLs and approved by multicast
4. Low-priority interfaces (not approved by multicast)
5. Normal-priority interfaces without VACLs and without multicast
6. Normal-priority interfaces without VACLs and approved by multicast
7. Normal-priority interfaces with VACLs and approved by multicast
8. Normal-priority interfaces (not approved by multicast)
9. High-priority interfaces without VACLs and without multicast
10. High-priority interfaces without VACLs and approved by multicast
11. High-priority interfaces with VACLs and approved by multicast
12. High-priority interfaces (not approved by multicast)

Examples

The following example shows how to set the priority to low:

```
Router(config-if)# tcam priority low
```

Related Commands

Command	Description
show tcam interface	Displays information about the interface-based TCAM.

termination

To configure the termination mode of the controller, use the **termination** command in the controller configuration mode.

termination [{**co** | **cpe**}]

Syntax Description

co	Set the line termination for the interface as CO (network)
cpe	Termination cpe (customer)

Command Default

The command default termination mode is CPE.

Command Modes

Controller configuration mode (config-controller)

Command History

Release	Modification
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Examples

The following example shows the line termination set to "co":

```
Router(config-controller)# termination
 co
```

Related Commands

Command	Description
controller shdsl	Configures a controller for single-pair high-bit-rate digital subscriber line (SHDSL) mode.
controller shdsl	Configures a controller for single-pair high-bit-rate digital subscriber line (SHDSL) mode.

test aim eeprom

To test the data compression Advanced Interface Module (AIM) after it is installed in the Cisco 2600 series router, use the **testaimeeprom**command in privileged EXEC mode.

test aim eeprom

Syntax Description

This command has no arguments or keywords.

Command Default

No tests are performed on the data compression AIM card.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command does not have a **no** form.

Caution Using this command can erase all locations in EEPROM memory.

This command is the AIM counterpart of the **testpaseeprom** command, which performs similar tasks for port modules.

The table below shows the questions asked of the user when the **testaimeeprom** command is entered, and the recommended user responses.

Table 285: Questions and Responses for test aim eeprom Command

Questions	Responses
AIM Slot [0]:	User responds by entering the slot number of the AIM whose EEPROM is to be modified. If the user presses ENTER, the default slot 0 is used.
Use NMC93C46 ID EEPROM [y]:	User responds with “y” if the AIM contains an NMC93C46 type EEPROM and “n” if the AIM contains an X2444 EEPROM. The compression Advanced Interface Module (CAIM) contains a NMC93C46 EEPROM, and this is the default if the user just pressed ENTER.
AIM Slot %d eeprom (? for help)[%c]	General command prompt for the **testaimeeprom** command dialog. The AIM slot number chosen is displayed, and the default command is the last command entered.

Questions	Responses
Address within slot %d eeprom, [0x%02x]	Enter the desired address within the EEPROM to modify. The default is the next address beyond the byte last modified. If the user wishes to enter a hexadecimal number, it must be preceded by “0x”.
Read or Write access to slot %d at 0x%02x [%c]?	Respond with a W to write to the addressed byte or with an R to read from the addressed byte. The default value is selected by just pressing Enter and is the same as the value specified in the last primitive access.
Write data (hex 8 bits) [%02x]?:	If you respond to prompt B with “W”, then prompt C is issued, requesting the user to enter the data to write to the addressed byte. The user enters the desired value. Note that if the user desires to enter a hex value, the hex value entered must be preceded by “0x”. Otherwise, the value entered is assumed to be in decimal radix.

There is a danger that you can erase all bytes in the entire EEPROM. Though it is good to have a diagnostic tool that allows you to read and write data, there is a danger that lost data will make the Advanced Interface Module (AIM) card fail.

During your session with the test dialog, you have access to the following commands:

H or**h**	Displays a summary of the available commands.
d	Dump EEPROM contents--Displays the contents of the EEPROM in hex.
e	Erase EEPROM--Erases the entire EEPROM (all bytes set to 0xff).
p	Primitive access--Erases the EEPROM.
q	Exit EEPROM test--Causes the **testaimeepromp** command dialog to exit to the command line interface (CLI).
z	Zero EEPROM--Zeros the entire EEPROM.

Examples

The following example displays the **testaimeeprom** command user dialog:

```
Router# test aim eeprom
 AIM Slot [0]: 0
 Use NMC93C46 ID EEPROM [y]: y
 AIM Slot 0 eeprom (? for help)[?]:  ?
  d - dump eeprom contents
  e - erase all locations (to 1)
  p - primitive access
  q - exit eeprom test
  z - zero eeprom
  'c' rules of radix type-in and display apply.
 AIM Slot 0 eeprom (? for help)[?]:
```

test cable-diagnostics

To test the condition of 10-Gigabit Ethernet links or copper cables on 48-port 10/100/1000 BASE-T modules, use the **testcable-diagnostics**command in privileged EXEC mode.

test cable-diagnostics tdr interface *type number*

Syntax Description

tdr	Activates the TDR test for copper cables on 48-port 10/100/1000 BASE-T modules.
interface *type*	Specifies the interface type; see the "Usage Guidelines" section for valid values.
number	Module and port number.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Cisco 7600 series routers.
12.2(17b)SXA	This command was changed to provide support for the 4-port 10GBASE-E serial 10-Gigabit Ethernet module (WS-X6704-10GE).
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Cable diagnostics can help you detect whether your cable has connectivity problems.

The TDR test guidelines are as follows:

- TDR can test cables up to a maximum length of 115 meters.
- The TDR test is supported on Cisco 7600 series routers running Release 12.2(17a)SX and later releases on specific mdoules. See the Release Notes for Cisco IOS Release 12.2SX on the Catalyst 6500 and Cisco 7600 Supervisor Engine 720, Supervisor Engine 32, and Supervisor Engine 2 for the list of the modules that support TDR.
- The valid values for **interface***type*are **fastethernet** and **gigabitethernet**.
- Do not start the test at the same time on both ends of the cable. Starting the test at both ends of the cable at the same time can lead to false test results.
- Do not change the port configuration during any cable diagnostics test. This action may result in incorrect test results.
- The interface must be up before running the TDR test. If the port is down, the **testcable-diagnosticstdr** command is rejected and the following message is displayed:

```
Router# test cable-diagnostics tdr interface gigabitethernet2/12
```

```
% Interface Gi2/12 is administratively down
% Use 'no shutdown' to enable interface before TDR test start.
```

- If the port speed is 1000 and the link is up, do not disable the auto-MDIX feature.
- For fixed 10/100 ports, before running the TDR test, disable auto-MDIX on both sides of the cable. Failure to do so can lead to misleading results.
- For all other conditions, you must disable the auto-MDIX feature on both ends of the cable (use the **nomdixauto**command). Failure to disable auto-MDIX will interfere with the TDR test and generate false results.
- If a link partner has auto-MDIX enabled, this action will interfere with the TDR-cable diagnostics test and test results will be misleading. The workaround is to disable auto-MDIX on the link partner.
- If you change the port speed from 1000 to 10/100, enter the **nomdixauto**command before running the TDR test. Note that entering the **speed1000** command enables auto-MDIX regardless of whether the **nomdixauto**command has been run.

Examples

This example shows how to run the TDR-cable diagnostics:

```
Router # test cable-diagnostics tdr interface gigabitethernet2/1
TDR test started on interface Gi2/1
A TDR test can take a few seconds to run on an interface
Use 'show cable-diagnostics tdr' to read the TDR results.
```

Related Commands

Command	Description
clear cable-diagnostics tdr	Clears a specific interface or clears all interfaces that support TDR.
show cable-diagnostics tdr	Displays the test results for the TDR cable diagnostics.

test interface fastethernet

To test the Fast Ethernet interface by causing the interface to ping itself, use the **testinterfacefastethernet** command in user EXEC or privileged EXEC mode.

test interface fastethernet *number*

Syntax Description

number	Port, connector, or interface card number. On a Cisco 4500 or Cisco 4700 series router, specifies the network processor module (NPM) number. The numbers are assigned at the factory at the time of installation or when added to a system and are displayed with the **showinterfaces** command.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command sends pings from the specified interface to itself. Unlike the **ping** command, the **testinterfacefastethernet** command does not require the use of an IP address.

Examples

The following example shows how to test a Fast Ethernet interface on a Cisco 4500 router:

```
Router# test interface fastethernet 0
```

Related Commands

Command	Description
ping (privileged)	Diagnoses basic network connectivity on AppleTalk, CLNS, DECnet, IP, or Novell IPX networks.
ping (user)	Provides simple ping diagnostics of network connectivity.
show interfaces	Displays information about interfaces.

test platform police get

To get the IPv6 internal police rate, use the *test platform police get* command in privileged EXEC mode.

test platform police get

Syntax Description

This command has no arguments or keywords.

Command Default

0 (No rate has been applied.)

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	The command was introduced on the Cisco 7600 series routers for the ES+ line cards, the SIP-400, and the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG.

Usage Guidelines

Use this command under the exec command of the line card console. It is not visible from the route processor (RP) console.

Examples

The following example shows how to get the IPv6 internal police rate:

```
Router> enable
Router# test platform police get
IPv6 with HBH header is policed at 100000 kbps
```

Related Commands

Command	Description
test platform police set	Sets the IPv6 internal police rate.

test platform debugger rommon

To configure the ROM monitor (ROMMON) variables on a Route Processor (RP) or a Switch Processor (SP), use the **test platform debugger rommon** command in privileged EXEC mode.

test platform debugger rommon[{**dump** | **get** *string* | **set** *string* | **unset** *string*}]

Syntax Description

dump	Displays all configured ROMMON variables.
get	Reads the specified ROMMON variable.
set	Modifies the specified ROMMON variable.
unset	Unsets the specified ROMMON variable.
string	Name of the specified ROMMON variable.

Command Default

None

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)S	This command was introduced.

Usage Guidelines

This command is supported on both Route Switch Processor (RSP) and Supervisor Engine (SUP), but works only on the RSP.

Examples

This example shows how to configure a ROMMON variable:

```
Router# test platform debugger rommon dump
Router# test platform debugger rommon unset string
Router# test platform debugger rommon get string
Router# test platform debugger rommon set string
```

test platform police ipv6 disable

To disable the IPv6 internal policer, use the **test platform police ipv6 disable** command in privileged EXEC mode.

test platform police ipv6 disable

Syntax Description

This command has no arguments or keywords.

Command Default

0 (No rate has been applied)

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.1(3)S1	The command was introduced on the Cisco 7600 series routers for the ES+ line cards, the SIP-400, and the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG.

Usage Guidelines

Use this command under the **exec** command of the line card console. It is not visible from the route processor (RP) console.

Examples

This example shows how to disable the IPv6 internal police rate:

```
Router(config)#test platform police ipv6 disable
```

Related Commands

Command	Description
test platform police ipv6 set	Sets the IPv6 internal police rate.
test platform police ipv6 get	Gets the IPv6 internal police rate.

test platform police set

To set the IPv6 internal police rate, use the *test platform police set* command in privileged EXEC mode. This command does not have a no form.

If you have set a rate limit and wish to cancel it, you will need to use this command to set the rate to 0.

test platform police set rate

Syntax Description

rate	Specifies the internal police rate. The range is from 0 to 100000 kbps.
	• For the SIP-400, you can configure a rate up to, and including 25600 packets per second (PPS).
	• For the ES+ line cards and the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG line cards, you can configure rates of:
	  • 16 Kbps to 2 Mbps; granularity of 16 kbps
	  • 2 Mbps to 100 Mbps; granularity of 64 kbps

Command Default

For ES40 line cards, the default police rate is 12.8 Mbps.

For the SIP-400, the default police rate is 21.36 kpps.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	The command was introduced on the Cisco 7600 series routers for the ES+ line cards, the SIP-400, and the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG.

Usage Guidelines

Use this command under the EXEC command of the line card console. It is not visible from the route processor (RP) console.

For both the ES+ line cards and the SIP-400, setting the police rate to 0 turns off the policing.

For both the ES+ line cards and the SIP-400, when the policer is set from the the line card console, the setting remains effective even if the line card is moved to another chassis running the Cisco IOS Release 12.2(33)SRD1 (or later) image.

For the SIP-400, IPv6 HBH packets will continue to go through the QoS policing configured on the line card. For ES+ line cards, IPv6 HBH packets will bypass any QoS configured on the line card.

Examples

The following examples shows how to set the IPv6 with HBH header to be policed at 100000 kbps:

```
Router> enable
Router# test platform police set 100000
```

Related Commands

Command	Description
test platform police get	Gets the IPv6 internal police rate.

test satellite satellite mfg link

To force the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT) to show that the backbone link to the hub is up, even when the link is actually down, use the **testsatellitesatellitemfglink** command in privileged EXEC mode.

test satellite satellite *slot/unit* **mfg link** {**force** | **normal**}

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
force	Forces the satellite link to appear to be UP.
normal	Allows the satellite link to display the actual status, UP or DOWN.

Command Default

The actual status (UP or DOWN) of the satellite link is displayed.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Use the **testsatellitesatellitemfglink**command only when instructed by your satellite service provider or a technical support representative.

Examples

The following example shows how to force the NM-1VSAT-GILAT network module to show that the backbone link to the hub is up, even if the link is actually down:

```
Router# test satellite satellite 1/0 mfg link force
```

The following example shows how to allow the NM-1VSAT-GILAT network module to show the actual status (UP or DOWN) of the satellite link:

```
Router# test satellite satellite 1/0 mfg link normal
```

test satellite satellite reset

To reset the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **testsatellitesatellitereset** command in privileged EXEC mode.

test satellite satellite *slot/unit* **reset** [**hard**]

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
hard	Hardware reset. Not available on all routers.

Command Default

Without the **hard** keyword, the command initiates a software reset.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Use the **testsatellitesatellitereset** command only when instructed by your satellite service provider or a technical support representative. You will lose satellite network connectivity while the NM-1VSAT-GILAT network module resets.

We recommend that you first try a software reset. The hardware reset option is not available on all routers.

Examples

The following example shows how to initiate a software reset of the NM-1VSAT-GILAT network module:

```
Router# test satellite satellite 1/0 reset
```

The following example shows how to initiate a hardware reset of the NM-1VSAT-GILAT network module:

```
Router# test satellite satellite 1/0 reset hard
```

test service-module

To perform self-tests on an integrated CSU/DSU serial interface module, such as a 4-wire, 56/64 kbps CSU/DSU, use the **testservice-module** command in privileged EXEC mode.

test service-module commandtest service-module *interface-type interface-number*

Syntax Description

interface-type	Interface type.
interface-number	Interface number.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The following tests are performed on the CSU/DSU:

- ROM checksum test
- RAM test
- EEPROM checksum test
- Flash checksum test
- DTE loopback with an internal pattern test

These self-tests are also performed at power on.

This command cannot be used if a DTE loopback, line loopback, or remote loopback is in progress.

Data transmission is interrupted for 5 seconds when you issue this command. To view the output of the most recent self-tests, use the**showservice-module**command.

This command does not have a **no** form.

Examples

The following example shows how to perform a self-test on serial interface 0:

```
Router# test service-module serial 0
SERVICE_MODULE(0): Performing service-module self test
SERVICE_MODULE(0): self test finished: Passed
```

Related Commands

Command	Description
channelized	Clears the interface counters.
clear service-module serial	Resets an integrated CSU/DSU.
show service-module serial	Displays the performance report for an integrated CSU/DSU.

test trunk

To configure the test port on a trunk card, use the **testtrunk** command in privileged EXEC mode.

test trunk stm1 {**drop** | **monitor**} {**tx** | **rx**} {**on** | **off**} **e1** *controller*

Syntax Description

stm1	Specifies the test port on an STM-1 trunk card. This keyword is supported only on the Cisco AS5850 platform.
drop	Specifies drop mode where the existing signal is dropped and the signal from the test port is sent to the controller.
monitor	Specifies monitor mode where the signal from the specified E1 controller is monitored via the test port. The original signal is not disturbed.
tx	Specifies that signal is sent on the transmit line.
rx	Specifies that signal is sent on the receive line.
on	Switches the test port on.
off	Switches the test port off.
e1	Specifies that an E1 controller is to be used for testing.
controller	Slot and port numbers to identify the E1 controller.

Command Default

The test port is disabled.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.0	This command was introduced.
12.2(15)T	The **stm-1** keyword was added.

Usage Guidelines

If a controller does not go up, or there are a large number of errors associated with a specific E1 controller, you might be able to determine whether the problem is in the server card or in an external line by using the test port. The test port is located on the front panel of the SDH/STM-1 trunk card.

This command does not have a **no** form because the command itself switches the test port on or off.

To use this command, one E1 controller is selected and the transmit and receive lines can be put into drop or monitor mode. Both drop and monitor modes can be used at the same time on either the transmit or receive lines, but both transmit and receive lines cannot be used in drop or monitor mode at the same time.

Examples

The following example shows how to configure a test port to use drop mode on the receive line of an E1 controller in the second path of an STM-1 trunk card in slot 2 of a Cisco AS5850 chassis:

```
Router# test trunk stm-1 drop rx on E1 2/0.2/1/2
```

threshold

To set the path BER threshold values, configure the **threshold** command in the controller configuration mode. To return to the default value, use the no form of this command.

threshold { *b1-tca* | *b2-tca* | *b3-tca* | *sd-ber* | *sf-ber* *bit-error-rate*

Syntax Description

b1-tca	Enables Bit Error Rate (BER) threshold crossing alerts for B1.
b2-tca	Enables BER threshold crossing alerts for B2.
b3-tca	Enables BER threshold crossing alerts for B3. Configures path threshold.
sd-ber	Enables the threshold of the Signal Degrade (SD) BER that is used to trigger a signal degrade alarm.
sf-ber	Configures the threshold of the Signal Failure (SF) BER that is used to trigger a link state change.
bit-error-rate	Specifies the BER.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

This command is used to configure line, section, and path threshold.

Examples

The following example shows the configuration of line and section threshold:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
sts-1 1
threshold b3-tca 3
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

timeslot

To enable framed mode on a serial interface on a G.703 E1 port adapter, an FSIP, or an E1-G.703/G.704 serial port adapter, use the **timeslot** command in interface configuration mode. To restore the interface to unframed mode, use the **no** form of this command or set the start slot to 0.

timeslot *start-slot* *stop-slot*
no timeslot

Syntax Description

start-slot	First subframe in the major frame. Valid range is from 1 to 31 and must be less than or equal to the *stop-slot*value.
stop-slot	Last subframe in the major frame. Valid range is from 1 to 31 and must be greater than or equal to the *start-slot*value.

Command Default

The default G.703 E1 interface is not configured for framed mode.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
11.1 CA	This command was modified to include the E1-G.703/G.704 serial port adapter and Cisco 7200 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Framed mode allows you to specify a bandwidth for the interface by designating some of the 32 time slots for data and reserving the others for framing (timing). Unframed mode, also known as clear channel, does not reserve any time slots for framing.

This command applies to Cisco 4000, 7000, 7200, and 7500 series routers. G.703 E1 interfaces have two modes of operation, framed and unframed. When in framed mode, the range from *start-slot* to *stop-slot* gives the number of 64-kbps slots in use. There are thirty-two 64-kbps slots available.

In framed mode, timeslot 16 is not used for data. To use timeslot 16 for data, use the **ts16** interface configuration command.

Examples

The following example shows how to enable framed mode on a serial interface on a G.703 E1 port adapter or an E1-G.703/G.704 port adapter:

```
Router(config
)
# interface serial 3/0
Router(config
```

```
-if)
# timeslot 1-3
```

Related Commands

Command	Description
ts16	Controls the use of timeslot 16 for data on a G.703 E1 interface or on an E1-G703/G.704 serial port adapter.

time-properties persist

To configure the time-properties holdover time, use the **time-properties persist** command in PTP clock configuration mode.

time-properties persist *value*

Syntax Description

value	Time-properties holdover time. Valid values are from 0 to 10000 seconds. The default value is 300 seconds.

Command Default

By default holdover time is 300 seconds.

Command Modes

PTP clock configuration (config-ptp-clk)

Command History

Release	Modification
Cisco IOS XE 3.18.1SP	This command was introduced.

Usage Guidelines

When a master clock is lost, the time properties holdover timer starts. During this period, the time properties flags (currentUtcOffset, currentUtcOffsetValid, leap61, leap59) persist for the holdover timeout period. Once the holdover timer expires, currentUtcOffsetValid, leap59, and leap61 flags are set to false and the currentUtcOffset remains unchanged.

The following example shows how to configure the current UTC offset, leap second event date and offset value:

```
Device(config)# ptp clock boundary domain 0 hybrid
Router(config-ptp-clk)# time-properties persist 600
Router(config-ptp-clk)#utc-offset 45 leap-second "01-01-2017 00:00:00" offset 1
```

Related Commands

Command	Description
utc-offset leap-second offset	Configures the current UTC offset, leap second event date and Offset value (+1 or -1).

tod

To configure the time of day message format used by the 1PPS interface, use the **tod** command in PTP clock port configuration mode. To remove a time of day configuration, use the **no** form of this command.

tod *slot/bay* {**iso8601** | **ubx** | **nmea** | **cisco** | **ntp**} [**delay** *delay-amount*]
no tod *slot/bay* {**iso8601** | **ubx** | **nmea** | **cisco** | **ntp**} [**delay** *delay-amount*]

Syntax Description

slot	Slot of the 1PPS interface.
bay	Bay of the 1PPS interface.
iso8601	Specifies ISO 8601 time of day format.
ubx	Specifies UBX time of day format.
nmea	Specifies NMEA time of day format.
cisco	Specifies Cisco time of day format.
ntp	Specifies NTP time of day format.
delay	(Optional) Specifies a delay between the 1PPS message and the time of day message.
delay-amount	Amount of delay between the 1PPS message and the time of day message, in milliseconds. The range is from 1 to 999.

Command Default

The time of day message format is not configured.

Command Modes

PTP clock port configuration (config-ptp-clk)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

This command applies only to platforms that have 1PPS ports.

Examples

The following example shows how to configure a time of day value:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# tod 3/0 ntp
Device(config-ptp-clk)# end
```

This example sows the configuration of the time of (ToD) message format for a 1588V2 primary on a Cisco ASR 901 Series Aggregation Services Router:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# tod 3/0 cisco
Device(config-ptp-clk)# input 1pps 3/3
Device(config-ptp-clk))# clock-port MASTER master
Device(config-ptp-clk)# transport ipv4 unicast interface Gi3/3/1 negotiation
Device(config-ptp-clk)# end
```

Related Commands

Command	Description
input	Enables PTP input clocking using the 1.544 Mhz, 2.048 Mhz, or 10 Mhz timing interface or phase using the 1PPS or RS-422 interface.
output	Enables output of time of day messages using the 1PPS interface.

transceiver type all

To enable the monitoring of all transceivers via the transceiver type configuration mode, use the **transceivertypeall** command in global configuration mode. This command does not have the **no** form.

transceiver type all

Syntax Description

This command has no arguments or keywords.

Command Default

Transceiver type configuration is disabled. If transceiver type configuration is enabled, the default monitoring interval is 600 seconds.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.2(33)SXH	This command was modified. The **interval** keyword was removed.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.2(2)SNI	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

You can enter the transceiver type configuration mode using the **transceiver type all** command. You can then monitor the transceiver types and also set the monitoring interval using the **monitoring** command.

Examples

This example shows how to enter in to transceiver type configuration mode and then enable the monitoring for all transceiver types:

```
Router(config)# transceiver type all
Router(config-xcvr-type)# monitoring interval 500
```

Related Commands

Command	Description
monitoring	Enables to monitor the transceiver types and also set the monitoring interval.
snmp-server enable traps transceiver type all	Enables all supported SNMP transceiver traps for all transceiver types.

transmit-buffers backing-store

To buffer short-term traffic bursts that exceed the bandwidth of the output interface, use the **transmit-buffersbacking-store**command in interface configuration mode. To disable this function, use the **no** form of this command.

transmit-buffers backing-store
no transmit-buffers backing-store

Syntax Description

This command has no arguments or keywords.

Command Default

The default is off, unless weighted fair queueing is enabled on the interface. If weighted fair queueing is enabled on the interface, the **transmit-buffersbacking-store** command is enabled by default.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced on the Cisco 7500 series router.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the **transmit-buffersbacking-store** command is enabled and a full hardware transmit queue is encountered, packets are swapped out of the original memory device (MEMD) into a system buffer in DRAM. If the **transmit-buffersbacking-store** command is not enabled and the output hold queue is full, packets are dropped instead of being copied if a full hardware transmit queue is encountered. In both cases, the original MEMD buffer is freed so that it can be reused for other input packets.

To preserve packet order, the router checks the output hold queue and outputs previously queued packets first.

Examples

The following example shows how to enable the **transmit-buffersbacking-store** command on a FDDI interface:

```
Router(config
)
# interface fddi 3/0
Router(config
-if)
# transmit-buffers backing-store
```

Related Commands

Command	Description
fair-queue (WFQ)	Enables WFQ for an interface.

transmit-clock-internal

To enable the internally generated clock on a serial interface on a Cisco 7200 series or Cisco 7500 series router when a DTE does not return a transmit clock, use the**transmit-clock-internal** command in interface configuration mode. To disable the internally generated clock, use the **no** form of this command.

transmit-clock-internal
no transmit-clock-internal

Syntax Description

This command has no arguments or keywords.

Command Default

The internally generated clock is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to enable the internally generated clock on serial interface 3/0 on a Cisco 7200 series or Cisco 7500 series router:

```
Router(config
)
# interface serial 3/0
Router(config
-if)
# transmit-clock-internal
```

transmit-interface

To assign a transmit interface to a receive-only interface, use the **transmit-interface** command in interface configuration mode. To return to normal duplex Ethernet interfaces, use the **no** form of this command.

trtransmit-interface commandansmit-interface *type number*
no transmit-interface

Syntax Description

type	Transmit interface type to be linked with the (current) receive-only interface.
number	Transmit interface number to be linked with the (current) receive-only interface.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Receive-only interfaces are used commonly with microwave Ethernet links.

Examples

The following example specifies Ethernet interface 0 as a simplex Ethernet interface:

```
interface ethernet 1
 ip address 128.9.1.2
 transmit-interface ethernet 0
```

transmitter-delay

To specify a minimum dead-time after transmitting a packet, use the **transmitter-delay**command in interface configuration mode. To restore the default, use the**no**form of this command.

transmitter-delay *delay*
no transmitter-delay

Syntax Description

delay	On the FSIP, high-speed serial interface (HSSI, and) on the IGS router, the minimum number of High-Level Data Link Control (HDLC) flags to be sent between successive packets. On all other serial interfaces and routers, approximate number of microseconds of minimum delay after transmitting a packet. The valid range is from 0 to 131071. Default is 0. For all interfaces using chipset CD2430 , the default is 2.

Command Default

0 flags or microseconds 2 for all interfaces using chipset CD2430

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is especially useful for serial interfaces that can send back-to-back data packets over serial interfaces faster than some hosts can receive them.

The transmitter delay feature is implemented for the following Token Ring cards: CSC-R16, CSC-R16M, CSC-1R, CSC-2R, and CSC-CTR. For the first four cards, the command syntax is the same as the existing command and specifies the number of microseconds to delay between sending frames that are generated by the router. Transmitter delay for the CSC-CTR uses the same syntax, but specifies a relative time interval to delay between transmission of all frames.

Examples

The following example shows how to specify a delay of 300 microseconds on serial interface 0:

```
Router(config
)
# interface serial 0
Router(config
-if)
# transmitter-delay 300
```

transport-mode

To configure a transport mode, use the **transport-mode**command in interface configuration mode. To return to the default state, use the **no** form of this command.

transport-mode {**lan** | **wan** | **otn** **bit-transparent** {**opu1e** | **opu2e**}}
no **transport-mode** {**lan** | **wan** | **otn** **bit-transparent** {**opu1e** | **opu2e**}}
transport-mode otn *otu4 100G*

Syntax Description

lan	10GBASE-R LAN pass-through mode (10.3125 Gb/s)
wan	10GBASE-W WAN (SONET/SDH) mode (9.95328 Gb/s)

otn	Optical Transport Network (G.709). The following modes are supported under interface OTN:
	• bit-transparent--XAUI transparently mapped into OTU-2 (11.096 or 11.049 Gb/s)
	  • opu1e--Over OPU1e (11.0491 Gb/s)
	  • opu2e--Over OPU2e (11.0957 Gb/s)

otu4	The encapsulation type

Command Default

LAN

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Examples

The following example shows how to configure a LAN transport mode:

```
Router(config-if)# transport-mode lan
```

Examples

The following example shows how to configure a LAN transport mode:

```
Router(config-if)# transport-mode otn otu4 100G
```

Related Commands

Command	Description
controller dwdm	Configures a DWDM controller.
g709 fec	Configures the FEC for the DWDM controller.
g709 odu threshold	Configures thresholds for selected ODU BER alarms.
g709 otu threshold	Configures thresholds for selected OTU BER alarms.

Command	Description
no g709 odu report	Disables the logging of selected ODU alarms.
no g709 otu report	Disables the logging of selected OTU alarms.
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.

transport ipv4

To specify IPv4 transport source mode and the transport source interface, use the **transportipv4** command in L3 VPN encapsulation configuration mode. To remove the transport source, use the **no** form of this command.

transport ipv4 [**source** *interface-type interface-number*]
no transport [**ipv4**]

Syntax Description

source	Specifies the IPv4 transport source.
interface-type	(Optional) The source interface type.
interface-number	(Optional) The source interface number.

Command Default

The IPV4 transport source mode and interface are not defined.

Command Modes

L3VPN Encapsulation Configuration (config-l3vpn-encap-ip)

Command History

Release	Modification
12.2(33)SRE	This command was introduced.

Usage Guidelines

The **transportipv4** command specifies IPv4 transport source mode and defines the transport source interface while configuring the L3VPN encapsulation profile. When you use this command, make sure that the specified source address is used as the nexthop in BGP updates advertised by the PE.

Examples

The following example shows how to specify IPv4 transport source mode and the transport source interface:

```
Router(config-l3vpn-encap-ip)# transport ipv4 source loopback 0
```

Related Commands

Command	Description
l3vpn encapsulation ip	Configures the L3VPN encapsulation profile.
protocol gre	Specifies GRE as the tunnel mode and sets the GRE key.
show l3vpn encapsulation ip	Displays the profile health and the underlying tunnel interface.

transport ipv4 (PTP)

To specify the IP version, transmission mode, and interface that a Precision Time Protocol clock port uses to exchange timing packets, use the **transport ipv4** command in PTP clock port configuration mode. To remove a transport configuration, use the **no** form of this command.

transport ipv4 {**unicast** | **multicast** | **multicast-mix**} **interface** *interface-type interface-number* [**negotiation**]
no transport ipv4 {**unicast** | **multicast** | **multicast-mix**} **interface** *interface-type interface-number* [**negotiation**]

Syntax Description

unicast	Configures the clock port to exchange timing packets in unicast mode.
multicast	Configures the clock port to exchange timing packets in multicast mode.
multicast-mix	Configures the clock port to exchange timing packets in multicast-unicast communication mode. In multicast-unicast mode, the clock port sends initial Announce and Sync messages as multicast; if a subordinate device responds with a unicast message, the clock port sends the Delay-Resp message as unicast.
interface	Specifies an interface on the device.
interface-type	The type of the interface.
interface-number	The number of the interface.
negotiation	(Optional) Enables dynamic discovery of subordinate devices and their preferred format for sync interval and announce interval messages.

Command Default

The IP version, transmission mode, and interface are not specified for exchanging timing packets.

Command Modes

PTP clock port configuration (config-ptp-clk)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

You can configure different transport values for each PTP clock port.

Examples

The following example shows how to use the **transportipv4** command:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# clock-port masterport master
Device(config-ptp-clk)# transport ipv4 unicast interface top5/2/2
Device(config-ptp-clk)# end
```

Related Commands

Command	Description
clock-port	Specifies the mode of a PTP clock port.

ts16

To control the use of time slot 16 for data on a G.703 E1 interface or on an E1-G.703/G.704 serial port adapter, use the **ts16** command in interface configuration mode. To restore the default, use the **no** form of this command.

ts16
no ts16

Syntax Description

This command has no arguments or keywords.

Command Default

Time slot 16 is used for signaling.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
11.1CA	This command was implemented on the E1-G.703/G.704 serial port adapter and Cisco 7200 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to Cisco 4000, 7000, 7200, and 7500 series routers. By default, time slot 16 is used for signaling. Use this command to configure time slot 16 to be used for data. When in framed mode, in order to get all possible subframes or time slots, you must use the **ts16** command.

Examples

The following example shows how to configure time slot 16 to be used for data on a G.703 E1 interface or an E1-G.703/G.704 serial port adapter:

```
Router(config
-if)
# ts16
```

Related Commands

Command	Description
timeslot	Enables framed mode serial interface on a G.703 E1 port adapter, an FSIP, or an E1-G.703/G.704 serial port adapter.

ttb

To send a trace trail buffer in E3 g832 framing mode, use the **ttb** command in interface configuration mode. To disable the trace, use the **no** form of this command.

ttb {**country** | **rnode** | **serial** | **snode** | **soperator** | **x**} *line*
no ttb {**country** | **rnode** | **serial** | **snode** | **soperator** | **x**} *line*

Syntax Description

country *line*	Two-character country code.
rnode *line*	Receive node code.
serial *line*	M.1400 Serial
snode *line*	Sending Town/Node ID code.
soperator *line*	Sending Operator code.
x *line*	XO

Command Default

No default behavior or values

Command Modes

Interface configuration

Command History

Release	Modification
12.2S	This command was introduced.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **ttb** command to attach a header that contains fields to send to a remote device.

Examples

The following example starts a TTB message on the first port on slot 5.

```
Router# configure terminal
Router(config)# int serial 5/0/0
Router(config-if)# ttb country us
Router(config-if)# ttb snode 123
Router(config-if)# ttb rnode rn
Router(config-if)# ttb x 9
Router(config-if)# ttb serial 432
```

Related Commands

Command	Description
show controller serial	Displays controller statistics.

ttl

Use this command to configure static pseudowire OAM class configuration .

ttl *value*

Syntax Description

Syntax Description:

value	TTL value for multi-segment pseudowire OAM data

Command Default

Default value is 1

Command Modes

Global configuration

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	This command was introduced into the Cisco ASR 920 Routers.

Examples

The following example shows how to configure static pseudowire OAM:

```
enable
configure terminal
pseudowire-static-oam class oam-class1
timeout refresh send 20
ttl 3
end
```

tu-ais

To enable the SDH device to detect the PDH AIS alarm TU-AIS alarms are generated and detected when the TDM circuits go down on the access layer of the network topology or a failure occurs in MPLS domain due to which SAToP connectivity goes down, use the tu-ais command in SONET configuration mode. To disable the TU-AIS alarms, use the no form of this command..

tu-ais

no tu-ais

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Default

This command is disabled by default; no TU-AIS alarm is sent.

Command Modes

SONET configuration

Command History

Release	Modification
IOS XE Everest 16.6.1	Support for this command was introduced on the Cisco ASR 900 Routers.

Usage Guidelines

The TU-AIS alarms are supported on the OC3 IM in Cisco ASR 903 RSP1 and RSP2 modules according to TU-12 section as defined in ITU-G. 707 (8.3.2). TU-AIS means that all TU-12 (i.e. all 144B) carries all "1" according to ITU-T G.707 (6.2.4.1.3).

Examples

The following example shows the configuration of AIS SHUT:

```
enable
configure terminal
controller sonet 0/5/0
tu-ais
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.
show run | se	Displays the TU-AIS alarm configuration.

tug-2

Use this command to configure mode Tributary Unit group type 2 (TUG-2) number that has been mapped to an AU-4.

tug-2 *tug-2 number* **payload** [*VC11* | *VC12*]

Syntax Description

Syntax Description

tug-2 number	The range is from 1 to 7.
payload	Specifies VC11 or VC12 payload.
VC11	TUG-2 payload VC-11 can be configured as VC or T1 and the range is 1 to 4.
VC12	TUG-2 payload VC-12 can be configured as VC or E1 and the range is 1 to 3.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

When you configure mode VC-1x, seven TUG-2 payloads are created. TUG-2 payloads can be of two types, VC-11 and VC-12. Default for TUG-2 payload mode is VC-11.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm4
au-4 1
mode tug-3
tug-3 1
mode vc1x
cem-group 100 unframed
end
```

Related Commands

Command	Description
show running configuration	Verifies TUG-3 configuration.

tug-2 e1

To create E1 controllers for a specified path under the Tributary Unit group type 2 (TUG-2), use the **tug-2e1**command in controller configuration mode.

tug-2 *tug-2-number* **e1** *e1-number*

Syntax Description

tug-2-number	Number, or range of numbers, from 1 to 7. To specify a range of TUG-2 numbers use a dash between the values, for example 1-5. An individual TUG-2 can be specified using a comma between values, for example 2,4. Default is 1.
e-1-number	Number, or range of numbers, from 1 to 3. To specify a range of E1 numbers use a dash between the values, for example 1-3. An individual E1 can be specified using a comma between values, for example 2,3.

Command Default

Default *tug-2-number* value for STM-1 card is 1.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

Use the **tug-2e1** command to create an E1 controller with the following name format:

slot/port.path/tug-2-number/e1-number

Up to 21 controllers can be created for one path. Only one path can be selected at a time.

Examples

The following example shows how to configure 15 E1 controllers on the second path of an STM-1 in physical slot number 2 of a Cisco AS5850 chassis:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-4
Router(config-ctrlr-tug3)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 5 e1 3
```

Related Commands

Command	Description
show controller sonet	Displays information about SONET controllers.

tug-2 e1 bert pattern

To send a BER test pattern on an E1 line that has been mapped to a TUG-3, use the **tug-2e1bertpattern**command in configuration controller tug3 mode.

To send a BER test pattern on an E1 line that has been mapped to an AU-3, use the **tug-2e1bertpattern**command in configuration controller au3 mode.

To stop the BER test, use the **no** form of this command.

tug-2 *tug-2 number* **e1** *e1-number* [**bert pattern** *pattern* **interval** *time*]
[**no**] **tug-2** *tug-2 number* **e1** *e1-number* [**bert pattern** *pattern* **interval** *time*]

Syntax Description

tug-2 number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
pattern	• 2^11, pseudorandom test pattern (2048 bits long). • 2^15, pseudorandom O.151 test pattern (32,768 bits long). • 2^20-O153, 2^20-1 O.153 test pattern. • 2^20-QRSS, pseudorandom QRSS O.151 test pattern (1,048,575 bits long).
time	An interval in the range of 1 to14,400 minutes.

Command Default

No BER test is configured.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	Support for this command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 bert pattern command in configuration controller tug3 command mode to send a BERT test on an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 bert pattern command in configuration controller au3 command mode to send a BERT test on an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

To view the test results of a BER test pattern, use the show controller sonet command.

Examples

The following example sends a BER 2^11 pseudorandom pattern through E1 line 1, that has been mapped to a TUG-3 on a Cisco 7500 series router, for five minutes:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 bert pattern 2^11 interval 5
```

The following example sends a BER 2^15 pseudorandom pattern through E1 line 1, that has been mapped to an AU-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch, for ten minutes:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 bert pattern 2^15 interval 10
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-2 e1 channel-group timeslots

To create a logical channel group on an E1 line that has been mapped to a TUG-3 or AU-3, use the **tug-2e1channel-grouptimeslots** command in the appropriate configuration mode. To remove a logical channel group, use no the form of this command.

tug-2 *tug-2-number* **e1** *e1-number* [[**channel-group** *channel-group-number*] [**timeslots** *list-of-timeslots*]]
no tug-2 *tug-2-number* **e1** *e1-number* [[**channel-group** *channel-group-number*] [**timeslots** *list-of-timeslots*]]

Syntax Description

tug-2-number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
channel-group	Defines a logical channel group to be a channelized E1 line.
channel-group-number	(Optional) A number in the range of 0 to 30.
timeslots	(Optional) Creates the time slots that make up the E1 line.
list-of-timeslots	(Optional) A number in the range of 1 to 31 or a combination of subranges within 1 to 31.

Command Default

No channel groups are configured on an E1 line.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	Support for this command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is supported on the C 10000 router. It is used with the Cisco channelized STM-1 card. Use the tug-2 e1 channel-group timeslots command in configuration controller tug3 command mode to configure a logical channel group on an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 channel-group timeslots command in configuration controller au3 command mode to configure a logical channel group on an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

Examples

The following example configures logical channel group 15 on E1 1, that is mapped to a TUG-3, and assigns channelized time slots 1 to 5 and 20 to 23 on a Cisco 7500 series router:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# framing sdh
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 channel group 15 timeslots 1-5, 20-23
```

The following example configures logical channel group 10 on E1 1, that is mapped to an AU-3, and assigns channelized time slots 1 to 5 and 20 to 23 on a Cisco 7200 VXR router or a Catalyst 6000 family switch:

```
Router(config)# controller sonet 2/0
Router(config-controller)# framing sdh
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 channel group 10 timeslots 1-5, 20-23
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.
tug-2 e1 unframed	Creates an unframed (clear channel) logical channel group on an E1 line.
tug-2 e1 framing	Specifies the type of framing used by the E1 lines.

tug-2 e1 clock source

To set the clock source on an E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1clocksource**command in the appropriate configuration mode.

tug-2 *tug-2-number* **e1** *e1-number* **clock source** {**internal** | **line**}

Syntax Description

tug-2-number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
internal	Specifies the PA-MC-STM-1 as the clock source.
line	Specifies the E1 line as the clock source.

Command Default

Clock source is configured from the E1 line.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 clock source command in configuration controller tug3 command mode to configure the clock source of an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 clock source command in configuration controller au3 command mode to configure the clock source of an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

Examples

The following example configures E1 line 1, that has been mapped to an AU-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch, to be the clock source:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 clock source line
```

The following example configures E1 line 1, that has been mapped to a TUG-3 on a Cisco 7500 series router to use the PA-MC-STM-1, as the clock source:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 clock source internal
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-2 e1 framing

To set the type of framing used by an E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1framing**command in appropriate configuration mode. To disable the framing mode, user the no form of this command.

tug-2 *tug-2-number* **e1** *e1-number* **framing** {**crc4** | **no-crc4**}
no **tug-2** *tug-2-number* **e1** *e1-number* **framing** {**crc4** | **no-crc4**}

Syntax Description

tug-2-number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
crc4	Specifies 4-bit cyclic redundancy check framing.
no-crc4	Specifies basic framing.

Command Default

Framing format is crc4.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.

12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 framing command in configuration controller tug3 command mode to configure the type of framing used by an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 framing command in configuration controller au3 command mode to configure the type of framing used by an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

Examples

The following example configures E1 line 1, that has been mapped to a TUG-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch, to use crc4 framing:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-4
```

```
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 framing crc4
```

The following example configures E1 line 1, that has been mapped to an AU-3 on a Cisco 7500 series router, to use basic framing:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 framing no-crc4
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.
tug-2 e1 unframed	Creates an unframed (clear channel) logical channel group on an E1 line.

tug-2 e1 loopback

To specify a loopback on an E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1loopback**command in appropriate configuration mode. To disable the loopback, use the **no** form of this command.

tug-2 *tug-2-number* **e1** *e1-number* **loopback** {**local** | **network** {**line** | **payload**}}
[**no**] **tug-2** *tug-2-number* **e1** *e1-number* **loopback** {**local** | **network** {**line** | **payload**}}

Syntax Description

tug-2-number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
local	Loops transmitted E1 output back to the router via the internal E1 framer.
network {**line**| **payload**	Sets the loopback toward the network before going through the framer (**line**) or after going through the framer (payload).

Command Default

No loopbacks are set on an E1 line.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR erouters and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

TUG-3 Command Mode

Use the tug-2 e1 loopback command in configuration controller tug3 command mode to specify a loopback for an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

AU-3Command Mode

Use the tug-2 e1 loopback command in configuration controller au3 command mode to specify a loopback for an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

tug-2 e1 loopback network line|path Command

If you configure a loopback to an e1 interface, it will be be looped as configured. However, if a channel group is configured while the loopback interface is still in configuration, the interface driver will ignore the loopback command in the configuration and the serial interface will be activated.

Examples

E1 Line Mapped to an AU-3 Interface

The following example sets E1 line 1 that has been mapped to an AU-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch, into network line loopback:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 loopback network line
```

E1 Line Mapped to a TUG-3 Interface

The following example sets E1 line 1, that has been mapped to a TUG-3 on a Cisco 7500 series router, into local loopback:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 loopback local
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-2 e1 national bits

To set the national reserved bits on an E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1nationalbits**command in appropriate configuration mode.

tug-2 *tug-2-number* **e1** *e1-number* **national bits** *pattern*

Syntax Description

tug-2 -umber	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.
pattern	The national reserved bit pattern is a hexadecimal value in the range 0x0 to 0x1F (hexadecimal) or 0 to 31 (decimal).

Command Default

0x1F

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 national bits command in configuration controller tug3 command mode to configure the national reserved bits for an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 national bits command in configuration controller au3 command mode to configure the national reserved bits for an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

Examples

The following example configures the national reserved bits for E1 line 1, that has been mapped to a TUG-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch, into a 0x0 hexadecimal pattern:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 national bits 0x0
```

The following example configures the national reserved bits for E1 line 1, that has been mapped to an AU-3 on a Cisco 7500 series router, into decimal pattern 0:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 national bits 0
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-2 e1 shutdown

To shut down an individual E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1shutdown**command in appropriate configuration mode. To enable an individual E1 line, use the **no** form of this command.

tug-2 *tug-2-number* **e1** *e1-number* **shutdown**
[**no**] **tug-2** *tug-2* *number* **e1** *e1-number* **shutdown**

Syntax Description

tug-2-number	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.

Command Default

E1 lines are not shut down.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 shutdown command in configuration controller tug3 command mode to shut down an individual E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 shutdown command in configuration controller au3 command mode to shut down an individual E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

Examples

The following example shuts down E1 line 1 that has been mapped to an AU-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 shutdown
```

The following example shuts down E1 line 1, that has been mapped to a TUG-3 on a Cisco 7500 series router:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 shutdown
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-2 e1 unframed

To create an E1 unframed (clear channel) logical channel group on an E1 line that has been mapped to a TUG-3 or an AU-3, use the **tug-2e1unframed**command in appropriate configuration mode. To remove a logical channel group, use the **no** form of this command.

tug-2 *tug-2-number* **e1** *e1-number* **unframed**
[**no**] **tug-2** *tug-2-number* **e1** *e1-number* **unframed**

Syntax Description

tug-2 -umber	A number in the range of 1 to 7.
e1-number	A number in the range of 1 to 3.

Command Default

No default behavior or values.

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E. Support for this command was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the tug-2 e1 unframed command in configuration controller tug3 command mode to create an unframed (clear channel) logical channel group on an E1 line that has been mapped to a TUG-3 via the aug mapping au-4 command.

Use the tug-2 e1 unframed command in configuration controller au3 command mode to create an unframed (clear channel) logical channel group on an E1 line that has been mapped to an AU-3 via the aug mapping au-3 command.

The channel group number for unframed E1 lines is always 0.

Examples

The following example configures an unframed logical channel group on E1 line 1 that has been mapped to a TUG-3 on a Cisco 7200 VXR router or a Catalyst 6000 family switch:

```
Router(config)# controller sonet 2/0
Router(config-controller)# aug mapping au-4
```

```
Router(config-controller)# au-4 1 tug-3 2
Router(config-ctrlr-tug3)# tug-2 4 e1 1 unframed
```

The following example configures an unframed logical channel group on E1 line 1 that has been mapped to an AU-3 on a Cisco 7500 series router:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au-3 1
Router(config-ctrlr-au3)# tug-2 4 e1 1 unframed
```

Related Commands

Command	Description
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1.
au-3	Configures a particular AU-3 of an E1 line that has been mapped to an AU-3.
au-4 tug-3	Specifies the AU-4 and TUG-3 number of an E1 line that has been mapped to an AU-4.

tug-3

Use this command to configure mode Tributary Unit group type 3 (TUG-3) number that has been mapped to an AU-4.

tug-3 *tug-3 number*

Syntax Description

Syntax Description

tug-3 number	The range is from 1 to 3.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

An AUG of an STM-1 can be derived from either AU-3s or an AU-4. Use the **aug mapping au-4** configuration controller command to map the AUG to a TUG-3. Configuring the **au-4** command enables you to enter configuration controller tug3 command mode and creates a serial interface.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm4
au-4 1
mode tug-3
tug-3 1
mode t3
cem-group 100 unframed
end
```

Related Commands

Command	Description
show running configuration	Verifies TUG-3 configuration.

tunnel bandwidth through yellow

tunnel bandwidth

To set the transmit bandwidth used by the tunnel interface, use the **tunnelbandwidth** command in interface configuration mode. To restore the default setting, use the no form of this command.

tunnel bandwidth {**receive** | **transmit**} *bandwidth*
no tunnel bandwidth

Syntax Description

receive	Specifies the bandwidth to be used to receive packets through the tunnel. **Note** This keyword is no longer used and will be removed in future releases.
transmit	Specifies the bandwidth to be used to send packets through the tunnel.
bandwidth	Bandwidth, in kbps. Range is from 0 to 2147483647. Default is 8000.

Command Default

8000 kbps

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **tunnelbandwidth** command to specify the capacity of the satellite link.

Examples

The following example shows how to set the satellite tunnel bandwidth to 1000 kbps for transmitting packets using Rate Based Satellite Control Protocol:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel bandwidth transmit 1000
```

Related Commands

Command	Description
tunnel destination	Specifies the destination for a tunnel interface.
tunnel mode	Sets the encapsulation mode for a tunnel interface.
tunnel source	Sets the source address of a tunnel interface.

tunnel checksum

To enable encapsulator-to-decapsulator checksumming of packets on a tunnel interface, use the **tunnelchecksum**command in interface configuration mode. To disable checksumming, use the **no** form of this command.

tunnel checksum
no tunnel checksum

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command currently applies to generic routing encapsulation (GRE) only. Some passenger protocols rely on media checksums to provide data integrity. By default, the tunnel does not guarantee packet integrity. By enabling end-to-end checksums, the routers will drop corrupted packets.

Examples

The following example shows how to enable encapsulator-to-decapsulator checksumming of packets for all protocols on the tunnel interface:

```
Router(config
-if)
# tunnel checksum
```

tunnel mpls-ip-only

To copy the inner IP header's Do Not Fragment bit from the payload into the tunnel packet's IP header, use the **tunnel mpls-ip-only** command in the interface configuration mode.

tunnel mpls-ip-only
no tunnel mpls-ip-only

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
17.5.1	This command was introduced.

Usage Guidelines

If the Do Not Fragment bit is not set, the payload is fragmented when the IP packet exceeds the MTU set for the interface. When you enable the **tunnel mpls-ip-only** command, the **tunnel path-mtu-discovery** automatically gets enabled due to the dependency.

Examples

The following example shows how to enable this command:

```
Router(config-if)# tunnel mpls-ip-only
```

tunnel destination

To specify the destination for a tunnel interface, use the **tunnel destination** command in interface configuration mode. To remove the destination, use the **no** form of this command.

tunnel destination {*host-nameip-addressipv6-address* | **dynamic**}
no tunnel destination

Command Syntax for Cisco Catalyst 3850 Series Switches

tunnel destination *ip-address*
no tunnel destination

Syntax Description

host-name	Name of the host destination.
ip-address	IP address of the host destination expressed in dotted decimal notation.
ipv6-address	IPv6 address of the host destination expressed in IPv6 address format.
dynamic	Applies the tunnel destination address dynamically to the tunnel interface.

Command Default

No tunnel interface destination is specified.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.0	This command was introduced.
12.3(7)T	This command was modified. The address field was modified to accept an *ipv6-address* argument to allow IPv6 nodes to be configured as a tunnel destination.
12.2(30)S	This command was integrated into Cisco IOS Release 12.2(30)S.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(25)SG	This command was integrated into Cisco IOS Release 12.2(25)SG.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was introduced on Cisco ASR 1000 Series Routers.
15.1SY	This command was integrated into Cisco IOS Release 15.1SY.
Cisco IOS XE Release 3.7S	This command was modified. The **dynamic** keyword was added.

Release	Modification
15.4(2)S	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

You cannot configure two tunnels to use the same encapsulation mode with exactly the same source and destination addresses. The workaround is to create a loopback interface and configure the packet source off of the loopback interface. Refer to the *Cisco IOS AppleTalk*, *ISO CLNS*, *and Novell IPX Configuration Guide* for more information about AppleTalk Cayman tunneling.

Note **Only GRE tunneling is supported on Cisco Catalyst 3850 Series Switches.**

Tunnel Destination Address for Cayman Tunnel

The following example shows how to configure the tunnel destination address for Cayman tunneling:

```
Device(config)# interface tunnel0
Device(config-if)# tunnel source ethernet0
Device(config-if)# tunnel destination 10.108.164.19
Device(config-if)# tunnel mode cayman
```

Tunnel Destination Address for Dynamic Tunnel

The following example shows how to set the tunnel destination address dynamically:

```
Device(config)# interface tunnel0
Device(config-if)# tunnel destination dynamic
Device(config-if)# *Nov 22 19:38:28.271: Tunnel notified destination change: dynamic is set
Device(config-if)# end
Device# show run interface tunnel0
Building configuration...

Current configuration : 63 bytes
!
interface Tunnel0
 no ip address
 tunnel source dynamic
 tunnel destination dynamic
end
```

If the tunnel destination address is configured to be set dynamically, you cannot configure the tunnel destination address without removing the dynamic configuration.

```
Device(config)# interface tunnel0
Device(config-if)# tunnel destination ethernet 0/0
Device(config-if)# end
Device# show run interface tunnel0
Building configuration...

Current configuration : 63 bytes
!
interface Tunnel0
```

```
 no ip address
 tunnel destination dynamic
end
Device# configure terminal
Device(config)# interface tunnel0
Device(config-if)# no tunnel destination
```

Tunnel Destination Address for GRE Tunneling

The following example shows how to configure the tunnel destination address for generic routing encapsulation (GRE) tunneling:

```
Device(config)# interface tunnel0
Device(config-if)# appletalk cable-range 4160-4160 4160.19
Device(config-if)# appletalk zone Engineering
Device(config-if)# tunnel source ethernet0
Device(config-if)# tunnel destination 10.108.164.19
Device(config-if)# tunnel mode gre ip
```

Tunnel Destination Address for GRE Tunneling on Cisco Catalyst 3850 Series Switches

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in Global or non- VRF environment on Cisco Catalyst 3850 Series Switches:

```
Device(config)# interface tunnel 2
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in VRF environment on Cisco Catalyst 3850 Series Switches. Use the **vrf definition** *vrf-name* and the**vrf forwarding** *vrf-name* commands to configure and apply VRF.

```
Device(config)# vrf definition RED
Device(config-vrf)#  address-family ipv4
Device(config-vrf-af)# exit-address-family
Device(config-vrf)#  exit
Device(config)# interface tunnel 2
Device(config)# vrf forwarding RED
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

Tunnel Destination Address for IPv6 Tunnel

The following example shows how to configure the tunnel destination address for GRE tunneling of IPv6 packets:

```
Device(config)# interface Tunnel0
Device(config-if)# no ip address
Device(config-if)# ipv6 router isis
```

```
Device(config-if)# tunnel source Ethernet0/0
Device(config-if)# tunnel destination 2001:0DB8:1111:2222::1/64
Device(config-if)# tunnel mode gre ipv6
Device(config-if)# exit
!
Device(config)# interface Ethernet0/0
Device(config-if)# ip address 10.0.0.1 255.255.255.0
Device(config-if)# exit
!
Device(config)# ipv6 unicast-routing
Device(config)# router isis
Device(config)# net 49.0000.0000.000a.00
```

Note **IPv6 GRE tunneling is not supported on Cisco Catalyst 3850 Series Switches.**

Related Commands

Command	Description
appletalk cable-range	Enables an extended AppleTalk network.
appletalk zone	Sets the zone name for the connected AppleTalk network.
tunnel mode	Sets the encapsulation mode for the tunnel interface.
tunnel source	Sets the source address of a tunnel interface.

tunnel endpoint service-policy output

To configure a Quality of Service (QoS) policy for a tunnel in an output direction, use the **tunnel endpoint service-policy output** command in configuration interface mode. To remove the QoS policy for a tunnel, use the **no** form of the command.

tunnel endpoint service-policy output *policy-name*

Syntax Description

policy-name	Name of the policy map to associate with a tunnel.

Command Default

By default no policy is configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
Cisco IOS XE 13.3S	This command was introduced.

Usage Guidelines

Use the **tunnel endpoint service policy output** command to associate a service policy with Ethernet over GRE (EoGRE) tunnels. Use the **policy-map** command in global configuration mode, to create a policy map.

The following example shows how to configure a Quality of Service (QoS) policy for outward traffic on a tunnel:

```
Device(config)# interface tunnel 1
Device(config-if)# tunnel source Loopback 0
Device(config-if)# tunnel vlan 10, 20
Device(config-if)# ip address unnumbered Loopback 0
Device(config-if)# tunnel mode ethernet gre ipv4
Device(config-if)# tunnel endpoint service-policy output tunnel-qos-policy
Device(config-if)# ip subscriber l2-connected
Device(config-subscriber)# initiator unclassified mac-address
Device(config-subscriber)# initiator dhcp
Device(config-subscriber)# exit
```

Related Commands

Command	Description
policy-map	Creates a policy map that can be attached to one or more interfaces.
show policy-map multipoint tunnel	Displays information about a specific QoS policy for a multipoint tunnel interface.

tunnel entropy

To achieve load balancing of tunnel packets in a network, use the **tunnel entropy** command in interface configuration mode. To stop load balancing, use the **no** form of the command.

tunnel entropy

no tunnel entropy

Command Default

Calculation of tunnel entropy is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
Cisco IOS XE Release 3.11S	This command was introduced.

Usage Guidelines

You can enable tunnel entropy calculation only in Generic Routing Encapsulation (GRE) mode. If you configure a 32-bit tunnel key, you must remove the existing key first.

To disable tunnel entropy calculation, you must remove the configured tunnel key before using the **no tunnel entropy** command to disable entropy calculation.

Use the **show interfaces tunnel** command to verify whether tunnel entropy calculation is enabled or not. If it is enabled, the key size is also displayed.

Example

The following example shows how to configure tunnel entropy calculation for GRE mode of the tunnel interface:

```
Device> enable
Device# configure terminal
Device(config)# interface tunnel 21
Device(config-if)# tunnel source 10.1.1.1
Device(config-if)# tunnel destination 172.168.2.1
Device(config-if)# tunnel mode gre ip
Device(config-if)# tunnel key 4683
Device(config-if)# tunnel entropy
Device(config-if)# end
```

The following is sample output from the **show interfaces tunnel** command, which displays that tunnel entropy calculation is enabled with a 24-bit key:

```
Device# show interfaces tunnel 21

Tunnel21 is up, line protocol is up
Hardware is Tunnel
MTU 17864 bytes, BW 100 Kbit/sec, DLY 50000 usec,
reliability 255/255, txload 1/255, rxload 1/255
Encapsulation TUNNEL, loopback not set
Keepalive not set
Tunnel source 10.1.1.1, destination 172.168.2.1
```

```
Tunnel protocol/transport GRE/IP
Key 0x124B, sequencing disabled
Checksumming of packets disabled
Tunnel Entropy Calculation Enabled (24-bit Key)
Tunnel TTL 255, Fast tunneling enabled
Tunnel transport MTU 1472 bytes
Tunnel transmit bandwidth 8000 (kbps)
Tunnel receive bandwidth 8000 (kbps)
Last input never, output never, output hang never
Last clearing of "show interface" counters 00:03:07
Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
Queueing strategy: fifo
Output queue: 0/0 (size/max)
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
0 packets input, 0 bytes, 0 no buffer
Received 0 broadcasts (0 IP multicasts)
0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
0 packets output, 0 bytes, 0 underruns
0 output errors, 0 collisions, 0 interface resets
0 unknown protocol drops
0 output buffer failures, 0 output buffers swapped out
```

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on a device or access server.
show ip route	Displays the current state of the routing table.

tunnel key

To enable an ID key for a tunnel interface, use the**tunnelkey** command in interface configuration mode. To remove the ID key, use the **no** form of this command.

tunnel key *key-number*
no tunnel key

Syntax Description

key-number	Number from 0 to 4294967295 that identifies the tunnel key.

Command Default

No tunnel ID keys are enabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 3.11S	This command was integrated into Cisco IOS XE Release 3.11S.

Usage Guidelines

This command currently applies to generic route encapsulation (GRE) only. Tunnel ID keys can be used as a form of *weak* security to prevent improper configuration or injection of packets from a foreign source.

Note IP multicast traffic is not supported when a tunnel ID key is configured unless the traffic is process-switched. You must configure the **noipmroute-cache** command in interface configuration mode on the interface if an ID key is configured. This note applies only to Cisco IOS Release 12.0 and earlier releases.

Note When GRE is used, the ID key is carried in each packet. We do *not* recommend relying on this key for security purposes.

Examples

The following example shows how to set the tunnel ID key to 3:

```
Device(config-if)# tunnel key 3
```

tunnel mode

To set the encapsulation mode for the tunnel interface, use the **tunnel mode** command in interface configuration mode. To return to the default mode, use the **no** form of this command.

tunnel mode {**aurp** | **cayman** | **dvmrp** | **eon** | **ethernet gre** {**ipv4** | **ipv6**} | **gre** | **gre multipoint** | **gre ipv6** | **ipip** [**decapsulate-any**] | **ipsec ipv4** | **iptalk** | **ipv6** | **ipsec ipv6** | **mpls** | **nos** | **rbscp** }
no tunnel mode

Command Syntax for Cisco Catalyst 3850 Series Switches

tunnel mode gre ip
no tunnel mode

Syntax Description

aurp	AppleTalk Update-Based Routing Protocol.
cayman	Cayman TunnelTalk AppleTalk encapsulation.
dvmrp	Distance Vector Multicast Routing Protocol (DMVRP).
ethernet gre ipv4	Ethernet over Generic Routing Encapsulation (GRE) IPv4.
ethernet gre ipv6	Ethernet over GRE IPv6.
eon	EON–compatible Connectionless Network Service (CLNS) tunnel.
gre	GRE protocol. This is the default.
gre multipoint	Multipoint GRE (mGRE).
gre ipv6	GRE tunneling using IPv6 as the delivery protocol.
ipip	IP-over-IP encapsulation.
decapsulate-any	(Optional) Terminates any number of IP-in-IP tunnels at one tunnel interface. This tunnel will not carry any outbound traffic; however, any number of remote tunnel endpoints can use a tunnel configured this way as their destination.
ipsec ipv4	Tunnel mode is IPSec, and the transport is IPv4.
iptalk	Apple IPTalk encapsulation.
ipv6	Static tunnel interface configured to encapsulate IPv6 or IPv4 packets in IPv6.
ipsec ipv6	Tunnel mode is IPSec, and the transport is IPv6.
mpls	Multiprotocol Label Switching (MPLS) encapsulation.
nos	KA9Q/NOS–compatible IP over IP.
rbscp	Rate Based Satellite Control Protocol (RBSCP).

Command Default

The default is GRE tunneling.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.0	This command was introduced.
10.3	This command was modified. The **aurp**, **dvmrp**, and **ipip** keywords were added.
11.2	This command was modified. The optional **decapsulate-any** keyword was added.
12.2(13)T	This command was modified. The **gre multipoint** keyword was added.
12.3(7)T	This command was modified. The following keywords were added: • **gre ipv6** to support GRE tunneling using IPv6 as the delivery protocol. • **ipv6** to allow a static tunnel interface to be configured to encapsulate IPv6 or IPv4 packets in IPv6. • **rbscp** to support RBSCP.
12.3(14)T	This command was modified. The **ipsec ipv4** keyword was added.
12.2(18)SXE	This command was modified. The **gre multipoint** keyword was added.
12.2(30)S	This command was integrated into Cisco IOS Release 12.2(30)S.
12.2(25)SG	This command was integrated into Cisco IOS Release 12.2(25)SG.
12.4(4)T	This command was modified. The **ipsec ipv6** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 2.1	This command was implemented on Cisco ASR 1000 Series Routers.
15.1SY	This command was integrated into Cisco IOS Release 15.1SY.
Cisco IOS XE Release 3.9S	This command was modified. The **ethernet gre** keyword was added.

Usage Guidelines

Source and Destination Address

You cannot have two tunnels that use the same encapsulation mode with exactly the same source and destination address. The workaround is to create a loopback interface and source packets off of the loopback interface.

Cayman Tunneling

Designed by Cayman Systems, Cayman tunneling enables tunneling to enable Cisco routers to interoperate with Cayman GatorBoxes. With Cayman tunneling, you can establish tunnels between two routers or between a Cisco router and a GatorBox. When using Cayman tunneling, you must not configure the tunnel with an AppleTalk network address.

DVMRP

Use DVMRP when a router connects to an mrouted (multicast) router to run DVMRP over a tunnel. You must configure Protocol Independent Multicast (PIM) and an IP address on a DVMRP tunnel.

Ethernet over GRE

Use Ethernet over GRE to send ethernet traffic from low-end resident gateways (RGs) or Customer Premises Equipment (CPE) to aggregation routers where Mobile Access Gateway (MAG) is enabled over GRE tunnels. The RGs and CPE can then provide mobility services to mobile nodes (MNs).

GRE with AppleTalk

GRE tunneling can be done between Cisco routers only. When using GRE tunneling for AppleTalk, you configure the tunnel with an AppleTalk network address. Using the AppleTalk network address, you can ping the other end of the tunnel to check the connection.

Multipoint GRE

After enabling mGRE tunneling, you can enable the **tunnel protection** command, which allows you to associate the mGRE tunnel with an IPSec profile. Combining mGRE tunnels and IPSec encryption allows a single mGRE interface to support multiple IPSec tunnels, thereby simplifying the size and complexity of the configuration.

Note GRE tunnel keepalives configured using the **keepalive** command under a GRE interface are supported only on point-to-point GRE tunnels.

RBSCP

RBSCP tunneling is designed for wireless or long-distance delay links with high error rates, such as satellite links. Using tunnels, RBSCP can improve the performance of certain IP protocols, such as TCP and IPSec, over satellite links without breaking the end-to-end model.

IPsec in IPv6 Transport

IPv6 IPsec encapsulation provides site-to-site IPsec protection of IPv6 unicast and multicast traffic. This feature allows IPv6 routers to work as a security gateway, establishes IPsec tunnels to another security gateway router, and provides crypto IPsec protection for traffic from an internal network when it is transmitted across the public IPv6 Internet. IPv6 IPsec is very similar to the security gateway model using IPv4 IPsec protection.

Note **Only GRE tunneling is supported on Cisco Catalyst 3850 Series Switches.**

Cayman Tunneling

The following example shows how to enable Cayman tunneling:

```
Device(config)# interface tunnel 0
Device(config-if)# tunnel source ethernet 0
Device(config-if)# tunnel destination 10.108.164.19
Device(config-if)# tunnel mode cayman
```

Ethernet over GRE Tunneling

The following example shows how to enable Ethernet over GRE tunneling for IPv6:

```
Device(config)# interface tunnel 0
Device(config)# mac-address 0000.0000.00001
Device(config-if)# ip address 10.1.1.2 255.255.255.0
Device(config-if)# tunnel source Loopback0
Device(config-if)# tunnel mode gre ipv6
Device(config-if)# tunnel vlan 1023
```

GRE Tunneling

The following example shows how to enable GRE tunneling:

```
Device(config)# interface tunnel 0
Device(config-if)# appletalk cable-range 4160-4160 4160.19
Device(config-if)# appletalk zone Engineering
Device(config-if)# tunnel source ethernet0
Device(config-if)# tunnel destination 10.108.164.19
Device(config-if)# tunnel mode gre
```

GRE Tunneling Examples for Cisco Catalyst 3850 Series Switches

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in Global or non- VRF environment on Cisco Catalyst 3850 Series Switches:

```
Device(config)# interface tunnel 2
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in VRF environment on Cisco Catalyst 3850 Series Switches. Use the **vrf definition** *vrf-name* and the**vrf forwarding** *vrf-name* commands to configure and apply VRF.

```
Device(config)# vrf definition RED
Device(config-vrf)#  address-family ipv4
Device(config-vrf-af)# exit-address-family
Device(config-vrf)#  exit
Device(config)# interface tunnel 2
Device(config)# vrf forwarding RED
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

Note **IPv6 GRE tunneling is not supported on Cisco Catalyst 3850 Series Switches.**

IPsec in IPv4 Transport

The following example shows how to configure a tunnel using IPsec encapsulation with IPv4 as the transport mechanism:

```
Device (config)# crypto ipsec profile PROF
Device (config)# set transform tset
Device (config)# interface tunnel 0
Device (config-if)# ip address 10.1.1.1 255.255.255.0
Device (config-if)# tunnel mode ipsec ipv4
Device (config-if)# tunnel source loopback 0
Device (config-if)# tunnel destination 172.16.1.1
```

IPsec in IPv6 Transport

The following example shows how to configure an IPv6 IPsec tunnel interface:

```
Device(config)# interface tunnel 0
Device(config-if)# ipv6 address 2001:0DB8:1111:2222::2/64
Device(config-if)# tunnel destination 10.0.0.1
Device(config-if)# tunnel source Ethernet 0/0
Device(config-if)# tunnel mode ipsec ipv6
Device(config-if)# tunnel protection ipsec profile profile1
```

Multipoint GRE Tunneling

The following example shows how to enable mGRE tunneling:

```
interface Tunnel0
 bandwidth 1000
 ip address 10.0.0.1 255.255.255.0
! Ensures longer packets are fragmented before they are encrypted; otherwise, the ! receiving
 router would have to do the reassembly.
 ip mtu 1416
! Turns off split horizon on the mGRE tunnel interface; otherwise, EIGRP will not ! advertise
 routes that are learned via the mGRE interface back out that interface.
 no ip split-horizon eigrp 1
 no ip next-hop-self eigrp 1
 delay 1000
! Sets IPSec peer address to Ethernet interface’s public address.
 tunnel source Ethernet0
 tunnel mode gre multipoint
! The following line must match on all nodes that want to use this mGRE tunnel.
 tunnel key 100000
 tunnel protection ipsec profile vpnprof
```

RBSCP Tunneling

The following example shows how to enable RBSCP tunneling:

```
Device(config)# interface tunnel 0
```

```
Device(config-if)# tunnel source ethernet 0
Device(config-if)# tunnel destination 10.108.164.19
Device(config-if)# tunnel mode rbscp
```

Related Commands

Command	Description
appletalk cable-range	Enables an extended AppleTalk network.
appletalk zone	Sets the zone name for the connected AppleTalk network.
mac-address	Specifies a MAC address to use as the common router MAC address for interfaces on the active and standby chassis.
tunnel destination	Specifies the destination for a tunnel interface.
tunnel protection	Associates a tunnel interface with an IPsec profile.
tunnel source	Sets the source address of a tunnel interface.
tunnel vlan	Associates a VLAN ID for the Ethernet over GRE tunnel interface.

tunnel path-mtu-discovery

To enable Path MTU Discovery (PMTUD) on a generic routing encapsulation (GRE) or IP-in-IP tunnel interface, use the **tunnelpath-mtu-discovery** command in interface configuration mode. To disable PMTUD on a tunnel interface, use the no form of this command.

tunnel path-mtu-discovery [{**age-timer** {*aging-mins* | **infinite**} | **min-mtu** *mtu-bytes*}]
no tunnel path-mtu-discovery

Syntax Description

age-timer	(Optional) Sets a timer to run for a specified interval, in minutes, after which the tunnel interface resets the maximum transmission unit (MTU) of the path to the default tunnel MTU minus 24 bytes for GRE tunnels or minus 20 bytes for IP-in-IP tunnels. • *aging-mins* --Number of minutes. Range is from 10 to 30. Default is 10. • **infinite** -- Disables the age timer.
min-mtu	(Optional) Specifies the minimum Path MTU across GRE tunnels. • *mtu-bytes*-- Number of bytes. Range is from 92 to 65535. Default is 92.

Command Default

Path MTU Discovery is disabled for a tunnel interface.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)WC5	This command was introduced.
12.0(7)T3	This command was integrated into Cisco IOS Release 12.0(7)T3.
12.2(13)T	The **min-mtu** keyword and *mtu-bytes* argument were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When PMTUD (RFC 1191) is enabled on a tunnel interface, the router performs PMTUD processing for the GRE (or IP-in-IP) tunnel IP packets. The router always performs PMTUD processing on the original data IP packets that enter the tunnel. When PMTUD is enabled, no packet fragmentation occurs on the encapsulated packets that travel through the tunnel. Without packet fragmentation, there is a better throughput of TCP connections, and this makes PMTUD a method for maximizing the use of available bandwidth in the network between the endpoints of a tunnel interface.

After PMTUD is enabled, the Don’t Fragment (DF) bit of the IP packet header that is forwarded into the tunnel is copied to the IP header of the external IP packets. The external IP packet is the encapsulating IP packet. Adding the DF bit allows the PMTUD mechanism to work on the tunnel path of the tunnel. The tunnel endpoint listens for Internet Control Message Protocol (ICMP) unreachable too-big messages and modifies the IP MTU of the tunnel interface, if required.

When the aging timer is configured, the tunnel code resets the tunnel MTU after the aging timer expires. After the tunnel MTU is reset, a set of full-size packets with the DF bit set is required to trigger the tunnel PMTUD and lower the tunnel MTU. At least two packets are dropped each time the tunnel MTU changes.

When PMTUD is disabled, the DF bit of an external (encapsulated) IP packet is set to zero even if the encapsulated packet has a DF bit set to one.

The *min-mtu* argument sets a low limit on the MTU that can be learned via the PMTUD process. Any ICMP signaling received specifying an MTU less than the minimum MTU configured will be ignored. This feature can be used to prevent a denial of service attack from any node that can send a specially crafted ICMP message to the router, specifying a very small MTU. For more information, see "*Crafted ICMP Messages Can Cause Denial of Service* " at the following URL:

http://www.cisco.com/en/US/products/products_security_advisory09186a0080436587.shtml

Note PMTUD on a tunnel interface requires that the tunnel endpoint be able to receive ICMP messages generated by routers in the path of the tunnel. Check that ICMP messages can be received before using PMTUD over firewall connections.

PMTUD works only on GRE and IP-in-IP tunnel interfaces.

Use the **showinterfacestunnel** command to verify the tunnel PMTUD parameters.

Examples

The following example shows how to enable tunnel PMTUD:

```
Router(config)# interface tunnel 0
Router(config-if)# tunnel path-mtu-discovery
```

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
show interfaces tunnel	Displays information about the specified tunnel interface.

tunnel rbscp ack_split

To enable TCP acknowledgement (ACK) splitting for Rate Based Satellite Control Protocol (RBSCP) tunnels, use the **tunnelrbscpack_split** command in interface configuration mode. To disable TCP acknowledgement splitting for RBSCP tunnels, use the **no** form of this command.

tunnel rbscp ack_split *split-size*
no tunnel rbscp ack_split *split-size*

Syntax Description

split-size	Number of ACKs to send for every ACK received. Range is from 1 to 32. Default is 4.

Command Default

TCP acknowledgement splitting for RBSCP tunnels is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Performance improvements can be made for clear-text TCP traffic using ACK splitting where a number of additional TCP ACKs are generated for each TCP ACK received. TCP will open a congestion window by one maximum transmission unit (MTU) for each TCP ACK received. Opening the congestion window results in increased bandwidth becoming available. Use the **tunnelrbscpack_split** command only when the satellite link is not using all the available bandwidth. Encrypted traffic cannot use ACK splitting.

Examples

The following example shows how to enable RBSCP tunnel TCP ACK splitting and configure three ACK packets to be sent for each ACK packet received:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel rbscp ack_split 3
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.

tunnel rbscp delay

To enable the Rate Based Satellite Control Protocol (RBSCP) tunnel delay, use the **tunnelrbscpdelay** command in interface configuration mode. To disable RBSCP tunnel delay, use the **no** form of this command.

tunnel rbscp delay
no tunnel rbscp delay

Syntax Description

This command has no arguments or keywords.

Command Default

RBSCP tunnel delay is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **tunnelrbscpdelay** command only if the RBSCP tunnel has a round-trip time (RTT) over 700 milliseconds.

Examples

The following example shows how to enable the RBSCP tunnel delay:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel rbscp delay
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.

tunnel rbscp input_drop

To configure the input queue size on a Rate Based Satellite Control Protocol (RBSCP) tunnel, use the **tunnelrbscpinput_drop** command in interface configuration mode. To restore the default input queue size, use the **no** form of this command.

tunnel rbscp input_drop *bw-delay-products*
no tunnel rbscp input_drop

Syntax Description

bw-delay-products	Number of bandwidth delay products (BDP) bytes that can be queued before packets are dropped on the input side. Range from 1 to 10. Default is 2.

Command Default

Input queue size is 2 BDP bytes.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **tunnelrbscpinput_drop** command to restrict the amount of data queued by the router. After the configured byte limit is reached, packets that would be encapsulated and sent via the tunnel are dropped on the input side. Congestion control of the satellite link is also provided by this command because the dropped packets will force the end hosts to reduce their sending rate of packets.

Use this command in conjunction with the **tunnelrbscplong_drop** command which allows packets that are waiting in an RBSCP tunnel encapsulation queue to be dropped after a period of time.

Examples

The following example shows how to set the RBSCP tunnel queue size to 5 BDP bytes:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel rbscp input_drop 5
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.
tunnel rbscp long_drop	Allows packets to be dropped after waiting in the RBSCP tunnel encapsulation queue for too long.

tunnel rbscp long_drop

To allow packets to be dropped that have been queued too long for Rate Based Satellite Control Protocol (RBSCP) tunnel encapsulation, use the **tunnelrbscplong_drop** command in interface configuration mode. To disable the dropping of queued packets, use the **no** form of this command.

tunnel rbscp long_drop
no tunnel rbscp long_drop

Syntax Description

This command has no arguments or keywords.

Command Default

No queued packets are dropped.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The **tunnelrbscplong_drop** command allows the transmitting router to drop packets that have been waiting in the queue for RBSCP tunnel encapsulation for a long time. The period of time after which packets are dropped is determined using the round-trip time (RTT) estimate of the tunnel.

Use this command in conjunction with the **tunnelrbscpinput_drop** command which configures the size of the input queue. After the configured byte limit of the input queue is reached, packets are dropped.

Examples

The following example shows how to allow packets to be dropped when they have been queued for RBSCP tunnel encapsulation too long:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel rbscp long_drop
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.
tunnel rbscp input_drop	Configures the input queue size on an RBSCP tunnel.

tunnel rbscp report

To report dropped Rate Based Satellite Control Protocol (RBSCP) packets to the Stream Control Transmission Protocol (SCTP), use the **tunnelrbscpreport** command in interface configuration mode. To disable dropped-packet reporting to SCTP, use the **no** form of this command.

tunnel rbscp report
no tunnel rbscp report

Syntax Description

This command has no arguments or keywords.

Command Default

RBSCP dropped-packet reporting is enabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **tunnelrbscpreport** command to provide early reporting of dropped RBSCP packets to SCTP instead of attempting retransmission of the packets at the router. SCTP will inform the end hosts of the dropped packets and allow the end hosts to retransmit the packets. Reporting dropped packets through SCTP provides better throughput because the packet dropping is not assumed to be caused by congestion.

Examples

The following example shows how to disable the SCTP drop reporting (reporting is enabled by default):

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 no tunnel rbscp report
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.

tunnel rbscp window_stuff

To enable TCP window stuffing by increasing the value of the TCP window scale for Rate Based Satellite Control Protocol (RBSCP) tunnels, use the **tunnelrbscpwindow_stuff** command in interface configuration mode. To restore the default TCP window scale value, use the **no** form of this command.

tunnel rbscp window_stuff *step-size*
no tunnel rbscp window_stuff

Syntax Description

step-size	Increment step size for the TCP window scale. Range is from 1 to 20. Default is 1.

Command Default

TCP window stuffing is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **tunnelrbscpwindow_stuff** command to make the sending host believe that the receiving host has a larger window by artificially increasing the TCP window size. RBSCP buffers the additional window and which be configured up to the satellite link bandwidth or the memory available on the router.

Note The actual TCP window size value that is used by the router may be smaller than the configured value because of the available bandwidth.

Examples

The following example shows how to enable TCP window stuffing on the RBSCP tunnel and configure a window size of 2:

```
Router(config
)
# interface tunnel 0
Router(config
-if)#
 tunnel rbscp window_stuff 2
```

Related Commands

Command	Description
show rbscp	Displays state and statistical information about RBSCP tunnels.

tunnel route-via

To specify the outgoing interface of the tunnel transport, use the **tunnelroute-via** command in interface configuration mode. To disable the source address selection, use the **no** form of this command.

tunnel route-via *interface-type interface-number* {**mandatory** | **preferred**}
no tunnel route-via

Syntax Description

interface-type	Indicates the type of interface.
interface-number	Indicates the interface number of the interface configured as the tunnel transport.
mandatory	Drops the traffic if the route is not available.
preferred	If the route is not available, forwards the traffic using any available route.

Command Default

This command is disabled by default. The tunnel transport cannot be routed using a subset of the routing table.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.4(11)T	This command was introduced.

Usage Guidelines

If the **tunnelroute-via***interface-typeinterface-number***mandatory** command is configured, and there is no route to the tunnel destination using that interface, a point-to-point tunnel interface will go into a down state.

Examples

The following example shows the options that are available to configure the interfaces of the tunnel transport and route the tunnel transport using a subset of the routing table:

```
Router> enable
Router# configure terminal
Router(config)# interface tunnel 0
Router(config-if)# tunnel route-via ethernet0 mandatory
```

Related Commands

Command	Description
debug tunnel route-via	Displays information about the source address selection.
show interfaces tunnel	Displays information about the physical output tunnel interface.

tunnel sequence-datagrams

To configure a tunnel interface to drop datagrams that arrive out of order, use the **tunnelsequence-datagrams** command in interface configuration mode. To disable this function, use the **no** form of this command.

tunnel sequence-datagrams
no tunnel sequence-datagrams

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command currently applies to generic routing encapsulation (GRE) only. This command is useful when carrying passenger protocols that behave poorly when they receive packets out of order (for example, LLC2-based protocols).

Examples

The following example shows how to configure the tunnel to drop datagrams that arrive out of order:

```
Router(config
-if)
# tunnel sequence-datagrams
```

tunnel source

To set the source address for a tunnel interface, use the **tunnel source** command in interface configuration mode. To remove the source address, use the **no** form of this command.

tunnel source {*ip-addressipv6-address* | *interface-type interface-number* | **dynamic**}
no tunnel source

Command Syntax for Cisco Catalyst 3850 Series Switches

tunnel source *ip-address*
no tunnel source

Syntax Description

dynamic	Applies the tunnel source address dynamically to the tunnel interface.
ip-address	Source IP address of packets in the tunnel. • In case of traffic engineering (TE) tunnels, the control packets are affected.
ipv6-address	Source IPv6 address of packets in the tunnel.
interface-type	Interface type.
interface-number	Port, connector, or interface card number. The numbers are assigned at the factory at the time of installation or when added to a system and can be displayed with the **show interfaces** command.

Command Default

No tunnel interface source address is set.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.0	This command was introduced.
12.3(7)T	The address field has been updated to accept an IPv6 address as the source address allowing an IPv6 node to be used as a tunnel source.
12.2(30)S	This command was integrated into Cisco IOS Release 12.2(30)S.
12.2(25)SG	This command was integrated into Cisco IOS Release 12.2(25)SG.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS Release 2.1 and implemented on Cisco ASR 1000 Series Aggregation Services Routers.

Release	Modification
15.1SY	This command was integrated into Cisco IOS Release 15.1SY.
Cisco IOS XE Release 3.7S	This command was modified. The **dynamic** keyword was added.
15.4(2)S	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

The source address is either an explicitly defined IP address or the IP address assigned to the specified interface.

You cannot have two tunnels using the same encapsulation mode with exactly the same source and destination addresses. The workaround is to create a loopback interface and source packets from the loopback interface. This restriction is applicable only for generic routing encapsulation (GRE) tunnels. You can have more than one TE tunnel with the same source and destination addresses.

Note **Only GRE tunneling is supported on Cisco Catalyst 3850 Series Switches.**

When using tunnels to Cayman boxes, you must set the **tunnel source** command to an explicit IP address on the same subnet as the Cayman box, and not the tunnel itself.

GRE tunnel encapsulation and deencapsulation for multicast packets are handled by the hardware. Each hardware-assisted tunnel must have a unique source. Hardware-assisted tunnels cannot share a source even if the destinations are different. You should use secondary addresses on loopback interfaces or create multiple loopback interfaces to ensure that the hardware-assisted tunnels do not share a source.

Cayman Tunnel Example

The following example shows how to set a tunnel source address for Cayman tunneling:

```
Device(config)# interface tunnel0
Device(config-if)# tunnel source ethernet0
Device(config-if)# tunnel destination 172.32.164.19
Device(config-if)# tunnel mode cisco1
```

Dynamic Tunnel Example

The following example shows how to set the tunnel source dynamically:

```
Device(config)# interface tunnel0
Device(config-if)# tunnel source dynamic
Device(config-if)# *Nov 22 19:38:28.271: Tunnel notified source change: dynamic is set
Device(config-if)# end
Device# show run interface tunnel0
Building configuration...

Current configuration : 63 bytes
!
interface Tunnel0
 no ip address
 tunnel source dynamic
end
```

If the tunnel source is configured to be set dynamically, you cannot configure the tunnel source address without removing the dynamic configuration.

```
Device(config)# interface tunnel0
Device(config-if)# tunnel source ethernet 0/0
Device(config-if)# *Nov 22 21:39:52.423: Tunnel notified source change: dynamic is set
*Nov 22 21:39:52.423: Tunnel notified source change, src ip 1.1.1.1
Device(config-if)# end
Device# show run interface tunnel0
Building configuration...

Current configuration : 63 bytes
!
interface Tunnel0
 no ip address
 tunnel source dynamic
end
Device# configure terminal
Device(config)# interface tunnel0
Device(config-if)# no tunnel source
Device(config-if)# *Nov 22 21:41:10.287: Tunnel notified source change: dynamic is not set
```

GRE Tunneling Example

The following example shows how to set a tunnel source address for GRE tunneling:

```
Device(config)# interface tunnel0
Device(config-if)# appletalk cable-range 4160-4160 4160.19
Device(config-if)# appletalk zone Engineering
Device(config-if)# tunnel source ethernet0
Device(config-if)# tunnel destination 172.32.164.19
Device(config-if)# tunnel mode gre ip
```

GRE Tunneling Examples for Cisco Catalyst 3850 Series Switches

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in Global or non- VRF environment on Cisco Catalyst 3850 Series Switches:

```
Device(config)# interface tunnel 2
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

The following example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2 in VRF environment on Cisco Catalyst 3850 Series Switches. Use the **vrf definition** *vrf-name* and the**vrf forwarding** *vrf-name* commands to configure and apply VRF.

```
Device(config)# vrf definition RED
Device(config-vrf)#  address-family ipv4
Device(config-vrf-af)# exit-address-family
Device(config-vrf)#  exit
Device(config)# interface tunnel 2
Device(config)# vrf forwarding RED
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# tunnel source 10.10.10.1
Device(config-if)# tunnel destination 10.10.10.2
```

```
Device(config-if)# tunnel mode gre ip
Device(config-if)# end
```

Note **IPv6 GRE tunneling is not supported on Cisco Catalyst 3850 Series Switches.**

MPLS TE Tunnel Example

The following example shows how to set a tunnel source for a Multiprotocol Label Switching (MPLS) TE tunnel:

```
Device> enable
Device# configure terminal
Device(config)# interface tunnel 1
Device(config-if)# ip unnumbered loopback0
Device(config-if)# tunnel source loopback1
Device(config-if)# tunnel mode mpls traffic-eng
Device(config-if)# end
```

Related Commands

Command	Description
appletalk cable-range	Enables an extended AppleTalk network.
appletalk zone	Sets the zone name for the connected AppleTalk network.
tunnel destination	Specifies the destination for a tunnel interface.

tunnel tos

To configure the type of service (ToS) byte value for a tunnel interface, use the **tunneltos** command in interface configuration mode. To use the payload ToS byte value (if payload protocol is IP) or 0, use the **no** form of this command.

tunnel tos *tos-bytes*
no tunnel tos

Syntax Description

tos-bytes	ToS byte value from 0 to 255 specified in the encapsulating IP header of a tunneled packet. The default value is 0.

Command Default

The default ToS byte value is the payload ToS byte value (if payload protocol is IP); otherwise, 0.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(17)S	This command was introduced.
12.0(17)ST	This command was integrated into Cisco IOS Release 12.0(17)ST.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If the **tunneltos** command is not configured and the packet to be encapsulated is not an IP packet, the tunnel interface will use a default value of 0. If the **tunneltos**command is not configured and the packet to be encapsulated is an IP packet, the tunnel interface will use the ToS byte value of the inner IP packet header.

Examples

The following example shows how to configure a ToS byte value of 55 on tunnel interface 1:

```
interface tunnel 1
 tunnel tos 55
```

Related Commands

Command	Description
show interfaces tunnel	Lists tunnel interface information.
tunnel ttl	Configures the TTL hop-count value for a tunnel interface.

tunnel ttl

To configure the Time-to-Live (TTL) hop-count value for a tunnel interface, use the **tunnelttl** command in interface configuration command. To use the payload TTL value (if payload protocol is IP) or 255, use the **no** form of this command.

tunnel destination commandtunnel ttl *hop-count*
no tunnel ttl

Syntax Description

hop-count	TTL hop-count value from 1 to 255 to be used in the encapsulating IP header of a tunneled packet. The default is 255.

Command Default

The TTL default hop-count value is 255.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(17)S	This command was introduced.
12.0(17)ST	This command was integrated into Cisco IOS Release 12.0(17)ST.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to configure a TTL hop-count value of 200 on tunnel interface 1:

```
interface tunnel 1
 tunnel ttl 200
```

Related Commands

Command	Description
show interfaces tunnel	Lists tunnel interface information.
tunnel tos	Configures the ToS byte value for a tunnel interface.

tunnel vrf

To associate a VPN routing and forwarding (VRF) instance with a specific tunnel destination, interface, or subinterface, use the **tunnel vrf** command in global configuration or interface configuration mode. To disassociate a VRF from the tunnel destination, interface, or subinterface, use the **no** form of this command.

tunnel vrf *vrf-name*
no tunnel vrf *vrf-name*

Syntax Description

vrf-name	Name assigned to a VRF.

Command Default

The default destination is determined by the global routing table.

Command Modes

Global configuration (config)

Interface configuration (config-if)

Command History

Release	Modification
12.0(23)S	This command was introduced.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA. Support was added for the Cisco 10000 Series Routers.
12.2(31)SB5	This command was integrated into Cisco IOS Release 12.2(31)SB5.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.
12.2(33)SRE	This command was integrated into Cisco IOS Release 12.2(33)SRE.
15.0(1)S	This command was integrated into Cisco IOS Release 15.0(1)S.

Usage Guidelines

To associate a VRF instance with a specific tunnel destination, ensure that the tunnel source and destination are in the same VRF.

Use the **ip vrf forwarding** command to associate a VRF instance with an interface or a subinterface other than a tunnel interface.

Use the **no ip vrf forwarding** *vrf-name* command or the **no tunnel vrf** *vrf-name* command to set either the IP VRF or the tunnel VRF to the global routing table.

The tunnel is disabled if no route to the tunnel destination is defined. If the tunnel VRF is set, you must configure a route to that destination in the VRF.

Cisco 10000 Series Routers and Cisco ASR 1000 Series Aggregation Services Routers

The VRF associated with the tunnel through the **tunnel vrf** command is the same as the VRF associated with the physical interface over which the tunnel sends packets (outer IP packet routing).

Examples

The following example shows how to associate a VRF with a tunnel destination. The tunnel endpoint 10.5.5.5 is looked up in the VRF named vrf2.

```
Device(config)# interface tunnel0
Device(config-if)# ip vrf forwarding vrf1
Device(config-if)# ip address 10.3.3.3 255.255.255.0
Device(config-if)# tunnel source loop 0
Device(config-if)# tunnel destination 10.5.5.5
Device(config-if)# tunnel vrf vrf2
```

Related Commands

Command	Description
ip route vrf	Establishes static routes for a VRF.
ip vrf	Configures a VRF routing table.
ip vrf forwarding	Associates a VRF instance with an interface or subinterface.
tunnel destination	Specifies the destination for a tunnel interface.
tunnel source	Sets the source address for a tunnel interface.

type STS48c

Use this command to configure protection group type.

type STS48c

There are no keywords for this command.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	Support for this command was introduced for the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Examples

The following example shows how to configure protection group:

```
enable
configure terminal
protection-group 401 type STS48c
controller protection group 401
type STS48c
cem-group 19001 cep
end
```

Related Commands

Command	Description
show protection-group	Verifies the protection group configuration.

tx-queue-limit

To control the number of transmit buffers available to a specified interface on the multiport communications interface (MCI) and serial communications interface (SCI) cards, use the **tx-queue-limit** command in interface configuration mode.

tx-queue-limit *number*

Syntax Description

number	Maximum number of transmit buffers that the specified interface can subscribe.

Command Default

Defaults depend on the total transmit buffer pool size and the traffic patterns of all the interfaces on the card. Defaults and specified limits are displayed with the **showcontrollersmci** command.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command should be used only under the guidance of a technical support representative.

This command does not have a **no** form.

Examples

The following example shows how to set the maximum number of transmit buffers on the interface to 5:

```
Router
(config)
# interface ethernet 0
Router
(config-if)
# tx-queue-limit 5
```

Related Commands

Command	Description
show controllers mci	Displays all information under the MCI card or the SCI.

ucse subslot imc password-reset

To reset the Cisco Integrated Management Controller (CIMC) password, use the **ucse subslot imc password-reset** command in privileged EXEC mode.

ucse subslot *slot/subslot* **imc password-reset**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Usage Guidelines

After you enter this command, at the next login, the system requests that you set a new password to access CIMC.

Examples

The following example shows how to reset the CIMC password in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 imc password-reset
Router#
 IMC ACK: UCSE password reset successful for IMC
```

ucse subslot server

To reload, reset, start, or stop the hardware on the server module, use the **ucse subslot server** command in privileged EXEC mode.

ucse subslot *slot/subslot* **server** {**reload** | **reset** | **start** | **stop**}

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
reload	Powers down the server module and then powers it on. **Note** The **reload** keyword is not supported on the NIM E-Series-NCE. Instead, we recommend that you use the following commands from the router: 1. Router # **ucse subslot** *slot/subslot* **shutdown** 2. Router # **ucse subslot** *slot/subslot* **start** If a reload is necessary, use the following command: Router # **hw-module subslot 0/***NIM-slot-number* **reload** **Note** This command power-cycles the module. The CIMC and server reboot.
reset	Resets the hardware on the server module.
start	Powers on the server module.
stop	Immediately powers down the server module. **Note** The **stop** keyword is not supported on the NIM E-Series-NCE. Instead, we recommend that you use the following command from the router: Router # **ucse subslot** *slot/subslot* **shutdown** If it is necessary to do an immediate power down of the server, use the following command: Router # **hw-module subslot 0/***NIM-slot-number* **stop** **Note** This command powers down the module. The CIMC and server power off.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Usage Guidelines

Use the **reset** keyword only to recover from a shutdown or failed state.

Caution Using the **reset** keyword does *not* provide an orderly software shutdown and may impact file operations that are in progress.

Examples

The following example shows how to reload the E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server reload
Router#
 IMC ACK: UCSE Server reload successful.
```

The following example shows how to reset the E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server reset
Router#
 IMC ACK: UCSE Server reset successful.
```

The following example shows how to start the E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server start
Router#
 IMC ACK: UCSE Server start successful.
```

The following example shows how to stop the E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server stop
Router#
 IMC ACK: UCSE Server stop successful.
```

ucse subslot server password-reset

To reset the BIOS or RAID password, use the **ucse subslot server password-reset** command in privileged EXEC mode.

ucse subslot *slot/subslot* **server password-reset** {**BIOS** | **RAID**}

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
BIOS	Resets the BIOS password.
RAID	Resets the RAID password. **Note** RAID is not supported on the NIM E-Series NCE.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Usage Guidelines

After you enter this command, at the next login, the system requests that you set a new password to access BIOS or configure RAID.

Examples

The following example shows how to reset the BIOS password in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server password-reset BIOS
Router#
 IMC ACK: UCSE password reset successful for BIOS
```

The following example shows how to reset the RAID password in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 server password-reset RAID
```

```
Router#
 IMC ACK: UCSE password reset successful for RAID
```

ucse subslot shutdown

To gracefully shut down the server module, use the **ucse subslot shutdown** command in privileged EXEC mode.

ucse subslot *slot/subslot* **shutdown**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Usage Guidelines

The NIM E-Series NCE might take up to 60 seconds to shut down. After two or three shut down attempts, if the NIM E-Series NCE does not shut down, enter the following commands from the router:

1. Router # **hw-module subslot 0/***NIM-slot-number* **stop**
2. Router # **hw-module subslot 0/***NIM-slot-number* **start**

Examples

The following example shows how to shut down an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# ucse subslot 1/0 shutdown
Router#
 IMC ACK: UCSE Server shutdown successful.
```

ucse subslot statistics

To display or clear server module statistics, use the **ucse subslot statistics** command in privileged EXEC mode.

ucse subslot *slot/subslot* **statistics** [**clear**]

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
clear	(Optional) Clears the server module statistics.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Examples

The following example shows how to display the statistics of an E-Series Server:

```
Router# ucse subslot 1/0 statistics
 Count of number of shutdowns command : 1
 Count of number of status commands : 0
 Count of number of server raid password  : 1
 Count of number of imc password-reset : 2
 Count of number of server bios password reset : 1
 Count of number of server reload : 1
 Count of number of server reset : 1
 Count of number of server start : 1
 Count of number of server stop : 1
 Count of number of vlan commands : 0
 Count of number of access-port commands : 1
 Count of number of IMC configured IP or DHCP commands: 1
```

ucse subslot status

To display configuration information related to the hardware and software on the server module, use the **ucse subslot status** command in privileged EXEC mode.

ucse subslot *slot/subslot* **status** [**detailed**]

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
detailed	(Optional) Displays detailed information about the server module, such as its status and settings of the reset and heartbeat-reset flags.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 Series.

Examples

The following example shows how to display the status of an E-Series Server:

```

ucse cmos-reset

To reset the BIOS CMOS, use the **ucse cmos-reset** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **cmos-reset**

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse subslot *slot/subslot* **cmos-reset**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Usage Guidelines

This command sets the BIOS CMOS back to the factory defaults. User changes made in the BIOS will be lost.

Examples

The following example shows how to reset the BIOS CMOS in an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 cmos-reset
```

Examples

The following example shows how to reset the BIOS CMOS in an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 cmos-reset
```

ucse heartbeat-reset

To enable or disable Cisco IOS software from rebooting the Cisco E-Series Server when the heartbeat is lost, use the **ucse heartbeat-reset** command in EXEC mode.

ucse *slot* **heartbeat-reset** [{**disable** | **enable**}]

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
enable	Does not allow the Cisco IOS software to reboot the Cisco E-Series Server when the heartbeat is lost.
disable	Allows the Cisco IOS software to reboot the Cisco E-Series Server when the heartbeat is lost.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

None.

Examples

The following example shows how to reset the slot server heartbeat:

```
Router# ucse 2 heartbeat-reset enable
```

ucse imc config

To save the CIMC configuration to a file on the router’s flash drive or to restore the CIMC configuration from a file on the router’s flash drive, use the **ucse imc config** command in EXEC mode.

ucse *slot* **imc config** {**restore** | **save**} **url**

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
restore	Restores the CIMC configuration from a file.
save	Saves the CIMC configuration to a file.
url	The url where the configuration file is located.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Itis important to store the CIMC configuration to a file in case you need to move the HDDs from one module to another.

Examples

The following example shows how to save the CIMC configuration to a file:

```
Router# ucse 2 imc config save flash0:my-imc-config
```

ucse imc file delete

To delete the CIMC image file, use the **ucse imc file delete** command in EXEC mode. The file can be either a .iso or .img file.

ucse *slot* **imc** **file** **delete** *file_name*

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
file_name	Name of the CIMC image file to delete. **Note** The name of the file must match exactly the name of the file as displayed by the output of the **show** **ucse** *slot* **imc files**command.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

You can only delete one file at a time.

Examples

The following example shows how to delete the CIMC image file:

```
Router# ucse 2 imc file delete xxxxx.iso

Delete the IMC file xxxxx.iso [confirm]
Deleted
```

ucse imc file download

To download the CIMC image file in the background to an internal storage device, use the **ucse imc file download** command in EXEC mode. The file must have a .iso file extension.

ucse *slot* **imc file download** {**URL** *url* | **abort**}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
url	Downloads the CIMC image file from the specified HTTP, HTTPS, SFTP, or FTPS server.
abort	Aborts the downloading of the file.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

You can only download one file at a time.

To check the download progress after initiating a download, issue the **show ucse** *slot* **imc download progress** command.

Examples

The following example shows how to download the CIMC image file:

```
Router# ucse 2 imc file download URL http://xxxxx.iso
Started downloading file from http://xxxxx.iso

Router# show ucse 2 imc file download progress
Downloaded 23%
```

The following example shows how to abort a download of the CIMC image file:

```
Router# ucse 2 imc file download abort

Abort the IMC file download? [confirm] y
Download aborted.
```

ucse password-reset

To reset the BIOS, CIMC, or RAID password, use the **ucse password-reset** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **password-reset** {**BIOS** | **BMC** | **RAID**}

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse **subslot** *slot/subslot* **password-reset** {**BIOS** | **BMC** | **RAID**}

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
BIOS	Resets the BIOS password.
BMC	Resets the CIMC password.
RAID	Resets the RAID password. **Note** RAID is not applicable for the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE).

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series NCE installed in an ISR G2.

Usage Guidelines

After this command has been entered, the system requests that a new password be set when accessing the BIOS or BMC.

RAID is not applicable for the EHWIC E-Series NCE.

Examples

The following example shows how to reset the BIOS password in an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 password-reset BIOS

Reset command sent
```

Examples

The following example shows how to reset the BIOS password in an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 password-reset BIOS

Reset command sent
```

ucse server boot

To reload, reset, or boot the Cisco E-Series Server from a particular URL, use the **ucse server boot** command in EXEC mode.

ucse *slot* **server** {**reload** | **reset** | **start**} **boot** {**url** *url* | **device** *device_type*} [**argument** *text*]

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
url *url*	Boots the Cisco E-Series Server from an externally stored file, which can be either a .iso or .img file. The URL can be one of the following types: • HTTP • FTP • SFTP • FTPS://XXXXX.iso Restrictions: • This argument accepts IPv6 and IPv4 addresses, as well as literal names. • The name of the file must match exactly the name of the file as displayed by the output of the **show ucse** *slot* **imc file**command.
device *device_type*	The device type from which the E-Series Server boots. It can be one of the following: • HDD:*device_name* —Hard disk drive • FDD—Floppy disk drive • CDROM:*device_name* —Bootable CD-ROM • PXE—PXE boot • EFI—Extensible Firmware Interface **Note** The name of the devices must match exactly the names as displayed by the output of the **show ucse** *slot* **server boot devices**command.
argument *text*	An arbitrary text string.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

This command works by first downloading the specified file to local storage, reloading the server from that file, and then booting the installed system.

After issuing this command, the system modifies the boot order so that the downloaded image is first.

After you have issued this command with the **url** argument and keyword, use the **show** *ucse* **slot server boot progress**command to see the results.

After you have issued this command with the **device** argument and keyword, use the **show** *ucse* **slot server boot order**command to see the results.

Examples

The following example shows how to boot the server from a URL:

```
Router# ucse 2 server reload boot url http://path/to/iso
Router# show ucse 2 server boot progress

Downloading http://path/to/iso 44%
```

The following example shows how to boot the server from an HDD:

```
Router# ucse 2 server reset boot device HDD
Router# show ucse 2 server boot progress

System started
```

The following example shows how to start the server from an HDD:

```
Router# ucse 2 server start boot device HDD
Router# show ucse 2 server boot progress
```

ucse server boot order

To configure the boot order for the Cisco E-Series Server, use the **ucse server boot order** command in EXEC mode.

ucse *slot* **server boot order device_1** [**device_2**] [**device_3**] [**device_4**]

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
device_1 device_2 device_3 device_4	Specifies the devices to boot. **Note** The name of the devices must match exactly the names as displayed by the output of the **show ucse** *slot* **server boot devices**command. The device can be any of the following, but you can only use each device name once when issuing this command: • PXE—PXE boot • FDD—Floppy disk drive • HDD:*device_name* —Hard disk drive • CDROM:*device_name* —Bootable CD-ROM

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Due to BIOS limitations, you can only specify each device type (PXE, FDD, HDD, and CDROM) once per group. Therefore, it is impossible to set up a boot order with two HDDs or two CDROMs.

To determine the devices available from which you can boot the server, issue the **show ucse** *slot* **server boot devices** command.

To check the boot order configuration after issuing this command, issue the **show ucse** *slot* **server boot order** command.

Examples

The following example shows how to configure the boot order:

```
Router# show ucse 2 server boot devices

PXE
FDD
HDD:HDD3
HDD:RAID-MD0
HDD:USB-FF5D6CC3DAA67F12-1
CDROM:USB-CD
Router# ucse 2 boot order PXE CDROM:USB-CD FDD HDD:RAID-MD0
```

```
Router# show ucse 2 server boot order
Currently booted from CDROM:USB-CD
Boot order:
1) PXE
2) CDROM:USB-CD
3) FDD
4) HDD:RAID-MD0
```

ucse server erase device hdd

To erase all existing data from the Cisco E-Series Server hard drive devices (HDDs), use the **ucse server erase device hdd** command in EXEC mode.

ucse *slot* **server erase device hdd** {**ALL** | **use** *device_list*}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
device_list	Erases the data from only the specified HDDs. **Note** The name of the devices must exactly match the names as displayed by the output of the **show ucse** *slot* **server boot devices**command.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command if you need to remove sensitive data from a hard drive before shipping the server. The system prompts you to confirm that you really want to erase the data from the hard drive device.

Caution Use this command with caution, as it erases the contents of the HDDs.

To check the status of the hard drive after you have issued this command, use the **show ucse** *slot* **server erase device status** command.

Examples

The following example shows how to erase the data from the device called HDD2, and then display the status:

```
Router# ucse 2 server erase device hdd use hdd2

You are about to erase all data on the selected hard drives.
Proceed with drive erasure? y

Erasing HDD2 started

Router# show ucse 2 server erase device status

HDD2 erased 0 %
```

ucse server raid level

To configure the RAID array on the Cisco E-Series Server, use the **ucse server raid level** command in EXEC mode.

ucse *slot* **server raid level** {**0** | **1** | **5** | **NONE** | **use** *device_list*}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
0	Data is stored evenly in stripe blocks across two or more disks without redundancy (mirroring).
1	Data is stored in mirrored set of disk drives with an optional hot spare disk drive.
5	Data is stored in stripe blocks with parity data staggered across all disk drives.
NONE	Disk drives of a computer are not configured as RAID and are put in a JBOD configuration.
use *device_list*	Allows you to configure more than one device at a time. If you do not use the **use** keyword, then the system configures all hard drives into a RAID in the order in which they are detected by the module. Enter the list of HDDs using a comma-separated list, such as HDD1, HDD2, HDD3. This command only applies to the internal HDDs, which are named according to their physical location. **Note** The name of the devices must match exactly the names as displayed by the output of the **show ucse** *slot* **server boot devices**command.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

This command only applies to HDDs.

Caution Use this command with caution, as it destroys the contents of the HDDs. Do not use this command to migrate the RAID configuration.

After you have issued this command, use the **show** *ucse* **slot server raid level**command to see the results.

Examples

The following example shows how to configure RAID level 1:

```
Router# ucse 2 server raid level 1

You are about to change RAID configuration.
This will destroy all data on the hard drives.
Proceed with setting new RAID level? [confirm] y
```

```
RAID reconfigured

Router# show ucse 2 server raid level

RAID 0 (Ctrl:SLOT-5 ID:0 Size:1905440 MB State:Optimal)
        HDD1 :              953869 MB online (0 errors)
        HDD255 :              953869 MB online (0 errors)

        HDDs not in the RAID:
        HDD2 :              286102 MB system (0 errors)
```

ucse server reload boot

To boot the Cisco E-Series Server from a particular url or device type, use the **ucse server reload boot** command in EXEC mode.

ucse *slot* **server reload boot** {**url** *url* | **device** *device_type*}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
url *url*	Boots the Cisco E-Series Server from the specified url.
device *device_type*	The device type from which the Cisco E-Series Server boots. It can be one of the following: • CDROM: Virtual-CD • EFI • FDD: Virtual-Floppy • HDD: RAID • HDD: SD2 • HDD: Virtual-HiFD • PXE: GIGETH0 • PXE: GIGETH1 • PXE: GIGETH3

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command to safely reload the server.

Examples

The following example shows how to reload the server:

```
Router# ucse 2 server reload boot url http://220.0.0.100/OS/image.iso
```

ucse server reset boot

To reset the hardware on the Cisco E-Series Server, use the **ucse server reset boot** command in EXEC mode.

ucse *slot* **server reset boot** {**url** *url* | **device** *device_type*}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
url *url*	Boots the Cisco E-Series Server from the specified url.
device *device_type*	The device type from which the Cisco E-Series Server boots. It can be one of the following: • CDROM: Virtual-CD • EFI • FDD: Virtual-Floppy • HDD: RAID • HDD: SD2 • HDD: Virtual-HiFD • PXE: GIGETH0 • PXE: GIGETH1 • PXE: GIGETH3

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command only to recover from a shutdown or failed state.

Caution Using this command does *not* provide an orderly software shutdown and may impact file operations that are in progress.

Examples

The following example shows how to reset the server:

```
Router# ucse 2 server reset boot url http://220.0.0.100/OS/image.iso
```

ucse session

To start or close a host or CIMC session, use the **ucse session** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **session** {**imc** [**clear**] | **host** [**clear**]}

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse subslot *slot/subslot* **session** {**imc** [**clear**] | **host** [**clear**]}

Note The **ucse** *slot* **session imc** command will work only if you have configured a router-side IP address (for instance, ip unnumbered GigabitEthernet0/0) on the interface.

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
imc	Starts a session with CIMC.
imc clear	Closes the existing CIMC session.
host	Starts a session with the host Cisco E-Series Server.
host clear	Closes the host Cisco E-Series Server session.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Usage Guidelines

The **imc clear** and **host clear** commands close the active session of the CIMC or the host. As a result, the system closes the sessions of any other users currently logged in.

Only one active session is allowed in the CIMC or host at any time. If you receive a “connection refused” message when sessioning in, close the current active session by entering the **imc clear** or **host clear** commands.

Examples

The following example shows how to clear the CIMC session in an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 session imc clear
```

Examples

The following example shows how to clear the CIMC session in an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 session imc clear
```

ucse shutdown

To shut down the system gracefully, use the **ucse shutdown** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **shutdown**

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse subslot *slot/subslot* **shutdown**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Usage Guidelines

Use this command when removing or replacing a hot-swappable module during online insertion and removal (OIR).

Examples

The following example shows how to gracefully shut down an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 shutdown
```

Examples

The following example shows how to gracefully shut down an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 shutdown
```

ucse server start boot

To power on the Cisco E-Series Server using the boot option, use the **ucse server start boot** command in EXEC mode .

ucse *slot* **server start boot** {**url** *url* | **device** *device_type*}

Syntax Description

slot	Router slot number in which the Cisco E-Series Server is installed.
url *url*	Boots the Cisco E-Series Server from the specified url.
device *device_type*	The device type from which the Cisco E-Series Server boots. It can be one of the following: • CDROM: Virtual-CD • EFI • FDD: Virtual-Floppy • HDD: RAID • HDD: SD2 • HDD: Virtual-HiFD • PXE: GIGETH0 • PXE: GIGETH1 • PXE: GIGETH3

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command to power on the server that was previously turned off.

Examples

The following example shows how to start the Cisco E-Series Server using the boot option:

```
Router# ucse 2 server start boot url http://220.0.0.100/OS/image.iso
```

ucse statistics

To display or clear the reset and reload server information, use the **ucse statistics** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **statistics** **[clear]**

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse **subslot** *slot*/*subslot* **statistics** **[clear]**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
clear	(Optional) Clears the E-Series Server's reset and reload information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Examples

The following example shows how to display the server statistics in an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 statistics

Module Reset Statistics:
  CLI reset count = 0
  CLI reload count = 0
  Registration request timeout reset count = 0
  Error recovery timeout reset count = 0
  Module registration count = 1
```

Examples

The following example shows how to display the server statistics in an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 statistics

Module Reset Statistics:
  CLI reset count = 0
  CLI reload count = 0
  Registration request timeout reset count = 0
  Error recovery timeout reset count = 0
  Module registration count = 1
```

ucse status

To display configuration information related to the hardware and software of a server, use the **ucse status** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **status** [**detailed**]

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse **subslot** *slot/subslot* **status** [**detailed**]

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
detailed	(Optional) Displays detail information about the Cisco E-Series Server such as the status of the service module and settings of the reset and heartbeat-reset flags.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Examples

The following example shows how to display server status in an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 status

Service Module is Cisco ucse 2/0
Service Module supports session via TTY line 131
Service Module is in Steady state
Service Module reset on error is disabled
Service Module heartbeat-reset is enabled
```

Examples

The following example shows how to display server status in an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 status

Service Module is Cisco ucse 0/3
Service Module supports session via TTY line 131
Service Module is in Steady state
Service Module reset on error is disabled
Service Module heartbeat-reset is enabled
```

ucse stop

To immediately power down the server, use the **ucse stop** command in privileged EXEC mode.

E-Series Servers Installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T

ucse *slot* **stop**

E-Series Servers and EHWIC E-Series NCE Installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M

ucse subslot *slot/subslot* **stop**

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the EHWIC E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.2(4)M	This command was introduced. This command was supported on Cisco UCS E-Series Servers (E-Series Server) installed in an ISR G2.
15.4(3)M	This command was modified to include the **subslot** keyword. This command was supported on an additional platform: the EHWIC E-Series Network Compute Engine (EHWIC E-Series NCE) installed in an ISR G2.

Examples

The following example shows how to power down an E-Series Server installed in an ISR G2—Applicable from Cisco IOS Release 15.2(4)M to 15.4(2)T:

```
Router# ucse 2 stop

Send server stop command
```

Examples

The following example shows how to power down an E-Series Server or EHWIC E-Series NCE installed in an ISR G2—Applicable in Cisco IOS Release 15.4(3)M:

```
Router# ucse subslot 0/3 stop

Send server stop command
```

unidirectional

To configure the software-based UDE, use the **unidirectional** command in interface configuration mode. To remove the software-based UDE configuration, use the **no** form of this command.

unidirectional {**send-only** | **receive-only**}
no unidirectional

Syntax Description

send-only	Specifies that the unidirectional transceiver transmits traffic only.
receive-only	Specifies that the unidirectional transceiver receives traffic only.

Command Default

UDE is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

UDE is supported on the interfaces of these switching modules:

- WS-X6704-10GE 4-port 10-Gigabit Ethernet
- WS-X6816-GBIC 16-port Gigabit Ethernet
- WS-X6516A-GBIC 16-port Gigabit Ethernet
- WS-X6516-GBIC 16-port Gigabit Ethernet

You do not need to configure software-based UDE on ports where you implement hardware-based UDE.

If an interface is configured with Unidirectional Ethernet or has a receive-only transceiver, UDLD is operationally disabled. Use the **showudld** command to display the configured and operational states of this interface.

When you apply the UDE configuration to an interface, the following warning message is displayed:

```
Warning!
Enable port unidirectional mode will automatically disable port udld. You must manually
ensure that the unidirectional link does not create a spanning tree loop in the network.
Enable l3 port unidirectional mode will automatically disable ip routing on the port. You
must manually configure static ip route and arp entry in order to route ip traffic.
```

Examples

This example shows how to configure 10-Gigabit Ethernet port 1/1 as a UDE send-only port:

```
Router(config-if)# unidirectional send-only
Warning!
Enable port unidirectional mode will automatically disable port udld. You must manually
ensure that the unidirectional link does not create a spanning tree loop in the network.
```

```
Enable l3 port unidirectional mode will automatically disable ip routing on the port. You
must manually configure static ip route and arp entry in order to route ip traffic.
```

This example shows how to configure 10-Gigabit Ethernet port 1/2 as a UDE receive-only port:

```
Router(config-if)# unidirectional receive-only
Warning!
Enable port unidirectional mode will automatically disable port udld. You must manually
ensure that the unidirectional link does not create a spanning tree loop in the network.
Enable l3 port unidirectional mode will automatically disable ip routing on the port. You
must manually configure static ip route and arp entry in order to route ip traffic.
```

Related Commands

Command	Description
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.
show interfaces unidirectional	Displays the operational state of an interface with a receive-only transceiver.

upgrade fpd auto

To configure the router to automatically upgrade the current FPD images on a SPA or any FPD-capable cards when an FPD version incompatibly is detected, enter the **upgradefpdauto** global configuration command. To disable automatic FPD image upgrades, use the **no** form of this command.

upgrade fpd auto
no upgrade fpd auto

Syntax Description

This command has no arguments or keywords.

Command Default

This command is enabled by default if your router has any installed SPAs or FPD-capable cards. The router checks the FPD image during bootup or after an insertion of a SPA or FPD-capable card. If the router detects an incompatibility between an FPD image and a SPA or FPD-capable card, an automatic FPD upgrade attempt occurs unless the user has disabled automatic FPD upgrades by entering the **noupgradefpdauto** command. The **upgradefpdpath** command can be used to direct the router to search for the FPD image package at another location (such as an FTP or TFTP server) when an FPD incompatibility is detected.

The router searches the disk2: Flash Disk for the FPD image package file when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

The **routersearchesthe**primary Flash file system (disk0:) for the FPD image package file when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

The router searches all of its Flash file systems for the FPD image package when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

Global configuration (config)

Command History

Release	Modification
12.2(20)S2	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD3	This command was integrated into Cisco IOS Release 12.4(4)XD3.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.

Usage Guidelines

This command is enabled by default. In most cases, this default configuration should be retained.

If this command is disabled but an FPD upgrade is required for a SPA, the**upgradehw-modulesubslot** command can be used to upgrade the SPA FPD image manually after the SPA is disabled because of the existing FPD incompatibility.

If this command is disabled but an FPD upgrade is required for an FPD-capable card on the Cisco 7200 VXR router, you cannot upgrade the card manually. Select the FPD image package and download it to the disk2: Flash Disk, enable the automatic FPD upgrade by using the upgrade fpd auto command, and reboot the router.

Upgrading the FPD image on a SPA or FPD-capable card places the SPA or card offline while the upgrade is taking place. The time required to complete an FPD image upgrade can be lengthy. The **showupgradefpdprogress** command can be used to gather more information about estimated FPD download times for a particular SPA.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), refer to the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

Cisco 7200 VXR

The following example shows the output that is displayed when a VSA in slot 0 requires an FPD image upgrade and the upgrade fpd auto command is enabled. The required FPD image is automatically upgraded.

```
*Apr 10 00:37:42.859: %FPD_MGMT-3-INCOMP_IMG_VER: Incompatible VSA (FPD ID=1) image version
 detected for VSA card in slot 0. Detected version = 0.9, minimum required version = 0.10.
 Current HW version = 0.0.
*Apr 10 00:37:42.859: %FPD_MGMT-5-UPGRADE_ATTEMPT: Attempting to automatically upgrade the

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module slot	Manually upgrades the current FPD image package on a SIP or any FPD-capable cards.
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.

upgrade fpd path

To configure the router to search for an FPD image package file in a location other than the default router Flash file system during an automatic FPD upgrade, enter the **upgradefpdpath** command in global configuration mode. To return to the default setting of the router searching for the FPD image package file in the router Flash file systems when an automatic FPD upgrade is triggered, use the **no** form of this command.

upgrade fpd path *fpd-pkg-dir-url*
no upgrade fpd path *fpd-pkg-dir-url*

Syntax Description

fpd-pkg-dir-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include disk0, slot0, tftp, or ftp) and followed by the path to the FPD image package file. It is important to note that the name of the FPD image package file should not be specified as part of *fpd-pkg-dir-url*; Cisco IOS will automatically download the correct FPD image package file once directed to the proper location. It is important to note that the last character of the *fpd-pkg-dir-url* is always a "/".

Command Default

The **upgradefpdpath** command is used to specify a new location for a router to locate the FPD image package file, if you want to store the FPD image package file in a location other than the default router Flash file system for automatic FPD upgrades. The default locations the router searches are as follows:

The router searches the disk2: Flash Disk for the FPD image package file when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

The **routersearchesthe**primary Flash file system (disk0:) for the FPD image package file when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

The router searches all of its Flash file systems for the FPD image package when an FPD incompatibility is detected and **upgradefpdauto** is enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(20)S2	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD3	This command was integrated into Cisco IOS Release 12.4(4)XD3.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.

Usage Guidelines

It is important to note that the last character of the *fpd-pkg-dir-url* is always a "/". This path points users to the directory that stores the file, but not the file itself.

When specifying the path to the location of the new FPD image package file, do not include the file name in the path. The Cisco IOS will automatically download the correct FPD image package file once directed to the proper location, even if multiple FPD image package files of different versions are stored in the same location.

If the **upgradefpdpath** command is not entered, the router searches the default router Flash file system for the FPD image.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), refer to the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide.

Examples

In the following example, the FPD image package file that is stored on the TFTP server using the path johnstftpserver/fpdfiles is scanned for the latest FPD image package file when an automatic FPD upgrade occurs:

```
upgrade fpd path tftp://johnstftpserver/fpdfiles/
```

In the following example, the FPD package file that is stored on the FTP server using the path johnsftpserver/fpdfiles is scanned for the latest FPD image package when an automatic FPD upgrade occurs. In this example, john is the username and XXXXXXX is the FTP password:

```
upgrade fpd path ftp://john:XXXXXXX@johnsftpserver/fpdfiles/
```

upgrade fpga

To set router behavior regarding handling of FPGA mismatches after FPGA mismatches are detected, use the **upgradefpga** command in privileged EXEC mode.

upgrade fpga [{**force** | **prompt**}]
no upgrade fpga

Syntax Description

force	If the **force** option is entered, an FPGA upgrade will be forced on the system if an FPGA mismatch is detected.
prompt	If the **prompt** option is entered, the user will be prompted to upgrade the FPGA when an FPGA mismatch is detected.

Command Default

Before Cisco IOS Release 12.2(20)S6, users were automatically prompted for an FPGA upgrade when an FPGA version mismatch was detected.

In Cisco IOS Release 12.2(20)S6, the default setting became **noupgradefpga**. By default, FPGA is not upgraded when an FPGA version mismatch is detected and the user is not prompted to upgrade the FPGA, although it is important to note that a message indicating the FPGA mismatch is displayed on the console. Users who want to upgrade FPGA must use the **upgradefpgaall** command to manually perform the upgrade when the default settings are set.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S4	The **upgradefpgaprompt**command was introduced
12.2(20)S6	The **noupgradefpga** command was introduced and became the default setting. The **force** option was introduced. The **noupgradefpgaprompt** command behavior was changed. The **noupgradefpgaprompt** configuration no longer automatically begins an FPGA upgrade when an FPGA mismatch is detected.

Usage Guidelines

Note that **noupgradefpga** is the default setting starting in Cisco IOS Release 12.2(20)S6. See the Defaults section of this command reference for additional information on the changes to the default setting in Cisco IOS Release 12.2(20)S6.

This command can be used to upgrade all of the FPGAs in a Cisco 7304 router except for the SPA FPGA. The SPA FPGA is upgraded using an FPD image package.

An FPGA match check is automatically run by the Cisco 7304 router during system bootup or after a piece of hardware with FPGA is installed into an operating Cisco 7304 router. This command defines the behavior for a router after an FPGA mismatch is detected during one of these FPGA match checks. When the default setting of **noupgradefpga** is maintained, FPGA is not upgraded when an FPGA mismatch is detected and the user is not prompted regarding an FPGA upgrade. If the **upgradefpgaprompt** command is entered, a prompt asking users whether they would like to perform an FPGA upgrade appears on the console when FPGA mismatches are detected. If the **upgradefpgaforce** command is entered, an FPGA upgrade occurs automatically when an FPGA mismatch is detected.

In Cisco IOS Releases 12.2(20)S4 and 12.2(20)S5, the **noupgradefpgaprompt** configuration automatically started an FPGA upgrade when an FPGA mismatch was detected. Starting in Cisco IOS Release 12.2(20)S6, the **noupgradefpgaprompt** configuration is the same configuration as **noupgradefpga**. When this setting of **noupgradefpga** is maintained, the FPGA is not upgraded when an FPGA mismatch is detected and the user is not prompted regarding an FPGA upgrade.

While the **noupgradefpga** command can be entered as a configuration command, the **upgradefpga** command cannot be entered unless the **force** or **prompt** options are also entered.

The **force** or **prompt** options are not necessary when entering the no upgrade fpga command. The options can be entered, but the system configuration will revert to the **noupgradefpga** configuration regardless of whether a keyword is entered.

Note that when the FPGA prompt is configured, the prompt appears on the console screen only. If you are connecting to a router using a telnet connection through a line card, SPA, or port adapter, you will not see this prompt. If you are connecting to the router through one of these methods, we recommend not configuring **upgradefpgaprompt** because you will not be able to see the prompt and the prompt will time out.

Examples

In the following example, the system configuration has been changed so that users will be prompted regarding an FPGA upgrade if an FPGA mismatch is detected during bootup or after an OIR hardware insertion.

```
Router# upgrade fpga prompt
```

The following example is the output of a router that has detected an FPGA mismatch when the **upgradefpgaprompt**command is configured. Note the “Upgrade slot 5 LC FPGA? [y/n]” prompt. In this example, the prompt is answered and the FPGA upgrade is performed.

```
The following board(s) have an FPGA image that is different
from the IOS bundled FPGA image
Please note the board(s) will be reset after FPGA update.
In the case of NSE, it will reload the whole system.
                          HARDWARE        FPGA VERSION ESTIMATED TIME
SLOT  FPGA                VERSION    CURRENT    IOS BUNDLED    TO UPDATE
----  ----                --------   -------    ----------- --------------
 5    6T3                  03.03      00.20        00.21       up to 12 minutes

In the following example, the system configuration has been changed so that an FPGA upgrade will occur automatically if an FPGA mismatch is detected during bootup or after an OIR hardware insertion:

```
Router# upgrade fpga force
```

The following example is from a router that has detected an FPGA mismatch when **upgradefpgaforce** is configured. Note that the upgrade occurs automatically without the user being prompted for any information.

```
The following board(s) have an FPGA image that is different
from the IOS bundled FPGA image
Please note the board(s) will be reset after FPGA update.
In the case of NSE, it will reload the whole system.
                          HARDWARE        FPGA VERSION ESTIMATED TIME

```

In the following example, the default configuration where no prompt and no forced upgrade occurs when an FPGA mismatch occurs is restored.

```
Router# no upgrade fpga
```

The following example is from a router that has detected an FPGA mismatch when **noupgradefpga** is configured. Note that the FPGA upgrade was not performed. If you receive these messages and want to upgrade FPGA, enter the **upgradefpgaall** command to manually perform an FPGA upgrade.

```
00:00:05:%PLATFORM-4-FPGA_MISMATCH:FPGA image in slot 0 (name = NPEG100, hardware version
= 01.00, current fpga version = 02.04) does not match the FPGA image in Cisco IOS software
 (version 02.05). Approximate time to update the FPGA image is 12 minutes.
00:00:08:%PLATFORM-4-FPGA_MISMATCH:FPGA image in slot 5 (name = 6T3, hardware version =

No default behaviors or values

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(10)EX	This command was introduced.
12.2(11)YZ	Support was added for the 7300-CC-PA.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2 S.
12.2(20)S6	The prompt asking users if they would like to reload the line card to complete the FPGA upgrade process was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to manually start the FPGA image update process. Automatic FPGA version checking is performed during every system startup for all line cards, processors, and jacket cards in the system. Automatic FPGA version checking is also performed for hardware after insertion of that hardware during an online insertion and removal (OIR).

Traffic disruption for traffic on the hardware upgrading FPGA usually occurs during FPGA upgrades. If you are going to upgrade FPGA using this command, keep this fact in mind.

Before Cisco IOS Release 12.2(20)S6, the hardware that had the FPGA upgrade would automatically be reloaded as the final procedure of the FPGA upgrade. In Cisco IOS Release 12.2(20)S6 onward, the user sees a prompt asking if the hardware should be reloaded to complete the FPGA upgrade. The user can choose to skip the hardware reload at the current time if desired, but the FPGA upgrade is not complete until the hardware is reloaded. If the user chooses not to reload the hardware that is getting the FPGA upgrade, the hardware will have to be reloaded using the **hw-module***slot-number***stop** command followed by the **hw-module***slot-number***start** command if the hardware is not a processor. If the hardware is a processor, the router must be reloaded.

In cases where the FPGA upgrade is performed but the hardware is not reloaded, users should note that the bundled FPGA version will be transferred to Flash memory but not to the hardware. Therefore, if the **showc7300** command is entered to see FPGA versions after an FPGA upgrade has been performed but not completed by reloading the hardware, the bundled FPGA version should match the Flash memory version. After the hardware is reloaded, the bundled, the Flash, and the system FPGA should all match and the upgrade should be complete.

Examples

The following example shows a manual FPGA upgrade for a router using Cisco IOS Release 12.2(20)S6 or later. Note that the user elects to reject the NPE-G100 upgrade. More importantly, note the user is prompted about reloading the 6T3 line card to complete the FPGA upgrade after electing to perform that FPGA upgrade. In this example, the user decides to reject the card reload for the 6T3 line card in slot 5 and the FPGA upgrade for that card is not finalized.

```
Router# upgrade fpga all

Related Commands

Command	Description
show c7300	Displays the types of hardware (processors, line cards, jacket cards, and so on) installed in the Cisco 7304 router slots, including the bundled, Flash, and current FPGA versions.
show diag	Displays hardware information for any slot or the chassis.
upgrade rom-monitor default	Configures a particular ROM monitor image as the default ROMmon image.

Command	Description
upgrade rom-monitor file	Upgrades the ROM monitor.

upgrade hw-module slot

Note The upgrade hw-module slot command is not available in Cisco IOS Release 12.2(33)SRB and later Cisco IOS 12.2SR releases. It is replaced by the upgrade hw-module slot fpd file command.

Note The upgrade hw-module slot command is not available in Cisco IOS Release 12.4(15)T and later Cisco IOS 12.4T releases. It is replaced by the upgrade hw-module slot fpd file command.

To manually upgrade the current FPD image package on a SIP or any FPD-capable cards, enter the **upgradehw-moduleslot** command in privileged EXEC mode.

Cisco 7200 VXR
upgrade hw-module slot {*slot* | **npe**} **file** *file-url*

Cisco 7600 Series
upgrade hw-module slot *slot* **file** *file-url* [**force**]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. For slot numbering in the Cisco 7200 VXR router, refer to refer to the Cisco 7200 VXR Installation and Configuration Guide.
npe	NPE-G2 network processing engine in the Cisco 7200 VXR router.
file	Specifies that a file will be downloaded.
file-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include **disk0**, **slot0**, **tftp**, or **ftp**) and followed by the path to the FPD image package file.
force	(Optional) Forces the update of all compatible FPD images in the indicated FPD image package file on the SPA that meet the minimal version requirements. Without this option, the manual upgrade will only upgrade incompatible FPD images.

Command Default

No default behavior or values.

No default behavior or values, although it is important to note that the router containing the SIP is configured, by default, to upgrade the FPD images when it detects a version incompatibility between the FPD image on the SIP and the FPD image required to run the SPA with the running Cisco IOS image. The **upgradehw-moduleslot** command is used to manually upgrade the FPD images; therefore, the **upgradehw-moduleslot**command should only be used when the automatic upgrade default configuration fails to find a compatible FPD image for one of the SPAs or when the automatic upgrade default configuration has been manually disabled. The **noupgradefpdauto** command can be entered to disable automatic FPD upgrades.

If no FPD incompatibility is detected, this command will not upgrade SPA FPD images unless the **force** option is entered.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(4)XD	This command was integrated into Cisco IOS Release 12.4(4)XD, and the npe keyword was added.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	This command was removed. It is not available in Cisco IOS Release 12.2(33)SRB and later Cisco IOS 12.2SR releases. It is replaced by the upgrade hw-module slot fpd file command.
12.4(15)T	This command was removed. It is not available in Cisco IOS Release 12.4(15)T and later Cisco IOS 12.4T releases. It is replaced by the upgrade hw-module slot fpd file command.

Usage Guidelines

Cisco 7200 VXR

This command is used to manually upgrade FPD images. Note that for a manual FPD upgrade to take effect on the NPE-G2, you must power cycle the router. The router will not use the new version of the NPE-G2 FPD image if you reload the router without a power cycle. Other FPD-capable cards require only a router reload after a manual FPD upgrade, not a router power cycle.

Cisco 7600 Series

This command is used to manually upgrade the FPD images on a SIP. In most cases, the easiest and recommended method of upgrading FPD images is the automatic FPD upgrade, which is enabled by default. The automatic FPD upgrade detects and automatically upgrades all FPD images when an FPD incompatibility is detected.

A manual FPD upgrade is usually used in the following situations:

- The target SIP was disabled by the system because of an incompatible FPD image (the system could not find the required FPD image package file).
- A recovery upgrade must be performed.
- A special bug fix to an FPD image is provided in the FPD image package file.

The FPD image upgrade process places the SIP and all the SPAs in the SIP offline. The time required to complete an FPD image upgrade can be lengthy. The **showupgradefpdprogress** command can be used to gather more information about estimated FPD image download times for a particular SIP.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide. For FPD upgrades on the Cisco 7200 VXR router, see the *Field-Programmable Device Upgrades* feature guide.

Examples

Cisco 7200 VXR

The following example shows a sample manual FPD upgrade of the FPD image package for the NPE-G2:

```
Router# upgrade hw-module slot npe file
tftp://mytftpserver/myname/myfpdpkg/c7200-fpd-pkg.124-4.XD.pkg
% The following FPD(s) will be updated for NPE-G2 (H/W ver = 0.0) in NPE slot:
         ================== =========== =========== ============
         Field Programmable   Current     Upgrade   Estimated

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatibility is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module subslot	Manually upgrades the current FPD image on the specified SPA.

upgrade hw-module slot fpd file

To manually upgrade the current FPD image package on a SIP or any FPD-capable cards, use the **upgradehw-moduleslotfpdfile**command in privileged EXEC mode.

Cisco 7200 VXR
upgrade hw-module slot {*slot* | **npe**} *fpd* **file** *file-url*

Cisco 7600 Series
upgrade hw-module slot *slot* **fpd file** *file-url* [**force**]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. For slot numbering in the Cisco 7200 VXR router, refer to refer to the Cisco 7200 VXR Installation and Configuration Guide .
npe	NPE-G2 network processing engine in the Cisco 7200 VXR router.
file-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include **disk0**, **slot0**, **tftp**, or **ftp**) and followed by the path to the FPD image package file.
force	(Optional) Forces the update of all compatible FPD images in the indicated FPD image package file on the SPA that meet the minimal version requirements. Without this option, the manual upgrade will only upgrade incompatible FPD images.

Command Default

No default behavior or values.

No default behavior or values, although it is important to note that the router containing the SIP is configured, by default, to upgrade the FPD images when it detects a version incompatibility between the FPD image on the SIP and the FPD image required to run the SPA with the running Cisco IOS image. Manual upgrade of FPD images is recommended only when the automatic upgrade default configuration fails to find a compatible FPD image for one of the SPAs, or when the automatic upgrade default configuration has been manually disabled. The **noupgradefpdauto** command can be entered to disable automatic FPD upgrades.

If no FPD incompatibility is detected, this command will not upgrade SPA FPD images unless the **force** option is entered.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRB	This command was introduced. This command replaces the upgrade hw-module slot command.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

Cisco 7200 VXR

This command is used to manually upgrade FPD images. In most cases, the easiest and recommended method of upgrading FPD images is the automatic FPD upgrade, which is enabled by default. Note that for a manual FPD upgrade to take effect on the NPE-G2, you must power cycle the router. The router will not use the new version of the NPE-G2 FPD image if you reload the router without a power cycle. Other FPD-capable cards require only a router reload after a manual FPD upgrade, not a router power cycle.

Cisco 7600 Series

This command is used to manually upgrade the FPD images on a SIP. In most cases, the easiest and recommended method of upgrading FPD images is the automatic FPD upgrade, which is enabled by default. The automatic FPD upgrade detects and automatically upgrades all FPD images when an FPD incompatibility is detected.

A manual FPD upgrade is usually used in the following situations:

- The target SIP was disabled by the system because of an incompatible FPD image (the system could not find the required FPD image package file).
- A recovery upgrade must be performed.
- A special bug fix to an FPD image is provided in the FPD image package file.

The FPD image upgrade process places the SIP and all the SPAs in the SIP offline. The time required to complete an FPD image upgrade can be lengthy. The **showupgradefpdprogress** command can be used to gather more information about estimated FPD image download times for a particular SIP.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide. For FPD upgrades on the Cisco 7200 VXR router, see the *Field-Programmable Device Upgrades* feature guide.

Examples

Related Commands

Command	Description
show hw-module all fpd	Displays the current versions of all FPDs for all of the supported card types on a router.
show hw-module slot fpd	Displays the current versions of all FPDs for a SIP in the specified slot location and for all of the SPAs installed in that SIP or any FPD-capable cards.
show hw-module subslot fpd	Displays the current versions of all FPDs for a particular SPA or all of the active SPAs on a router.
show upgrade fpd file	Displays the contents of an FPD image package file.
show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs or other FPD-capable cards.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatibility is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module subslot fpd file	Manually upgrades the current FPD image on the specified SPA.

upgrade hw-module subslot

Note The upgradehw-module subslot command is not available in Cisco IOS Release 12.2(33)SRB and later Cisco IOS 12.2SR releases. It is replaced by the upgrade hw-module subslot fpd file command.

Note The upgrade hw-module subslot command is not available in Cisco IOS Release 12.2(33)SB and later Cisco IOS 12.2SB releases. It is replaced by the upgrade hw-module subslot fpd file command.

Note The upgrade hw-module subslot command is not available in Cisco IOS Release 12.0(33)S2 and later Cisco IOS 12.0S releases. It is replaced by the upgrade hw-module subslot fpd file command.

To manually upgrade the current FPD image package on a SPA, use the **upgradehw-modulesubslot** command in privileged EXEC mode.

Cisco 7304
upgrade hw-module subslot *slot/subslot* **file** *file-url* [**reload**]

Cisco 7600 Series, Cisco 12000 Series
upgrade hw-module subslot *slot/subslot* **file** *file-url* [**force**]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
file	Specifies that a file will be downloaded.
file-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include disk0, slot0, tftp, or ftp) and followed by the path to the FPD image package file.
reload	(Optional) Reloads the SPA to complete the FPD upgrade.
force	(Optional) Forces the update of all compatible FPD images in the indicated FPD image package on the SPA that meet the minimal version requirements. Without this option, the manual upgrade will only upgrade incompatible FPD images.

Command Default

No default behavior or values, although it is important to note that the router containing the SPA is configured, by default, to upgrade the FPD images when it detects a version incompatibility between a the FPD image on the SPA and the FPD image required to run the SPA with the running Cisco IOS image. The **upgradehw-modulesubslot** command is used to manually upgrade the FPD images; therefore, the **upgradehw-modulesubslot**command should only be used when the automatic upgrade default configuration fails to find a compatible FPD image for one of the SPAs or when the automatic upgrade default configuration has been manually disabled. The **noupgradefpdauto** command can be entered to disable automatic FPD upgrades.

By default the SPA is not reloaded to complete the FPD upgrade unless the **reload** option is entered. Reloading the SPA drops all traffic traversing that SPA's interfaces. If you want to reload the SPA later to complete the upgrade, do not enter the **reload** option and perform OIR of the SPA later to complete the FPD upgrade.

If no FPD incompatibility is detected, this command will not upgrade SPA FPD images unless the **force** option is entered.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S2	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.2(25)S3	The **force** option was removed and replaced by the **reload** option (Cisco 7304 router).
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRB	This command was removed. It is not available in Cisco IOS Release 12.2(33)SRB and later Cisco IOS 12.2SR releases. It is replaced by the upgrade hw-module subslot fpd file command.
12.2(33)SB	This command was removed. It is not available in Cisco IOS Release 12.2(33)SB and later Cisco IOS 12.2SB releases. It is replaced by the upgrade hw-module slot fpd file command.

Usage Guidelines

This command is used to manually upgrade the FPD images on a SPA. In most cases, the easiest and recommended method of upgrading FPD images is the automatic FPD upgrade, which is enabled by default. The automatic FPD upgrade will detect and automatically upgrade all FPD images when an FPD incompatibility is detected.

A manual FPD upgrade is usually used in the following situations:

- The target SPA was disabled by the system because of an incompatible FPD image (the system could not find the required FPD image package file).
- A recovery upgrade must be performed.
- A special bug fix to an FPD image is provided in the FPD image package file.

The FPD image upgrade process places the SPA offline. The time required to complete an FPD image upgrade can be lengthy. The **showupgradeprogress** command can be used to gather more information about estimated FPD download times for a particular SPA.

For more information about FPD upgrades on SPA interface processors (SIPs) and shared port adapters (SPAs), see the *Cisco 7304 Router Modular Services Card and Shared Port Adapter Software Configuration Guide*, the *Cisco 7600 Series Router SIP, SSC, and SPA Software Configuration Guide*, or the *Cisco 12000 Series Router SIP and SPA Software Configuration Guide*.

Examples

The following example shows a sample manual FPD upgrade:

```
Router# upgrade hw-module subslot 2/0 file disk0:spa_fpd.122-20.S2.pkg
% Uncompressing the bundle ...  [OK]

% The following FPD(s) will be upgraded for card in subslot 2/0 :

         ================== =========== =========== ============
         Field Programmable   Current     Upgrade   Estimated
         Device:"ID-Name"     Version     Version   Upgrade Time
         ================== =========== =========== ============
         1-Data & I/O FPGA
     4.12        4.13      00:06:00
         ================== =========== =========== ============
% Are you sure that you want to perform this operation? [no]:y
% Restarting the target card (subslot 2/0) for FPD image upgrade. Please wait ...

show upgrade fpd package default	Displays which FPD image package is needed for the router to properly support the SPAs.
show upgrade fpd progress	Displays the progress of the FPD upgrade while an FPD upgrade is taking place.
show upgrade fpd table	Displays various information used by the Cisco IOS software to manage the FPD image package file.

Command	Description
upgrade fpd auto	Configures the router to automatically upgrade the FPD image when an FPD version incompatability is detected.
upgrade fpd path	Specifies the location from where the FPD image package should be loaded when an automatic FPD upgrade is initiated by the router.
upgrade hw-module slot	Manually upgrades the current FPD image on the specified SPA.

upgrade hw-module subslot fpd file

To manually upgrade the current FPD image package on a SPA, use the **upgradehw-modulesubslotfpdfile**command in privileged EXEC mode.

Cisco 7304 and Cisco uBR10012 Universal Broadband Router
upgrade hw-module subslot *slot/subslot* **fpd file** *file-url* [**reload**]

Cisco 7600 Series
upgrade hw-module subslot *slot/subslot* **fpd file** *file-url* [**force**]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
file-url	Specifies the location of the FPD image package file, beginning with the location or type of storage device (examples include disk0, slot0, tftp, or ftp) and followed by the path to the FPD image package file.
reload	(Optional) Reloads the SPA to complete the FPD upgrade.
force	(Optional) Forces the update of all compatible FPD images in the indicated FPD image package on the SPA that meet the minimal version requirements. Without this option, the manual upgrade will only upgrade incompatible FPD images.

Command Default

No default behavior or values, although it is important to note that the router containing the SPA is configured, by default, to upgrade the FPD images when it detects a version incompatibility between a the FPD image on the SPA and the FPD image required to run the SPA with the running Cisco IOS image. Manual upgrade of FPD images is recommended only when the automatic upgrade default configuration fails to find a compatible FPD image for one of the SPAs, or when the automatic upgrade default configuration has been manually disabled. The **noupgradefpdauto** command can be entered to disable automatic FPD upgrades.

By default the SPA is not reloaded to complete the FPD upgrade unless the **reload** option is entered. Reloading the SPA drops all traffic traversing that SPA’s interfaces. If you want to reload the SPA later to complete the upgrade, do not enter the **reload** option and perform OIR of the SPA later to complete the FPD upgrade.

If no FPD incompatibility is detected, this command will not upgrade SPA FPD images unless the **force** option is entered.

upgrade hw-programmable

To perform a Complex Programmable Logic Device (CPLD) or Field-Programmable Gate Array (FPGA) upgrade on a Cisco ASR 1000 Series Router, use the **upgradehw-programmable** command in Privileged EXEC configuration mode.

upgrade hw-programmable [{**all** | **CPLD** | **FPGA**}] **filename** *filename* {**R0** | **R1** | **F0** | **F1** | **0 . . 5**}

Syntax Description

all	Select to perform both a CPLD and FPGA upgrades on a Cisco ASR 1000 Series Router. **Note** This option is not supported in Cisco IOS XE Release 3.1.0S.
CPLD	Select to perform a Complex Programmable Logic Device (CPLD) upgrade on the Cisco ASR1000-SIP10, standby or active Cisco ASR1000-RP in a Cisco ASR 1013 Router.
FPGA	Select to perform a Field-Programmable Gate Array (FPGA) upgrade on a Cisco ASR 1000 Series Router. **Note** This option is not supported in Cisco IOS XE Release 3.1.0S.
filename	Specifies the hw-programmable upgrade package file.
filename	Specifies the hw-programmable upgrade package file and its file system location. For filename, specify one of the following system locations and a package file name: • bootflash: RP-relative HW programmable package name • flash: RP-relative HW programmable package name • harddisk: RP-relative HW programmable package name This is the hw-programmable upgrade package file that contains a new version of the CPLD and FPGA code, used for performing the CPLD on a Cisco ASR 1013 Router or FPGA upgade on a Cisco ASR 1000 Series Router. The package file name is typically named asr1000-hw-programmables.<release_name>.pkg.
R0	RP slot 0. In the Cisco ASR 1006 Routers and Cisco ASR 1013 Routers, it is the lower RP slot. In the Cisco ASR 1002 and Cisco ASR 1004 Routers, it is the only slot.
R1	RP slot 1. This is only in the Cisco ASR 1006 and Cisco ASR 1013 Routers. It is the higher RP slot.
F0	This is the embedded services processor (ESP) slot 0. In the Cisco ASR 1006 Routers and Cisco ASR 1013 Routers, it is the lower ESP slot. In the Cisco ASR 1002 and Cisco ASR 1004 Routers, it is the only slot.
F1	This is the embedded services processor (ESP) slot 2. This is only in the Cisco ASR 1006 and Cisco ASR 1013 Routers. It is the higher ESP slot.

0..5	This is one of the SIP carrier card slots. Select a slot number zero through five. **Note** A CPLD upgrade cannot be performed in Slot 5 in the ASR100-SIP10. Move the card to another slot.

Command Default

CPLD or FPGA is not upgraded.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.1S	This command was introduced in Cisco IOS XE Release 3.1S.

Usage Guidelines

For procedures on performing a CPLD upgrade, see the Upgrading Field Programmable Hardware Devices for Cisco ASR 1000 Series Routers document.

Examples

The following example upgrades the Cisco ASR1000-RP2 CPLD with the following command:

```
Router# upgrade hw-programmable cpld filename harddisk: asr1000-hw-programmables.15.01s.pkg
 R0
Upgrade CPLD on Route-Processor 0 from current version 08103002 to 10021901 [confirm] This
 command could take up to 10 minutes, please wait and do not power cycle the box or the
card (hardware may be unrecoverable). This command  also issues a reset to the linecard at
 the end of upgrade.[confirm]
```

Related Commands

Command	Description
show hw-programmable	Displays the current CPLD and FPGA versions on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable progress	Displays the upgrade progress of the line card-field upgradeable device (LC-FPD) on a Cisco ASR 1000 Series Router.
show upgrade hw-programmable	Displays the names and versions of individual files in the hw_programmable package file.

upgrade rom-monitor default

To configure a particular ROM monitor image as the default ROMmon image, use the **upgraderom-monitordefault** command in privileged EXEC mode.

upgrade rom-monitor {**rom0** | **rom1** | **rom2**} **default**

Syntax Description

rom0	One-time programmable, always-there "golden" ROMmon.
rom1	Upgradable ROM monitor 1.
rom2	Upgradable ROM monitor 2.

Command Default

ROM 0, the one-time programmable, always there "golden" ROMmon is the default ROM monitor.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.2(18)S	This command was implemented on Cisco 7304 routers running Cisco IOS Release 12.2 S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to set a ROMmon image as the default ROMmon image. If this command is not configured, the system uses ROM 0 as the default ROMmon image.

There are three ROMmon images. ROM 0 is a one-time programmable, always-there ROMmon image, referred to as the "golden" ROMmon. ROM 1 and ROM 2 are upgradeable ROMmon images. At bootup, the system uses the golden ROMmon by default. If either ROM 1 or ROM 2 are configured, the system still begins bootup with the golden ROMmon, then switches to the configured ROMmon. If a new configured ROMmon image fails to boot up Cisco IOS, the router marks this ROMmon image as invalid and reverts to the golden image for the next Cisco IOS bootup.

After downloading a new ROMmon image to the writeable ROMmon, you must reload Cisco IOS for the new ROMmon to take effect. The first time a new ROMmon image is loaded, you must allow the system to boot up Cisco IOS before doing any resets or power cycling. If the ROMmon loading process is interrupted, the system interprets this as a bootup failure of the new ROMmon image and reverts the ROMmon back to the golden ROMmon image in ROM 0.

Examples

The following example configures ROM 2 as the default ROMmon image:

```
Router# upgrade rom-monitor rom2 default
done!
Will take effect on next reload/reset
```

Related Commands

Command	Description
show c7300	Displays the types of hardware installed in a Cisco 7304 router.
show platform	Displays the platform.
show diag	Displays hardware information for any slot or the chassis.
upgrade rom-monitor file	Upgrades the ROM monitor.

upgrade satellite satellite

To upgrade the firmware of an NM-1VSAT-GILAT network module through TFTP, use the **upgradesatellitesatellite** command in privileged EXEC mode.

upgrade satellite satellite *slot/unit tftp-server-address firmware-filename*

Syntax Description

slot/	Router chassis slot in which the network module is installed. The / must be typed in between *slot* and *unit*.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
tftp-server-address	The IP address of the TFTP server that contains the firmware upgrade.
firmware-filename	The name of the file with the upgraded firmware.

Command Default

Firmware will not be upgraded through TFTP.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(11)XJ2	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

The **upgradesatellitesatellite** command is used to provide a firmware upgrade of VSATs locally at remote sites through TFTP. This method reduces dependency on a central hub, and allows for ease of update when connected to a service provider who uses third-party hubs.

When the TFTP server is configured on the router, the VSAT firmware is copied to the router flash memory. The TFTP server configuration would be as follows:

```
tftp-server flash:< <firmware filename>
```

This configuration would be within the overall router configuration.

When this configuration is done, the upgrade is accomplished by pointing the VSAT to the router IP address in the **upgradesatellitesatellite** command. The upgrade process will take several minutes.

Examples

The following example shows the response of the NM-1VSAT-GILAT network module to a firmware upgrade command.

```
Router# upgrade satellite satellite 1/0 9.1.0.1 VSAT_99.06.01.26_Bin.bin

Download of new firmware will proceed after a reboot of
 the satellite network module. This could take up to two minutes.
 Please wait...

*Mar 4 03:18:15.006: %LINEPROTO-5-UPDOWN: Line protocol on Interface Satellite1/0, changed
```

```
 state to up
The upgrade process will complete in several minutes.
 It will take place in the background.
 Please monitor the console for errors.
*Mar 4 03:21:16.006: %LINEPROTO-5-UPDOWN: Line protocol on Interface Satellite1/0, changed
 state to down
*Mar 4 03:27:20.842: %LINEPROTO-5-UPDOWN: Line protocol on Interface Satellite1/0, changed
 state to up
```

Related Commands

Command	Description
service-module satellite status	Verifies the image version of the downloaded firmware.

utc offset leap-second offset

To configure the current UTC offset, leap second event date and Offset value (+1 or -1), use the **utc offset leap-second offset** command in PTP clock configuration mode.

utc offset *value* **leap-second** *"date time"* **offset** {**-1** | **1**}

Syntax Description

value	Current UTC offset value. Valid values are from 0-255. The default value is 36.
"date time"	Leap second effective date in dd-mm-yyyy hh:mm:ss format.

Command Default

By default no UTC offset or leap second is configured.

Command Modes

PTP clock configuration (config-ptp-clk)

Command History

Release	Modification
Cisco IOS XE 3.18SP	This command was introduced.
Cisco IOS XE 3.18.1SP	This command was modified. The **leap-second** and **offset** keywords were added.

Usage Guidelines

Use the **utc offset leap-second offset** command to configure the current UTC offset, leap second event date and Offset value (+1 or -1).

The following example shows how to configure the current UTC offset, leap second event date and offset value:

```
Device(config)# ptp clock boundary domain 0 hybrid
Router(config-ptp-clk)# time-properties persist 600
Router(config-ptp-clk)#utc-offset 45 leap-second "01-01-2017 00:00:00" offset 1
```

Related Commands

Command	Description
time-properties persist	Configures time properties holdover time.

vectoring

To enable the vectoring mode in C86xVAE platforms, use the **vectoring** command in controller configuration mode. To restore the default value, use the **no** form of this command.

vectoring {friendly | none}

no vectoring

Syntax Description

friendly	Enables friendly vectoring mode in both Annex A and Annex B.
none	Disables vectoring mode completely.

Command Default

Default mode is Vectoring friendly in Annex A and Annex B from Release 15.6(3)M.

Command Modes

Controller Configuration (config-controller)

Command History

Release	Modification
15.6(3)M	This command was introduced on the Cisco C86xVAE series routers.

Usage Guidelines

This command is used to enable or disable vectoring on C867VAE-K9 and C866VAE-K9 platforms. By default, the vectoring is friendly on both annex A and Annex B. This command is introduced under "controller vdsl 0" mode.

Examples

The following example shows how to enable vectoring :

```
Router(config-controller)#vectoring friendly
```

The following example shows how to disable vectoring :

```
Router(config-controller)#vectoring none
```

Related Commands

Command	Description
controller vdsl	Configures the controller status.

vtg

To configure the Circuit Emulation Services over Packet Switched Network (CESoPSN) CEM group, use the **vtg** command in controller configuration STS mode.

vtg *vtg_number* **t1** *t1_line_number* **cem-group** *channel-number* **timeslots** *list-of-timesolts*

Syntax Description

For NCS 4200 Series Routers:

vtg *vtg-number* **vt** *vt-line-number* **cem-group** *cem-group-number* **cep**

vtg_number	Specifies the VTG number. The range is 1 to 7.
t1	Specifies the T1 line configuration.
t1_line_number	Specifies the T1 line number. The range is 1 to 4.
cem-group	Specifies the timeslots to CEM group mapping.
channel-number	Specifies the channel number. The range is 0 to 2015.
timeslots	Specifies the timeslots in the CEM group.
list-of-timesolts	Specifies the list of timeslots. The range is 1 to 24
vt	Specifies the Virtual Tributary (VT) under vtg of STS.
vt-line-number	Specifies the VT line number.
cem-group	Specifies the CEM group for T1 line.
cem-group-number	The *cem-group-number* keyword identifies the channel number to be used for this channel. For T1 ports, the range is 0 to 23. For E1 ports, the range is 0 to 30.
cep	Configures Circuit Emulation Service over Packet (CEP) mode.

Command Default

None

Command Modes

Controller configuration STS

Command History

Release	Modification
15.1(01)S	This command was introduced on the Cisco 7600 routers.
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Examples

This example shows how to configure the (CESoPSN) CEM group:

```
Router(config)# controller sonet-acr 1
```

```
Router(config-controller)#
sts-1 2
Router (config-ctrlr-sts1)#vtg 2 T1 2 cem-group 2 timeslots 2
```

Examples

For NCS 4200 Series, this command is used to configure the VT-15 CEP mode:

```
enable
configure terminal
controller Mediatype 0/5/0
controller sonet 0/5/0
sts-1 1
vtg 1 vt 1 cem-group 100 cep
end
```

Related Commands

Command	Description
sts-1	Configures the Synchronous Transport Signal (STS) (level)-1 in the SONET hierarchy.
mode vt-15	Configures the path operation mode.
controller sonet-acr	Configures the SONET Access Circuit Redundancy (ACR) virtual controller.
show controller sonet	Displays SONET controller configuration.

wanphy flag j1 transmit

T o configure the J1 byte values on the local SPA and to check the connectivity to the remotely connected SPA by passing the J1 byte values, use the **wanphyflagj1transmit***byte-value*commandin the Controller configuration mode. To deconfigure the J1 byte value and stop the J1 byte value from being sent to the remote end, use the **no** form of this command.

wanphy flag j1 transmit *byte-value*
no wanphy flag j1 transmit

Syntax Description

byte-value	J1 byte value that is sent from the local SPA to the remote SPA. Length of string in bytes. The range is from 0 to 16 bytes.
j1	Specifies that the J1 byte value is passed from the local SPA to the remote SPA.
transmit	Transmits the specified byte value passed from the local SPA to the remote SPA.

Command Default

No default behavior or values are available.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The **wanphyflagj1transmit**command has been has been introduced on the Cisco ASR 1000 Series Routers in Cisco IOS XE Release 3.3.0S. The main purpose of this command is to pass a J1 string value from the local Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter to the remote SPA in order to check the connectivity between the two SPAs.

Note Both the local and remotely connected Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter must operate in the WAN mode.

Examples

The following example shows how to pass a J1 byte value string from locally installed SPA to a remote SPA:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy flag j1 transmit messagefromlocalspa
```

Related Commands

Command	Description
show controllers wanphy	Displays the SPA mode (LAN mode or WAN mode), alarms, and the J1 byte string value.

wanphy report-alarm

T o enable selective alarm reporting for line-level, path-level, or section-level alarms, use the **wanphyreport-alarm**commandin Controller configuration mode. To reset the alarm reporting to its default, use the **no** form of this command.

wanphy report-alarm {*defaultlinepathsectionwis*}
no wanphy threshold

Syntax Description

default	Alarm reporting of line, section, and path to their default configured values.
line	The line-level alarm reporting status.
path	The path-level alarm reporting status.
section	The section-level alarm reporting status.
wis	The WIS-level alarm reporting status.

Command Default

No default values are available.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The **wanphyreport-alarm**command has been introduced on the Cisco ASR 1000 Series Routers in Cisco IOS XE Release 3.3.0S. The main purpose of this command is to selectively add more line-level, section-level, WIS-level, and path-level alarms over and above the default configured alarms. To set alarm reporting to its default value, use the **nowanphyreport-alarm** command.

Examples

The following example shows how to configure the line-level alarms:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy report-alarm line
```

The following example shows how to configure the path-level alarms:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy report-alarm path
```

The following example shows how to configure the section-level alarms:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy report-alarm section
```

The following example shows how to configure the WIS-level alarms:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy report-alarm wis
```

The following example shows how to reconfigure the alarms to their default values:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy report-alarm default
```

Related Commands

Command	Description
show controllers wanphy	Displays the SPA mode (LAN mode or WAN mode), alarms, and the J1 byte string value.

wanphy threshold

T o configure the physical layer threshold values for b1-tca, b2-tca, the Signal Degrade (SD) Bit Error Rate (BER), and Signal Failure (SF) BER, use the **wanphythreshold**commandin the Controller configuration mode. To reset the threshold alarm values to its default values, use the **no** form of the command.

wanphy threshold {*b1-tcab2-tcasd-bersf-ber*}
no wanphy threshold

Syntax Description

b1-tca	The B1 BER threshold-crossing alarm value. The default b1-tca value is 10e-6. The valid range is 4 to 9.
b2-tca	The B2 BER threshold-crossing alarm values. The default b2-tca value is 10e-6. The valid range is 3 to 9.
sd-ber	The SD BER threshold-crossing alarm value. The range value is expressed exponentially as 10e-n. The default sd-ber value is 6 (10e-6). The valid range is 3 to 9.
sf-ber	The SF BER threshold-crossing alarm value. The range value is expressed exponentially as 10e-n. The default sf-ber value is 3 (10e-3). The valid range is 3 to 9.

Command Default

By default, SF-BER, SD-BER, B1-tca, and B2-tca are enabled. However, alarm logging is enabled only for SF-BER.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The **wanphythreshold**command has been introduced on the Cisco ASR 1000 Series Routers in Cisco IOS XE Release 3.3.0S. The main purpose of this command is to configure the threshold values for SF-BER and SD-BER.

Examples

The following example shows how to configure the B1 TCA value:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy threshold b1-tca 4
```

The following example shows how to configure the B2 TCA value:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy threshold b2-tca 5
```

The following example shows how to configure the SD-BER threshold value:

```
Router# config
```

```
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy threshold sd-ber 8
```

The following example shows how to configure the SF-BER threshold value:

```
Router# config
Router(config)# controller wanphy 2/1/0
Router(config-controller)# wanphy threshold sf-ber 9
```

Related Commands

Command	Description
show controllers wanphy	Displays the SPA mode (LAN mode or WAN mode), alarms, and the J1 byte string value.

xconnect (CEM)

To build one end of a circuit emulation (CEM) connection and to enter CEM xconnect configuration mode, use the **xconnect** command in CEM configuration mode. To remove any existing CEM connections from this CEM channel, use the **no** form of this command.

xconnect *remote-ip-address* *virtual-connect-ID* **encapsulation** *encapsulation-type*
no xconnect

Syntax Description

remote-ip-address	IP address of an interface--physical or loopback--on the destination router.
virtual-connect-ID	Virtual connect ID (VCID). For CEM over IP (CEoIP), you must enter a value of 0.
encapsulation	Sets the encapsulation type.
encapsulation-type	Encapsulation type. You must set the encapsulation type to UDP. For Cisco NCS 4200 Series, you must set the encapsulation type to mpls.

Command Default

No CEM connections are built.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
XE 3.18SP	This command was implemented on the Cisco NCS 4200 Series.
XE 3.18.1SP	This command was implemented on the Cisco ASR 900 Series Routers.
XE Everest 16.5.1	This command was implemented on the Cisco ASR 920 Routers.

Examples

The following example shows how to build one end of a CEoIP connection and to enter CEM xconnect configuration mode.

```
Router(config-cem)# xconnect 10.0.5.1 0 encapsulation udp
Router(config-cem-xconnect)#
```

Examples

The following example shows how to enter CEM xconnect configuration mode.

```
Router(config-if-cem)# xconnect 10.10.10.10 200 encapsulation mpls
Router(config-if-xconnect)#
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.

Command	Description
local ip address	Defines the IP address of the local router.
local udp port	Defines the local UDP port.
remote udp port	Defines the UDP port of a remote endpoint.
show cem	Displays CEM channel statistics.

yellow

To enable generation and detection of yellow alarms, use the **yellow** command in interface configuration mode.

yellow {**generation** | **detection**}

Syntax Description

generation	Enables or disables generation of yellow alarms.
detection	Enables or disables detection of yellow alarms.

Command Default

Yellow alarm generation and detection are enabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)XE	This command was introduced.
12.0(7)XE1	This command was implemented on Cisco 7100 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to generate and detect yellow alarms. If the received signal is lost the yellow alarm can be generated to indicate a frame loss event. Generation of a yellow alarm will ensure that the alarm is sent to the remote end of the link. When the remote end is transmitting a yellow alarm, detection must be enabled to detect the alarm condition.

Examples

The following example shows how to enable generation and detection of yellow alarms on a Cisco 7500 series router:

```
Router
(config)
# interface atm 3/1/0
Router
(config-if)
# yellow generation
Router
(config-if)
# yellow detection
```
