CONTENTS

A through B

1pps

To configure the pulse per second parameters of the global navigation satellite system (GNSS) module on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers, use the **1pps** command in the gnss mode. To remove the 1pps configuration, use the **no** form of this command.

1pps {**offset** | **polarity [negative]**}
no 1pps {**offset** | **polarity negative**}

Syntax Description

offset	Configures the 1PPS cable compensation. The valid values are from 0 to 1000 nano seconds.
polarity	Configures the 1PPS polarity.
negative	Configures the polarity as negative. Default polarity is positive.

Command Default

No default behavior or values.

Command Modes

GNSS configuration (config-gnss)

Command History

Release	Modification
IOS-XE 3.17	This command was introduced on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers.

Usage Guidelines

The pulse per second is used to synchronize time with other sensors and is crucial for the accuracy of the sensor integration.

Examples

The following example shows how to configure the PPS:

```
Router# configure terminal
Router(config)# gnss slot r0
Router(config-gnss)# 1pps polarity negative
```

Related Commands

Command	Description
gnss	Configures the GNSS on the router.
anti-jam	Enables or disables the anti-jam mode on the GNSS module.
constellation	Configures the GNSS module based on the specified satellite constellations.
default	Resets the device to its default state.
exit	Exists the GNSS sub mode.
no	Negates the command or sets the value of the command to its default values.
shutdown	Enables GNSS module.

ais-core-failure

To enable AIS alarms to detect core failure events on a 8/16 T1E1 IM, use the ais-core-failure command in controller configuration mode. To disable the AIS alarms, use the no form of this command..

ais-core-failure

no ais-core-failure

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Default

This command is disabled by default; AIS alarm is not reported during core failure events.

Command Modes

Controller configuration

Command History

Release	Modification
IOS XE Everest 16.7.1	Support for this command was introduced on the Cisco ASR 900 Routers.

Usage Guidelines

AIS alarms are generated and detected either when the TDM circuits goes down on the access layer of the network topology or a failure occurs in the MPLS domain due to which SAToP connectivity goes down. This alarm is only applicable for SDH-E1 and unframed (SAToP) type and is not applicable for framed (CESoP) type.

You cannot configure AIS alarms if CEM group is enabled.You must first remove the CEM group configuration and then configure AIS alarms.

Examples

The following example shows the configuration of AIS alarm:

```
Router> enable
Router#configure terminal
Router(config)#controller t1 0/1/2
Router(config-controller)#ais-core-failure
```

Related Commands

Command	Description
show run | sec	Displays the AIS alarm configuration.

ais-shut

To enable automatic insertion of a Line Alarm Indication Signal (LAIS) in the sent SONET signal whenever the SONET port enters the administrative shutdown state, use the **ais-shut** command in SONET configuration mode. To disable automatic insertion of a LAIS, use the **no** form of this command..

ais-shut

no ais-shut

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Default

This command is disabled by default; no AIS is sent.

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

When the line is placed in administrative shutdown state, use the **ais-shut** command to send a signal to downstream equipment that indicates that there is a problem with the line.

Examples

The following example shows the configuration of AIS SHUT:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
ais-shut
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

alarm-interface

To enter alarm-interface mode and configure the alarm interface controller (AIC), use the **alarm-interface** command in global configuration mode. To leave alarm-interface mode, use the **exit** command.

alarm-interface *slot-number*

Syntax Description

slot-number	Number of the port in which the AIC is installed.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.2(2)XG	This command was introduced for the Cisco 2600 series and the Cisco 3600 series.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.

Examples

The following examples show how the **alarm-interface** command is used in conjunction with the **ipaddress** and the **reset** commands:

```
Router(config)# alarm-interface 5
Router(config-aic)# ip address 10.2.130.105
```

A change in the AIC IP configuration might not take effect until the next time the card is started. Use the **reset** command to restart the card, as in the following example:

```
Router(config-aic)# reset
Alarm Interface Card in slot 5 restarted
Router(config-aic)# end
```

Related Commands

Command	Description
ip address	Sets a primary or secondary IP address for an interface.
reset	Resets the AIC CPU.

alarm-profile

To create an alarm profile for chassis, card or interface module, and port, use the **alarm-profile** command in configuration mode. To delete the alarm profile, use the **no** form of this command.

The alarm profile is associated to an alarm with controller types such as SONET, SDH, DS1, or DS3.

alarm-profile *profile-name* {**chassis** | **card** | **port**}

Syntax Description

Syntax Description

profile-name	The name of the alarm profile. The name should be a string with alpha numeric characters and should not exceed 32 characters.
chassis	Alarm profile created for chassis.
card	Alarm profile created for card.
port	Alarm profile created for port.

Command Default

None

Command Modes

Configuration mode

Command History

Release	Modification
Cisco IOS XE 16.8.1	Support for this command was introduced on ASR 900 Series.

Usage Guidelines

This command is used to create alarm profile for chassis, card, or port in the configuration mode.

Examples

The following example shows how to create an alarm profile for chassis:

```
router(config)#alarm profile CHASSIS chassis
router(config-alarm-profile)#alarm sonet/sdh
router(config-alarm-properties)#SLOF syslog
router(config-alarm-properties)#SLOF severity critical
```

Examples

The following example shows how to create an alarm profile for card:

```
 router(config)#alarm profile CARD card
router(config-alarm-profile)#alarm ds3
router(config-alarm-properties)#DS3_RX_LOS syslog
router(config-alarm-properties)#DS3_RX_LOS severity major
```

Examples

The following example shows how to create an alarm profile for port:

```
 router(config)#alarm profile PORT port
router(config-alarm-profile)#alarm ds1
router(config-alarm-properties)#DS1_LOS syslog
router(config-alarm-properties)#DS1_LOS severity major
```

Related Commands

Command	Description
alarm-profile *name***attach**	Attaches alarm profile to chassis or card.
attach profile *profile-name*	Attaches alarm profile to port.
show alarm-profile	Displays alarm profile configured for chassis.

alarm-profile attach

To attach an alarm profile to chassis or card, use the **alarm-profile** *name* **attach** command in configuration mode. To detach the alarm profile from chassis or card, use the **no** form of this command.

After attaching the alarm profile only, the alarm serverity and other alarm functionalities are applied to the chassis, card, or port.

alarm-profile *profile-name* attach {**chassis** | **card** *slot/bay*}

alarm-profile *telcordia* **attachchassis**

Syntax Description

Syntax Description

profile-name	The name of the alarm profile.
chassis	Specify to attach the alarm profile to chassis.
card *slot/bay*	Specify to attach the alarm profile to card.
telcordia	Specify to attach the Telcordia alarm profile to chassis.

Command Default

None

Command Modes

Configuration mode

Command History

Release	Modification
Cisco IOS XE 16.8.1	Support for this command was introduced on ASR 900 Series.
Cisco IOS XE 17.3.1	Support for attaching the Telcordia alarm profile to chassis was introduced.

Usage Guidelines

This command is used to attach alarm profile to chassis or card in the configuration mode.

For Telcordia alarm profile, the alarm severities Not Alarmed (NA) and Not Reported (NR) are included by default. The alarm profile attached to chassis inherits the alarm severities of the Telcordia profile.

Note Ensure that you use the complete **`alarm-profile telcordia attach chassis`** command while attaching the alarm profile based on Telcordia.

Examples

The following example shows how to attach an alarm profile for chassis:

```
 router>enable
router#configure terminal
router(config)#alarm-profile CHASSIS attach chassis
router(config)#end
```

Examples

The following example shows how to attach a Telcordia alarm profile to chassis:

```
 router>enable
router#configure terminal
router(config)#alarm-profile telcordia attach chassis
router(config)#end
```

Examples

The following example shows how to attach an alarm profile to card:

```
 router>enable
router#configure terminal
router(config)#alarm-profile CARD attach card 0/1
router(config)#end
```

Related Commands

Command	Description
alarm-profile *profile-name*	Creates a new alarm profile for chassis, card or port.
show alarm-profile	Displays alarm profile configured for chassis.

alarm report all

To permit selected SONET alarms to be logged to the console for a SONET controller, use the **alarm report all** command in SONET configuration mode. To disable logging of select SONET alarms, use the **no** form of this command.

alarm-report all {*b1-tca* | *lias* | *lrdi* | *pais* | *plop* | *pplm* | *pplm* | *prdi* | *sd-ber*}

Syntax Description

Syntax Description

b1-tca	The name of a CEM interface parameters class.
lias	Reports Line Alarm Indication signal (LAIS) errors.
lrdi	Reports line remote defect indication errors.
pais	Enables reporting of Path Alarm Indication Signal (PAIS).
plop	Enables reporting of Path Loss Of Pointer (PLOP).
pplm	Sets Path Payload Mismatch (PPLM) defect reporting status.
prdi	Sets Path Remote Defect Indication (PRDI) reporting status.
sd-ber	Enables Signal Degrade (SD) Bit Error Rate (BER) reporting.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

This command is used to configure the alarm reports in SONET mode.

Examples

The following example shows the configuration of alarm reports:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
alarm report all b1-tcs
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.

Command	Description
show controller sonet	Displays SONET controller configuration.

als

To enable the Automatic Laser Shutdown (ALS) mode, use the **als**command in interface configuration mode. To disable ALS mode, use the no form of this command.

als
no als

Syntax Description

This command has no arguments or keywords.

Command Default

ALS is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router for the ES+ line cards.

Examples

The following example shows how to enable ALS:

```
Router> enable
Router# configure terminal
Router(config)# interface tengigabitethernet 2/1
Router(config-if)# als
```

Related Commands

Command	Description
als restart	Requests an ALS restart mode.
als restart mode	Selects the ALS restart mode.
als restart pulse	Select the ALS pulse mode.
hw-module als restart	Requests a restart pulse.
show als	Displays ALS status.

als restart

To request an Automatic Laser Shutdown (ALS) restart mode, use the **alsrestart**command in interface configuration mode. To disable an ALS restart mode, use the no form of this command.

als restart {**mode** | **pulse**}
no als restart {**mode** | **pulse**}

Syntax Description

mode	Specifies the ALS mode.
pulse	Specifies the ALS pulse.

Command Default

Command default is automatic.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router for the ES+ line cards.

Examples

The following example restarts the ALS mode:

```
Router> enable
Router# configure terminal
Router(config)# interface tengigabitethernet 2/1
Router(config-if)# als
Router(config-if)# als restart mode
```

Related Commands

Command	Description
als	Enables the ALS mode.
als restart mode	Selects the ALS restart mode.
als restart pulse	Selects the ALS pulse mode.
hw-module als restart	Requests a restart pulse.
show als	Displays ALS status.

als restart mode

To select the Automatic Laser Shutdown (ALS) restart mode, use the **alsrestartmode**command in interface configuration mode. To reset to the command default mode, use the no form of this command.

als restart mode {**automatic** | **manual**}
no als restart mode {**automatic** | **manual**}

Syntax Description

automatic	Selects automatic mode.
manual	Selects manual mode.

Command Default

Command default is automatic.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router for the ES+ line cards.

Usage Guidelines

In manual restart, you request a single restart pulse from the ALS agent. In automatic restart, you configure the ALS agent to send a periodic restart pulse.

Examples

The following example shows how to select automatic mode:

```
Router> enable
Router# configure terminal
Router(config)# interface tengigabitethernet 2/1
Router(config-if)# als
Router(config-if)# als restart mode automatic
```

Related Commands

Command	Description
als	Enables the ALS mode.
als restart	Requests an ALS restart mode.
als restart pulse	Select the ALS pulse mode.
hw-module als restart	Requests a restart pulse.
show als	Displays ALS status.

als restart pulse

To select the Automatic Laser Shutdown (ALS) pulse mode, use the **alsrestartpulse**command in inteface configuration mode. To disable an ALS pulse mode, use the no form of this command.

als restart pulse {**interval** **seconds** | **width** **seconds**}
no als restart pulse {**interval** **seconds** | **width** **seconds**}

Syntax Description

interval **seconds**	Specifies the interval of the ALS pulse. The range is 100 to 20,000 seconds. Default is 300 seconds.
width seconds	Specifies the width of the ALS pulse. The range is 2 to 200 seconds. Default is 200 seconds.

Command Default

Pulse interval default is 300 seconds. Pulse width default is 200 seconds.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router for the ES+ line cards.

Usage Guidelines

If a particular platform/OS/interface/controller has the capability to support two ranges, one range for Wave Division Multiplexing (WDM) and another for non-WDM, use the following pulse width ranges:

- WDM: 60 - 200 (default: 100)
- Non-WDM: 2 - 100 (default: 4)

The recovery pulse interval is the period between the rising edge of pulses. The pulse interval needs to be greater than the pulse width. If a particular platform/OS/interface/controller has the capability to support two ranges, one range for WDM and another for non-WDM, use the following pulse width ranges:

- WDM: 200 - 20000 (default: 300)
- Non-WDM: 100 - 2000 (default: 100)

Examples

The following example shows how to select an ALS pulse interval:

```
Router> enable
Router# configure terminal
Router(config)# interface tengigabitethernet 2/1
Router(config-if)# als
Router(config-if)# als restart mode
Router(config-if)# als restart mode automatic
Router(config-if)# als restart pulse interval 2000
```

The following example shows how to select an ALS pulse width:

```
Router> enable
Router# configure terminal
```

```
Router(config)# interface tengigabitethernet 2/1
Router(config-if)# als
Router(config-if)# als restart mode
Router(config-if)# als restart mode automatic
Router(config-if)# als restart pulse width 200
```

Related Commands

Command	Description
als	Enables the ALS mode.
als restart	Requests an ALS restart mode.
als restart mode	Selects the ALS restart mode.
hw-module als restart	Requests a restart pulse.
show als	Displays ALS status.

analysis-module monitoring

To enable Network Analysis Module (NAM) packet monitoring on an interface, use the **analysis-modulemonitoring** command in interface configuration mode. To disable NAM packet monitoring, use the **no** form of this command.

analysis-modulemonitoring
noanalysis-modulemonitoring

Syntax Description

This command has no arguments or keywords.

Command Default

NAM packet monitoring is disabled on the interface.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, Cisco 2851, and Cisco 3800 series.
12.3(11)T	This command was implemented on the Cisco 3800 series.
Cisco IOS XE Fuji 16.9.1	This command was implemented on the Cisco ISR 4000 Series Integrated Services Routers.

Usage Guidelines

When you enable NAM packet monitoring on an interface, Cisco Express Forwarding (CEF) sends an extra copy of IP packet that is received or sent on that interface to the NAM through the analysis module and then through the internal NM-NAM interface.

Note The traffic is sent through the internal NAM interface and through the the analysis module interface uses the router's resources such as CPU, SDRAM bandwidth, and backplane Peripheral Component Interconnect (PCI) bandwidth. Therefore, it is recommended to use the internal NAM interface to monitor WAN interfaces and use the external NAM interface to monitor LAN interfaces.

In Cisco IOS XE Fuji 16.9.1, Encapsulated Remote Switched Port Analyzer (ERSPAN) supports the NAM feature on Cisco 4000 Series ISRs. The Cisco ERSPAN feature allows you to monitor traffic on one or more ports and then sends the monitored traffic to one or more destination ports.

To enhance the performance of NAM and simplify the configuration of NAM data port, ERSPAN sessions are extended to a special souce session called NAM SPAN. NAM SPAN supports Layer 2 mode as local span and monitors the interface on Layer 3 interface on Cisco 4000 Series ISRs.

Note If an interface is monitored by NAM SPAN, it can not be configured as output interface. Each interface can configure only one interface as output interface.

Examples

The following example shows how to enable NAM packet monitoring on a serial interface:

```
Router(config)# interface serial 0/0
Router(config-if)# analysis-module monitoring
```

The following example shows how to enable NAM packet monitoring on a serial interface of a Cisco 4000 Series ISRs:

```
Router(config)# interface serial 0/0
Router(config-if)# analysis-module monitoring ucse0/0/0
```

Note The output interface is ucse0/0/0 which is configured as NAM/vNAM data port and the source interface is serial 0/0 in this example.

announce interval

To set an interval value for timing announcement packets, use the **announceinterval** command in Precision Time Protocol clock port mode. To remove an announcement interval configuration, use the **no** form of this command.

announce interval *interval-value*
no announce interval *interval-value*

Syntax Description

interval-value	Specifies the interval for announce messages. The intervals use log base 2 values, as follows: • 4--1 packet every 16 seconds • 3--1 packet every 8 seconds • 2--1 packet every 4 seconds • 1--1 packet every 2 seconds • 0--1 packet every second

Command Default

For the IE 3000 switch, the default value is 1. For the MWR 2941 router, the default value is 2.

Command Modes

PTP clock port configuration (config-ptp-port)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

The interval value defined by this command impacts the timeout value defined by the **announcetimeout** command.

Examples

The following example shows how to configure an announcement interval:

```
Router# configure terminal
Router(config)# ptp clock ordinary domain 0
Router(config-ptp-clk)# clock-port slave slaveport
Router(config-ptp-port)# announce interval 3
Router(config-ptp-port)# end
```

Related Commands

Command	Description
announce timeout	Sets the timeout value for timing announcement packets.

announce timeout

To set a timeout value for timing announcement packets, use the **announcetimeout** command in Precision Time Protocol clock port mode. To remove an announcement timeout configuration, use the **no** form of this command.

announce timeout *timeout-value*
no announce timeout *timeout-value*

Syntax Description

timeout-value	Specifies the number of announcement intervals before the session times out. The range is from 1 to 10. The default is 3.

Command Default

The default timeout value is 3.

Command Modes

PTP clock port configuration (config-ptp-port)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

This command configures the number of announcement intervals before the session times out. To define the length of the announcement intervals, use the **announceinterval** command.

Examples

The following example shows how to configure an **announcementtimeout**:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# clock-port slave slaveport
Device(config-ptp-port)# announce timeout 7
Device(config-ptp-port)# end
```

Related Commands

Command	Description
announce interval	Sets interval value for timing announcement packets.

anti-jam

To configure the anti-jam mode for the GNSS module on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers, use the **anti-jam** command in gnss mode.

anti-jam disable

Syntax Description

disable	Disables the anti-jam mode.

Command Default

Anti-jam is enabled on the GNSS module by default.

Command Modes

GNSS configuration (config-gnss)

Command History

Release	Modification
IOS-XE 3.17	This command was introduced on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers.

Examples

The following example shows how to disable the anti-jam mode on the GNSS module:

```
Router# configure terminal
Router(config)# gnss slot r0
Router(config-gnss)# anti-jam disable
```

Related Commands

Command	Description
gnss	Configures the GNSS on the router.
1pps	Configures the pulse per second from the GNSS module.
constellation	Configures the GNSS module based on the specified satellite constellations.
default	Resets the device to its default state.
exit	Exists the GNSS sub mode.

apply (satellite initial configuration)

To save new or changed satellite initial configuration parameters and to reset the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **apply** command in satellite initial configuration mode.

apply

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration mode

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **apply** command saves any new or changed satellite initial configuration parameters to the nonvolatile memory of the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT) and initiates a network module software reset. Commands entered in satellite initial configuration mode do not appear in the router configuration.

When you enter the **exit** or **end** command to exit satellite initial configuration mode, the system automatically saves any changed parameters to the NM-1VSAT-GILAT network module's nonvolatile memory and resets the NM-1VSAT-GILAT network module.

Note This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows what appears when you enter the **apply** command after changing some initial configuration parameters:

```
Router(sat-init-config)# apply

Applying changed parameters to the satellite module.
Parameter update succeeded.  Module is now resetting.
Router(sat-init-config)#
```

The following example shows what appears when you enter the **apply** command when no parameters have been changed:

```
Router(sat-init-config)# apply

% No new or changed parameters to apply.
Router(sat-init-config)#
```

Related Commands

Command	Description
end (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
exit (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

aps authenticate

To enable authentication and specify the string that must be present to accept any packet on the out-of-band (OOB) communications channel on a Packet-over-SONET (POS) interface, use the **apsauthenticate** command in interface configuration mode. To disable authentication, use the **no** form of this command.

aps authenticate *string*
no aps authenticate

Syntax Description

string	Text that must be present to accept the packet on a protected or working interface. A maximum of eight alphanumeric characters are accepted.

Command Default

Authentication is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **apsauthenticate**command to ensure that only valid packets are accepted on the OOB communications channel.

The **apsauthenticate** command must be configured on both the working and protect interfaces.

Examples

The following example shows how to enable authentication on POS interface 0 in slot 4:

```
Router# configure terminal
Router(config)# interface pos 4/0/0
Router(config-if)# aps working 1
Router(config-if)# aps authenticate sanjose
Router(config-if)# end
```

Related Commands

Command	Description
aps protect	Enables a POS interface as a protect interface.
aps working	Configures a POS interface as a working interface.

aps adm

Use this command to configure unidirectional ACR (SONET Framing).

aps adm *slot* / *bay* / *port*

Syntax Description

Syntax Description

There are no keywords for this command.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

The command is used to enable Add Drop Multiplexer (ADM) with unidirectional APS protection.

Examples

The following example shows how to configure unidirectional ACR (SONET Framing):

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
clock source internal
aps group acr 1
aps working 1
aps unidirectional
aps adm
exit
controller sonet 0/5/0
aps group acr 1
aps protect 1 10.7.7.7
aps revert 3
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

aps clear sonet

To remove all externally initiated SONET automatic protection switching (APS) commands configured on a Cisco AS5850, use the **apsclearsonet**command in privileged EXEC mode.

aps clear sonet *slot*/*port*

Syntax Description

slot	Slot number on an STM-1 trunk card.
/ *port*	SONET port number on an STM-1 trunk card. The slash mark is required between the *slot* argument and the *port* argument.

Command Default

No APS switch commands are removed.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(11)T	This command was introduced on the Cisco AS5850.

Usage Guidelines

Use the **apsclearsonet**command to remove any SONET APS commands, such as the **apsforcesonet**command, that could switch the working fiber to the protect fiber on an STM-1 trunk card.

This command applies to the Cisco AS5850 universal gateway only.

Examples

The following example shows how to remove all externally initiated SONET APS switch commands:

```
Router# aps clear sonet 1/0
```

Related Commands

Command	Description
aps force sonet	Requests an APS forced switch of a specified port to the alternate port unless a request of equal or higher priority is in effect.
aps lockout sonet	Prevents a working SONET port from switching to a protect SONET port unless a request of equal or higher priority is in effect.
aps manual sonet	Requests a manual APS switch on a SONET port.
aps protect (SONET)	Enables SONET APS.

aps force

To manually switch the specified circuit to a protect interface, unless a request of equal or higher priority is in effect, use the **apsforce**command in interface configuration mode. To cancel the switch, use the **no** form of this command.

aps force *circuit-number*
no aps force *circuit-number*

Syntax Description

circuit-number	Number of the circuit to switch to the protect interface.

Command Default

No circuit is switched.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **apsforce**command to manually switch the interface to a protect interface when you are not using the **apsrevert**command. For example, if you need to change the fiber connection, you can manually force the working interface to switch to the protect interface.

In a one-plus-one (1+1) configuration only, you can use the **apsforce0** command to force traffic from the protect interface back onto the working interface.

The**apsforce** command has a higher priority than any of the signal failures or the **apsmanual** command.

The **apsforce** command is configured only on protect interfaces.

Examples

The following example shows how to force the circuit on POS interface 0 in slot 3 (a protect interface) back onto a working interface:

```
Router# configure terminal
Router(config)# interface pos 3/0/0
Router(config-if)# aps protect 10/30/1/1
Router(config-if)# aps force 1
Router(config-if)# end
```

Related Commands

Command	Description
aps manual	Manually switches a circuit to a protect interface.
aps protect	Enables a POS interface as a protect interface.

Command	Description
aps working	Configures a POS interface as a working interface.

aps force sonet

To force a specified port to switch to the alternate port within a redundant pair unless a request of equal or higher priority is in effect, use the **apsforcesonet**command in privileged EXEC mode.

aps force sonet *slot/port* **from** {**protection** | **working**}

Syntax Description

slot	Slot number on an STM-1 trunk card.
/ *port*	SONET port number on an STM-1 trunk card. The slash mark is required between the *slot* argument and the *port* argument.
from protection	Specifies that you want to switch from the protect port to the working port.
from working	Specifies that you want to switch from the working port to the protect port.

Command Default

No port is switched.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(11)T	This command was introduced on the Cisco AS5850.

Usage Guidelines

Forced is a defined APS request priority level. The request succeeds if no higher priority request (lockout is the only higher priority request) is posted. The **apsforcesonet**command does not persist after a system restart. The *slot* and *port* arguments indicate the SONET interface on which you want to issue the **apsforcesonet** command. The**apsforcesonet** command has a higher priority than any of the signal failures or the **apsmanualsonet** command.

For more information about APS priority requests, see the ITU-T G.841 standard.

This command applies to the Cisco AS5850 universal gateway only.

Examples

The following example shows how to force the protect port in the SONET controller to become an active port:

```
Router# configure terminal
Router(config)# controller sonet 1/0
Router(config-controller)# aps protect
Router(config-controller)# end
Router# aps force sonet 1/0 from working
```

Related Commands

Command	Description
aps clear sonet	Removes any APS switch commands configured using CLI.
aps lockout sonet	Prevents a working SONET port from switching to a protect SONET port unless a request of equal or higher priority is in effect.

Command	Description
aps manual sonet	Requests a manual APS switch on a SONET port.
aps protect (SONET)	Enables SONET APS.

aps group

To allow more than one protect and working interface and Access Circuit Redundancy (ACR) group to be supported on a router, use the **aps group** command in interface configuration or controller configuration mode. To remove a group, use the **no** form of this command.

aps group [**acr**] *group-number*
no aps group [**acr**] *group-number*

Syntax Description

acr	(Optional) Specifies an ACR group.
group-number	Number of the group. The default is 0.

Command Default

No groups exist.

Note 0 is a valid group number.

Command Modes

Interface configuration (config-if)
Controller configuration (config-controller)

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(1)S	This command was modified. The **acr** keyword was added.

Usage Guidelines

Use the **aps group**command to specify more than one working and protect interface on a router--for example, working channel for group 0 and protect channel for group 1 on one router, and working channel for group 1 and protect channel for group 0 on another router.

The default group number is 0. The **aps group 0** command does not imply that no groups exist.

The **aps group** command must be configured on both the protect and working interfaces.

Use the **acr**keyword to configure an ACR working or protect interface.

Examples

The following example shows how to configure two working/protect interface pairs. Working interface (3/0/0) is configured in group 10 (the protect interface for this working interface is configured on another router), and protect interface (2/0/1) is configured in group 20.

```
Router# configure terminal
Router(config)# interface ethernet 0/0
```

```
Router(config-if)# ip address 10.7.7.6 255.255.255.0
Router(config-if)# exit
Router(config)# interface pos 3/0/0
Router(config-if)# aps group 10
Router(config-if)# aps working 1
Router(config-if)# exit
Router(config)# interface pos 2/0/1
Router(config-if)# aps group 20
Router(config-if)# aps protect 1 10.7.7.7
Router(config-if)# end
```

On the second router, protect interface (4/0/0) is configured in group 10, and working interface (5/0/0) is configured in group 20 (the protect interface for this working interface is configured on another router).

```
Router(config)# interface ethernet 0/0
Router(config-if)# ip address 10.7.7.7 255.255.255.0
Router(config-if)# exit
Router(config)# interface pos 4/0/0
Router(config-if)# aps group 10
Router(config-if)# aps protect 1 10.7.7.6
Router(config-if)# exit
Router(config)# interface pos 5/0/0
Router(config-if)# aps group 20
Router(config-if)# aps working 1
Router(config-if)# end
```

Related Commands

Command	Description
aps protect	Enables a POS interface as a protect interface.
aps working	Configures a POS interface as a working interface.

aps hspw-icrm-grp

To associate an Automatic Protection Switching (APS) group to an Interchassis Redundancy Manager (ICRM) group number, use the **aps hspw-icrm-grp** command in controller configuration mode. To remove the association, use the **no** form of this command.

aps hspw-icrm-grp *group-number*
no aps hspw-icrm-grp *group-number*

Syntax Description

group-number	ICRM group number. Valid values are from 1 to 4294967295.

Command Default

Interface connections do not switch from one circuit to another if a circuit fails.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
Cisco IOS 15.2(1)S	This command was introduced.
Cisco IOS XE 3.11S	This command was integrated into Cisco IOS XE Release 3.11S.

Usage Guidelines

Use the **aps hspw-icrm-grp** command to protect SONET networks by enabling SONET connections to switch to another SONET circuit when a circuit failure occurs.

A protect interface serves as the backup interface for the working interface. When the working interface fails, the protect interface quickly assumes the former's traffic load.

Examples

The following example shows how to configure the Multi Router Automatic Protection Switching (MR-APS) integration with HSPW on a Circuit Emulation (CEM) interface on the working router with framing mode as SONET on router P1:

```
RouterP1> enable
RouterP1# configure terminal
RouterP1(config)# pseudowire-class hspw_aps
RouterP1(config-pw-class)# encapsulation mpls
RouterP1(config-pw-class)# status peer topology dual-homed
RouterP1(config-pw-class)# exit
RouterP1(config)# redundancy
RouterP1(config-red)# interchassis group 1
RouterP1(config-r-ic)# member ip 10.2.0.2
RouterP1(config-r-ic)# backbone interface GigabitEthernet 0/1/0
RouterP1(config-r-ic)# backbone interface GigabitEthernet 0/1/1
RouterP1(config-r-ic)# exit
RouterP1(config)# controller SONET 0/1/0
RouterP1(config-controller)# framing sonet
RouterP1(config-controller)# clock source line
RouterP1(config-controller)# sts-1 1
RouterP1(config-ctrlr-sts1)# mode vt-15
RouterP1(config-ctrlr-sts1)# vtg 1 t1 1 cem-group 0 timeslots 1-24
RouterP1(config-ctrlr-sts1)# exit
RouterP1(config-controller)# aps group 3
RouterP1(config-controller)# aps working 1
```

```
RouterP1(config-controller)# aps hspw-icrm-grp 1
RouterP1(config-controller)# exit
RouterP1(config)# interface cem 0/1/0
RouterP1(config-if)# cem 0
RouterP1(config-if)# xconnect 3.3.3.3 1 encapsulation mpls pw-class hspw_aps
RouterP1(config-if)# backup peer 4.4.4.4 2 pw-class hspw_aps
RouterP1(config-if)# exit
RouterP1(config)# end
```

Examples

The following example shows how to configure the MR-APS integration with hot standby pseudowire (HSPW) on a CEM interface on the protect router with framing mode as SONET on router PE1:

```
RouterPE1> enable
RouterPE1# configure terminal
RouterPE1(config)# pseudowire-class hspw_aps
RouterPE1(config-pw-class)# encapsulation mpls
RouterPE1(config-pw-class)# status peer topology dual-homed
RouterPE1(config-pw-class)# exit
RouterPE1(config)# redundancy
RouterPE1(config-red)# interchassis group 1
RouterPE1(config-r-ic)# member ip 10.2.0.1
RouterPE1(config-r-ic)# backbone interface GigabitEthernet 0/1/0
RouterPE1(config-r-ic)# backbone interface GigabitEthernet 0/1/1
RouterPE1(config-r-ic)# exit
RouterPE1(config)# controller SONET 0/2/0
RouterPE1(config-controller)# framing sonet
RouterPE1(config-controller)# clock source line
RouterPE1(config-controller)# sts-1 1
RouterPE1(config-ctrlr-sts1)# mode vt-15
RouterPE1(config-ctrlr-sts1)# vtg 1 t1 1 cem-group 0 timeslots 1-24
RouterPE1(config-ctrlr-sts1)# exit
RouterPE1(config-controller)# aps group 3
RouterPE1(config-controller)# aps protect 1 10.2.0.1
RouterPE1(config-controller)# aps hspw-icrm-grp 1
RouterPE1(config-controller)# exit
RouterPE1(config)# interface cem 0/2/0
RouterPE1(config-if)# cem 0
RouterPE1(config-if)# xconnect 3.3.3.3 3 pw-class hspw_aps
RouterPE1(config-if)# backup peer 4.4.4.4 4 pw-class hspw_aps
RouterPE1(config-if)# exit
RouterPE1(config)# end
```

Examples

The following example shows how to configure the MR-APS integration with HSPW on a CEM interface on the working router with framing mode as SONET on router P2:

```
RouterP2> enable
RouterP2# configure terminal
RouterP2(config)# pseudowire-class hspw_aps
RouterP2(config-pw-class)# encapsulation mpls
RouterP2(config-pw-class)# status peer topology dual-homed
RouterP2(config-pw-class)# exit
RouterP2(config)# redundancy
RouterP2(config-red)# interchassis group 1
RouterP2(config-r-ic)# member ip 10.6.0.2
RouterP2(config-r-ic)# backbone interface GigabitEthernet 0/2/0
RouterP2(config-r-ic)# backbone interface GigabitEthernet 0/2/1
RouterP2(config-r-ic)# exit
RouterP2(config)# controller SONET 0/1/0
RouterP2(config-controller)# framing sonet
```

```
RouterP2(config-controller)# clock source line
RouterP2(config-controller)# sts-1 1
RouterP2(config-ctrlr-sts1)# mode vt-15
RouterP2(config-ctrlr-sts1)# vtg 1 t1 1 cem-group 0 timeslots 1-24
RouterP2(config-ctrlr-sts1)# exit
RouterP2(config-controller)# aps group 3
RouterP2(config-controller)# aps working 1
RouterP2(config-controller)# aps hspw-icrm-grp 1
RouterP2(config-controller)# exit
RouterP2(config)# interface cem 0/1/0
RouterP2(config-if)# cem 0
RouterP2(config-if)# xconnect 1.1.1.1 1 encapsulation mpls pw-class hspw_aps
RouterP2(config-if)# backup peer 2.2.2.2 3 pw-class hspw_aps
RouterP2(config-if)# exit
RouterP2(config)# end
```

Examples

The following example shows how to configure the MR-APS Integration with HSPW on a CEM interface on the protect router with framing mode as SONET on router PE2:

```
RouterPE2> enable
RouterPE2# configure terminal
RouterPE2(config)# pseudowire-class hspw_aps
RouterPE2(config-pw-class)# encapsulation mpls
RouterPE2(config-pw-class)# status peer topology dual-homed
RouterPE2(config-pw-class)# exit
RouterPE2(config)# redundancy
RouterPE2(config-red)# interchassis group 1
RouterPE2(config-r-ic)# member ip 10.6.0.1
RouterPE2(config-r-ic)# backbone interface GigabitEthernet 0/2/0
RouterPE2(config-r-ic)# backbone interface GigabitEthernet 0/2/1
RouterPE2(config-r-ic)# exit
RouterPE2(config)# controller SONET 0/2/0
RouterPE2(config-controller)# framing sonet
RouterPE2(config-controller)# clock source line
RouterPE2(config-controller)# sts-1 1
RouterPE2(config-ctrlr-sts1)# mode vt-15
RouterPE2(config-ctrlr-sts1)# vtg 1 t1 1 cem-group 0 timeslots 1-24
RouterPE2(config-ctrlr-sts1)# exit
RouterPE2(config-controller)# aps group 2
RouterPE2(config-controller)# aps protect 1 10.6.0.1
RouterPE2(config-controller)# aps hspw-icrm-grp 1
RouterPE2(config-controller)# exit
RouterPE2(config)# interface cem 0/2/0
RouterPE2(config-if)# cem 0
RouterPE2(config-if)# xconnect 1.1.1.1 2 pw-class hspw_aps
RouterPE2(config-if)# backup peer 2.2.2.2 4 pw-class hspw_aps
RouterPE2(config-if)# exit
```

Related Commands

Command	Description
aps protect	Configures a POS interface as a protect interface.
aps working	Configures a POS interface as a working interface.

aps lockout

To prevent a working interface from switching to a protect interface, use the **apslockout** command in interface configuration mode. To remove the lockout, use the **no** form of this command.

aps lockout *circuit-number*
no aps lockout *circuit-number*

Syntax Description

circuit-number	Number of the circuit to lock out.

Command Default

No lockout exists.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **apslockout** command is configured only on protect interfaces.

Examples

The following example shows how to lock out POS interface 3/0/0 (that is, prevents the circuit from switching to a protect interface if the working circuit becomes unavailable):

```
Router# configure terminal
Router(config)# interface pos 3/0/0
Router(config-if)# aps protect 1 10.7.7.7
Router(config-if)# aps lockout 1
Router(config-if)# end
```

Related Commands

Command	Description
aps protect	Enables a POS interface as a protect interface.
aps working	Configures a POS interface as a working interface.

aps lockout sonet

To prevent a working port from switching to a protect port unless a request of equal or higher priority is in effect, use the **apslockoutsonet** command in privileged EXEC mode.

aps lockout sonet *slot/port*

Syntax Description

slot	Slot number on an STM-1 trunk card.
/ *port*	SONET port number on an STM-1 trunk card. The slash mark is required between the *slot* argument and the *port* argument.

Command Default

No lockout exists; that is, a working port is not prevented from switching to a protect port.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(11)T	This command was introduced on the Cisco AS5850.

Usage Guidelines

Lockout is defined as the highest APS request priority level.

The **apslockoutsonet**command does not persist after a system restart. The *slot* and *port* arguments indicate the SONET interface from which the protect port is to be locked out. When the specified port is locked out, SONET APS switching from the working port is not allowed.

For more information about APS priority requests, see the ITU-T G.841 standard.

This command applies to the Cisco AS5850 universal gateway only.

Examples

The following example shows how to lock out SONET port 1/0 (prevents SONET APS switching to a protect interface if the working circuit becomes unavailable):

```
Router# configure terminal
Router(config)# controller sonet 1/0
Router(config-controller)# aps protect
Router(config-controller)# end
Router# aps lockout sonet 1/0
```

Related Commands

Command	Description
aps clear sonet	Removes any APS switch commands configured using CLI.
aps force sonet	Requests an APS forced switch of a specified port to the alternate port unless a request of equal or higher priority is in effect.
aps manual sonet	Requests a manual APS switch on a SONET port.
aps protect (SONET)	Enables SONET APS.

aps manual

To manually switch a circuit to a protect interface, use the **aps manual** command in interface configuration mode. To cancel the switch, use the **no** form of this command.

aps manual *circuit-number*
no aps manual *circuit-number*

Syntax Description

circuit-number	Number of the circuit to switch to a protect interface.

Command Default

No circuit is switched.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **aps manual** command to manually switch the interface to a protect interface. For example, you can use this feature when you need to perform maintenance on the working channel. If a protection switch is already up, you can also use the **aps manual** command to revert the communication link back to the working interface before the wait to restore (WTR) time has expired. The WTR time period is set by the **aps revert** command.

In a one-plus-one (1+1) configuration only, you can use the **aps manual 0** command to force traffic from the protect interface back onto the working interface.

The**aps manual** command is a lower priority than any of the signal failures or the**aps force** command.

Examples

The following example shows how to force the circuit on POS interface 0 in slot 3 (a working interface) back onto the protect interface:

```
Router# configure terminal
Router(config)# interface pos 3/0/0
Router(config-if)# aps working 1
Router(config-if)# aps manual 1
Router(config-if)# end
```

Related Commands

Command	Description
aps force	Manually switches the specified circuit to a protect interface, unless a request of equal or higher priority is in effect.
aps protect	Enables a POS interface as a protect interface.

Command	Description
aps revert	Enables automatic switchover from the protect interface to the working interface after the working interface becomes available.
aps working	Configures a POS interface as a working interface.

aps manual sonet

To manually switch to the alternate port within a redundant pair unless a request of equal or higher priority is in effect, use the **apsmanualsonet** command in privileged EXEC mode.

aps manual sonet *slot/port* **from** {**protection** | **working**}

Syntax Description

slot	Slot number on an STM-1 trunk card.
/ *port*	SONET port number on an STM-1 trunk card. The slash mark is required between the *slot* argument and the *port* argument.
from protection	Specifies that you want to switch from the protect port to the working port.
from working	Specifies that you want to switch from the working port to the protect port.

Command Default

No port is switched.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(11)T	This command was introduced on the Cisco AS5850.

Usage Guidelines

Use the **apsmanualsonet**command to manually switch the active port to the alternate port. For example, you can use this command when you need to perform maintenance on the working port.

Manual is a defined APS request priority level. The request succeeds if no higher priority request is posted. The **apsmanualsonet**command does not persist after a system restart. The *slot* and *port* arguments indicate the SONET interface on which you want to issue the **apsmanualsonet** command. The**apsmanualsonet** command has a lower priority than any of the signal failures or the **apsforcesonet**command.

For more information about APS priority requests, see the ITU-T G.841 standard.

This command applies to the Cisco AS5850 universal gateway only.

Examples

The following example shows how to manually switch the working port, SONET port 1/0, to the protect port:

```
Router# configure terminal
Router(config)# controller sonet 1/0
Router(config-controller)# aps protect
Router(config-controller)# end
Router# aps manual sonet 1/0 from working
```

Related Commands

Command	Description
aps clear sonet	Removes any APS switch commands configured using CLI.

Command	Description
aps force sonet	Requests an APS forced switch of a specified port to the alternate port unless a request of equal or higher priority is in effect.
aps lockout sonet	Prevents a working SONET port from switching to a protect SONET port unless a request of equal or higher priority is in effect.
aps protect (SONET)	Enables SONET APS.

aps protect

To enable a POS interface as a protect interface, use the **apsprotect**command in interface configuration mode. To remove the POS interface as a protect interface, use the **no** form of this command.

aps protect *circuit-number ip-address*
no aps protect *circuit-number ip-address*

Syntax Description

circuit-number	Number of the circuit to enable as a protect interface.
ip-address	IP address of the router that has the working POS interface.

Command Default

No circuit is protected.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **apsprotect**command to configure the POS interface used by a working interface if the working interface becomes unavailable because of a router failure, degradation or loss of channel signal, or manual intervention.

Caution Configure the working interface before configuring the protect interface to keep the protect interface from becoming the active circuit and disabling the working circuit when it is finally discovered.

Examples

The following example shows how to configure circuit 1 on POS interface 5/0/0 as a protect interface for the working interface on the router with the IP address of 10.7.7.7. For information on how to configure the working interface, refer to the **apsworking** command.

```
Router# configure terminal
Router(config)# interface pos 5/0/0
Router(config-if)# aps protect 1 10.7.7.7
Router(config-if)# end
```

Related Commands

Command	Description
aps working	Configures a POS interface as a working interface.

aps protect (SONET)

To enable automatic protection switching (APS) on a SONET port in an STM-1 trunk card, use the **apsprotect**command in controller configuration mode. To disable APS on the SONET port, use the **no** form of this command.

aps protect
no aps protect

Syntax Description

This command has no arguments or keywords.

Command Default

APS is disabled.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(11)T	This command was introduced on the Cisco AS5850.

Usage Guidelines

Use the **apsprotect**command to enable APS on a protect SONET port as a working port if the working port becomes unavailable because of a fiber failure, degradation or loss of channel signal, or manual intervention.

Examples

The following example shows how to enable APS on SONET port 0/1 in an STM-1 trunk card.

```
Router# configure terminal
Router(config)# controller sonet 1/0
Router(config-controller)# aps protect
Router(config-controller)# end
```

Related Commands

Command	Description
aps unidirectional	Configures a protect SONET port for unidirectional mode.
show controllers sonet	Displays information about SONET controllers.

aps revert

To enable automatic switchover from the protect interface to the working interface after the working interface becomes available, use the **apsrevert**command in interface configuration mode. To disable automatic switchover, use the **no** form of this command.

aps revert *minutes*
no aps revert

Syntax Description

minutes	Number of minutes until the circuit is switched back to the working interface after the working interface is available.

Command Default

Automatic switchover is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **apsrevert**command to return the circuit to the working interface when it becomes available.

The **apsrevert** command is configured only on protect interfaces.

Examples

The following example shows how to enable circuit 1 on POS interface 5/0/0 to revert to the working interface after the working interface has been available for 3 minutes:

```
Router# configure terminal
Router(config)# interface pos 5/0/0
Router(config-if)# aps protect 1 10.7.7.7
Router(config-if)# aps revert 3
Router(config-if)# end
```

Related Commands

Command	Description
aps protect	Enables a POS interface as a protect interface.

aps timers

To change the time between hello packets and the time before the protect interface process declares a working interface router to be down, use the **apstimers**command in interface configuration mode. To return to the default timers, use the **no** form of this command.

aps timers *seconds1 seconds2*
no aps timers

Syntax Description

seconds1	Number of seconds to wait before sending a hello packet (hello timer). Default is 1.
seconds2	Number of seconds to wait to receive a response from a hello packet before the interface is declared down (hold timer). Default is 3.

Command Default

Hello time is 1 second Hold time is 3 seconds.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **apstimers**command to control the time between an automatic switchover from the protect interface to the working interface after the working interface becomes available.

Normally, the hold time is greater than or equal to three times the hello time.

The **apstimers** command is configured only on protect interfaces.

Examples

The following example shows how to specify a hello time of 2 seconds and a hold time of 6 seconds on circuit 1 on POS interface 5/0/0:

```
Router# configure terminal
Router(config)# interface pos 5/0/0
Router(config-if)# aps working 1
Router(config-if)# aps timers 2 6
Router(config-if)# end
```

aps unidirectional

To configure a protect interface for unidirectional mode, use the **apsunidirectional** command in controller configuration or interface configuration mode. To return to the default, bidirectional mode, use the **no** form of this command.

aps unidirectional
no aps unidirectional

Syntax Description

This command has no arguments or keywords.

Command Default

Bidirectional mode

Command Modes

Controller configuration Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.3(11)T	Support for SONET APS using an STM-1 card was added on the Cisco AS5850.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **apsunidirectional**command is configured only on protect interfaces.

Use the **apsunidirectional**command when you must interoperate with SONET network equipment, add/drop multiplexors (ADMs) that supports unidirectional mode.

Note We recommend bidirectional mode when it is supported by the interconnecting SONET equipment. When the protect interface is configured as bidirectional, the working and protect interfaces must cooperate to switch the transmit and receive SONET channel in a bidirectional fashion. This happens automatically when the SONET network equipment is in bidirectional mode.

Examples

The following example shows how to configure POS interface 3/0/0 for unidirectional mode on a Cisco 12000 series router:

```
Router# configure terminal
Router(config)# interface pos 3/0/0
Router(config-if)# aps unidirectional
Router(config-if)# aps protect 1 10.7.7.7
Router(config-if)# end
```

The following example shows how to configure SONET port 0/0 for unidirectional mode on a Cisco AS5850 universal gateway using an STM-1 trunk card:

```
Router# configure terminal
Router(config)# controller sonet 0/0
Router(config-controller)# aps protect
Router(config-controller)# aps unidirectional
Router(config-controller)# end
```

aps working

To configure a Packet over SONET (POS) interface as a working interface, use the **apsworking** command in interface configuration mode. To remove the protect option from the POS interface, use the **no** form of this command.

aps working *circuit-number*
no aps working *circuit-number*

Syntax Description

circuit-number	Circuit number associated with this working interface.

Command Default

No circuit is configured as working.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When a working interface becomes unavailable because of a router failure, degradation or loss of channel signal, or manual intervention, the circuit is switched to the protect interface to maintain the connection.

To enable the circuit on the protect interface to switch back to the working interface after the working interface becomes available again, use the **apsrevert** command in interface configuration mode.

Caution Configure the working interface before configuring the protect interface to keep the protect interface from becoming the active circuit and disabling the working circuit when it is finally discovered.

Examples

The following example shows how to configure POS interface 0 in slot 4 as a working interface. For information on how to configure the protect interface, refer to the **apsprotect** command.

```
Router# configure terminal
Router(config)# interface pos 4/0/0
Router(config-if)# aps working 1
Router(config-if)# end
```

Related Commands

Command	Description
aps protect	Enables a POS interface as a protect interface.

Command	Description
aps revert	Enables automatic switchover from the protect interface to the working interface after the working interface becomes available.

associate slot

To logically associate slots for automatic protection switching (APS) processor redundancy, use the associate slot command in redundancy configuration mode. To disable slot associations, use the no form of this command.

Single Router APS--Cisco 10000 Series Routers and Cisco uBR10012 Universal Broadband Router
associate slot *slot-one* [*slot-two*]
no associate slot *slot-one* [*slot-two*]

Multirouter APS--Cisco 10000 Series Routers
associate slot *slot-one* **mr-aps**
no associate slot *slot-one* **mr-aps**

Syntax Description

slot-one	**Cisco 10000 Series Router** First slot number to be associated for redundancy. Valid range is from 1 to 8. **Cisco uBR10012 Universal Broadband Router** Specifies the slot that contains the working (primary) card. The available range is 1 to 8, but on the Cisco uBR10012 router the only valid numbers are 1 and 3, and the card must support APS redundancy.
slot-two	**Cisco 10000 Series Router** (Optional) Second slot number to be associated for redundancy. Valid range is from 1 to 8. **Cisco uBR10012 Universal Broadband Router** (Optional) Specifies the slot that contains the redundant (backup) card. The available range is 1 to 8, but on the Cisco uBR10012 router the only valid numbers are 2 and 4. If not specified, the next higher adjacent slot is automatically configured as the redundant slot.
mr-aps	(Cisco 10000 Series Routers Only) Specifies that the slot association is between slots in different routers as part of a multirouter APS configuration.

Command Default

No slots are associated.

Command Modes

Redundancy configuration

Command History

Release	Modification
12.1(5a)EY	This command was introduced.
12.0(23)SX	The mr-aps keyword was added to support multirouter APS on the OC3ATM and OC12ATM line cards for the Cisco 10000 series router.
12.0(26)S	This command was integrated into Cisco IOS Release 12.0(26)S, and support was added for the CHOC12, CHSTM1, OC32POS, and OC12POS line cards for the Cisco 10000 series router.
12.2(4)XF1	This command was introduced for the Cisco uBR10012 router.

Release	Modification
12.2(13)BC1	Support was added for the Cisco OC-48 DPT/POS adapter card on the Cisco uBR10012 router.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB
12.2(33)SCA	This command was integrated into Cisco IOS Release 12.2(33)SCA. Support for the Cisco uBR7225VXR router was added.

Usage Guidelines

Cisco 10000 Series Router

Use the **associate** command to associate two cards for single-router APS or multirouter APS redundancy protection. Multirouter APS support is specific to the Cisco 10000 series router. Use the mr-aps keyword in a multirouter APS configuration to allow a protect interface on a second router to be a backup for a working interface on the first router.

The associated slots must use the same type of interface module and must support APS redundancy. The cards also must be located in adjacent slots, for example slots 3 and 4.

Cisco uBR10012 Universal Broadband Router

The two cards must be in adjacent slots, with the working card in slot 1 or 3, and the backup card in slot 2 or 4, respectively. The two cards must be identical cards and must support APS redundancy (such as the OC-12 POS line card).

Note You cannot use the **associate** command with any of the Performance Routing Engine (PRE) modules or TCC+ cards, because these cards are automatically configured for redundant operation when two cards are installed in the chassis.

Examples

Single Router APS Example

The following example shows how to associate two slots in the same router in a single router APS configuration:

```
redundancy
 associate slot 3 4
```

Multirouter APS Example on the Cisco 10000 Series Router Only

The following example shows how to associate two separate slots in different routers in a multirouter APS configuration:

```
! Associate slot 3 on first router for APS redundancy
!
redundancy
 associate slot 3 mr-aps
!
! Associate slot 2 on second router for APS redundancy
!
```

```
redundancy
 associate slot 2 mr-aps
```

Related Commands

Command	Description
redundancy	Enters redundancy configuration mode.

association

To configure an association between current node and a remote node, use the **association** command in interprocess communication (IPC) zone configuration mode. To disable this functionality, use the **no** form of this command.

association *association-ID*
no association *association-ID*

Syntax Description

association-ID	Association ID assignment. The value range is from 1 through 255. The association ID must be unique within a specific zone.

Command Default

No association between a current node and a remote node exists.

Command Modes

IPC zone configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Use the **association** command to configure an association between current node and a remote node. There can be multiple associations within a zone.

Examples

The following example configures an association with an ID of 1:

```
Router(config-ipczone)# association 1
```

Related Commands

Command	Description
ipc zone default	Enters IPC zone configuration mode.
show ipc	Displays IPC statistics.

attach profile-name

To attach alarm profile to port, enter into controller configuration mode, and use the **attach profile-name** command in global configuration mode.

Command to enter into controller configuration mode:

controller **{sonet** | **sdh** | **t1** | **e1** | **t3** | **e3**} *slot*/ /*bay*/*port*
Command to attach alarm profile to port

`attach`*profile-name*

Syntax Description

sonet	Specifies SONET controller
sdh	Specifies SDH controller
t1	Specifies T1 controller
e1	Specifies E1 controller
slot	Specifies the slot number of the interface.
bay	Specifies the bay number of the interface.
port	Specifies the port number of the interface.
profile-name	Alarm profile to attach to the port.

Command Default

None

Command Modes

Configuration mode

Command History

Release	Modification
Cisco IOS XE 16.8.1	Support for this command was introduced on ASR 900 Series.

Usage Guidelines

Enter into the controller configuration mode and then attach the alarm profile to the interface.

Examples

The following example shows how to configure SONET controller in slot 0, bay 3, port 3 and then attach the alarm profile *PORT* to the interface:

```
Router(config)# controller sonet 0/3/3
Router(config-controller)#attach profile PORT
Router(config-controller)#end
```

Related Commands

Command	Description
alarm-profile *name* **chassis** | **card** | **port**}	Creates new alarm profile for chassis, card, or port.

Command	Description
show alarm-profile	Displays alarm profile configured for chassis.

atm sonet

To set the mode of operation and thus control the type of the ATM cell used for cell-rate decoupling on the SONET physical layer interface module (PLIM), use the **atmsonet**command in interface configuration mode. To restore the default Synchronous Transport Signal level 12, concatenated (STS-12c) operation, use the **no** form of this command.

atm sonet [**stm-4**]
no atm sonet [**stm-4**]

Syntax Description

stm-4	(Optional) Synchronous Digital Hierarchy/Synchronous Transport Signal level 4 (SDH/STM-4) operation (ITU-T specification).

Command Default

STS-12c

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
11.2GS	The **stm-4** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use STM-4 in applications in which SDH framing is required.

Use the default (STS-12c) in applications in which the ATM switch requires "unassigned cells" for rate adaptation. An unassigned cell contains 32 zeros.

Examples

The following example shows how to set the mode of operation to SONET STM-4 on ATM interface 3/0:

```
Router(config)#
 interface atm 3/0
Router(config-if)#
 atm sonet stm-4
Router(config-if)#
 end
```

au-3

To configure a particular Administrative Unit type 3 (AU-3) of an E1 line that has been mapped to an AU-3, use the **au-3**command in controller configuration mode.

au-3 *au-3-number*

Syntax Description

au-3-number	Number in the range from 1 to 3.

Command Default

No default behavior or values

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

An administrative unit group (AUG) of an STM-1 can be derived from either AU-3s or an AU-4. Use the **augmappingau-3**configuration controller command to map the AUG to an AU-3 with the following muxing/alignment/mapping:

C-12 <--> VC-12 <--> TU-12 <--> TUG-2 <--> VC-3 <--> AU-3 <--> AUG

Configuring the **au-3**command enables you to enter configuration controller au3 command mode and creates a serial interface with the following name format:

slot/port-adapter/port.au-3-number/tug-2-number/e1-number

The aug mapping au-3 and **au-3** commands are available only when Synchronous Digital Hierarchy (SDH) framing is configured.

Examples

The following example shows how to configure AUG mapping to be derived from an AU-3 and selects AU-3 3 to configure as a serial interface:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-3
Router(config-ctrlr-au3)# au-3 3
```

Related Commands

Command	Description
au-4 tug-3	Specifies a TUG-3 for configuration.
aug mapping	Configures the AUG mapping mode of the PA-MC-STM-1 to AU-3.

au-4 tug-3

To specify the Administrative Unit type 4 (AU-4) and Tributary Unit group type 3 (TUG-3) number of an E1 line that has been mapped to an AU-4, use the **au-4tug-3**command in controller configuration mode.

au-4 *au-4-number* **tug-3** *tug-3-number*

Syntax Description

au-4-number	Number in the range from 1 to *x*where *x*is the STM level. Default is 1.
tug-3-number	Number in the range from 1 to 3.

Command Default

Default *au-4-number* value for the STM-1 card is 1.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

An AUG of an STM-1 can be derived from either AU-3s or an AU-4. Use the **augmappingau-4**configuration controller command to map the AUG to a TUG-3 with the following muxing/alignment/mapping:

C-12 <--> VC-12 <--> TU-12< --> TUG-2 <--> TUG-3 <--> VC-4 <--> AU-4 <--> AUG

Configuring the **au-4**command enables you to enter configuration controller tug3 command mode and creates a serial interface with the following name format:

slot/port-adapter/port.au-4-number/tug-2-number/e1-number

The aug mapping au-4 and **au-4tug-3**commands are available only when SDH framing is configured.

Examples

The following example shows how to configure AUG mapping to be derived from a TUG-3 and selects TUG-3 1 of AU-4 1:

```
Router(config)# controller sonet 2/0/0
Router(config-controller)# aug mapping au-4
Router(config-ctrlr-tug3)# au-4 1 tug-3 1
```

Related Commands

Command	Description
au-3	Specifies an AU-3 for configuration.
aug mapping	Configures the AUG mapping mode.

aug mapping

To configure administrative unit group (AUG) mapping when Synchronous Digital Hierarchy (SDH) framing is selected, use the **augmapping** command in controller configuration mode.

aug mapping {**au-3** | **au-4**}

Syntax Description

au-3	Specifies use of three paths--a path is known as an Administrative Unit (AU)--consisting of seven Tributary Unit group type 2s (TUG-2s). Each TUG-2 consists of three virtual containers (VC-12s), which carry E1 lines resulting in 21 E1 lines within one AU-3 path.
au-4	Specifies use of one path consisting of three TUG-3 types. Each TUG-3 consists of seven TUG-2s, resulting in a total of 63 E1 lines within one AU-4 path. This is the default.

Command Default

au-4

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.0(17)S	Support for the two-port STM-1/OC-3 channelized E1/T1 line card was added.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

In SDH, there are two possible mapping/multiplexing schemes for most payload types: ANSI and ETSI.

In ANSI mapping, the Low Order payloads are aggregated into a VC-3 High Order Path. An AU pointer is added to the VC-3 to create an AU-3. Three such AU-3s are then synchronously multiplexed into an AUG. The multiplexing scheme is as follows:

... VC-3 <-> AU-3 (x3) <-> AUG <-> STM-1

SDH ANSI mapping is very similar to the SONET frame structure.

In ETSI mapping, the Low Order payloads are aggregated into a VC-4 High Order Path. An AU pointer is added to the VC-4 to create an AU-4 (Administrative Unit type 4). One AU-4 is "multiplexed" into an AUG (AU group), which is to say, the AUG is, in fact, equivalent to an AU-4. The multiplexing scheme is as follows:

... TUG-3 (x3) <-> VC-4 <-> AU-4 (x1) <-> STM-1

This command is available only when SDH framing is configured.

This command does not have a **no** form because data must flow using one of the two mapping/multiplexing schemes.

Examples

The following example shows how to configure AU-3 mapping for the STM-1 trunk card:

```
Router(config)# controller sonet 1/0
Router(config-controller)# aug mapping au-3
```

aug mapping [au-3 | au-4] stm [stm number] stm1 number [number]

Use this command to configure mixed AU-3 and AU-4 mapping

aug mapping [*au-3* | *au-4*] **stm** [*stm number*] **stm1 number** [*number*].

Syntax Description

Syntax Description

au-3	Mode of augment mapping
au-4	Mode of augment mapping
stm	The STM-1 (Synchronous Transport Module level-1) is the SDH ITU-T fiber optic network transmission standard. It has a bit rate of 155.52 Mbit/s.
stm1 number	The STM number ranges from 1 to 4.

Command Default

The default mode is AU-4.

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

The **aug mapping** command is available only when SDH framing is configured. AUG mapping is supported at STM-1 level.

Examples

```
enable
configure terminal
aug mapping [au-3 | au-4 stm [1-1] stm1 number [1-4]
end
```

Related Commands

Command	Description
show running configuration	Verifies aug mapping configuration.

aug mapping au-3 stm [stm number] path number [path number]

Use this command to change the AUG mapping of a particular STM-1 to AU-3.

aug mapping *au-3* **stm** [*1-16*] **path number** [*1-16*].

Syntax Description

Syntax Description

au-3	Mode of augment mapping
au-4	Mode of augment mapping
stm	The STM-1 (Synchronous Transport Module level-1) is the SDH ITU-T fiber optic network transmission standard. It has a bit rate of 155.52 Mbit/s.
path number	The path parameter number ranges from 1 to 16.

Command Default

The default mode is AU-4.

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Examples

```
enable
configure terminal
aug mapping [au-3 | au-4 stm [1-16] path number [1-16]
end
```

Related Commands

Command	Description
show running configuration	Verifies aug mapping configuration.

auto-polarity

To enable automatic receiver polarity reversal on a hub port connected to an Ethernet interface of a Cisco 2505 or Cisco 2507 router, use the **auto-polarity** command in hub configuration mode. To disable this function, use the **no** form of this command.

auto-polarity
no auto-polarity

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Hub configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to a port on an Ethernet hub only.

Examples

The following example shows how to enable automatic receiver polarity reversal on hub 0, ports 1 through 3:

```
Router(config)#
 hub ethernet 0 1 3
Router(config-hub)#
 auto-polarity
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

b2 sd-ber

To set the signal degrade bit-error rate (BER) threshold values, use the **b2sd-ber**command in controller configuration mode. To return to the default setting, use the **no** form of this command.

b2 sd-ber *rate*
no b2 sd-ber

Syntax Description

rate	Bit-error rate from 3 to 9 (10-n). The value of 9 represents better quality, and the value of 3 represents lower quality. The default is 6.

Command Default

rate: 6

Command Modes

Controller configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to configure the threshold for degradation of quality of signal with b2 errors.

Examples

The following example shows how to configure a signal degrade BER threshold value of 7 on the SONET controller:

```
Router(config)# controller sonet 1/0
Router(config-controller)# b2 sd-ber 7
```

Related Commands

Command	Description
show controllers sonet	Displays information about the SONET controllers.

b2 sf-ber

To set the signal failure bit-error rate (BER) threshold values, use the **b2sf-ber**command in controller configuration mode. To return to the default setting, use the **no** form of this command.

b2 sf-ber *rate*
no b2 sf-ber *rate*

Syntax Description

rate	Bit-error rate from 3 to 9 (10-n). The value of 9 represents better quality, and the value of 3 represents lower quality. The default is 3.

Command Default

rate : 3

Command Modes

Controller configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

Use this command to configure the threshold for failure of quality of signal with b2 errors. The value of 9 represents better quality and the value of 3 represents lower quality.

Examples

The following example shows how to configure a signal failure BER threshold value of 7 on the SONET controller:

```
Router(config)# controller sonet 1/0
Router(config-controller)# b2 sf-ber 7
```

Related Commands

Command	Description
show controllers sonet	Displays information about the SONET controllers.

backup delay

To define how much time should elapse before a secondary line status changes after a primary line status has changed, use the **backupdelay**command in interface configuration mode. To return to the default so that as soon as the primary fails, the secondary is immediately brought up without delay, use the **no** form of this command.

backup delay {*enable-delay-period* | **never**} {*disable-delay-period* | **never**}
no backup delay {*enable-delay-period* | **never**} {*disable-delay-period* | **never**}

Syntax Description

enable-delay-period	Number of seconds that elapse after the primary line goes down before the Cisco IOS software activates the secondary line.
disable-delay-period	Number of seconds that elapse after the primary line comes up before the Cisco IOS software deactivates the secondary line.
never	Secondary line is never activated or deactivated.

Command Default

0 second delay

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRB1	This command was integrated into Cisco IOS Release 12.2(33)SRB1.
15.1(2)SNH	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

For environments in which spurious signal disruptions appear as intermittent lost carrier signals, we recommend that you enable some delay before activating and deactivating a secondary line.

For the Cisco 7600 Backup Interface for Flexible UNI feature to work correctly, the enable and disable backup delay must be 0.

Examples

The following example sets a 10-second delay on deactivating the secondary line (serial interface 0); however, the line is activated immediately.

```
interface serial 0
 backup delay 0 10
```

backup interface

To configure an interface as a secondary or a dial backup, use the **backupinterface**command in interface configuration mode. To disable the interface from serving as a backup, use the **no** form of this command.

Cisco 7200 Series and Cisco 7600 Series Routers Only

backup interface *slot / port-adapter / port*

no backup interface *slot / port-adapter / port*

Other Cisco Routers

backup interface *type number*

no backup interface *type number*

Syntax Description

slot / port-adapter / port	Chassis slot, port adapter, and port number of the interface to configure as a backup. Include a slash (/) between the slot, port adapter, and port (for example, 1/1/1). See your hardware installation manual for the specific slot, port adapter, and port numbers.
type number	Type and port number of the interface that is being configured as a backup.

Command Default

An interface is not configured as a backup.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRB1	This command was integrated into Cisco IOS Release 12.2(33)SRB1.

Usage Guidelines

The interface that you define with the **backupinterface** command can back up only one interface.

Serial, ISDN, and Ethernet backup interfaces are supported by the routers. Access servers support both asynchronous backup interfaces and serial backup interfaces.

In Cisco IOS Release 12.2(33)SRB1 and later releases, you can configure a backup interface for Gigabit Ethernet interface on the Cisco 7600 router. The backup interface works only when the configurations on the primary and backup interfaces are identical. This is applicable to all Cisco IOS platforms and interfaces.

Note If the interface configuration includes the **xconnect**command, you must specify a different virtual circuit ID (VCID) on the primary and backup interfaces.

Examples

The following example sets serial interface 1 as the backup line to serial interface 0:

```
Router(config)# interface serial 0
Router(config-if)# backup interface serial 1
```

The following example sets Gigabit Ethernet interface 4/0/1 as the backup interface for Gigabit Ethernet interface 3/0/1 on the Cisco 7600 router:

```
Router(config)# interface gigabitEthernet 3/0/1
Router(config-if)# backup interface gigabitEthernet 4/0/1
```

Related Commands

Command	Description
aps protect (SONET)	Enables SONET APS.
show version	Displays information about the currently loaded software along with hardware and device information.

backup interface atm

To back up a locally switched ATM connection, use the **backupinterfaceatm**command in **theconnectsub**mode. To deconfigure the active routing policy set, leaving the SBE with no active routing policy set, use the **no** form of this command.

backup interface atm *x/y/z vpi/vci*
no backup interface atm *x/y/z vpi/vci*

Syntax Description

interface	Identifies the interface.
atm > *x* / *y* / *z* >	Specifies the backup location for the ATM slot/subslot/port to be backed up.
vpi / *vci* >	Specifies the backup location for the ATM virtual path identifier/virtual channel identifier (VPI/VCI).

Command Default

No default behavior or values.

Command Modes

Connect submode (config-connection)

Command History

Release	Modification
12.2(33)SRC	This command was introduced on the Cisco 7600 series routers.

Usage Guidelines

- Only the tail end AC can be backed up; if head end fails there is no protection.
- The circuit type of the primary and backup AC must be identical (failover operation will not switch between different types of interfaces).
- Autoconfiguration is allowed for backup ATM Permanent Virtual Circuits (PVCs) or ATM Permanent Virtual Paths (PVPs).
- Dynamic modification of parameters in a local switching connection is not supported in the case where the tail-end segment is backed up to a segment using the **backupinterfaceatm**command. If you want to modify the parameters in any of the three segments (head-end, tail-end, or backup segment), you must first unconfigure with the **backupinterfaceatm** command, make the changes in the individual segments, and then reconfigure the backup with the **backupinterfaceatm** command.

Examples

The following is an example of a ATM virtual path local switching backup:

```
Router(config)# connect ATM atm2/0/0 0 atm3/0/0 0
Router(config-connection)# backup interface atm 4/0/0 1
```

The following is an example of a ATM virtual channel local switching backup:

```
Router(config)# connect ATM atm2/0/0 24/56 atm3/0/0 24/57
Router(config-connection)# backup interface atm 4/0/0 25/58
!
```

Related Commands

Command	Description
connect atm	Configures a local switching connection.

backup interface cem

To back up a locally switched CEM connection, use the **backupinterfacecem** command in **theconnectsub**mode. To deconfigure the locally switched CEM connection backup, use the **no** form of this command.

backup interface cem *x/y/z cemckt*
no backup interface cem *x/y/z cemckt*

Syntax Description

interface >	Identifies the interface.
cem > *x* / *y* / *z*	Specifies the CEM interface slot, subslot, and port to be backed up.
cemckt	Specifies the backup location for the CEM.

Command Default

No default behavior or values.

Command Modes

Connect submode (config-connection)

Command History

Release	Modification
12.2(33)SRC	This command was introduced on the Cisco 7600 series routers.

Usage Guidelines

- Autoconfiguration of CEM interfaces is not supported.
- Only the tail end AC can be backed up; if head end fails there is no protection.
- The circuit type of the primary and backup AC must be identical (failover operation will not switch between different types of interfaces or different CEM circuit types).
- Backs up a local switching connection to cem-ckt3 of CEM interface cem3. Only one backup AC is allowed for each connection.
- Autoconfiguration of backup CEM circuits is not allowed.
- The CEM circuit used as a backup in a local switching connection cannot be used for xconnect configurations.
- Dynamic modification of parameters in a local switching connection is not supported in the case where the tail-end segment is backed up to a segment using the **backupinterfacecem**command. If you want to modify the parameters in any of the three segments (head-end, tail-end, or backup segment), you must first unconfigure with the **backupinterfacecem**command, make the changes in the individual segments, and then reconfigure the backup with the **backupinterfacecem** command.

Examples

The following is an example of a CEM local switching backup:

```
Router(config)# connect cema cem4/3/0 0 cem2/0/0 0
Router(config-connection)# backup interface cem 2/0/0 1
```

Related Commands

Command	Description
connect cem	Configures a local switching connection.

backup load

To set a traffic load threshold for dial backup service, use the **backupload**command in interface configuration mode. To return to the default value, use the **no** form of this command.

backup load {*enable-threshold* | **never**} {*disable-load* | **never**}
no backup load {*enable-threshold* | **never**} {*disable-load* | **never**}

Syntax Description

enable-threshold	Percentage of the primary line's available bandwidth that the traffic load must exceed to enable dial backup.
disable-load	Percentage of the available bandwidth that the traffic load must be less than to disable dial backup. The transmitted or received load on the primary line plus the transmitted or received load on the secondary line is less than the value entered for the *disable-load*argument to disable dial backup.
never	The secondary line is never activated or deactivated because of the traffic load.

Command Default

No threshold is defined.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRB1	This command was integrated into Cisco IOS Release 12.2(33)SRB1.

Usage Guidelines

When the transmitted or received load on the primary line is greater than the value assigned to the *enable-threshold* argument, the secondary line is enabled.

The secondary line is disabled when one of the following conditions occurs:

- The transmitted load on the primary line plus the transmitted load on the secondary line is less than the value entered for the *disable-load*argument.
- The received load on the primary line plus the received load on the secondary line is less than the value entered for the *disable-load* argument.

If the **never**keyword is used instead of an *enable-threshold*argument, the secondary line is never activated because of traffic load. If the **never** keyword is used instead of a *disable-load* argument, the secondary line is never activated because of traffic load.

Examples

The following example sets the traffic load threshold to 60 percent of the primary line serial 0. When that load is exceeded, the secondary line is activated and will not be deactivated until the combined load is less than 5 percent of the primary bandwidth.

```
interface serial 0
 backup load 60 5
 backup interface serial 1
```

bandwidth (interface configuration)

To set the inherited and received bandwidth values for an interface, use the **bandwidth** command in interface or virtual network interface config mode. To restore the default values, use the **no** form of this command.

bandwidth [{**receive**}] {*kbps* | **inherit** [{*kbps*}]}
no bandwidth [{**receive**}] {*kbps* | **inherit** [{*kbps*}]}

Syntax Description

kbps	Intended bandwidth, in kilobits per second. The range is from 1 to 10000000. For a full bandwidth DS3 line, enter the value 44736.
inherit	(Optional) Specifies how a subinterface inherits the bandwidth of its main interface.
receive	(Optional) Enables asymmetric transmit/receive operations so that the transmitted (**inherit** *kbps*) and received bandwidth are different.

Command Default

Default bandwidth values are set during startup. The bandwidth values can be displayed using the **show interfaces** or **show ipv6 interface** command. If the **receive** keyword is not used, by default, the transmit and receive bandwidths will be assigned the same value.

Command Modes

Interface configuration (config-if)

Virtual network interface (config-if-vnet)

Command History

Release	Modification
10.0	This command was introduced.
12.2T	This command was modified. The **inherit** keyword was added.
12.4(6)T	This command was modified. Support for IPv6 was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was implemented on Cisco ASR 1000 Aggregation Services Series Routers.
Cisco IOS XE Release 3.2S	This command was modified. Support was added for this command in virtual network interface configuration mode.
15.1(03)S	This command was modified. Support was added for the **receive** keyword.

Usage Guidelines

Bandwidth Information

The **bandwidth** command sets an informational parameter to communicate only the current bandwidth to the higher-level protocols; you cannot adjust the actual bandwidth of an interface using this command.

Note This is only a routing parameter. It does not affect the physical interface.

Changing Bandwidth

For some media, such as Ethernet, the bandwidth is fixed; for other media, such as serial lines, you can change the actual bandwidth by adjusting the hardware. For both classes of media, you can use the **bandwidth** command to communicate the current bandwidth to the higher-level protocols.

Bandwidth Inheritance

Before the introduction of the **bandwidth inherit** command option, when the bandwidth value was changed on the main interface, the existing subinterfaces did not inherit the bandwidth value. If the subinterface was created before the bandwidth was changed on the main interface, the subinterface would receive the default bandwidth of the main interface, and not the configured bandwidth. Additionally, if the router was subsequently reloaded, the bandwidth of the subinterface would then change to the bandwidth configured on the main interface.

The **bandwidth inherit** command controls how a subinterface inherits the bandwidth of its main interface. This functionality eliminates inconsistencies related to whether the router has been reloaded and what the order was in entering the commands.

The **no bandwidth inherit** command enables all subinterfaces to inherit the default bandwidth of the main interface, regardless of the configured bandwidth. If the **bandwidth inherit** command is used without configuring a bandwidth on a subinterface, all subinterfaces will inherit the current bandwidth of the main interface. If you configure a new bandwidth on the main interface, all subinterfaces will use this new value.

If you do not configure a bandwidth on the subinterface and you configure the **bandwidth inherit** *kbps* command on the main interface, the subinterfaces will inherit the specified bandwidth.

In all cases, if an explicit bandwidth setting is configured on an interface, the interface will use that setting, regardless of whether the bandwidth inheritance setting is in effect.

Bandwidth Receipt

Some interfaces (such as Asymmetric Digital Subscriber Line (ADSL), V.35, RS-449, and High-Speed Serial Interface (HSSI)) can operate with different transmit and receive bandwidths. The **bandwidth receive** command permits this type of asymmetric operation. For example, for ADSL, the lower layer detects the two bandwidth values and configures the Integrated Data Base (IDB) accordingly. Other interface drivers, particularly serial interface cards on low- and midrange-platforms, can operate in this asymmetric bandwidth mode but cannot measure their clock rates. In these cases, administrative configuration is necessary for asymmetric operations.

Examples

The following example shows how to set the full bandwidth for DS3 transmissions:

```
Router(config)# interface serial 0
Router(config-if)# bandwidth 44736
```

The following example shows how to set the receive bandwidth:

```
Router(config)# interface serial 0
Router(config-if)# bandwidth receive 1000
```

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on the router.
show ipv6 interface	Displays statistics for all interfaces configured on the IPv6 router.

batch

To allow better cache utilization at the interface level, use the batch command under interface configuration mode.

batch {allowed | **count***number* | **threshold***range* **}**

Syntax Description

allowed	Enables the batch process for packets received.
count *number*	Number of interrupts received for the batch process. Value ranges from 2 to 8. When batching is enabled, the packets in the receive ring are processed on every nth RX interrupt, where "n" is configured by "batch count n".
threshold *range*	Packets per 4ms threshold to enable the batch. Range is from 2 to 100 packets/4ms. If the number of packets received within a 4ms period exceeds 'x' then batching is turned on, otherwise it is turned off.

Command Default

Batch is disabled.

Command Modes

configuration-Interface

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use this command to increase the performance of packets processing through the interface to optimize the cache usage. The performance improvement varies depending on the burstiness of the traffic. The traffic with high burstiness provides better performance.

The **batch** command is disabled by default. The batch process depends on the batch threshold (x) which is the number of packets received within a ‘y’ ms period. The batch process is turned on if the number of packets received within a ‘y’ ms period exceeds ‘x’, otherwise it is turned off.

Currently, the batch command is supported at the interface level on Cisco 890 routers only.

Examples

The following example shows the batch command configured in interface fastethernet ports:

```
        !
!
interface FastEthernet0
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet1
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
```

```
interface FastEthernet2
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet3
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet4
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet5
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet6
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
interface FastEthernet7
 no ip address
 batch allowed
 batch count 6
 batch threshold 75
!
!
```

bert abort controller

To end a bit error rate testing (BERT) session, use the **bertabortcontroller**command in privileged EXEC mode.

bert abort controller *controller-type slot*/*port*

Syntax Description

controller-type	Type of controller being tested. Use either T1 or E1 depending on the type of facility.
slot / *port*	Slot number and port number to end a BERT session.

Command Default

A BERT session is configured.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **bertabortcontroller**command to cancel bit error rate testing on each port of the Cisco AS5300 router.

The BERT feature enables you to test the quality of the connected Primary Rate Interface (PRI) links by direct comparison of a pseudorandom or repetitive test pattern with an identical locally generated test pattern.

Examples

The following is sample output from the **bertabortcontroller**command when no bit error rate test is running:

```
Router# bert abort controller t1 0/0
Router#
17:53:33: There is no BERT Test running ....
```

The following is sample output from the **bertabortcontroller**command when a bit error rate test is running:

```
Router# bert abort controller t1 0/0
Do you really want to abort the current BERT [confirm] Y17:56:56: %BERT-6-BERT_RESULTS:
Controller T1 0 Profile default : The Test was
aborted by User
```

Related Commands

Command	Description
bert controller	Starts a bit error rate test for a particular port.

Command	Description
bert pattern (**T1/E1**)	Sets up various bit error rate testing profiles.

bert controller

To start a bit error rate test (BERT) for a particular port, use the **bertcontroller**command in privileged EXEC mode.

bert controller *controller-type controller-number last-controller-number* **profile** {*profile-number* [*last-profile-number*] [**timeslot** *timeslot-number* [*last-timeslot-number*]] | **default**}

Syntax for Cisco 2600 Platforms

bert controller *type-controller slot/port* [**channel-group** *channel-number*] [**pattern** *pattern-name*] [**interval** *range*]

Syntax Description

controller-type	Type of controller being tested. Use either T1 or E1 depending on the type of facility.
controller-number	Controller number. The valid range is from 0 to 7.
last-controller-number	Last contoller number. The valid range is from 2 to 7.
profile	Sets the profile numbers for the bit error rate test.
profile-number	Numbers of the test profiles to use. The valid range is from 0 to 15. The default is 0.
last-profile-number	(Optional) Last profile number. The default is 0.
timeslot	(Optional) Generates the data based on the timeslots associated with the controller.
timeslot-number	(Optional) Timeslot number. The valid range is from 1 to 22.
last-timeslot-number	(Optional) Last timeslot number. The valid range is from 1 to 24.
default	Executes the default bit error rate test (0).
slot/port	Slot and port number for the ports to be tested.
channel-group *channel-number*	(Optional) Specifies the channel group number that you want the BERT test to run on. Numbers can be 0 or 1.

pattern *pattern-name*	(Optional) BERT patterns available for testing are: • 0s--repetitive pattern; all zeros test pattern • 1s--n repetitive pattern; all ones test pattern • qrw--215-1 QRW test pattern • qrss (default)--220-1 Quasi-Random Signal Sample 0.151 test pattern • alt-0-1--alternating zeros and ones test pattern • 1in8--n repetitive pattern; 1 in 8 • 3in24--n repetitive pattern; 3 in 24 • 63--26-1 63 test pattern • 511--29-1 511 test pattern • 2047--211-1 test pattern
interval *range*	(Optional) Range for the test, in minutes. The valid range is from 1 to 14400. The default is 1.

Command Default

The test profile 0 is configured by default.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The following keywords and arguments were added: • *last-controller-number* • *last-profile-number* • **timeslot** • *timeslot-number* • *last-timeslot-number* • **default**

Usage Guidelines

Use the **bertcontroller** command to start a bit error rate test for a particular port on a Cisco AS5300 router.

Quality Testing

The BERT feature enables you to test the quality of the connected Primary Rate Interface (PRI) links by direct comparison of a pseudorandom or repetitive test pattern with an identical locally generated test pattern.

E1 Controllers

The E1 controller cannot be set in loopback mode from the Cisco AS5300 router. For the **bertcontroller** command to work correctly with the E1 controller, the controller must be configured as a channel group or as channel-associated signaling (CAS) and the line must be configured as a remote loop from the switch side of the link.

You can use the **channel-group***channel-group-number* keyword and argument combination to specify a channel-group. If the channel-group is specified, BERT will be run on the timeslots associated with the channel group only. Otherwise, BERT will run on all the timeslots of the specified controller.

Examples

The following is sample output from the **bertcontroller** command:

```
Router#
bert controller T1 T2 profile default
Press <Return> to start the BERT [confirm]
Y
17:55:34: %BERT-6-BERT_START: Starting BERT on Interface 0 with Profile default
Data in current interval (10 seconds elapsed):
     0 Line Code Violations, 0 Path Code Violations
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

Table 1 describes the significant fields shown in the display.

*Table 1: **bert controller** Field Descriptions*

Field	Description
Data in current interval	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. As the latest 15-minute accumulation period enters the buffer, the oldest 15-minute period is deleted. The accumulation period is from 1 to 900 seconds.
Line Code Violations	For alternate mark inversion (AMI)-coded signals, a line code violation is a bipolar violation (BPV) occurrence. Indicates the occurrence of either a BPV or an excessive zeros (EXZ) error event.
Path Code Violations	When super frame (SF) (D4) framing is used, a path code violation is a framing error. When extended super frame (ESF) framing is used, a path code violation is a cyclic redundancy check type 6 (CRC-6) error. Indicates a frame-synchronization bit error in the D4 and E1-non-CRC formats, or a CRC error in the ESF and E1-CRC formats.
Slip Secs	Indicates the replication or deletion of the payload bits of a DS1 frame. A slip may be indicated when there is a difference between the timing of a synchronous receiving terminal and the received signal.
Fr Loss Secs	Seconds during which the framing pattern has been lost. Indicates the number of seconds for which an Out-of-Frame error is detected.

Field	Description
Line Err Secs	A line error second (LES) is a second in which one or more line code violation (LCV or CV-L) errors are detected.
Degraded Mins	A degraded minute is one in which the estimated error rate exceeds 1-6 but does not exceed 1-3.
Errored Secs	In extended superframe (ESF) and E1-CRC links, an errored second is a second in which one of the following is detected: one or more path code violations; one or more Out-of-Frame defects; one or more controlled slip events; an alarm indication signal (AIS) defect. For D4 and E1-non-CRC links, the presence of bipolar violations also triggers an errored second.
Bursty Err Secs	Seconds with fewer than 320 and more than 1 path code violation error, no severely errored frame defects, and no detected incoming AIS defects. Controlled slips are not included in this parameter.
Severely Err Secs	For ESF signals, a second with one of the following errors: 320 or more path code violation errors; one or more Out-of-Frame defects; a detected AIS defect. For E1-CRC signals, a second with one of the following errors: 832 or more path code violation errors; one or more Out-of-Frame defects. For E1-non-CRC signals, a second with 2048 or more line code violations. For D4 signals, a count of 1-second intervals with framing errors, or an Out-of-Frame defect, or 1544 line code violations.
Unavail Secs	Count for every second in which an unavailable signal state occurs. This term is used by new standards in place of failed seconds (FS).

The following example shows a BERT test started on a T1 port 0/0 and channel group 0 with a QRSS signaling pattern for a duration of 5 minutes:

```
Router# bert controller t1 0/0 channel-group 0 pattern qrss interval 5
```

Related Commands

Command	Description
bert abort	Aborts a bit error rate testing session.
bert pattern (T1/E1)	Sets up various bit error rate testing profiles.
bert abort controller	Stops a BERT test prematurely.

bert errors

To transmit bit error ratio test (BERT) errors while running any BERT pattern, use the**berterror**command in interface configuration mode.

bert errors [*number*]

Syntax Description

number	(Optional) Range of **1-255**BERT errors that may be introduced in a BERT pattern.

Command Default

Default is 1.

Command Modes

Interface configuration

Command History

Release	Modification
12.1(12c)EX1	This command was introduced for Cisco 7304 routers.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series router and Catalyst 6500 series switch.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use this command to test link availability by injecting a fixed number of bert errors when a pattern is running and check that the same number of errors were received on the remote end.

Examples

This example injects 200 BERT errors in a running bit pattern on slot 5, subslot 0.

```
Router# configure terminal
Router(config)# interface serial 5/0/0
Router(config-if)# bert errors 200
```

Related Commands

Command	Description
bert pattern	Starts a BERT pattern on a port.
show controller serial	Displays serial line statistics.

bert pattern

To start a BERT pattern on a port, use the **bertpattern**command in interface configuration mode. Use the no bert pattern command to stop the sequence.

bert pattern {**0s** | **1s** | **2^11** | **2^15** | **2^20** | **2^23** | **alt-0-1** | **qrss**} **interval** *minutes*
no bert pattern {**0s** | **1s** | **2^11** | **2^15** | **2^20** | **2^23** | **alt-0-1** | **qrss**} **interval** *minutes*

Syntax Description

0s	Repeating pattern of zeros (...000...).
1s	Repeating pattern of ones (...111...).
2^11	Pseudo-random repeating test pattern that consists of 2,048 bits.
2^15	Pseudorandom 0.151 test pattern that is 32,768 bits in length.
2^20	Pseudorandom 0.153 test pattern that is 1,048,575 bits in length.
2^23	Pseudorandom 0.151 test pattern that is 8,388,607 bits in length.
alt-0-1	Repeating pattern of alternating zeros and ones (...01010...).
qrss	Pseudorandom quasi-random signal sequence (QRSS) 0.151 test pattern that is 1,048,575 bits in length.
interval *minutes*	Specifies the length of the BERT test in minutes.

Command Default

Bert is disabled by default.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	The command was introduced.
12.0(5)XE	The command was enhanced as an ATM interface configuration command
12.0(7)XE1	Support for Cisco 7100 series routers was added.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.1(12c)EX1	Support for Cisco 7304 routers was added.
12.2(18)S	Support for Cisco 7304 routers was added.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series router and the Catalyst 6500 series switch.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
XE3.18SP	This command was integrated into Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was implemented on the Cisco ASR 920 Routers and Cisco NCS 4200 Series.

Usage Guidelines

Use the bert pattern commamd to start or stop a specific bit pattern. To test link availability, start a pattern on one end and put the remote end in network loopback and verify that there are no bert errors.

Examples

This example starts a bert pattern on slot 5, bay 0.

```
Router# configure terminal
Router(config)# int serial 5/0/0
Router(config-if)# bert pattern 0s
```

This example starts a bert pattern pRBS.

```
Router#enable
Router#configure terminal
Router(config)#bert pattern pRBS interval 5 direction line
exit
```

Related Commands

Command	Description
bert errors	Transmit bert errors while running any bert pattern.
loopback	Loopback at various points in the transmit and receive path.
show controller serial	Displays serial line statistics.
show controller sonet	Displays sonet interface module statistics.
show controller t1	Displays t1 interface module statistics.
show controller t3	Displays t3 interface module statistics.

bert pattern (T1 E1)

To enable a bit error rate test (BERT) pattern on a T1 or E1 line, use the**bertpattern**command in controller configuration mode. To disable a BER test pattern, use the **no** form of this command.

bert pattern *pattern* **interval** *time*
no bert pattern *pattern* **interval** *time*

Syntax Description

pattern	The test pattern indicated by any of the following allowable values:
2^23	Invokes a pseudorandom 0.151 test pattern that is 8,388,607 bits in length.
2^20	Invokes a pseudorandom 0.153 test pattern that is 1,048,575 bits in length.
2^20-QRSS	Invokes a pseudorandom quasi-random signal sequence (QRSS) 0.153 test pattern that is 1,048,575 bits in length.
2^15	Invokes a pseudorandom 0.151 test pattern that is 32,768 bits in length.
2^11	Invokes a pseudorandom test pattern that is 2,048 bits in length.
1s	Invokes a repeating pattern of ones (...111...).
0s	Invokes a repeating pattern of zeros (...000...).
alt-0-1	Invokes a repeating pattern of alternating zeros and ones (...01010...).
interval *time*	Specifies the duration (in minutes) of the BER test. The interval can be a value from 1 to 14400. There is no default.

Command Default

Disabled

12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

BER testing is supported on each of the T1 or E1 lines, is done only over an unframed T1 or E1 signal, and is run on only one port at a time.

To view the BER test results, use the **showcontrollersatm**EXEC command. The BERT results include the following information:

- Type of test pattern selected
- Status of the test
- Interval selected
- Time remaining on the BER test
- Total bit errors
- Total bits received

When the T1 or E1 line has a BER test running, the line state is DOWN and the status field shows the current/last result of the test.

The**bertpattern**command is not written to NVRAM because this command is only used to test the T1 or E1 line for a short predefined interval, and to avoid accidentally saving the command.

Examples

The following example shows how to run a BERT pattern of all zeros on a Cisco 7200 series router for 30 minutes on the T1 controller in slot 1:

```
Router(config)#
controller T1 1/0
Router(config-if)#
bert pattern 0s interval 30
```

Related Commands

Command	Description
show controllers atm	Displays information about T1/E1 links in Cisco 7100 series routers, Cisco 7200 series routers, and Cisco 7500 series routers.

bert pattern (T3 E3)

To enable a bit error rate test (BERT) pattern on a T3 or E3 controller, use the **bertpattern** command in controller configuration mode. To disable a BER test pattern, use the no form of this command.

bert pattern *pattern* **interval** *time*
no bert pattern

Syntax Description

pattern	The pattern indicated by any of the following allowable values:
2^23	Invokes a pseudorandom 0.151 test pattern that is 8,388,607 bits in length.
2^20	Invokes a pseudorandom 0.153 test pattern that is 1,048,575 bits in length.
2^15	Invokes a pseudorandom 0.151 test pattern that is 32,768 bits in length.
1s	Invokes a repeating pattern of ones (...111...).
0s	Invokes a repeating pattern of zeros (...000...).
alt-0-1	Invokes a repeating pattern of alternating zeros and ones (...01010...).
interval *time*	Specifies the duration (in minutes) of the BER test. The interval can be a value from 1 to 14400. There is no default.

Command Default

Disabled

Command Modes

Controller configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

BER testing is supported on T3/E3 links and is done only over framed T3 or E3 signals, unless E3 framing is in bypass mode.

To display the BER test results, use the show controllers t3 or show controllers e3 EXEC command. The BER test results include the following information:

- Type of test pattern selected
- Status of the test
- Interval selected
- Time remaining on the BER test
- Total bit errors
- Total bits received

When the T3 or E3 line has a BER test running, the line state is DOWN and the status field shows the current or last result of the test.

The**bertpattern**command is not written to NVRAM because this command is used only to test the T3 or E3 line for a short predefined interval, and to avoid accidentally saving the command.

Examples

The following example shows how to run a BERT pattern of all zeros for 30 minutes on the T3 controller in slot 1:

```
Router(config)#
controller T3 1/0
Router(config-if)#
bert pattern 0s interval 30
```

Related Commands

Command	Description
show controllers e3	Displays information about E3 controllers.
show controllers t3	Displays information about T3 controllers.

bert profile

To set up various bit error rate testing profiles, use the **bert profile** command in global configuration mode. To disable the particular bit error rate test (BERT) profile indicated by profile number, use the **no** form of this command.

bert profile *number* **pattern** *pattern* **threshold** *threshold* **error-injection** *err-inj* **duration** *time*
no bert profile *number* **pattern** *pattern* **threshold** *threshold* **error-injection** *err-inj* **duration** *time*

Syntax Description

number	BERT profile number. The valid range is from 1 to 15. This is the number assigned to a particular set of parameters. If no such profile of the same number exists in the system, a new profile is created with that number; otherwise, an existing set of parameters with that profile number is overwritten by the new profile.
pattern	Pattern that BERT will generate on the line.
pattern	**0s** --Repetitive pattern, all zeros.**1_in_16**--n repetitive pattern, 1 in 16.**1s**--n repetitive pattern, all ones.**211-O.152**--n pseudorandom pattern, 211 -1 O.152.**215-O.15**--n pseudorandom pattern, 215 -1 O.151.**220-O.151QRSS**--n pseudorandom pattern, 220 -1 O.151 QRSS. (This is the default.)**220-O.153**--n pseudorandom pattern, 220 -1 O.153.**3_in_24**--n repetitive pattern, 3 in 24.
threshold	Test failure (error) threshold that determines if the BERT on this line passed.
threshold	**10^-2** --Bit error rate of 10-2.**10^-3**--Bit error rate of 10-3.**10^-4**--Bit error rate of 10-4.**10^-5**--Bit error rate of 10-5.**10^-6**--Bit error rate of 10-6. (This is the default.)**10^-7**--Bit error rate of 10-7.**10^-8**--Bit error rate of 10-8.
error-injection	Error injection rate for bit errors injected into the BERT pattern generated by the chip.
err-inj	**10^-1** --Error injection of 10-1.**10^-2**--Error injection of 10-2.**10^-3**--Error injection of 10-3.**10^-4**--Error injection of 10-4.**10^-5**--Error injection of 10-5.**10^-6**--Error injection of 10-6.**10^-7**--Error injection of 10-7.**none**--No error injection in the data pattern. (This is the default.)
duration	Duration, in minutes, for which BERT is to be executed.
time	Duration of BERT, in minutes. The valid range is from 1 to 1440. The default is 10.

Command Default

The default profile created internally by the system has parameters that cannot be changed. This profile has been defined so that you can execute BERT on a line without having to configure a new profile. The default profile is displayed when the running configuration is displayed and is not stored in NVRAM:

bert profile *number* **pattern 220-0151QRSS threshold 10^-6 error-injection none duration 10**

Command Modes

Global configuration

Command History

Release	Modification
12.0(2)XD	This command was introduced.

Release	Modification
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **bert profile** command to set up bit error rate testing profiles for the Cisco AS5300 router.

The bit error rate test (BERT) feature enables you to test the quality of the connected PRI links by direct comparison of a pseudorandom or repetitive test pattern with an identical locally generated test pattern. A BERT profile is a set of parameters related to a BERT test and is stored as part of the configuration in NVRAM. You can define up to 15 BERT profiles on the system. By setting up the BERT profiles in this way, you do not have to enter the parameters each time you want to run a BERT--just select the number of the BERT profile that you want to run.

Examples

The following example shows a configured BERT profile number 1 to have a 0s test pattern, with a 10-2 threshold, no error injection, and a duration of 125 minutes:

```
Router(config)#
bert profile 1 pattern 0s threshold 10^-2 error-injection none duration 125
```

Related Commands

Command	Description
bert abort	Aborts a bit error rate testing session.
bert controller	Starts a bit error rate test for a particular port.

bitswap line

To divert the data of a disturbed transmission channel to other channels, use the **bitswap line** command in controller configuration mode. To disable bitswapping, use the **no** form of this command.

bitswap [line *line-number***]**
no bitswap [line *line-number***]**

Syntax Description

line-number	Line number. Valid values are either 0 or 1.

Command Default

Bit swapping is enabled.

Command Modes

Controller configuration (config-controller)#

Command History

Release	Modification
15.4(4)T	This command was introduced.

Usage Guidelines

- After you enable bit swapping, whenever the line conditions change, the modem swaps the bits around different channels without retraining.
- If you enable bonded mode, bit swapping will be enabled on both the lines.
- If you specify only the line number, bit swapping will be enabled only on that line.
- In case of single mode, bit swapping will be enabled only on that line.

Examples

The following example shows how to enable bit swapping on line 0:

```
Router(config-controller)# bitswap line 0
```

The following example shows how to disable bit swapping:

```
Router(config-controller)# no bitswap
```

Related Commands

Command	Description
sra line	Accommodates changes to the total link capacity with less disruption to communications.

bridge-domain

To enable RFC 1483 ATM bridging or RFC 1490 Frame Relay bridging to map a bridged VLAN to an ATM permanent virtual circuit (PVC) or Frame Relay data-link connection identifier (DLCI), use the **bridge-domain**command in Frame Relay DLCI configuration, interface configuration, interface ATM VC configuration, or PVC range configuration mode. To disable bridging, use the **no** form of this command.

bridge-domain *vlan-id* [{**access** | **dot1q** [*tag*] | **dot1q-tunnel**}] [**broadcast**] [**ignore-bpdu-pid**] [**pvst-tlv** *CE-vlan*] [**increment**] [**lan-fcs**] [**split-horizon**]
no bridge-domain *vlan-id*

Syntax Description

vlan-id	The number of the VLAN to be used in this bridging configuration. The valid range is from 2 to 4094.
access	(Optional) Enables bridging access mode, in which the bridged connection does not transmit or act upon bridge protocol data unit (BPDU) packets.
dot1q	(Optional) Enables Institute of Electrical and Electronic Engineers (IEEE) 802.1Q tagging to preserve the class of service (CoS) information from the Ethernet frames across the ATM network. If this keyword is not specified, the ingress side assumes a CoS value of 0 for quality of service (QoS) purposes.
tag	(Optional--ATM PVCs only) Specifies the 802.1Q value in the range 1 to 4095. You can specify up to 32 **bridge-domain** command entries using **dot1q***tag* for a single PVC. The highest tag value in a group of **bridge-domain** commands must be greater than the first tag entered (but no more than 32 greater).
dot1q-tunnel	(Optional) Enables IEEE 802.1Q tunneling mode, so that service providers can use a single VLAN to support customers who have multiple VLANs, while preserving customer VLAN IDs and segregating traffic in different customer VLANs.
broadcast	(Optional) Enables bridging broadcast mode on this PVC. This option is not supported for multipoint bridging. Support for this option was removed in Cisco IOS Release 12.2(18)SXF2 and Cisco IOS Release 12.2(33)SRA.
ignore-bpdu-pid	(Optional for ATM interfaces only) Ignores BPDU protocol identifiers (PIDs) and treats all BPDU packets as data packets to allow interoperation with ATM customer premises equipment (CPE) devices that do not distinguish BPDU packets from data packets.
pvst-tlv	(Optional) When the router or switch is transmitting, translates Per-VLAN Spanning Tree Plus (PVST+) BPDUs into IEEE BPDUs. When the router or switch is receiving, translates IEEE BPDUs into PVST+ BPDUs.
CE-vlan	Customer-edge VLAN in the Shared Spanning Tree Protocol (SSTP) tag-length-value (TLV) to be inserted in an IEEE BPDU to a PVST+ BPDU conversion.
increment	(PVC range configuration mode only) (Optional) Increments the bridge domain number for each PVC in the range.

lan-fcs	(Optional) Specifies that the VLAN bridging should preserve the Ethernet LAN frame checksum (FCS) of the Ethernet frames across the ATM network. **Note** This option applies only to routers using a FlexWAN module. Support for this option was removed in Cisco IOS Release 12.2(18)SXF2 and Cisco IOS Release 12.2(33)SRA.
split-horizon	(Optional) Enables RFC 1483 split horizon mode to globally prevent bridging between PVCs in the same VLAN.

Command Default

Bridging is disabled.

Command Modes

Frame Relay DLCI configuration (config-fr-dlci) Interface configuration (config-if)--Only the **dot1q** and **dot1q-tunnel** keywords are supported in interface configuration mode. Interface ATM VC configuration (config-if-atm-vc) PVC range configuration (config-if-atm-range)

Command History

Release	Modification
12.1(13)E	This command was introduced as the **bridge-vlan** command for the 2-port OC-12 ATM WAN Optical Services Modules (OSMs) on Cisco 7600 series routers and Catalyst 6500 series switches.
12.1(12c)E	This command was integrated into Cisco IOS Release 12.1(12c)E.
12.1(14)E1	This command was integrated into Cisco IOS Release 12.1(14)E1. The **dot1q-tunnel** keyword was added.
12.2(14)SX	This command was integrated into Cisco IOS Release 12.2(14)SX. The **dot1q-tunnel** keyword is not supported in this release.
12.1(19)E	The **split-horizon** keyword was added.
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)S. The **dot1q-tunnel** and **split-horizon** keywords are supported in this release.
12.2(17a)SX	Support was added for the **dot1q-tunnel** keyword in Cisco IOS Release 12.2(17a)SX.
12.2(18)SXE	This command was renamed from **bridge-vlan** to **bridge-domain**. The **access**, **broadcast**, **ignore-bpdu-pid**, and **increment** keywords were added.
12.2(18)SXF2	Support for the **lan-fcs** and **broadcast**keywords was removed. The **ignore-bpdu-pid**and **pvst-tlv**keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

RFC 1483 bridging on ATM interfaces supports the point-to-point bridging of Layer 2 packet data units (PDUs) over Ethernet networks. RFC 1490 Frame Relay bridging on Packet over SONET (POS) or serial interfaces that are configured for Frame Relay encapsulation provides bridging of Frame Relay packets over Ethernet networks.

The Cisco 7600 router can transmit BPDUs with a PID of either 0x00-0E or 0x00-07. When the router connects to a device that is fully compliant with RFC 1483 Appendix B, in which the IEEE BPDUs are sent and received by the other device using a PID of 0x00-0E, you must not use the **ignore-bpdu-pid**keyword.

If you do not enter the **ignore-bpdu-pid** keyword, the PVC between the devices operates in compliance with RFC 1483 Appendix B. This is referred to as *strict mode* . Entering the **ignore-bpdu-pid** keyword creates *loose mode* . Both modes are described as follows:

- Without the **ignore-bpdu-pid**keyword, in strict mode, IEEE BPDUs are sent out using a PID of 0x00-0E, which complies with RFC 1483.
- With the **ignore-bpdu-pid**keyword, in loose mode, IEEE BPDUs are sent out using a PID of 0x00-07, which is normally reserved for RFC 1483 data.

Cisco-proprietary PVST+ BPDUs are always sent out on data frames using a PID of 0x00-07, regardless of whether you enter the **ignore-bpdu-pid** keyword.

Use the **ignore-bpdu-pid** keyword when connecting to devices such as ATM digital subscriber line (DSL) modems that send PVST (or 802.1D) BPDUs with a PID of 0x00-07.

The **pvst-tlv** keyword enables BPDU translation when the router interoperates with devices that understand only PVST or IEEE Spanning Tree Protocol. Because the Catalyst 6500 series switch ATM modules support PVST+ only, you must use the **pvst-tlv** keyword when connecting to a Catalyst 5000 family switch that understands only PVST on its ATM modules, or when connecting with other Cisco IOS routers that understand IEEE format only.

When the router or switch is transmitting, the **pvst-tlv** keyword translates PVST+ BPDUs into IEEE BPDUs.

When the router or switch is receiving, the **pvst-tlv** keyword translates IEEE BPDUs into PVST+ BPDUs.

Note The **bridge-domain**and **bre-connect** commands are mutually exclusive. You cannot use both commands on the same PVC for concurrent RFC 1483 and BRE bridging.

To preserve class of service (CoS) information across the ATM network, use the **dot1q** option. This configuration uses IEEE 802.1Q tagging to preserve the VLAN ID and packet headers as they are transported across the ATM network.

To enable service providers to use a single VLAN to support customers that have multiple VLANs, while preserving customer VLAN IDs and segregating traffic in different customer VLANs, use the **dot1q-tunnel** option on the service provider router. Then use the **dot1q** option on the customer routers.

Note The **access**, **dot1q**, and **dot1q-tunnel** options are mutually exclusive. If you do not specify any of these options, the connection operates in “raw” bridging access mode, which is similar to access, except that the connection does act on and transmit BPDU packets.

RFC 1483 bridging is supported on AAL5-MUX and AAL5-LLC Subnetwork Access Protocol (SNAP) encapsulated PVCs. RFC-1483 bridged PVCs must terminate on the ATM interface, and the bridged traffic must be forwarded over an Ethernet interface, unless the **split-horizon** option is used, which allows bridging of traffic across bridged PVCs.

Note RFC 1483 bridging is not supported for switched virtual circuits (SVCs). It also cannot be configured for PVCs on the main interface.

In interface configuration mode, only the **dot1q** and **dot1q-tunnel** keyword options are supported.

Examples

The following example shows a PVC being configured for IEEE 802.1Q VLAN bridging using a VLAN ID of 99:

```
Router# configure terminal

Router(config)# interface ATM6/2

Router(config-if)# pvc 2/101

Router(config-if-atm-vc)# bridge-domain 99 dot1q

Router(config-if-atm-vc)# end
```

The following example shows how to enable BPDU translation when a Catalyst 6500 series switch is connected to a device that understands only IEEE BPDUs in an RFC 1483-compliant topology:

```
Router(config-if-atm-vc)# bridge-domain
100 pvst-tlv 150
```

The **ignore-bpdu-pid** keyword is not used because the device operates in an RFC 1483-compliant topology for IEEE BPDUs.

The following example shows how to enable BPDU translation when a Catalyst 5500 ATM module is a device that understands only PVST BPDUs in a non-RFC1483-compliant topology. When a Catalyst 6500 series switch is connected to a Catalyst 5500 ATM module, you must enter both keywords.

```
Router(config-if-atm-vc)# bridge-domain
100 ignore-bpdu-pid pvst-tlv 150
```

To enable BPDU translation for the Layer 2 Protocol Tunneling (L2PT) topologies, use the following command:

```
Router(config-if-atm-vc)# bridge-domain
100 dot1q-tunnel ignore-bpdu-pid pvst-tlv 150
```

The following example shows a range of PVCs being configured, with the bridge domain number being incremented for each PVC in the range:

```
Router(config)# interface atm 8/0.100

Router(config-if)# range pvc 102/100 102/199
Router(config-if-atm-range)# bridge-domain 102 increment
```

Related Commands

Command	Description
bre-connect	Enables the BRE over a PVC or SVC.

Command	Description
show atm pvc	Displays the configuration of a particular PVC.

bridge-domain (subinterface)

To enable bridging across Gigabit Ethernet subinterfaces, use the **bridge-domain**command in subinterface configuration mode. To disable bridging, use the **no** form of this command.

bridge-domain *vlan-id* {**dot1q** | **dot1q-tunnel**} [**bpdu** {**drop** | **transparent**}] [**split-horizon**]
no bridge-domain *vlan-id* {**dot1q** | **dot1q-tunnel**} [**bpdu** {**drop** | **transparent**}] [**split-horizon**]

Syntax Description

vlan-id	Specifies the number of the virtual LAN (VLAN) to be used in this bridging configuration. The valid range is from 2 to 4094.
dot1q	Enables IEEE 802.1Q tagging to preserve the class of service (CoS) information from the Ethernet frames across the ATM network. If not specified, the ingress side assumes a CoS value of 0 for QoS purposes.
dot1q-tunnel	Enables IEEE 802.1Q tunneling mode, so that service providers can use a single VLAN to support customers who have multiple VLANs, while preserving customer VLAN IDs and keeping traffic in different customer VLANs segregated.
bpdu {**drop** | **transparent**}	(Optional) Specifies whether or not BPDUs are processed or dropped: • **drop** --Specifies that BPDU packets are dropped on the subinterface. • **transparent** --Specifies that BPDU packets are forwarded as data on the subinterface, but not processed.
split-horizon	(Optional) Enables RFC 1483 split horizon mode to globally prevent bridging between PVCs in the same VLAN.

Command Default

Bridging is disabled.

Command Modes

Subinterface configuration (config-subif)

Command History

Release	Modification
12.2(33)SRA	This command was introduced.

Usage Guidelines

This command has the following restrictions in Cisco IOS Release 12.2(33)SRA:

- The command is available on the Cisco 7600 SIP-400 with a 2-Port Gigabit Ethernet SPA only.
- You can place up to 120 subinterfaces in the same bridge domain on a single Cisco 7600 SIP-400.

To enable service providers to use a single VLAN to support customers who have multiple VLANs, while preserving customer VLAN IDs and keeping traffic in different customer VLANs segregated, use the **dot1q-tunnel** option on the service provider router. Then use the **dot1q** option on the customer routers.

Examples

The following example shows configuration of IEEE 802.1Q encapsulation for VLANs on Gigabit Ethernet subinterfaces with configuration of multipoint bridging (MPB). The MPB feature requires configuration of 802.1Q encapsulation on the subinterface.

The first subinterface bridges traffic on VLAN 100 and preserves CoS information in the packets by specifying the **dot1q** keyword.

```
Router(config)# interface GigabitEthernet 1/0/1.1
Router(config-subif)# encapsulation dot1q 10
Router(config-subif)# bridge-domain 100 dot1q
```

The second subinterface shows bridging of traffic on VLAN 200 in tunneling mode using the **dot1q-tunnel** keyword, which preserves the VLAN IDs of the bridged traffic.

```
Router(config)# interface GigabitEthernet 2/0/2.2
Router(config-subif)# encapsulation dot1q 20
Router(config-subif)# bridge-domain 200 dot1q-tunnel
```

The following example shows bridging of traffic from different VLANs on two separate Gigabit Ethernet subinterfaces into the same VLAN. First, the bridging VLAN 100 is created using the **vlan** command. Then, the Gigabit Ethernet subinterfaces implement IEEE 802.1Q encapsulation on VLAN 10 and VLAN 20 and bridge the traffic from those VLANs onto VLAN 100 using the **bridge-domain** command:

```
Router(config)# vlan 100
Router(config-vlan)# exit
!
Router(config)# interface GigabitEthernet 1/0/1.1
Router(config-subif)# encapsulation dot1q 10
Router(config-subif)# bridge-domain 100 dot1q
Router(config-subif)# exit
!
Router(config)# interface GigabitEthernet 1/0/2.1
Router(config-subif)# encapsulation dot1q 20
Router(config-subif)# bridge-domain 100 dot1q
```

Related Commands

Command	Description
encapsulation dot1q	Enables IEEE 802.1Q encapsulation of traffic on a specified subinterface in a VLAN.
vlan	Adds the specified VLAN IDs to the VLAN database and enters VLAN configuration mode.

cable bundle through clock mode

cable bundle

To configure a cable interface to belong to an interface bundle, use the **cablebundle**command in interfaceconfiguration mode. To delete a cable interface bundle definition, use the **no** form of this command.

cable bundle *number* [**master**]
no cable bundle *number* [**master**]

Syntax Description

number	Specifies the bundle identifier. Valid range is from 1 to 255.
master	(Optional) Defines the specified interface as primary.

Command Default

No cable interface bundle is defined.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(7)XR	This command was introduced.
12.1(1a)T1	This command was integrated into Cisco IOS Release 12.1(1a)T1.
12.0(8)SC	This command was integrated into Cisco IOS Release 12.0(8)SC
12.1(2)EC1	This command was integrated into Cisco IOS Release 12.1(2)EC1.

Usage Guidelines

You can configure up to four interface bundles. In each bundle, specify one interface as the primary interface by using the optional **master** keyword.

Configure only an IP address on the primary interface. If an IP address is configured and the interface is not specified as the primary interface, any attempt to add an interface to a bundle is rejected.

Specify all generic IP networking information (such as IP address, routing protocols, and switching modes) on the bundle primary interface. Do not specify generic IP networking information on bundle subordinate interfaces.

If you attempt to add an interface to a bundle as non-primary interface and an IP address is assigned to this interface, the command will fail. You must remove the IP address configuration before you can add the interface to a bundle.

If you have configured an IP address on a bundled interface and the interface is not the primary interface, a warning message appears.

Specify generic (not downstream or upstream related) cable interface configurations, such as source-verify or Address Resolution Protocol (ARP) handling, on the primary interface. Do not specify generic configuration on non-primary interfaces.

If you configure an interface as a part of a bundle and it is not the primary interface, all generic cable configuration for this interface is removed. The primary interface configuration will then apply to all interfaces in the bundle.

If you shut down or remove the primary interface in a bundle, no data packets are sent to any of the interfaces in this bundle. Packets are still physically received from non-primary interfaces that have not been shut down, but those packets will be discarded. Modems connected to those interfaces will not be disconnected immediately, but modems going online are not able to obtain an IP address, download their configuration file, or renew their IP address assignment if the Dynamic Host Configuration Protocol (DHCP) lease expires.

If you shut down a subordinate interface, only this interface is affected.

Examples

The following example shows how to configure interface 25 to be the primary interface:

```
Router(config-if)# cable bundle 25 master
Router(config-if)#
07:28:17: %UBR7200-5-UPDOWN: Interface Cable3/0 Port U0, changed state to down
07:28:18: %UBR7200-5-UPDOWN: Interface Cable3/0 Port U0, changed state to up
```

The following example shows the error message that appears if you try to configure an interface with an IP address that is not the primary interface:

```
Router(config-if)# cable bundle 5
Please remove ip address config first then reenter this command
```

Related Commands

Command	Description
show cable bundle	Displays the forwarding table for the specified interface bundle.

cable helper-address

To specify a destination address for User Datagram Protocol (UDP) broadcast Dynamic Host Configuration Protocol (DHCP) packets, use the **cablehelper-address**command in interface configuration mode. To remove the specified destination address for UDP DHCP packets, use the **no** form of this command.

cable helper-address *ip-address* {**cable-modem** | **host**}
no cable helper-address *ip-address* {**cable-modem** | **host**}

Syntax Description

ip-address	The IP address of a DHCP server. Based on whether you add the **host** or **cable-modem** keyword at the end of the **cablehelper-address** command, it is the IP address of the multiple service operators (MSOs) Cisco Network Registrar (CNR) server or the Internet service providers (ISPs) DHCP server.
cable-modem	Specifies that only cable modem UDP broadcasts are forwarded.
host	Specifies that only host UDP broadcasts are forwarded.

Command Default

This command is disabled by default.

Command History

Release	Modification
11.3NA	This command was introduced.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you specify a secondary interface address, the giaddr field in the DHCP requests will be sent to the primary address for DHCP requests received from cable modems, and to the secondary IP address for DHCP requests received from hosts.

Examples

The following example shows how to forward UDP broadcasts from cable modems to the DHCP server at 172.23.66.44:

```
Router(config-if)#
cable helper-address 172.23.66.44 cable-modem
```

The following example shows how to forward UDP broadcasts from hosts to the DHCP server at 172.23.66.44:

```
Router(config-if)# cable helper-address 172.23.66.44 host
```

cablelength

To specify the distance of the cable from the routers to the network equipment, use the **cablelength** command in controller configuration mode. To restore the default cable length, use the **no** form of this command.

cablelength *feet*
no cablelength

Syntax Description

feet	Number of feet in the range of 0 to 450.

Command Default

224 feet for a CT3IP interface processor and Clear Channel T3/E3 network module

49 feet for PA-T3 and PA-2T3 port adapters

450 feet for an interface cable between the near and far-end CSU/DSU device

Command Modes

Controller configuration

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers. Support for the Clear Channel T3/E3 network module was added.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

CT3IP Interface Processor and Clear Channel T3/E3 Network Module

The default cable length of 224 feet is used by the CT3IP interface processor and the Clear Channel T3/E3 network module.

PA-T3 and PA-2T3 Port Adapters

The default cable length of 49 feet is used by the PA-T3 and PA-2T3 port adapters.

Note Although you can specify a cable length from 0 to 450 feet, the hardware recognizes only two ranges: 0 to 49 and 50 to 450. For example, entering 35 feet uses the 0 to 49 range. If you later change the cable length to 40 feet, there is no change because 40 is still within the 0 to 49 range. However, if you change the cable length to 50, the 50 to 450 range is used. The actual number you enter is stored in the configuration file.

Cisco 1000 Series Router

The table below lists the cable length distances and their relationships to line buildout for E3 and T3 controllers on Cisco 1000 Series Routers:

Table 2: Cable Length Distances and Line Buildout for E3/T3 Controllers

Interface	Cable Length (Feet)	Buildout
E3	0 to 244	No line buildout
E3	225 to 450	Line buildout
T3	0 to 299	No line buildout
T3	300 to 450	Line buildout

Note Although you can specify a cable length from 0 to 450 feet, the hardware recognizes only two ranges: 0 to 49 and 50 to 450. For example, entering 35 feet uses the 0 to 49 range. If you later change the cable length to 40 feet, there is no change because 40 is still within the 0 to 49 range. However, if you change the cable length to 50, the 50 to 450 range is used. The actual number you enter is stored in the configuration file.

Examples

Cable Length to 300 Feet Example

The following example shows how to set the cable length for the router to 300 feet:

```
Router(config)#
 controller t3 9/0/0
Router(config-controller)#
 cablelength 300
```

Cisco 10000 Series Series Router Example

The following example sets the cable length to 120 feet:

```
Router(config)# controller dsx3 4/0/6
Router(config-controller)# cablelength 120
```

Related Commands

Command	Description
cablelength long	Increases the pulse of a signal at the receiver and decreases the pulse from the transmitter using pulse equalization and line buildout for a T1 cable.
cablelength short	Sets a cable length of 655 feet or shorter for a DS1 link on the Cisco MC3810 or Cisco 2600 and Cisco 3600 series routers.

cablelength (E1 controller)

To fine-tune the pulse of a signal at the receiver for an E1 cable on a Cisco AS5300 or Cisco AS5400, use the **cablelength** command in controller configuration mode. To restore the default receiver sensitivity, use the **no** form of this command.

cablelength {**custom** *gain-value* [**squelch-on**] | **long** [**squelch-on**] | **medium** [**squelch-on**] | **short** [**squelch-on**]}
no cablelength

Syntax Description

custom	Fine-tunes the receiver sensitivity for long-haul, medium-haul, and short-haul applications.
gain-value	Custom gain value for the receiver in the range of 0x1 to 0x3F. These settings are mapped to values in the range of 0 to -45 dB.
long	Fine-tunes the receiver sensitivity for long-haul applications.
medium	Fine-tunes the receiver sensitivity for medium-haul applications.
short	Fine-tunes the receiver sensitivity for short-haul applications.
squelch-on	(Optional) Enables squelch to improve the signal-to-noise ratio.

Command Default

Default receiver sensitivity for E1 cables is applied.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(17)	This command was introduced.

Usage Guidelines

This command is supported on E1 controllers only.

Note The cable line pulse gain values are not dependent upon the E1 line being configured in balanced (120-ohm) mode or unbalanced (75-ohm) mode.

Examples

The following example shows how to fine-tune the receiver sensitivity for an E1 cable on a Cisco AS5300 to support a long-haul configuration:

```
Router(config-controller)# cablelength long squelch-on
```

cablelength long

To increase the pulse of a signal at the receiver and to decrease the pulse from the transmitter using pulse equalization and line build-out for a T1 cable, use the **cablelengthlong**command in controller configuration or interface configuration mode. To return the pulse equalization and line build-out values to their default settings, use the **no** form of this command.

cablelength long *db-gain-value db-loss-value*
no cablelength long

Syntax Description

db-gain-value	Number of decibels (dB) by which the receiver signal is increased. Use one of the following values: • **gain26** • **gain36** The default is 26 dB.
db-loss-value	Number of decibels by which the transmit signal is decreased. Use one of the following values: • **0db** • **-7.5db** • **-15db** • **-22.5db** The default is 0 dB.

Command Default

db-gain-value : **gain26** *db-loss-value*: **0db**

Command Modes

Controller configuration for the Cisco AS5800 and Cisco MC3810. Interface configuration for the Cisco 2600 and Cisco 3600 series routers.

Command History

Release	Modification
11.2	This command was introduced.
11.3	The following keywords were added: **gain26**, **gain36**, **0db**,**-7.5db**,**-15db**,**-22.5db**.
12.0(5)XK	This command was modified to include support as an ATM interface configuration command for the Cisco 2600 and Cisco 3600 series routers and as a controller configuration command for the Cisco AS5800 universal access server.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Cisco AS5800 and Cisco MC3810

Use this command for configuring the controller T1 interface on the Cisco AS5200 access server, on the Cisco AS5800 universal access server, or on the Cisco MC3810 multiservice access concentrator. The **cablelengthlong** command is used to configure DS1 links (meaning, to build CSU/DSU links) when the cable length is no longer than 655 feet.

On the Cisco MC3810, this command is supported on T1 controllers only and applies to Voice over Frame Relay, Voice over ATM, and Voice over HDLC.

Note On the Cisco MC3810, you cannot use the **cablelengthlong** command on a DSX-1 interface only. The **cablelengthlong** command can be used only on CSU interfaces.

A pulse equalizer regenerates a signal that has been attenuated and filtered by a cable loss. Pulse equalization does not produce a simple gain, but it filters the signal to compensate for complex cable loss. A **gain26** receiver gain compensates for a long cable length equivalent to 26 dB of loss, whereas a **gain36** compensates for 36 dB of loss.

The lengthening or *buildingout* of a line is used to control far-end crosstalk. Line build-out attenuates the stronger signal from the customer installation transmitter so that the transmitting and receiving signals have similar amplitudes. A signal difference of less than 7.5 dB is ideal. Line build-out does not produce simple flat loss (also known as *resistive* flat loss). Instead, it simulates a cable loss of 7.5 dB, 15 dB, or 22.5 dB so that the resulting signal is handled properly by the receiving equalizer at the other end.

Cisco 2600 and Cisco 3600 Series Routers

This command is supported on T1 long-haul links only. If you enter the **cablelengthlong** command on a DSX-1 (short-haul) interface, the command is rejected.

The transmit attenuation value is best obtained by experimentation. If the signal received by the far-end equipment is too strong, reduce the transmit level by entering additional attenuation.

Examples

Cisco AS5800 and Cisco MC3810

The following example shows how to increase the receiver gain by 36 decibels and decreases the transmitting pulse by 15 decibels for a long cable on a Cisco AS5800:

```
AS5800(config)# controller t1 0
AS5800(config-controller)# cablelength long gain36 -15db
```

The following example shows how to configure the cable length for controller T1 0 on a Cisco MC3810 to a decibel pulse gain of 36 decibels and a decibel pulse rate of -22.5 decibels:

```
MC3810(config)# controller t1 0
MC3810(config-controller)# cablelength long gain36 -22.5db
```

Cisco 2600 and Cisco 3600 Series Routers

On a Cisco 2600 or Cisco 3600 series router, the following example shows how to specify a pulse gain of 36 decibels and a decibel pulse rate of -7.5 decibels:

```
Router(config)#
 interface atm 0/2
Router(config-if)#
 cablelength long gain36 -7.5db
```

Related Commands

Command	Description
cablelength short	Sets a cable length of 655 feet or shorter for a DS1 link.

cablelength short

To set a cable length of 655 feet or shorter for a DS1 link on the Cisco MC3810, Cisco 2600, Cisco NCS 4200 series, and Cisco 3600 series routers, use the **cablelengthshort** command in controller configuration or interface configuration mode. To delete the **cablelengthshort** value, use the **no** form of this command.

cablelength short *length*
no cablelength short

Syntax Description

length	Specifies a cable length. Use one of the following values: • **133** --Specifies a cable length from 0 to 133 feet. • **266** --Specifies a cable length from 134 to 266 feet. • **399** --Specifies a cable length from 267 to 399 feet. • **533** --Specifies a cable length from 400 to 533 feet. • **655** --Specifies a cable length from 534 to 655 feet.

Command Default

The default is 133 feet for the Cisco AS5200 access server, Cisco AS5800 universal access server, and Cisco MC3810 multiservice access concentrator.

There is no default cable length for the Cisco 2600 and Cisco 3600 series routers.

Command Modes

Controller configuration for the Cisco AS5200 access server, Cisco AS5800 universal access server, and Cisco MC3810 multiservice access concentrator. Interface configuration for the Cisco 2600 and Cisco 3600 series routers.

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.0(5)XK	This command was modified to include support as an ATM interface command for the Cisco 2600 and 3600 series routers and as a controller configuration command for the Cisco AS5800 universal access server.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
XE 3.18SP	This command was integrated in the Cisco NCS 4200 Series. For Configuring MDL, by default setting of cablelength is short.

Usage Guidelines

Cisco AS5200 Access Server, Cisco AS5800 Universal Access Server, and Cisco MC3810 Multiservice Access Concentrator

On the Cisco MC3810, the **cablelengthshort** command is used to configure DSX-1 links when the cable length is 655 feet or less than 655 feet. On the Cisco MC3810, this command is supported on T1 controllers only.

Note On the Cisco MC3810, you cannot enter the **cablelengthshort** command on a CSU interface. The **cablelengthshort** command can be used only on DSX-1 interfaces.

Cisco 2600 and Cisco 3600 Series Routers

This command is supported on T1 short-haul links only. If you enter the **cablelengthshort** command on a long-haul interface, the command is rejected.

To set cable lengths longer than 655 feet, use the **cablelengthlong** command.

This command is supported on T1 controllers only.

Cisco AS5200 Access Server, Cisco AS5800 Universal Access Server, and Cisco MC3810 Multiservice Access Concentrator

The following example shows how to set the cable length to 266 for the T1 controller in slot 1 on dial shelf 0:

```
Router# configure terminal
Router(config)# controller t1 1/1/0
Router(config-controller)# cablelength short 266
Router(config-controller)# end
```

Cisco 2600 and Cisco 3600 Series Routers

On a Cisco 2600 or Cisco 3600 series router, the following example shows how to specify a cable length from 0 to 133 feet:

```
Router(config)#
 interface atm 0/2
Router(config-if)#
 cablelength short 133
```

Related Commands

Command	Description
cablelength long	Increases the pulse of a signal at the receiver and decreases the pulse from the sender using pulse equalization and line build-out.

card

To preprovision a router slot for an interface card, use the **card**command in global configuration mode. To remove the preprovisioning for a card, use the **no** form of this command.

card {*slot/subslot* | *slot/subslot/bay*} *card-type*
no card {*slot/subslot* | *slot/subslot/bay*} *card-type*

Cisco 10000 Series Router
card *slot/subslot* {**lchoc12-1** | **lgigethernet-l** | **1gigethernet-hh-1** | **loc12atm-1** | **loc12pos-1** | **1oc48dpt-pos-1** | **24che1t1-1** | **4chstm-1** | **4cht3-hh-1** | **4oc3atm-1** | **4oc3atm_lr-1** | **4jacket-1** | **6cht3-1** | **6oc3pos-1** | **8e3ds3-1** | **8e3ds3atm-1** | **8fastethernet-1** [**mode** {**e1** | **t1**}]*spa-type*}

Cisco uBR10012 Universal Broadband Router
card {*slot* {**2jacket-1** | **4jacket-1**} | *slot/subslot* | *slot/bay*} *card-type* [**license** *license*]
no card {*slot* | *slot/subslot* | *slot/bay*} *card-type* [**license** *license*]

Syntax Description

slot/subslot	Chassis slot and subslot for the card. The following are the valid values: • *slot* --1 to 8 • *subslot* --0 or 1
slot/subslot/bay	Chassis slot and subslot for the Cisco Wideband SIP, and the bay number in the SIP where the Cisco Wideband SPA is located. The following are the valid values: • *slot* --1 to 3 • *subslot* --0 or 1 (0 is always specified) • *bay* --0 (upper bay) or 1 (lower bay) **Note** The Cisco uBR10012 router running Cisco IOS Release 12.3(21)BC supports *slot/subslot/bay* option.
slot	(Cisco uBR10012 router) Chassis slot for the Cisco SPA Interface Processor (SIP). The valid value of the *slotis*1 or 3.

slot/subslot	(Cisco uBR10012 router) Chassis slot and subslot where the Cisco Cable line card, the Timing, Communication, and Control (TCC) card, Cisco Shared Port Adaptor (SPA), or the Half-Height Gigabit Ethernet (HHGE) line card is located. **Note** Effective with Cisco IOS Release 12.2(33)SCB, the SPA slot numbering is changed to *slot*/*subslot*. For the Cisco Cable line cards, the valid values are: • *slot* --5 to 8 • *subslot* --0 or 1 For the TCC card, the valid values are: • *slot* --1 or 2 • *subslot* --1 For the HHGE line card, the valid values are: • *slot* --3 or 4 • *subslot* --0 or 1 For the SPA, the valid values are: • *slot* --0 or 3 (for SIP-600) • *slot* --1 (for Wideband SIP) • *subslot* --0 to 3
slot/bay	(Cisco uBR10012 router) Chassis slot and bay where the Cisco Shared Port Adaptor (SPA) is located. For the SPA, the valid values are: • *slot* --1 or 3 (for SIP-600) • *slot* --1 (for Wideband SIP) • *bay* --0 to 3
license	(Cisco uBR10012 router) License supported on the card. For a list of license types supported on the card, see the second table below.
card-type	Type of card for which to preprovision the slot. For a list of the supported cards, which varies by platform, see the first table below.
lchoc12-1	Preprovisions a line card slot for a 1-Port Channelized OC-12/STM-4 line card.
lgigethernet-l	Preprovisions a line card slot for a 1-Port Gigabit Ethernet line card.
1gigethernet-hh-1	Preprovisions a line card slot for a 1-Port Gigabit Ethernet Half-Height line card.
loc12atm-1	Preprovisions a line card slot for a 1-Port OC-12 ATM line card.

loc12pos-1	Preprovisions a line card slot for a 1-Port OC-12 Packet over SONET line card.
1oc48dpt-pos-1	Preprovisions a line card slot for a 1-Port OC-48/STM-16 Packet over SONET line card.
2jacket-1	(Cisco uBR10012 router) Preprovisions a slot for the Cisco Wideband SPA Interface Processor (SIP).
24che1t1-1	Preprovisions a line card slot for a 24-Port Channelized E1/T1 line card.
4chstm-1	Preprovisions a line card slot for a 4-Port Channelized OC-3/STM-1 line card.
4cht3-hh-1	Preprovisions a line card slot for a 4-port Channelized Half-Height line card.
4jacket-1	(Cisco uBR10012 router) Preprovisions a slot for the Cisco SIP-600.
4jacket-1	Preprovisions a line card slot in the Cisco 10000 series router to accept a Cisco 10000 SIP-600.
4oc3atm-1	Preprovisions a line card slot for a 4-Port OC-3/STM-1 ATM line card with intermediate-reach optics.
4oc3atm_lr-1	Preprovisions a line card slot for a 4-Port OC-3/STM-1 ATM line card with long-reach optics.
6cht3-1	Preprovisions a line card slot for a 6-Port Channelized T3 line card.
6oc3pos-1	Preprovisions a line card slot for a 6-Port OC-3/STM-1 Packet over SONET line card.
8e3ds3-1	Preprovisions a line card slot for an 8-Port Unchannelized E3/T3 line card.
8e3ds3atm-1	Preprovisions a line card slot for an 8-Port E3/DS3 ATM line card.
8fastethernet-1	Preprovisions a line card slot for an 8-Port Fast Ethernet Half-Height line card.
mode {**e1**|**t1**}	Indicates the mode of operation of the 24-Port Channelized E1/T1 line card.
spa-type	SPA type to preprovision a SPA interface.

Command Default

An empty card slot is not preprovisioned and cannot be configured or displayed.

The default mode of operation for the 24-Port Channelized E1/T1 line card is E1.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(17)ST	This command was introduced on the Cisco 10000 series routers.
12.0(21)SX	This command was integrated into Cisco IOS Release 12.0(21)SX.
12.0(22)S	This command was integrated into Cisco IOS Release 12.0(22)S.

Release	Modification
12.2(1)XF1	This command was introduced on the Cisco uBR10012 Universal Broadband Router for the following line cards: • Cisco uBR-LCP-MC28C cable interface line card • Cisco uBR-LCP-MC28C-BNC cable interface line card • Cisco uBR10-1GE Gigabit Ethernet (GigE) uplink line card • Cisco uBR10-1OC12/P-SMI OC-12 POS uplink line card
12.2(4)XF1	Support was added for the Cisco uBR-LCP-MC16C and Cisco uBR-LCP-MC16E cable interface line cards.
12.2(4)BC1	Support was added for the Cisco uBR10-SRP-OC12SML DPT WAN uplink line card.
12.2(8)BC1	Support was added for the Cisco LCP2 line card processor, and all of its combinations with the supported cable interface line cards.
12.2(11)BC3	Support was added for the Cisco uBR10012 OC-48 DPT/POS Interface Module uplink line card and Cisco uBR-MC5X20S cable interface line card.
12.2(15)BX	This command was integrated into Cisco IOS Release 12.2(15)BX.
12.2(15)CX1	Support was added for the Cisco uBR-MC16U/X and Cisco uBR-MC28U/X cable interface line cards.
12.2(15)BC2	Support was added for the Cisco uBR-MC16U/X, Cisco uBR-MC28U/X, and Cisco uBR-MC5X20U cable interface line cards.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB. This command was modified to support the 4-port Channelized Half-Height line card and the 4-Port OC-3/STM-1 ATM line card with long-reach optics by adding the 4cht3-hh-1 and the 4oc3atm_lr-1 keywords.
12.3(7)XI1	This command was integrated into Cisco IOS Release 12.3(7)XI1.
12.3(21)BC	Support was added for the Cisco Wideband SIP and Wideband SPA.
12.2(33)SCA	This command was integrated into Cisco IOS Release 12.2(33)SCA. Support for the Cisco uBR7225VXR router was added.
12.2(33)SB	This command was enhanced to provide the 4jacket-1 keyword and the spa-type option, which enable you to preprovision a line card slot to accept a Cisco 10000 SIP-600 and a SPA interface, respectively. This enhancement was implemented on the Cisco 10000 series router for the PRE3 and PRE4.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB. Support for the Cisco SIP-600 was added. This command was modified to change the addressing format for: • SIPs--From *slot/subslottoslot* • SPAs--From *slot/subslot/baytoslot/bay*

Release	Modification
12.2(33)SCC	This command was modified to support the Cisco UBR-MC20X20V cable interface line card.
12.2(33)SCE	This command was modified to support the Cisco uBR-MC3GX60V cable interface line card.
12.2(33)SCH	This command was modified to support the Cisco 3 Gbps Wideband SPA card.

Usage Guidelines

This command is supported on the Cisco uBR10012 universal broadband router and the Cisco 10000 series routers.

Use this command to preprovision a slot in the router to accept a particular line card, so that you can configure the interface without the card being physically present in the chassis. This command allows system administrators to plan for future configurations, without having to wait for the physical hardware to arrive. When the line card does arrive, the installer can bring the card online by inserting the card into the chassis and connecting the necessary cables, without having to do any further configuration using the command-line interface.

The type of card must be appropriate for the slot being specified. The list of supported card types depends on the Cisco IOS software release in use and your platform. For the latest information about supported hardware for your platform, see the release notes that correspond to your Cisco IOS software release and platform.

The table below lists the types of cards that are supported as *card-types* for the **card** command.

Table 3: Card Types Supported by the card Command

Card Type	Description
lchoc12-1	(Cisco 10000 series router) Preprovisions a line card slot for a 1-Port Channelized OC-12/STM-4 line card.
1gigethernet-1	(Cisco 10000 series and Cisco uBR10012 routers) Preprovisions a slot for a Cisco uBR10-1GE Gigabit Ethernet (GigE) uplink line card.
1gigethernet-hh-1	(Cisco 10000 series router and Cisco uBR10012 routers) Preprovisions a line card slot for a 1-Port Gigabit Ethernet Half-Height line card.
loc12atm-1	(Cisco 10000 series router) Preprovisions a line card slot for a 1-Port OC-12 ATM line card.
1oc12pos-1	(Cisco 10000 series and Cisco uBR10012 routers) Preprovisions a slot for a Cisco uBR10-1OC12/P-SMI OC-12 POS uplink line card.
1oc48dpt-pos-1	(Cisco 10000 series and Cisco uBR10012 routers) Preprovisions a slot for a Cisco uBR10012 OC-48 DPT/POS Interface Module uplink line card.
2cable-tccplus	(Cisco uBR10012 router) Preprovisions a slot for a Timing, Control, and Communications Plus (TCC+) utility card. **Note** This option is informational only, because slots 1/1 and 2/1 can be used only for the TCC+ card.
24che1t1-1	(Cisco 10000 series router) Preprovisions a line card slot for a 24-Port Channelized E1/T1 line card.

Card Type	Description
2oc12srp-sm-lr	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-SRP-OC12SML DPT WAN uplink line card.
24rfchannel-spa-1	(Cisco uBR10012 router) Preprovisions a bay in the Cisco Wideband SIP for the Cisco 1-Gbps Wideband Shared Port Adapter (SPA).
4chstm-1	(Cisco 10000 series router) Preprovisions a line card slot for a 4-Port Channelized OC-3/STM-1 line card.
4cht3-hh-1	(Cisco 10000 series router) Preprovisions a line card slot for a 4-port Channelized Half-Height line card.
4oc3atm-1	(Cisco 10000 series router) Preprovisions a line card slot for a 4-Port OC-3/STM-1 ATM line card with intermediate-reach optics.
4oc3atm_lr-1	(Cisco 10000 series router) Preprovisions a line card slot for a 4-Port OC-3/STM-1 ATM line card with long-reach optics.
5cable-mc520h-d	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20H-D cable interface line card.
5cable-mc520s	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20S cable interface line card.
5cable-mc520s-d	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20S-D cable interface line card.
5cable-mc520u-d	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20U-D cable interface line card.
5cable-mc520u-f	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20U-F cable interface line card.
6cht3-1	(Cisco 10000 series router) Preprovisions a line card slot for a 6-Port Channelized T3 line card.
6oc3pos-1	(Cisco 10000 series router) Preprovisions a line card slot for a 6-Port OC-3/STM-1 Packet over SONET line card.
8e3ds3-1	(Cisco 10000 series router) Preprovisions a line card slot for an 8-Port Unchannelized E3/T3 line card.
8e3ds3atm-1	(Cisco 10000 series router) Preprovisions a line card slot for an 8-Port E3/DS3 ATM line card.
8fastethernet-1 mode {e1 | t1}	(Cisco 10000 series router) Preprovisions a line card slot for an 8-Port Fast Ethernet Half-Height line card and optionally specifies its mode of operation. E1 is the default.
ubr10k-clc-3g60	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR-MC3GX60V cable interface line card.

Card Type	Description
ubr10k-clc-mc2020v	(Cisco uBR10012 router) Preprovisions a slot for a Cisco UBR-MC20X20V cable interface line card.
ubr10k-clc-5x20s	(Cisco uBR10012 router) Preprovisions a slot for a Cisco uBR10-MC5X20S cable interface line card.
SPA-DOCSIS-HD-V1 {**1x10GE** | **3x1GE**}	(Cisco uBR10012 router) Preprovisions a bay in the Cisco SIP-600 for the Cisco 3 Gbps Wideband SPA card.

The license supported depends on the card being specified. The list of supported license types depends on the Cisco IOS software release in use and your platform. For the latest information about supported hardware for your platform, see the release notes that correspond to your Cisco IOS software release and platform.

The table below lists the license supported by a card.

Table 4: License Supported by a card

Card Type	License Supported	Description
Cisco UBR-MC20X20V	0X20	Zero downstream and 20 upstream
	10X20	10 downstream and 20 upstream
	15X20	15 downstream and 20 upstream
	20X20	20 downstream and 20 upstream
	5X20	5 downstream and 20 upstream
	invalid	Invalid license
Cisco uBR-MC3GX60V	0 to 72	Downstream license count
	none	No license
Cisco 3 Gbps Wideband SPA	none	No license
	0 to 71	Downstream license count
	72	Downstream license count

Cisco uBR10012 Universal Broadband Router Usage Guidelines

On the Cisco uBR10012 router, you can use the **card** command to preprovision a router slot for a line card or to preprovision one or more slots for a SPA interface processor (SIP), such as the Cisco Wideband SIP. You can also use the **card** command to preprovision a SIP bay or subslot for a SPA, such as the Cisco Wideband SPA or Cisco 3 Gbps Wideband SPA.

The Cisco uBR10012 universal broadband router has the following card slot requirements:

Note Slot 0/0 is an invalid value for this command.

- Slots 1/1 and 2/1 are reserved for TCC+ utility cards. A utility card and a SPA can co-exist on a Cisco uBR10012 router with an index of 1/1.
- Slots 1/0 through 4/0 are reserved for network uplink line cards.
- Slots 1 and 3 can be used for SIPs. Each SIP occupies two physical slots in a Cisco uBR10012 router (slot pair 1/2 or slot pair 3/4). Slot 1 is recommended for the Cisco Wideband SIP.
- Slot 5/0 through 8/1 are reserved for cable interface line cards.

Tip A preprovisioned card is displayed the same way as a card physically present in the chassis. Some **show** commands might also list the preprovisioned card in their displays. In addition, using the **card** command does not change the output of the ENTITY-MIB, which displays physically and logical components installed in the router.

When a line card is inserted in the Cisco uBR10012 chassis, the router performs the following actions, depending on whether the card slot is preprovisioned for the card:

- If the inserted line card matches the type of line card preprovisioned for the slot, the system applies the preprovisioned configuration to the line card.
- If the line card slot was not preprovisioned, the system applies a basic configuration to the line card and adds that configuration to the running configuration file.
- If the line card slot was preprovisioned for one type of line card, but another type of line card has been inserted, the system replaces the preprovisioned configuration (in the running configuration file) with a basic configuration for the line card that was actually inserted. The startup configuration file is not changed.

Tip Use the **showrunning-config|includecard**command to display which slots, if any, are preprovisioned for a particular card type.

The **noversionofthe**command removes the preprovisioning information from the given card slot. This also removes all configuration information for that card slot, as well as any information in the SNMP MIB database about the card and its card slot.

Cisco 10000 Series Router Usage Guidelines

You must specify a line card slot and subslot, and the line card for which you want to preprovision the line card slot.

If you insert a line card into a line card slot that has been preprovisioned for a different line card, the line card will fail.

You can specify a mode of operation for the 24-Port Channelized E1/T1 line card. If you do not, the line card operates in the E1 mode.

In Cisco IOS releases earlier than 12.0(28)S, 12.2(16)BX, and 12.3(7)XI1, you used only the card command to change the provisioning of a line card slot. It was not necessary to remove the old line card before using the card command to change the line card provisioning.

In Cisco IOS releases after 12.0(28)S, 12.2(16)BX, and 12.3(7)XI1, you must deactivate the installed line card using the hw-module and no card commands before using the card command to provision the line card slot for a different line card. This is a general best practice when using the **card** command.

Examples

Cisco uBR10012 Universal Broadband Router Examples

The following example shows a list of supported card types, and then shows that slot 8/0 is being preprovisioned for a Cisco uBR10-MC5X20S cable interface line card. The cable interface for slot 8/0/0 can then be configured.

```
Router# config t
Router(config)# card 8/0 ?

  5cable-mc520h-d     create a uBR10000 line card with MC520H-D
  5cable-mc520s       create a uBR10000 line card with MC520S
  5cable-mc520s-d     create a uBR10000 line card with MC520S-D
  5cable-mc520u-d     create a uBR10000 line card with MC520U-D
  5cable-mc520u-f     create a uBR10000 line card with MC520U
  ubr10k-clc-3g60     create a uBR10000 line card with MC3Gx60
  ubr10k-clc-5x20s    create a uBR10000 line card with MC520S
  ubr10k-clc-mc2020v  create a uBR10000 line card with MC20x20
Router(config)# card 8/0
ubr10k-clc-5x20s
Router(config)# int c8/0/0

Router(config-if)#
```

The following example shows how to preprovision a Cisco Wideband SIP:

```
Router# configure terminal
Router(config)# card 1 2jacket-1
```

The following example shows how to preprovision a Cisco Wideband SPA on a Cisco Wideband SIP:

```
Router# configure terminal
Router(config)# card 1/0 24rfchannel-spa-1
```

The following example shows how to preprovision a Cisco SIP-600:

```
Router# configure terminal
Router(config)# card 3 4jacket-1
```

The following example shows how to preprovision a Cisco Wideband SPA on a Cisco SIP-600:

```
Router# configure terminal
Router(config)# card 3/0 24rfchannel-spa-1
```

The following example shows how to preprovision a Cisco 3 Gbps Wideband SPA on a Cisco SIP-600:

```
Router# configure terminal
Router(config)# card 1/0 SPA-DOCSIS-HD-V1 1x10GE license 1
```

Cisco 10000 Series Router Examples

The following example preprovisions line card slot 2 to accept a 24-Port Channelized E1/T1 line card operating in E1 mode:

```
Router(config)# card 2/
0 24che1t1-1
 mode e1
```

The following example shows how to change the provisioning for line card slot 5 from the 1-Port Gigabit Ethernet Half-Height line card to the 4-Port OC-3/STM-1 ATM line card.

```
Router(config)# hw-module subslot 5/0 shut
Aug 22 21:52:19.619 UTC: %IPCOIR-3-TIMEOUT: Timeout waiting for a response from slot 5/0.
Aug 22 21:52:19.619 UTC: %IPCOIR-2-CARD_UP_DOWN: Card in slot 5/0 is down.  Notifying
1gigethernet-hh-1 driver.
Aug 22 21:52:21.627 UTC: %LINK-3-UPDOWN: Interface GigabitEthernet5/0/0, changed state to
down
Aug 22 21:52:22.627 UTC: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet5/0/0,
 changed state to down
Router(config)# no card 5/0 1gigethernet-hh-1
Aug 22 21:53:20.008 UTC: %C10K-3-DEACTIVATED: card in slot [5/0] disabled.
Router(config)# card 5/0 4oc3atm-1
[ Remove the 1-Port Gigabit Ethernet Half-Height line card and
insert the 4-Port OC-3/STM-1 ATM line card ]
```

Related Commands

Command	Description
show interface	Displays the current configuration and status for a specified interface type.

card type (T1-E1)

To configure a T1 or E1 card type, use the **cardtype** command in global configuration mode. To deselect the card type on non-SPA platforms, use the **no** form of this command. The no form of this command is not available on the SPA platforms.

card type {**t1** | **e1**} *slot* [*bay*]
no card type {**t1** | **e1**} *slot* [*bay*]

Channelized T1/E1 Shared Port Adapters
card type {**t1** | **e1**} *slot* *subslot*

Syntax Description

t1	Specifies T1 connectivity of 1.544 Mbps through the telephone switching network, using AMI or B8ZS coding.
e1	Specifies a wide-area digital transmission scheme used predominantly in Europe that carries data at a rate of 2.048 Mbps.
slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
bay	(Optional) Card interface bay number in a slot (route switch processor [RSP] platform only). This option is not available on other platforms.
subslot	(Channelized T/E1 Shared Port Adapters Only) Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.

Command History

Release	Modification
12.0(5)XE	This command was introduced.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.3(1)	This command was integrated into Cisco IOS Release 12.3(1) and support was added for Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 platforms.
12.2S	This command was integrated into Cisco IOS Release 12.2S.

Release	Modification
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series.

Usage Guidelines

Changes made using this command on non-SPA platforms, do not take effect unless the **reload** command is used or the router is rebooted.

Channelized T1/E1 Shared Port Adapters

There is no card type when the SPA is inserted for first time. The user must configure this command before they can configure individual ports.

The no form of this command is not available on the SPA platforms. To change an existing card type on SPA platforms, perform the following steps:

1. Remove the SPA from its subslot.
2. Save the configuration.
3. Reboot the router.
4. Insert the new SPA into the subslot.
5. Configure the new card using this command.

Examples

The following example configures T1 data transmission on slot 1 of the router:

```
Router(config)# card type t1 1
```

The following example configures all ports of an 8-Port Channelized T1/E1 SPA, seated in slot 5, subslot 2, in T1 mode:

```
Router(config)# card type t1 5 2
```

card type (T3-E3)

To configure a T3 or E3 card type, use the **cardtype** command in global configuration mode. To deselect the card type, use the **no** form of this comand. The no form of this command is not supported on the 2-Port and 4-Port Clear Channel T3/E3 SPA on Cisco 12000 series routers.

T3 or E3 Controllers
card type {**t3** | **e3**} *slot*
no card type {**t3** | **e3**} *slot*

Clear Channel T3/E3 Shared Port Adapters
card type {**t3** | **e3**} *slot subslot*
no card type {**t3** | **e3**} *slot subslot*

Clear Channel T3/E3 Shared Port Adapters on Cisco 12000 Series Routers
card type {**t3** | **e3**} *slot subslot*

Syntax Description

t3	Specifies T3 connectivity of 44210 kbps through the network, using B8ZS coding.
e3	Specifies a wide-area digital transmission scheme used predominantly in Europe that carries data at a rate of 34010 kbps.
slot	Slot number of the interface.
subslot	(Clear Channel T3/E3 Shared Port Adapters Only) Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.

Command Default

No default behavior or values.

Command History

Release	Modification
12.1(1)T	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.3(1)	This command was integrated into Cisco IOS Release 12.3(1) and support was added for Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 platforms.
12.2S	This command was integrated into Cisco IOS Release 12.2S.

Release	Modification
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Usage guidelines vary slightly from platform to platform as follows:

T3 or E3 Controllers

Once a card type is issued, you enter the **nocardtype** command and then another **cardtype** command to configure a new card type. You must save the configuration to the NVRAM and reboot the router in order for the new configuration to take effect.

When the router comes up, the software comes up with the new card type. Note that the software will reject the configuration associated with the old controller and old interface. You must configure the new controller and serial interface and save it.

Clear Channel T3/E3 Shared Port Adapters

To change all the SPA ports from T3 to E3, or vice versa, you enter the **nocardtype** command and then another **cardtype** command to configure a new card type.

When the router comes up, the software comes up with the new card type. Note that the software will reject the configuration associated with the old controller and old interface. You must configure the new controller and serial interface and save it.

Clear Channel T3/E3 Shared Port Adapters on Cisco 12000 Series Routers

The no form of this command is not available on the 2-Port and 4-Port Clear Channel T3/E3 SPA on Cisco 12000 series routers. To change an existing card type on Cisco 12000 series routers, perform the following steps:

1. Remove the SPA from its subslot.
2. Save the configuration.
3. Reboot the router.
4. Insert the new SPA into the subslot.
5. Configure the new card using this command.

Examples

The following example shows T3 data transmission configured in slot 1:

```
Router(config)# card type t3 1
```

The following example configures all ports of 2-Port and 4-Port Clear Channel T3/E3 SPA, seated in slot 5, subslot 2, in T3 mode:

```
Router(config)# card type t3 5 2
```

Related Commands

Command	Description
controller	Configures a T3 or E3 controller and enters controller configuration mode.
reload	Reloads the operating system.
show interface serial	Displays the serial interface type and other information.

card-protection

Use this command to configure card protection that protects traffic when the interface module is out of service, there is any software failure, or any hardware issues.

Card Protection Creation Commands:

card-protection *CPGN*

card-protection {*primary* | *backup*}

card-protection *revertive time*

Card Protection Maintenance Commands:

card-protection *CPGN* [**manual** {*primary* | *backup*} | **force** {*primary* | *backup*} | **lockout**]

Use **no card-protection** *CPGN* [**manual** {*primary* | *backup*} | **force** {*primary* | *backup*} | **lockout**] command to remove the configuration.

Syntax Description

Syntax Description:

CPGN	The card protection number 1 to 16 refers to the Card Protection Group Number (CPGN).
primary	Configures the primary card in card protection.
backup	Configures the backup card in card protection.
revertive time (Optional)	Configures card protection in revertive mode. The value ranges from 30 seconds to 720 seconds.
manual	Configures manual switch on primary or backup card in card protection. Traffic switches to selected card if there is no fault condition on that card.
force	Configures force switch on primary or backup card in card protection. Traffic switches to selected card, even if there is a fault on the card.
lockout	Configures lockout on backup card in card protection. Prevents card protection switching and forces traffic to remain on the primary card.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.7.1	This command was integarted into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

For the **manual** option, traffic switches to selected card if there is no fault condition on that card. It has lower priority than alarm and card failure. For the **force** option, traffic switches to selected card if there is fault condition. It has higher priority than manual, alarms and card failure. For the **lockout** option, it prevents card protection switching and forces traffic to remain on the primary card. The **revertive time** option has the lowest priority.

Examples

```
enable
configure terminal
card-protection [1-16]
primary slot 0 bay 0
backup slot 0 bay 5
end
card-protection 4
card-protection [manual {backup|primary} | force {backup|primary} | lockout]
end
```

Related Commands

Command	Description
show card-protection CPGN detail	Verifies the card protection configuration.

carrier-delay

To modify the default carrier delay time on a main physical interface, use the **carrier-delay** command in interface configuration or template configuration mode. To return to the default carrier delay time, use the **no** form of this command.

Conventional Carrier Delay
carrier-delay {*seconds* | **msec** *milliseconds*}
no carrier-delay

Asymmetric Carrier Delay for SIP-200- and SIP-400-Based WAN Cards on Cisco ASR 1000 Series Aggregation Services Routers
carrier-delay [{**up** | **down**}] {*seconds* | **msec** *milliseconds*}
no carrier-delay [{**up** | **down**}]

Syntax Description

seconds	For Conventional Carrier Delay: • Specifies the carrier transition delay, in seconds. The range is from 0 to 60. The default is 2. For Asymmetric Carrier Delay: • In SIP-200- and SIP-400-based WAN cards, *seconds* indicate the unit use for configuration.
msec *milliseconds*	For Conventional Carrier Delay: • Specifies the carrier transition delay, in milliseconds. The range is from 0 to 1000. For Asymmetric Carrier Delay: • In SIP-200- and SIP-400-based WAN cards, **msec** *milliseconds* indicate the unit use for configuration.
up	(Optional) Indicates that the carrier-delay configuration is for up link.
down	(Optional) Indicates that the carrier-delay configuration is for down link

Command Default

The default carrier delay (conventional) is 2 seconds.

Template configuration (config-template)

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SRD	This command was modified. The **up** and **down** keywords were added.
12.2(33)SXI	This command was modified. Support for the **up** and **down** keywords was added.
Cisco IOS XE Release 2.3	This command was modified. Support for Cisco ASR 1000 Series Aggregation Services Routers was added.
15.2(2)E	This command was integrated into Cisco IOS Release 15.2(2)E. This command is supported in template configuration mode.
Cisco IOS XE Release 3.6E	This command was integrated into Cisco IOS XE Release 3.6E. This command is supported in template configuration mode.
Cisco IOS XE Fuji 16.8.x	The **up** and **down** keywords were added to the **no** form of the command

Usage Guidelines

The default carrier transition delay is 10 milliseconds on all Ethernet interfaces. This enables the carrier-delay time to ensure fast link detection.

Conventional Carrier Delay

If a link goes down and comes back before the carrier delay timer expires, the down state is effectively filtered, and the rest of the software on the router is not aware that a link-down event has occurred. Therefore, a large carrier delay timer results in fewer link-up/link-down events being detected. However, setting the carrier delay time to 0 means that *every* link-up/link-down event is detected.

In most environments a lower carrier delay is better than a higher one. The exact value that you choose depends on the nature of the link outages that you expect in your network and how long you expect those outages to last.

If data links in your network are subject to short outages, especially if those outages last less than the time required for your IP routing to converge, you should set a relatively long carrier delay value to prevent these short outages from causing disruptions in your routing tables. If outages in your network tend to be longer, you might want to set a shorter carrier delay so that the outages are detected sooner and the IP route convergence begins and ends sooner.

The following restrictions apply to carrier delay configuration:

- The Fast Link and Carrier Delay features are mutually exclusive. If you configure one feature on an interface, the other is disabled automatically.
- Administrative shutdown of an interface will force an immediate link-down event regardless of the carrier delay configuration.

Asymmetric Carrier Delay

Cisco IOS releases that support the **up** and **down** keywords allow asymmetric carrier delay (ACD) configuration. ACD allows you to configure separate delay times for link-up and link-down event notification on physical interfaces that support ACD, such as the SIP-200- and SIP-400-based interfaces. With ACD, link-up and link-down events can be notified with different delay times.

The following restrictions apply to ACD configurations:

- You cannot configure ACD on an interface if conventional carrier delay (the **carrier-delay** command without an **up** or **down** keyword) is configured on the interface.
- Link-down and link-up carrier delay times are configured in milliseconds, using the **msec** keyword, or in seconds.

Asymmetric carrier delay is supported by the following Ethernet Shared Port Adapters (SPA)s on Cisco ASR 1000 Series Aggregation Services Routers:

- SPA-1X10GE-L-V2
- SPA-2X1GE-V2
- SPA-4X1FE-TX-V2
- SPA-5X1GE-V2
- SPA-8X1GE-V2
- SPA-8X1FE-TX-V2
- SPA-10X1GE-V2

Examples

The following example shows how to change the carrier delay to 5 seconds:

```
Router(config)# interface serial2/3/0
Router(config-if)# carrier-delay 5
```

The following example shows how to change the carrier delay to 5 seconds for an interface template:

```
Device# configure terminal
Device(config)# template user-template1
Device(config-template)# carrier-delay 5
Device(config-template)# end
```

Asymmetric Carrier Delay

The following example shows how to configure a carrier delay of 8 seconds for link-up transitions and 50 milliseconds for link-down transitions:

```
Router(config)# interface GigabitEthernet2/0/0
Router(config-if)# carrier-delay up 8
Router(config-if)# carrier-delay down msec 50
```

The following example shows the output of the **show interfaces** command after the **carrier-delay** command is configured on the Gigabit Ethernet interface:

```
Router# show interfaces GigabitEthernet 0/1/0

GigabitEthernet0/1/0 is up, line protocol is up
  Hardware is SPA-8X1GE-V2, address is 001a.3046.9410 (bia 001a.3046.9410)
  MTU 1500 bytes, BW 1000000 Kbit/sec, DLY 10 usec,
```

```
   reliability 255/255, txload ½55, rxload ½55
Encapsulation ARPA, loopback not set
Keepalive not supported
Full Duplex, 1000Mbps, link type is auto, media type is 1000BaseBX10U
output flow-control is on, input flow-control is on
Asymmetric Carrier-Delay Up Timer is 4 sec
Asymmetric Carrier-Delay Down Timer is 500 msec

   0 output buffer failures, 0 output buffers swapped out
```

cem

To enter circuit emulation (CEM) configuration mode, use the **cem** command in global configuration mode.

cem *slot/port/channel*

Syntax Description

slot	Slot number in which the Circuit Emulation over IP (CEoIP) network module (NM) is installed on the networking device.
/ *port*	Port number on the CEoIP NM. The slash mark is required between the *slot* argument and the *port* argument.
/ *channel*	Channel number that identifies the channel that you want to configure (T1/E1 only). The channel number on a serial port is always 0. The slash mark is required between the *port* argument and the *channel* argument.

Command Default

CEM configuration mode is not available.

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
XE 3.18SP	This command was integrated on Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated on Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

Use this command to enter CEM configuration mode to allow the configuration of all CEM options.

Examples

The following example shows how to enter CEM configuration mode:

```
Router(config)# cem 1/2/0
Router(config-cem)#
```

Related Commands

Command	Description
clear cem	Clears CEM statistics.
show cem	Displays CEM statistics.

cem-group

To create a circuit emulation (CEM) channel from one or more time slots of a T1 or E1 line of an NM-CEM-4TE1 network module, use the **cem-group** command in controller configuration mode. To remove a CEM group and release the associated time slots, use the **no** form of this command.

cem-group *group-number* {**unframed** | **timeslots** *time-slot-range* [**speed** *kbps*]}
no cem-group *group-number*

cem-group *group-number* **framed**

Syntax Description

For NCS 4200 Series:

cem-group *cem-group-number* **cep**

group-number	Channel number to be used for this group of time slots. • For T1 ports, the range is from 0 to 23. • For E1 ports, the range is from 0 to 30. • For 4xC37.94 interface, only 0 group-number is supported.
unframed	Specifies that a single CEM channel is being created including all time slots and the framing structure of the line.
framed	Specifies that a single CEM channel is being created including all the timeslots and framing configured.
timeslots	Specifies that a list of time slots is to be used as specified by the *time-slot-range* argument.
time-slot-range	List of the time slots to be included in the CEM channel. The list may include commas and hyphens with no spaces between the numbers. The range of time slots supported for 4xC37.94 interface is from 1 to 12.
speed	(Optional) Specifies the speed of the channels by specifying the number of kbps of each time slot to be used. This keyword applies only to T1 channels.
kbps	(Optional) Speed of the channel, in kbps. Must be one of the following: • **56** --Specifies a speed of 56 kbps where only the seven most significant bits (MSBs) of each eight-bit time slot are used. • **64** --Specifies a speed of 64 kbps where all eight bits of each eight-bit time slot are used.
cep	Configures Circuit Emulation Service over Packet (CEP) mode.

Command Default

No CEM groups are defined.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
15.1(2)SNH	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.
XE Everest 16.5.1	This command was implemented on the Cisco ASR 920 Routers and Cisco NCS 4200 Series.
XE Fuji 16.8.x	The framed keyword was introduced for Cisco ASR 900 Routers and Cisco NCS 4200 Series Routrers.

Usage Guidelines

Use this command to create CEM channels on the T1 or E1 network module, NM-CEM-4TE1. A maximum of 64 channels may be created on an NM-CEM-4TE1.

Examples

The following example shows how to create circuit emulation group number 0 with a single CEM channel including all time slots and the framing structure of the line on an NM-CEM-4TE1.

```
Router(config-controller)# cem-group 0
 unframed
```

The following example shows how to create circuit emulation channel number 6 with T1 channel time slots one through four, nine, and ten using all eight bits of each time slot on an NM-CEM-4TE1.

```
Router(config-controller)# cem-group 6 timeslots 1-4,9,10
 speed 64
```

Examples

For NCS 4200 Series routers, the following example shows the configuration of CEP:

```
enable
configure terminal
controller Mediatype 0/5/0
controller sonet 0/5/0
sts-1 1
mode unframed
cem-group 100 cep
end
```

Examples

For 4-Ports C37.94 interface module, the following example shows the configuration:

```
enable
configure terminal
controller c3794 0/0/0
timeslots3
end
```

Examples

To configure framed SAToP:

```
enable
configure terminal
controller mediatype 0/5/0
mode sonet
controller sonet 0/5/0
cem-group0 framed
end
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
show cem circuit	Displays the CEM statistics for the configured CEM circuits.

channel-group

To configure serial WAN on a T1 or E1 interface, use the **channel-group** command in controller configuration mode. To clear a channel group, use the **no** form of this command.

Cisco 2600 Series
channel-group *channel-group-number* **timeslots** *range* [**speed** {**56** | **64**}] [**aim** *aim-slot-number*]
no channel-group *channel-group-number*

Cisco 2611 (Cisco Signaling Link Terminal [SLT])
channel-group *channel-number*
no channel-group *channel-number*

Cisco ASR 901 Series, Cisco 2600XM Series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745
channel-group *channel-group-number* {**timeslots** *range* [**speed** {**56** | **64**}] | **unframed**} [**aim** *aim-slot-number*]
no channel-group [*channel-group-number* **timeslots** *range*]

Cisco AS5350 and Cisco AS5400 Series
channel-group *channel-group-number*
no channel-group *channel-group-number*

Cisco MC3810
channel-group *channel-number* **timeslots** *range* [**speed** {**56** | **64**}]
no channel-group [*channel-number* **timeslots** *range*]

Syntax Description

channel-group-number	Channel-group number on the Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers. When a T1 data line is configured, channel-group numbers can be values from 0 to 23. When an E1 data line is configured, channel-group numbers can be values from 0 to 30. Valid values can be 0 or 1 on the Cisco AS5350 and Cisco AS5400.
timeslots *range*	Specifies one or more time slots separated by commas, and spaces or ranges of time slots belonging to the channel group separated by a dash. The first time slot is numbered 1. • For a T1 controller, the time slots range from 1 to 24. • For an E1 controller, the time slots range from 1 to 31. You can specify a time slot range (for example, 1-29), individual time slots separated by commas (for example 1, 3, 5), or a combination of the two (for example 1-14, 15, 17-31). See the "Examples" section for samples of different timeslot ranges.

speed {**56**|**64**}	(Optional) Specifies the speed of the underlying DS0s in kilobits per second. Valid values are 56 and 64. The default line speed when configuring a T1 controller is 56 kbps on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and Cisco MC3810. The default line speed when configuring an E1 controller is 64 kbps on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and Cisco MC3810. The line speed controls real-time (VBR-RT) traffic shaping, and the maximum burst size (MBS) is 255 cells.
aim *aim-slot-number*	(Optional) Directs HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 digital signaling processor (DSP) card on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.
channel-number	Number of the channel. Valid values can be 0 or 1 on the Cisco SLT (Cisco 2611).
unframed	Specifies the use of all 32 time slots for data. None of the 32 time slots is used for framing signals on the Cisco ASR 901 Series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745. This keyword is applicable to E1 only.

Command Default

The T1/E1 line is connected to the Motorola MPC-860x processor serial communication controller (SCC) or network module with two voice or WAN interface card (VIC or WIC) slots and 0/1/2 FastEthernet ports DSCC4 by default on Cisco 2600 series, Cisco 2600XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers.

There is no default behavior or values on the Cisco SLT (Cisco 2611).

The serial interface object encapsulation is set to HDLC on a network access server (NAS) (Cisco AS5350 and Cisco AS5400 series routers).

The default line speed is 56 kbps when a T1 controller is configured on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810.

The default line speed is 64 kbps when an E1 controller is configured on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, Cisco 3745, and the Cisco MC3810.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
11.3MA	This command was introduced on the Cisco MC3810.
12.0	This command was integrated into Cisco IOS Release 12.0 on the Cisco MC3810.
12.0(7)XE	This command was implemented on the Catalyst 6000 family switches.
12.1(1)E	This command was integrated into Cisco IOS Release 12.1(1)E.

Release	Modification
12.1(1)T	This command was modified to accommodate two channel groups on a port on 1- and 2-port T1/E1 multiflex voice or WAN interface cards on the Cisco 2600 and Cisco 3600 series routers.
12.1(3a)E3	The number of valid values for the *kbps*argument was changed on the Cisco MC3810; see the "Usage Guidelines" section for valid values.
12.2(11)T	This command was implemented on the Cisco AS5350 and Cisco AS5400.
12.2(15)T	The **aim** keyword was added for use on the Cisco 2600 series (including the Cisco 2691), Cisco 2600XM, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(1)	The **unframed** keyword was added for use on the Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.4(3)S	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Use this command to direct HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card. A channel group is created using Advanced Integration Module (AIM) HDLC resources when a **channel-group** command with the **aim** keyword is parsed during system initialization or when the command is entered during configuration. You must specify the **aim** keyword under a T1/E1 controller port to direct HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card on the Cisco 2600 series, Cisco 2600XM series, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745.

Note Neither the Cisco AS5400 series NAS nor the Cisco MC3810 is supported with the integrated voice and data WAN on T1/E1 interfaces using the AIM-ATM-VOICE-30 module.

If previous **channel-group** commands are configured with the **aim** keyword, subsequent **channel-group** commands without the **aim** keyword are rejected. Similarly, if a regular **channel-group** command is followed by another **channel-group** command with the **aim** keyword implemented, the second command is rejected on the Cisco 2600 and Cisco 2600XM.

A channel group using AIM HDLC resources is deleted only when a **nochannel-group** command is entered.

By default, the**channel-group** command on a NAS sets the serial interface object encapsulation to HDLC. You must override the default by entering the **encapsulationss7** command for that serial interface object. Once you override the default, encapsulation cannot be changed again for that object. The SS7 encapsulation option is new to the Integrated Signaling Link Terminal feature and is available only for interface serial objects created by the**channel-group** command. The Integrated Signaling Link Terminal feature added SLT functionality on Cisco AS5350 and Cisco AS5400 platforms.

A digital SS7 link can be deleted by entering the **nochannel-group***channel-group-number* command on the associated T1/E1 controller. The link must first be stopped using the **noshutdown** command. It is not necessary to remove the channel ID association first.

Use the **channel-group** command in configurations where the router or access server must communicate with a T1 or E1 fractional data line. The channel group number may be arbitrarily assigned and must be unique for the controller. The time-slot range must match the time slots assigned to the channel group. The service provider defines the time slots that comprise a channel group.

Note Channel groups, channel-associated signaling (CAS) voice groups, DS0 groups, and time-division multiplexing (TDM) groups all use group numbers. All group numbers configured for channel groups, CAS voice groups, and TDM groups must be unique on the local Cisco MC3810 concentrator. For example, you cannot use the same group number for a channel group and for a TDM group. Furthermore, on the Cisco MC3810, only one channel group can be configured on a controller.

The channel group number can be 0 or 1 on the Cisco SLT (Cisco 2611).

The **channel-group** command also applies to Voice over Frame Relay, Voice over ATM, and Voice over HDLC on the Cisco MC3810.

Examples

The following example shows basic configuration directing HDLC traffic from the T1/E1 interface to the AIM-ATM-VOICE-30 DSP card, starting in global configuration mode:

```
Router(config)# controller e1 1/0
Router(config-controller)# clock source internal
Router(config-controller)# channel-group 0 timeslots 1-31 aim 0
```

The following example explicitly sets the encapsulation type to PPP to override the HDLC default:

```
Router# configure terminal
Router(config)# controller t1 6/0
Router(config-controller)# channel-group 2 timeslots 3 aim 0
Router(config-controller)# exit
Router(config)# interface serial 6/0:2
Router(config-if)# encapsulation ppp
Router(config-if)# ip address 10.0.0.1 255.0.0.0
Router(config-if)# no shutdown
Router(config-if)# end
```

The following example shows how to explicitly set the encapsulation type to SS7 to override the HDLC default using the Integrated Signaling Link Terminal feature. This example uses an 8PRI DFC card inserted into slot 7, and DS0-timeslot 3 on trunk 5 of that card is used as an SS7 link:

```
Router# configure terminal
Router(config)# controller t1 7/5
Router(config-controller)# channel-group 2 timeslots 3
Router(config-controller)# exit
Router(config)# interface serial 7/5:2
Router(config-if)# encapsulation ss7
Router(config-if)# channel-id 0
Router(config-if)# no shutdown
Router(config-if)# end
```

The following example defines three channel groups. Channel-group 0 consists of a single time slot, channel-group 8 consists of seven time slots and runs at a speed of 64 kbps per time slot, and channel-group 12 consists of two time slots.

```
Router(config-controller)# channel-group 0 timeslots 1
Router(config-controller)# channel-group 8 timeslots 5,7,12-15,20 speed 64
Router(config-controller)# channel-group 12 timeslots 2
```

The following example configures a channel group on controller T1 0 on a Cisco MC3810:

```
Router(config)# controller T1 0
Router(config-controller)# channel-group 10 timeslots 10-64
```

The following example configures a channel group on controller E1 1 and specifies that all time slots are used for data:

```
controller e1 1
channel-group 1 unframed
```

Note SS7 digital F-link support for the 8PRI line card requires use of a third onboard TDM stream to route trunk DS0 messages to the onboard MGCs.

Related Commands

Command	Description
framing	Specifies the frame type for the T1 or E1 data line.
invert data	Enables channel inversion.
linecode	Specifies the line code type for the T1 or E1 line.
voice-card	Configures a card with voice processing resources and enters voice card configuration mode.
encapsulation	Sets the encapsulation type.

channel-group (interface)

To assign and configure an EtherChannel interface to an EtherChannel group, use the **channel-group** command in interface configuration mode. To remove the channel-group configuration from the interface, use the **no** form of this command.

channel-group *channel-group-number* **mode** {**active** | **on** | **passive**}
no channel-group *channel-group-number*

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers
channel-group *channel-group-number* **mode on**
no channel-group *channel-group-number*

Cisco ASR 1000 Series Routers
channel-group *channel-group-number* **mode** {**active** | **passive**}
no channel-group

Cisco Catalyst Switches
channel-group *channel-group-number* **mode** {**active** | **on** | **auto** [**non-silent**] | **desirable** [**non-silent**] | **passive**}
no channel-group *channel-group-number*

Syntax Description

channel-group-number	Integer that identifies the channel-group. Valid values are from 1 to 256; the maximum number of integers that can be used is 64. • For Fast EtherChannel groups, the number is an integer from 1 to 4. This number is the one previously assigned to the port-channel interface. • On the Cisco ASR 1000 series router, valid values are from 1 to 64.
mode	Specifies the EtherChannel mode of the interface.
active	Enables Link Aggregation Control Protocol (LACP) unconditionally.
on	Enables EtherChannel only.
auto	Places a port into a passive negotiating state in which the port responds to Port Aggregation Protocol (PAgP) packets that it receives but does not initiate PAgP packet negotiation.
non-silent	(Optional) Used with the **auto** or **desirable** mode when traffic is expected from the other device.
desirable	Places a port into an active negotiating state in which the port initiates negotiations with other ports by sending PAgP packets.
passive	Enables LACP only when an LACP device is detected.

Command Default

No channel groups are assigned.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.1CA	This command was introduced.
12.0(7)XE	Support for this command was implemented on Cisco Catalyst 6000 series switches.
12.1(3a)E3	The number of valid values for the *number*argumentwas changed; see the "Usage Guidelines" section for valid values.
12.2(2)XT	This command was implemented on the Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	Support for this command was implemented on the Cisco 2600 series, the Cisco 3600 series, and the Cisco 3700 series routers and integrated into Cisco IOS Release 12.2(8)T .
12.2(14)SX	Support for this command was implemented on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was integrated into Cisco IOS Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed to support advanced QinQ translation on QinQ link bundles using GE-WAN interfaces on an OSM-2+4GE-WAN+ OSM on Cisco 7600 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	Support for this command on the Cisco 7600 router was integrated into Cisco IOS Release 12.2(33)SRB.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.

Usage Guidelines

OSMs are not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

IP Address for the Physical Interface

You do not have to disable the IP address that is assigned to a physical interface that is part of a channel group, but Cisco highly recommends doing so.

Layer 2 and Layer 3 Port Channels

You can create both Layer 2 and Layer 3 port channels by entering the **interface port-channel** command or, when the channel-group gets its first physical interface assignment. The port channels are not created at run time, nor are they created dynamically.

You do not have to create a port-channel interface before assigning a physical interface to a channel group. A port-channel interface is automatically created when the channel group gets its first physical interface, if it is not already created.

Propagation of Configuration and Attribute Changes

Any configuration or attribute changes you make to the port-channel interface are propagated to all interfaces within the same channel group as the port channel. (for example, configuration changes are also propagated to the physical interfaces that are not part of the port-channel, but are part of the channel group.)

The on Keyword

When you use the **on** keyword, a usable EtherChannel exists only when a port group in on mode is connected to another port group in the on mode.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

You do not have to create a port-channel interface before assigning a physical interface to a channel group. A port-channel interface is created automatically when the channel group gets its first physical interface, if it is not already created.

Cisco ASR 1000 Series Routers

The Cisco ASR 1000 series router has the following prerequisites and restriction:

- A port-channel must be created before member links are assigned to it.
- IP addresses must be disabled on member links before those links can be included in a port-channel.
- Fast Ethernet interfaces are not supported.

Cisco Catalyst Switches

The number of valid values for *number*depends on the software release. For software releases prior to Cisco IOS Release 12.1(3a)E3, valid values are from 1 to 256; for Cisco IOS Release 12.1(3a)E3, 12.1(3a)E4, and 12.1(4)E1, valid values are from 1 to 64. Cisco IOS Release 12.1 E and later releases support a maximum of 64 values ranging from 1 to 256.

The channel-group number is global and is shared between all the channeling protocols. If a specific channel number is used for the PAgP-enabled interfaces of a channel group, that same channel number cannot be used for configuring a channel that has LACP-enabled interfaces or vice versa.

Entering the **auto** or **desirable** keyword enables PAgP on the specified interface; the command will be rejected if it is issued on an LACP-enabled interface.

The **active** and **passive** keywords are valid on PAgP-disabled interfaces only.

You can change the mode for an interface only if it is the only interface that is designated to the specified channel group.

The **on** keyword forces the bundling of the interface on the channel without any negotiation.

You can manually configure a switch with PAgP on one side and LACP on the other side in the **on** mode.

With the **on** mode, a usable EtherChannel exists only when a port group in **on** mode is connected to another port group in **on** mode.

If you enter the **channel group** command on an interface that is added to a channel with a different protocol than the protocol you are entering, the command is rejected.

If the interface belongs to a channel, the **no** form of this command is rejected.

All ports in the same channel group must use the same protocol; you cannot run two protocols on one channel group.

PAgP and LACP are not compatible; both ends of a channel must use the same protocol.

You can change the protocol at any time, but this change causes all existing EtherChannels to reset to the default channel mode for the new protocol.

Configure all ports in an EtherChannel to operate at the same speed and duplex mode (full duplex only for LACP mode).

All ports in a channel must be on the same DFC-equipped module. You cannot configure any of the ports to be on other modules.

On systems that are configured with nonfabric-enabled modules and fabric-enabled modules, you can bundle ports across all modules, but those bundles cannot include a DFC-equipped module port.

You do not have to create a port-channel interface before assigning a physical interface to a channel group. A port-channel interface is created automatically when the channel group gets its first physical interface, if it is not already created.

You do not have to disable the IP address that is assigned to a physical interface that is part of a channel group, but it is highly recommended.

You can create both Layer 2 and Layer 3 port channels by entering the **interface port-channel** command or when the channel group gets its first physical interface assignment. The port channels are not created at runtime or dynamically.

Any configuration or attribute changes that you make to the port-channel interface are propagated to all interfaces within the same channel group as the port channel (for example, configuration changes are also propagated to the physical interfaces that are not part of the port channel but are part of the channel group).

When configuring Layer 2 EtherChannels, you cannot put Layer 2 LAN ports into manually created port-channel logical interfaces.

Only the **on** mode is supported when using this command with GE-WAN ports on the OSM-2+4GE-WAN+ OSM to create QinQ link bundles for advanced QinQ translation. Also, you cannot use the **channel-group** command on GE-WAN interfaces if MPLS is configured. You must remove all IP, MPLS, and other Layer 3 configuration commands before using the **channel-group** command with GE-WAN interfaces.

Note The GE-WAN interfaces on an OSM-2+4GE-WAN+ OSM behave slightly differently than other interfaces if you want to move the interface from one group to another. To move most other interfaces, you can enter the **channel-group** command again to delete the interface from the old group and move it to the new group. For GE-WAN ports, however, you must manually remove the interface from the group by entering the **no channel-group** command before assigning it to a new group.

Caution Do not enable Layer 3 addresses on the physical EtherChannel interfaces. Assigning bridge groups on the physical EtherChannel interfaces causes loops in your network.

For a complete list of guidelines, see the "Configuring EtherChannel" section of the *Cisco 7600 Series Router Cisco IOS Software Configuration Guide*.

Fast EtherChannel

Before you assign a Fast Ethernet interface to a Fast EtherChannel group, you must first create a port-channel interface. To create a port-channel interface, use the **interface port-channel** global configuration command.

If the Fast Ethernet interface has an IP address assigned, you must disable it before adding the Fast Ethernet interface to the Fast EtherChannel. To disable an existing IP address on the Fast Ethernet interface, use the **no ip address**command in interface configuration mode.

The Fast EtherChannel feature allows multiple Fast Ethernet point-to-point links to be bundled into one logical link to provide bidirectional bandwidth of up to 800 Mbps. Fast EtherChannel can be configured between Cisco 7500 series routers and Cisco 7000 series routers with the 7000 Series Route Switch Processor (RSP7000) and 7000 Series Chassis Interface (RSP7000CI) or between a Cisco 7500 series router or a Cisco 7000 series router with the RSP7000 and RSP700CI and a Cisco Catalyst 5000 switch.

A maximum of four Fast Ethernet interfaces can be added to a Fast EtherChannel group.

Caution The port-channel interface is the routed interface. Do not enable Layer 3 addresses on the physical Fast Ethernet interfaces. Do not assign bridge groups on the physical Fast Ethernet interfaces because it creates loops. Also, you must disable spanning tree.

To display information about the Fast EtherChannel, use the **show interfaces port-channel**EXEC command.

For more guidelines see the “Configuring EtherChannel” section of the *Cisco 7600 Series Router Cisco IOS Software Configuration Guide* and the “Configuring EtherChannel” section of the *Catalyst 6500 Series Switch Cisco IOS Software Configuration Guide*

Examples

This example shows how to add EtherChannel interface 1/0 to the EtherChannel group that is specified by port-channel 1:

```
Router(config-if)#
channel-group 1 mode on
Router(config-if)#
```

The following example shows how to add interface Fast Ethernet 1/0 to the Fast EtherChannel group specified by port-channel 1:

```
Router(config)#
interface port-channel 1
Router(config-if)#
exit
Router(config)#
interface fastethernet 1/0
Router(config-if)#
channel-group 1
```

Related Commands

Command	Description
interface	Creates a port-channel virtual interface and puts the CLI in interface configuration mode when the **port-channel** keyword is used.
ip address	Sets a primary or secondary IP address on an interface.
show etherchannel	Displays the EtherChannel information for a channel.
show interfaces port-channel	Displays traffic that is seen by a specific port channel.

channel-protocol (interface)

To enable Port Aggretation Control Protocol (PAgP) or Link Aggregation Control Protocol (LACP) on an interface to manage channeling, use the**channel-protocol** command in interface configuration mode. Use the **no** form of this command to deselect the protocol.

channel-protocol {**lacp** | **pagp**}
no channel-protocol

Syntax Description

lacp	Specifies LACP to manage channeling.
pagp	Specifies PAgP to manage channeling.

Command Default

pagp

Command Modes

Interface configuration

Command History

Release	Modification
10.2	This command was introduced.
12.1(11b)EX	Support for this command was introduced on the Catalyst 6500 series switches.
12.1(12c)EA1	Support for this command was introduced on the Catalyst 2900 series switches.
12.1(13)E	Support for this command on the Catalyst 6500 series switches was extended to Cisco IOS Release 12.1(13)E. This command was changed to support the use of the **nochannel-protocol** command (without arguments) to deselect the protocol.
12.1(13)EW	Support for this command was introduced on the Catalyst 4500 series switches.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is valid on multiple interfaces (for example, Fast Ethernet) and routers and switches including the Cisco 2900, 4500/4000, 6500/6000, and 7600 series.

Examples

The following example shows how to set the lacp.

```
(config-if)# channel-protocol lacp
```

channelized

To configure the T3/E3 controller for channelized mode, use the **channelized** command in controller configuration mode. To configure the T3/E3 controller for unchannelized mode, use the**no** form of this command.

channelized
no channelized

Syntax Description

This command has no arguments or keywords.

Command Default

The T3 controller is channelized.

The E3 controller is channelized.

Maximum transmission unit (MTU) size is set to 1500.

MTU size is set to 4470.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(5a)E	This command was integrated into Cisco IOS Release 12.1(5a)E.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series.

Usage Guidelines

Use the no channelized controller configuration command to configure the T3/E3 controller for unchannelized mode for Cisco NCS 4200 Series. When you configure the PA-MC-2T3+ port adapter on a Cisco 7500 series router with the no channelized command, the MTU size is set to 4470. In channelized mode, the default MTU size is 1500. The change in MTU sizes will cause a memory recarve and CBus complex to occur, disrupting all traffic on the router for several minutes.

The following message will be displayed when commands initiate switching between channelized and unchannelized modes on a Cisco 7500 series router:

```
Change to subrate mode will cause cbus complex reset. Proceed? [yes/no]:
Y
```

Type Y for “yes” at the end of the warning. At the prompt, type ^Z to exit. You will exit configuration mode and enter unchannelized mode.

Caution The no channelized command removes all channel groups from a channelized T3 interface. If you have already configured channel groups, use this command with caution.

Examples

Cisco 7500 Series Router

The following example shows how to configure unchannelized mode on a PA-MC-2T3+ port adapter in slot 1 of a Versatile Interface Processor version 2 (VIP2) or VIP4 in a Cisco 7500 series router:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# controller T3 1/1/0
Router(config-controller)# no channelized
Change to subrate mode will cause cbus complex reset. Proceed? [yes/no]:
Y
^Z
```

Cisco 10000 Series Router

The following example eliminates the T1 interfaces to create a full-rate T3 interface:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# controller T3 2/0/0
Router(config-controller)# no channelized
Router(config-controller)# exit
Router(config)#
```

Cisco NCS 4200 Series

The following example shows how to configure channelized controller as T3 interface.

```
Router# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# controller T3 0/4/40
Router(config-controller)# channelized
```

The following example shows how to configure channelized controller as E3 interface.

```
Router# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# controller E3 0/4/40
Router(config-controller)# channelized mode e1
```

class cem

To configure CEM interface parameters in a class that is applied to CEM interfaces together, use the **class cem** command in global configuration mode. This command works in the same manner for CEM interfaces as the pseudowire-class command does for xconnect.

class cem *class name*

Syntax Description

Syntax Description

class name	The name of a CEM interface parameters class.

Command Default

CEM configuration mode is not available.

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

The **class cem** command allows you to configure CEM interface parameters in a class that is applied to CEM interfaces together. A class cem command includes the following configuration settings:

- dejitter-buffer dejitter-in-ms
- idle-pattern 8-bit-idle-pattern
- payload-size payload-size-in-ms

Note The **rtp-present** command cannot be configured from **class cem** and has to be configured from the interface for NCS 4200 Series routers.

Note You can improve the performance of packet reordering on TDM/PWE connections by using the increasing the size of the dejitter buffer using the dejitter-buffer parameter.

Examples

The following example shows how to enter CEM interface parameters:

```
enable
configure terminal
class cem mycemclass
payload-size 512
dejitter-buffer 10
idle-pattern 0x55
```

```
exit
interface cem 0/0
no ip address
cem 0
cem class mycemclass
xconnect 10.10.10.10 200 encapsulation mpls
exit
```

Related Commands

Command	Description
clear cem	Clears CEM statistics.
show cem	Displays CEM statistics.

clear aim

To clear the data compression Advanced Interface Module (AIM) daughter card registers and reset the hardware, use the **clearaim** command in privileged EXEC mode.

clear aim *element-number*

Syntax Description

element-number	Number of AIM slot. AIM slots begin with 0.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **clearaim**command is used to reset the data compression AIM hardware. This command is used if the compression Advanced Interface Module (CAIM) hardware becomes "stuck" or hangs for some reason. The CAIM registers are cleared, and the hardware is reset upon execution. All compression history is lost when the CAIM is reset.

This command is supported only on Cisco 2600 series routers.

Examples

The following example shows how to use the **clearaim** command. This command will reset the hardware, flushing the buffers and history for all compression tasks currently under operation:

```
Router# clear aim 0
Router#
1w0d: %CAIM-6-SHUTDOWN: CompressionAim0 shutting down
1w0d: %CAIM-6-STARTUP: CompressionAim0 starting up
```

Related Commands

Command	Description
show pas caim	Displays the IDPROM contents for each AIM board in the Cisco 2600 series routers.
test aim eeprom	Tests the data compression AIM after it is installed in a Cisco 2600 series router.

clear cable-diagnostics tdr

To clear a specific interface or clear all interfaces that support Time Domain Reflectometry (TDR), use the **clearcable-diagnosticstdr**command in privileged EXEC mode.

clear cable-diagnostics tdr [**interface** *interface* *interface-number*]

Syntax Description

interface *interface*	(Optional) Specifies the interface type; possible valid values are **ethernet**, **fastethernetgigabitethernet**, and **tengigabitethernet**. See the "Usage Guidelines" section for additional valid values.
interface-number	Module and port number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The valid values for *interface* include the**ge-wan**, **atm**, and **pos** keywords that are supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

See the *Release Notes for Cisco IOS Release 12.2 SX on the Catalyst 6500 and Cisco 7600 Supervisor Engine 720, Supervisor Engine 32, and Supervisor Engine 2* for the list of modules that support TDR

Examples

This example shows how to clear a specific interface:

```
Router# clear cable-diagnostics tdr interface gigabitethernet 4/1
Router#
```

Related Commands

Command	Description
show cable-diagnostics tdr	Displays the test results for the TDR cable diagnostics.
test cable-diagnostics	Tests the condition of 10-Gigabit Ethernet links or copper cables on 48-port 10/100/1000 BASE-T modules.

clear catalyst6000 traffic-meter

To clear the traffic meter counters, use the **clear catalyst6000 traffic-meter**command in privileged EXEC mode.

clear catalyst6000 traffic-meter

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to clear the traffic meter counters:

```
Router# clear catalyst6000 traffic-meter
Router#
```

clear cem

To clear circuit emulation (CEM) statistics, use the **clearcem** command in privileged EXEC mode.

clear cem {*slot* | *slot*/*port*/*channel* | **all**}

Syntax Description

slot	Clears the statistics for all CEM channels on the card in the specified slot (if the card is a Circuit Emulation over IP [CEoIP] card).
slot	Specifies the slot of the CEM channel to clear.
/ *port*	Specifies the port of the CEM channel to clear. The slash mark is required between the *slot* argument and the *port* argument.
/ *channel*	Specifies the CEM channel to clear. The slash mark is required between the *port* argument and the *channel* argument.
all	Clears the statistics for all CEM channels on the router.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(7)T	This command was introduced.

Examples

The following example shows how to clear CEM statistics for CEM channel number 10 on the card installed in slot 1, port 1.

```
Router# clear cem 1/1/10
```

Related Commands

Command	Description
cem	Enters CEM configuration mode.
show cem	Displays CEM statistics.

clear controller

To reset the T1 or E1 controller, use the **clearcontroller**command in user EXEC or privileged EXEC mode.

Cisco 7200 Series and Cisco 7500 Series Routers
clear controller {**t1** | **e1**} *slot/port*

Cisco AS5200 Series and Cisco AS5300 Series Routers
clear controller {**t1** | **e1**} *number*

Syntax Description

t1	T1 controller.
e1	E1 controller.
slot / *port*	Backplane slot number and port number on the interface. Refer to your hardware installation manual for the specific slot and port numbers.
number	Network interface module (NIM) number, in the range from 0 to 2.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example resets the T1 controller at slot 4, port 0 on a Cisco 7500 series router:

```
Router# clear controller t1 4/0
```

The following example resets the E1 controller at NIM 0:

```
Router# clear controller e1 0
```

Related Commands

Command	Description
controller	Configures a T1, E1, or J1 controller and enters controller configuration mode.

clear controller lex

To reboot the LAN Extender chassis and restart its operating software, use the **clearcontrollerlex** command in privileged EXEC mode.

clear controller lex *number* [**prom**]

Cisco 7500 Series
clear controller lex *slot/port* [**prom**]

Cisco 7200 Series and 7500 Series with a Packet over SONET Interface Processor
clear controller lex [*type*] *slot/port*

Cisco 7500 Series with Ports on VIP Cards
clear controller lex [*type*] *slot/port-adapter/port*

Syntax Description

number	Number of the LAN Extender interface corresponding to the LAN Extender to be rebooted.
prom	(Optional) Forces a reload of the PROM image, regardless of any Flash image.
slot	Number of the slot being configured. Refer to the appropriate hardware manual for slot and port information.
port	Number of the port being configured. Refer to the appropriate hardware manual for slot and port information.
type	(Optional) Specifies the interface type. See Table 4 under the **clearcounters** command for keywords.
port-adapter	Number of the port adapter being configured. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

The **clearcontrollerlex** command halts operation of the LAN Extender and performs a cold restart.

Without the **prom** keyword, if an image exists in Flash memory, and that image has a newer software version than the PROM image, and that image has a valid checksum, then this command runs the Flash image. If any one of these three conditions is not met, this command reloads the PROM image.

With the **prom** keyword, this command reloads the PROM image, regardless of any Flash image.

Examples

The following example halts operation of the LAN Extender bound to LAN Extender interface 2 and causes the LAN Extender to perform a cold restart from Flash memory:

```
Router#
clear controller lex 2
reload remote lex controller? [confirm] yes
```

The following example halts operation of the LAN Extender bound to LAN Extender interface 2 and causes the LAN Extender to perform a cold restart from PROM:

```
Router#
clear controller lex 2 prom
reload remote lex controller? [confirm] yes
```

clear controller wanphy

T o clear the triggered alarm counters for the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter and reset it to zero, use the **clearcontrollerwanphy**commandin Privileged EXEC mode.

clear controller wanphy *slot/subslot/port*

Syntax Description

slot	The SIP slot number in which the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter has been installed.
subslot	The subslot number in which the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter has been installed.
port	The port number of the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter. **Note** There is only 1 port (0) in the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter.

Command Default

No default values are available.

Command Modes

Privileged EXEC Mode (EXEC)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The **clearcontrollerwanphy**command has been introduced on the Cisco ASR 1000 Series Router in Cisco IOS XE Release 3.3.0S. This command is used to clear the counter of alarms generated, and reset it back to zero.

Examples

The following example shows the output of the **showcontrollerswanphy** command. The example shows the alarm counter values for the line, path, and section alarms:

```
Router# show controllers wanphy 0/1/0
TenGigabitEthernet0/1/0
Mode of Operation: WAN Mode
SECTION
  LOF = 1              LOS    = 0                            BIP(B1) = 22
LINE
  AIS = 1              RDI    = 0           FEBE = 0         BIP(B2) = 3099
PATH
  AIS = 1              RDI    = 0           FEBE = 4         BIP(B3) = 4
  LOP = 0              NEWPTR = 0           PSE  = 0         NSE     = 0
WIS ALARMS
  SER    = 1           FELCDP = 0           FEAISP = 0
  WLOS   = 0           PLCD   = 0
  LFEBIP = 857         PBEC   = 4
Active Alarms[All defects]: None
Active Alarms[Highest Alarms]: None
Alarm reporting enabled for: SF SWLOF B1-TCA B2-TCA PLOP WLOS
  Rx(K1/K2): 00/00  Tx(K1/K2): 00/00
  S1S0 = 00, C2 = 0x1A
```

```
PATH TRACE BUFFER: STABLE
  Remote J1 Byte : wert
BER thresholds:  SD = 10e-6  SF = 10e-3
TCA thresholds:  B1 = 10e-6  B2 = 10e-6  B3 = 10e-6
[Output is Cut]
```

The following example shows how to clear the alarm counter values and reset it back to zero:

```
Router# clear controller wanphy 0/1/0
```

The following example shows that the alarm counter values are cleared and have been reset to zero:

```
Router# show controllers wanphy 0/1/0
TenGigabitEthernet0/1/0
Mode of Operation: WAN Mode
SECTION
  LOF = 0             LOS    = 0                            BIP(B1) = 0
LINE
  AIS = 0             RDI    = 0          FEBE = 0          BIP(B2) = 0
PATH
  AIS = 0             RDI    = 0          FEBE = 0          BIP(B3) = 0
  LOP = 0             NEWPTR = 0          PSE  = 0          NSE     = 0
WIS ALARMS
  SER    = 0          FELCDP = 0          FEAISP = 0

  LFEBIP = 0          PBEC   = 0
```

Related Commands

Command	Description
show controllers wanphy	Displays the SPA mode (LAN/WAN), alarms, and J1 byte string value.

clear controller vdsl

To reset the VDSL line related counters, use the **clearcontrollervdsl** command in privileged EXEC mode.

clear controller vdsl *slot/subslot/port number*

Syntax Description

vdsl	VDSL2 controller.
slot	Controller slot number.
subslot	Controller subslot number.
port number	Controller port number.

Command Default

None.

Command Modes

Privileged EXEC mode.

Command History

Release	Modification
15.0(1)M1	This command was first introduced.

Usage Guidelines

None.

Examples

The following example shows how to reset the VDSL line related counters.

```
Router#clear controller vdsl 0/2/0
```

Related Commands

Command	Description
show controller vdsl	Displays VDSL controller related information.

clear counters

To clear the interface counters, use the **clearcounters** command in user EXEC or privileged EXEC mode.

clear counters commandclear counters [*interface-type interface-number*]

Cisco 7200 Series and 7500 Series with a Packet over SONET Interface Processor
clear counters [*interface-type*] *slot/port*

Cisco 7500 Series with Ports on VIP Cards
clear counters [*interface-type*] *slot/port-adapter/port*

Cisco 7600 Series
clear counters [{*interface interface-number* | **null** *interface-number* | **port-channel** *number* | **vlan** *vlan-id*}]

Syntax Description

interface-type	(Optional) Specifies the interface type; one of the keywords listed in Table 1 .
interface -number	(Optional) Specifies the interface number displayed with the **showinterfaces** command.
slot	Slot number. Refer to the appropriate hardware manual for slot and port information.
port	Port number. Refer to the appropriate hardware manual for slot and port information.
port-adapter	Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.
interface	(Optional) Interface type; possible valid values are **ethernet**, **fastethernetgigabitethernet**, and **tengigabitethernet**. See the "Usage Guidelines" section for additional valid values.
interface-number	(Optional) Module and port number; see the "Usage Guidelines" section for valid values.
null *interface-number*	(Optional) Specifies the null interface; the valid value is **0**.
port-channel *number*	(Optional) Specifies the channel interface; valid values are a maximum of 64 values ranging from 1 to 256.
vlan *vlan-id*	(Optional) Specifies the VLAN ID; valid values are from 1 to 4094.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.2F	The **virtual-access** keyword was added.

Release	Modification
11.3	The following keywords were added or modified: • **vg-anylan** keyword was added. • **posi** keyword was changed to **pos**.
12.2(15)T	The **ethernet** and **serial** keywords were removed because the LAN Extension feature is no longer available in Cisco IOS software.
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command clears all the current interface counters from the interface unless the optional arguments *interface*-type and *interface*-numberare specified to clear only a specific interface type (serial, Ethernet, Token Ring, and so on). The table below lists the command keywords and their descriptions.

Note This command does not clear counters retrieved using Simple Network Management Protocol (SNMP), but only those seen with the **showinterface** command. However, variables seen with the **showinterface** command that could affect routing, such as load and reliability, or non-cumulative variables, such as input or output rates, are not cleared.

The *interface-number* argument designates the module and port number. Valid values for *interface-number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

Table 5: clear counters Interface Type Keywords

Keyword	Interface Type
async	Asynchronous interface
bri	ISDN BRI
dialer	Dialer interface
ethernet	Ethernet interface
fast-ethernet	Fast Ethernet interface
fddi	FDDI
hssi	High-Speed Serial Interface (HSSI)
line	Terminal line

Keyword	Interface Type
loopback	Loopback interface
null	Null interface
port-channel	Port channel interface
pos	Packet OC-3 interface
serial	Synchronous serial interface
switch	Switch interface
tokenring	Token Ring interface
tunnel	Tunnel interface (IEEE 02.5)
vg-anylan	100VG-AnyLAN port adapter
virtual-access	Virtual-access interface (Refer to the *Cisco IOS Dial Technologies Command Reference* for details on virtual templates.)
virtual-template	Virtual-template interface (Refer to the *Cisco IOS Dial Technologies Command Reference* for details on virtual templates.)
virtual-tokenring	Virtual Token Ring interface

Examples

The following example shows how to clear all interface counters:

```
Router#
 clear counters
```

The following example shows how to clear the Packet OC-3 interface counters on a POSIP card in slot 1 on a Cisco 7500 series router:

```
Router#
 clear counters pos 1/0
```

The following example shows how to clear the interface counters on a Fast EtherChannel interface:

```
Router# clear counter port-channel 1
Clear "show interface" counters on all interfaces [confirm] Y
%CLEAR-5-COUNTERS: Clear counter on all interfaces by console 1
```

Related Commands

Command	Description
show interfaces	Displays the statistical information specific to a serial interface.
show interfaces port-channel	Displays the information about the Fast EtherChannel on Cisco 7500 series routers and Cisco 7000 series routers with the RSP7000 and RSP7000CI.
show queueing interface	Displays queuing information.

clear debug platform condition all

To remove the debug conditions applied to a platform, use the **clear debug platform condition all** command in privileged EXEC mode.

clear debug platform condition all

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.10.0S	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.

The following example shows how to remove the conditional debugging applied to the platform.

```
Router# clear debug platform condition all
```

clear diagnostic event-log

To clear the diagnostic event logs for a specific module or event type, use the **cleardiagnosticevent-log**command in Priveleged exec mode.

clear diagnostic event-log {**event-type** {**error** | **info** | **warning**} | **module** {**num** | *slot subslot* | **all**}}

Syntax Description

event-type error	Specifies clearing error events.
event-type info	Specifies clearing informative events.
event-type warning	Specifies clearing warning events.
module *num* | *slotsubslot*	Specifies clearing events for a specific module.
module all	Specifies clearing all linecards.

Command Default

This command has no default settings.

Command Modes

Priveleged Exec mode(#)

Command History

Release	Modification
12.2(33)SXH	This command was introduced on the Supervisor Engine 720.

Usage Guidelines

The **cleardiagnosticevent-log** command clears all the events for all the modules.

The **cleardiagnosticevent-logmodule***num* command clears events only for a specific module.

The **cleardiagnosticevent-logevent-type**command clears only specific event types such as error, informative, or warning events.

Examples

This example shows how to clear error event logs:

```
Router# clear diagnostic event-log event-type error
```

This example shows how to clear event logs on module 3:

```
Router# clear diagnostic event-log module 3
```

This example shows how to clear error event logs on all the modules:

```
Router# clear diagnostic event-log module all
```

Related Commands

Command	Description
show diagnostic events	Displays the diagnostic event log

clear dsip tracing

To clear Distributed System Interconnect Protocol (DSIP) tracing statistics (trace logging), use the **cleardsiptracing** command in privileged EXEC mode.

clear dsip tracing {**counters** | **tracing**} [{**control** | **data** | **ipc**}]

Syntax Description

counters	DSIP counters.
tracing	DSIP tracing buffers.
control	(Optional) Control counters or tracing buffers.
data	(Optional) Data counters or tracing buffers.
ipc	(Optional) Inter-process communication counters or tracing buffers.

Command Default

If no option is specified, all control, data, and inter-process communication counters or tracing buffers are cleared.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to clear the counters displayed with the **showdsiptracing** EXEC command.

Examples

In the following example, the DSIP counters are cleared (including data, control, and ipc counters):

```
Router# clear dsip tracing
```

Related Commands

Command	Description
show dsip tracing	Displays DSIP tracing buffer information.
show dsip version	Displays DSIP version information.

clear facility-alarm

To clear alarm conditions and reset the alarm contacts, use the **clearfacility-alarm**command in privileged EXEC mode.

clear facility-alarm [{**critical** | **major** | **minor** | **source pem** {**0** | **1**}}]

Syntax Description

critical	(Optional) Clears all critical alarms.
major	(Optional) Clears all major alarms.
minor	(Optional) Clears all minor alarms.
source pem {**0** | **1**}	(Optional--Cisco uBR10012 only) Clears all alarms for either the first or second Power Entry Module (PEM).

Command Default

If specified without any options, clears all facility alarms with the exception of:

- An alarm that illuminates the CRIT, MIN, or MAJ LED
- A visual alarm (DC lightbulb) that is wired to the DB-25 connector on a power supply

If specified without any options, clears all facility alarms.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(17)SL	This command was introduced on the Cisco 10000 series router.
12.2(1)XF1	This command was introduced for the Cisco uBR10012 router.
12.2(16)BX	This command was introduced on the PRE2.
12.2(31)SB2	This command was introduced on the PRE3 for the Cisco 10000 series router.
12.3BC	This command was integrated into Cisco IOS Release 12.3BC.
12.2(33)SCA	This command was integrated into Cisco IOS Release 12.2(33)SCA.
Cisco IOS XE Release 2.1	This command was integrated into Cisco IOS XE Release 2.1 on the Cisco ASR 1000 Series Routers.

Usage Guidelines

Cisco ASR 1000 Series Routers

The clear facility-alarm command clears audible alarms. A recurrence of the original alarm source after the original alarm condition is removed restarts the audible alarm.

The clear facility-alarm command does not clear an alarm that illuminates the CRIT, MIN, or MAJ LED. This command does not turn off a visual alarm (DC light bulb) that is wired to the DB-25 connector on a power supply.

To clear a CRIT, MIN, or MAJ alarm LED or a visual alarm, you must resolve the alarm condition. For example, if a critical alarm LED is illuminated because an active SPA was removed without a graceful deactivation of the SPA, the only way to resolve that alarm is to replace the SPA.

Cisco uBR10012 Universal Broadband Router

The **clearfacility-alarm** command clears the contacts to an external alarm panel. Only a recurrence of the original alarm source after the original alarm condition is removed can restart the audible alarm. These alarms are displayed by the **showfacility-alarmstatus**command.

The alarm LEDs remain lit on the Performance Routing Engine (PRE) as long as the alarm condition continues and is not cleared by the **clearfacility-alarm** command. An alarm can only be removed from the list by correcting the issue that is triggering the alarm.

Examples

The following example shows how to clear all facility alarms on the router:

```
Router# clear facility-alarm
Clearing all alarms
```

The following example shows how to clear all critical facility alarms on the router:

```
Router# clear facility-alarm critical

Clearing critical alarms
```

The following example shows how to clear minor facility alarms only:

```
Router# clear facility-alarm minor
Clearing minor alarms
```

Cisco uBR10012 Universal Broadband Router

The following example shows how to clear all alarms for both PEM modules on a Cisco uBR10012 universal broadband router:

```
Router# clear facility-alarm source pem 0
Router# clear facility-alarm source pem 1
```

Related Commands

Command	Description
facility-alarm	Sets the temperature thresholds at which the processor generates a critical, major, or minor alarm to warn of potential equipment damage.
facility-alarm critical exceed-action shutdown	Allows automatic router shutdown.
show facility-alarm	Displays the status of a generated alarm.

clear hub

To reset and reinitialize the hub hardware connected to an interface of a Cisco 2505 or Cisco 2507 router, use the **clearhub**command in user EXEC or privileged EXEC mode.

clear hub commandclear hub ethernet *number*

Syntax Description

ethernet	Hub in front of an Ethernet interface.
number	Hub number to clear, starting with 0. Because there is only one hub, this number is 0.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example clears hub 0:

```
Router#
 clear hub ethernet 0
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

clear hub counters

To set the hub counters on an interface of a Cisco 2505 or Cisco 2507 router to zero, use the **clearhubcounters** command in user EXEC or privileged EXEC mode.

clear hub counters commandclear hub counters [**ether** *number* [*port* [*end-port*]]]

Syntax Description

ether	(Optional) Hub in front of an Ethernet interface.
number	(Optional) Hub number for which to clear counters. Because there is currently only one hub, this number is 0. If you specify the keyword **ether**, you must specify the *number*.
port	(Optional) Port number on the hub. On the Cisco 2505 router, port numbers range from 1 to 8. On the Cisco 2507 router, port numbers range from 1 to 16. If a second port number follows, this port number indicates the end of a port range. If you do not specify a port number, counters for all ports are cleared.
end-port	(Optional) Ending port number of a range.

Command Default

If no port numbers are specified, counters for all ports are cleared.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to clear the counters displayed by a **showhub** command for all ports on hub 0:

```
Router#
 clear hub counters ether 0
```

Related Commands

Command	Description
show hub	Displays information about the hub (repeater) on an Ethernet interface of a Cisco 2505 or Cisco 2507 router.

clear interface

To reset the hardware logic on an interface, use the **clearinterface** command in user EXEC or privileged EXEC mode.

clear interface commandclear interface {*type number* [*name-tag*] | **range** *type number*}

Cisco 7200 Series and Cisco 7500 Series with a Packet OC-3 Interface Processor
clear interface {*type slot*/*port* | **range** *type number*}

Cisco 7500 Series with Ports on VIP Cards
clear interface *type slo* **t**/*port-adapter*/*port*

Cisco 7500 Series
clear interface *type slot*/*port* [**:** *channel-group*]

Cisco 7500 Series with a CT3IP Port Adapter
clear interface *type slot*/*port-adapter*/*port* [**:** *t1-channel*]

Syntax Description

type	Interface type; it is one of the keywords listed in Table 1 .
number	Port, connector, or interface card number.
name-tag	(Optional for use with the Redundant Link Manager [RLM] feature) Logic name to identify the server configuration so that multiple server configurations can be entered.
range	Clears all the interfaces within the specified range.
slot	Number of the slot being configured. Refer to the appropriate hardware manual for slot and port information.
/ *port*	Number of the port being configured. Refer to the appropriate hardware manual for slot and port information.
port-adapter	Number of the port adapter being configured. Refer to the appropriate hardware manual for information about port adapter compatibility.
: *channel-group*	(Optional) Channel number, on Cisco 7500 series routers that support channelized T1. The range is from 0 to 23. This number is preceded by a colon.
: *t1-channel*	(Optional) For the CT3IP port adapter, the T1 channel is a number between 1 and 28. T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based scheme (0 to 27) used with other Cisco products. This numbering scheme ensures consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
10.0	This command was introduced.
11.3	This command was modified. The following changes were made: • The **vg-anylan** keyword was added • The **posi** keyword was changed to **pos**
12.0(3)T	This command was modified. The following optional argument was added for the RLM feature: • *name-tag*
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **range** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

Under normal circumstances, you do not need to clear the hardware logic on interfaces.

This command clears all the current interface hardware logic unless the type and number arguments are specified to clear only a specific interface type (serial, Ethernet, Token Ring, and so on). The table below lists the command keywords and their descriptions.

Table 6: clear interface Type Keywords

Keyword	Interface Type
acr	Virtual Automatic Call Reconnect (ACR) interface
analysis-module	Cisco network analysis service module
async	Async interface
atm	ATM interface
auto-template	Auto-Template interface
bdi	Bridge-Domain interface
bri	ISDN BRI
bvi	Bridge-Group Virtual interface
cdma-ix	CDMA Ix interface

Keyword	Interface Type
container	Container interface
ctunnel	CTunnel interface
dialer	Dialer interface
esconphy	ESCON interface
ethernet	Ethernet interface
fcpa	Fiber Channel
fddi	FDDI
filter	Filter interface
filtergroup	Filter Group interface
gigabitethernet	Gigabit Ethernet IEEE 802.3z
gmpls	MPLS interface
hssi	High-Speed Serial Interface (HSSI)
lex	Lex interface
longreachethernet	Long-Reach Ethernet interface
loopback	Loopback interface
lspvif	LSP virtual interface
mfr	Multilink Frame Relay bundle interface
multilink	Multilink-group interface
multiservice	Multiservice interface
null	Null interface
port-channel	Ethernet Channel of interfaces
portgroup	Portgroup interface
pos	Packet over SONET.
pos-channel	POS Channel of interfaces
sbc	Session Border Controller
serial	Synchronous serial interface
service-engine	Cisco service engine module
sslvpn-vif	SSLVPN Virtual Interface

Keyword	Interface Type
switch	Switch interface
sysclock	Telecom-Bus Clock Controller
tokenring	Token Ring interface
tunnel	Tunnel interface
vasileft	VasiLeft interface
vasiright	VasiRight interface
vg-anylan	100VG-AnyLAN port adapter
vif	PGM Multicast Host interface
virtual-dot11radio	Virtual dot11 interface
virtual-ppp	Virtual PPP interface
virtual-tokenring	Virtual Token Ring interface
vlan	Catalyst VLAN
vmi	Virtual Multipoint interface
voabypassin	VOA-Bypass-In interface
voabypassout	VOA-Bypass-Out interface
voafilterin	VOA-Filter-In interface
voafilterout	VOA-Filter-Out interface
voain	VOA-In interface
voaout	VOA-Out interface

Examples

The following example shows how to reset the interface logic on HSSI interface 1:

```
Router#
 clear interface hssi 1
```

The following example shows how to reset the interface logic on Packet OC-3 interface 0 on the POSIP in slot 1:

```
Router#
 clear interface pos 1/0
```

The following example shows how to reset the interface logic on T1 0 on the CT3IP port adapter in slot 9:

```
Router#
 clear interface serial 9/0/0:0
```

The following example shows how to reset the interface logic on Fast EtherChannel interface 1:

```
Router# clear interface port-channel 1
```

The following example shows how to reset demonstrates the use of the **clearinterface** command with the RLM feature:

```
Router# clear interface loopback 1
Router#
02:48:52: rlm 1: [State_Up, rx ACTIVE_LINK_BROKEN] over link [10.1.1.1(Loopback1), 10.1.4.1]

02:49:52: rlm 1: link [10.1.1.1(Loopback1), 10.1.4.1] is activated
```

Related Commands

Command	Description
interface	Defines the IP addresses of the server, configures an interface type, and enters interface configuration mode.
show rlm group	Displays the status of the RLM group.
shutdown (RLM)	Shuts down all of the links under the RLM group.

clear interface cem

T o clear the cem channel, use the **clearinterfacecem**commandin privilege exec mode.

clear interface cem *slot/subslot/port*

Syntax Description

slot	Slot number where the SIP is installed.
subslot	Subslot number of the SIP where CEOPS SPA has been installed and circuit emulation has been configured.
port	Port number of the interface on the CEOPS SPA where circuit emulation has been configured.

Command Default

No default behavior or values.

Command Modes

Privilege Exec Mode (Exec)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced.

Usage Guidelines

The **clearinterfacecem**command has been introduced on Cisco ASR 1000 Series Router in Cisco IOS XE Release 3.3.0S. The **clearinterfacecem** command is used to clear the statistics information of the cem group.

Examples

The following example shows how to clear the cem channel using the clear interface cem command:

```
Router# clear interface cem
```

Related Commands

Command	Description
show interfaces cem	Displays the statistics of the cem group.

clear interface fastethernet

To reset the controller for a specified Fast Ethernet interface, use the **clearinterfacefastethernet** command in privileged EXEC mode.

Cisco 4500 and Cisco 4700 Series
clear interface fastethernet *interface-number*

Cisco 7200 and Cisco 7500 Series
clear interface fastethernet *slot* / *port*

Cisco 7500 Series with a VIP
clear interface fastethernet *slot* / *port-adapter* / *port*

Syntax Description

interface-number	Port, connector, or interface card number. On a Cisco 4500 or Cisco 4700 Series router, specifies the number of the network processor module (NPM). The numbers are assigned at the factory at the time of installation or when added to a system.
slot	Slot number. Refer to the appropriate hardware manual for slot and port information.
/ *port*	Port number. Refer to the appropriate hardware manual for slot and port information.
/ *port-adapter*	Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

Cisco 4500 Series

The following example resets the controller for Fast Ethernet interface 0 on a Cisco 4500:

```
Router#
 clear interface fastethernet 0
```

Cisco 7200 and Cisco 7500 Series

The following example resets the controller for the Fast Ethernet interface located in slot 1, port 0 on a Cisco 7200 series router or Cisco 7500 series router:

```
Router#
 clear interface fastethernet 1/0
```

Cisco 7500 SerieswithaVIP

The following example resets the controller for the Fast Ethernet interface located in slot 1, port adapter 0, port 0 on a Cisco 7500 series router with a virtual interface processor (VIP):

```
Router#
 clear interface fastethernet 1/0/0
```

Related Commands

Command	Description
clear counters	Clears the interface counters.
show interfaces	Displays statistics for all interfaces configured on the router or access server.
show interfaces serial	Displays information about a serial interface.

clear interface gigabitethernet

To clear the hardware logic on a Gigabit Ethernet IEEE 802.3z interface, use the **clearinterfacegigabitethernet** command in privileged EXEC mode.

clear interface gigabitethernet *number*

Syntax Description

number	Gigabit Ethernet interface number; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *number* argument designates the module and port number. Valid values for *number* depend on the specified interface type and the chassis and module that are used. For example, if you specify a Gigabit Ethernet interface and have a 48-port 10/100BASE-T Ethernet module that is installed in a 13-slot chassis, valid values for the module number are from 1 to 13 and valid values for the port number are from 1 to 48.

Examples

This example shows how to clear the hardware logic on a Gigabit Ethernet IEEE 802.3z interface:

```
Router#
clear interface gigabitethernet 5
Router#
```

Related Commands

Command	Description
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.

clear interface serial

To reset the statistical information specific to a serial interface, use the **clearinterfaceserial**command in user EXEC or privileged EXEC mode.

clear interface serial *dial-shelf/slot/t3-port* **:** *t1-num* **:** *chan-group*

Syntax Description

dial-shelf	Dial shelf chassis in the Cisco AS5800 access server that contains the CT3 interface card.
/ *slot*	Location of the CT3 interface card in the dial shelf chassis.
/ *t3-port*	T3 port number. The only valid value is 0.
: *t1-num*	T1 time slot in the T3 line. The value can be from 1 to 28.
: *chan-group*	Channel group identifier.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.

Usage Guidelines

The **clearinterfaceserial**command clears the interface hardware. To reset the counters for an interface, use the **clearcounters**command with the **serial** keyword specified. To confirm at the prompt, use the **showinterfacesserial**command.

Examples

The following example clears the interface hardware, disconnecting any active lines:

```
Router# clear interface serial 1/4/0:2:23
```

Related Commands

Command	Description
clear counters	Clears the interface counters.
show interfaces	Displays statistics for all interfaces configured on the router or access server.
show interfaces fastethernet	Displays information about a fastethernet interface.

clear interface vlan

To clear the hardware logic on a virtual local area network (VLAN), use the **clearinterfacevlan** command in privileged EXEC mode.

clear interface vlan *vlan-id*

Syntax Description

vlan-id	VLAN ID; valid values are from 1 to 4094.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on theSupervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to clear the hardware logic on a specific VLAN:

```
Router#
clear interface vlan 5
Router#
```

Related Commands

Command	Description
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.

clear ipc statistics

To clear all interprocess communication (IPC) statistics, use the **clearipcstatistics** command in privileged EXEC mode.

clear ipc statistics

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

The **clearipcstatistics**command clears all the IPC statistics and is useful for troubleshooting issues with IPC services.

Examples

The following example shows how to clear all of the statistics used by IPC services. A **showipcstatus** command is issued first to display the current IPC counters for a local IPC server. The **clearipcstatistics** command is then entered to clear and reset the counters. A final **showipcstatus** command is issued to show that all the counters, except those counters that show the packets sent since the clearing, are reset to zero.

```
Router# show ipc status
IPC System Status
Time last IPC stat cleared : never
This processor is the IPC master server.
Do not drop output of IPC frames for test purposes.
1000 IPC Message Headers Cached.
                                                      Rx Side     Tx Side
Total Frames                                              189         140
Total from Local Ports                                    189          70

Related Commands

Command	Description
show ipc	Displays IPC statistics.

clear lacp counters

To clear the statistics for all interfaces belonging to a specific channel group, use the **clearlacpcounters** command in privileged EXEC mode.

clear lacp [*channel-group*] **counters**

Syntax Description

channel-group	(Optional) Channel group number; valid values are from 1 to 256.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you do not specify a *channel-group*, all channel groups are cleared.

If you enter this command for a channel group that contains members in PAgP mode, the command is ignored.

Examples

This example shows how to clear the statistics for a specific group:

```
Router# clear lacp 1 counters
Router#
```

Related Commands

Command	Description
show lacp	Displays LACP information.

clear platform netint

To clear the interrupt-throttling counters for the platform, use the **clear platform netint** command in privileged EXEC mode.

clear platform netint

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17b)SXA	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to clear the interrupt-throttling counters for the platform:

```
Router#
clear platform netint
Router#
```

Related Commands

Command	Description
show platform netint	Displays the platform network-interrupt information.

clear platform software vnic-if-nvtable

To clear the virtual router's persistent interface database on the original VM and update the interface mapping to the hypervisor, use the **clear platform software vnic-if-nvtable** command in EXEC mode.

clear platform software vnic-if-nvtable

Command Default

No default.

Command Modes

EXEC

Command History

Release	Modification
Cisco IOS XE 3.9S	This command was introduced on the Cisco CSR 1000V.

Usage Guidelines

When the Cisco CSR 1000V boots for the first time, the vNICs on the hypervisor are mapped to the Gigabit Ethernet network interfaces on the router. The system maintains a database for mapping the interfaces, and the mapping stays persistent as long as vNICs are not removed from the system.

The **clear platform software vnic-if-nvtable** command is used when you clone the Cisco CSR 1000V configuration to a new VM. You enter the command on the cloned VM instance of the Cisco CSR 1000V so that the Gigabit Ethernet router interfaces on the cloned VM map to new vNICs. If the interface mapping from the original VM is not cleared on the cloned VM, then the Cisco CSR 1000V feature license may be invalidated.

Use the **show platform software vnic-if interface-mapping** command to verify the updated interface mapping.

Example

The following example clears the Cisco CSR 1000V interface mapping to the vNICs on the hypervisor:

```
se-10-0-0-0(config)# clear platform software vnic-if-nvtable
```

Related Commands

Command	Description
show platform software vnic-if interface-mapping	Displays the mapping between the virtual Network Interface Cards (vNICs) on the VM and the network interfaces on a virtual router.

Note Starting with the IOS XE 17.1 release, you no longer need to execute the `clear platform software vnic-int interface` command before you remove the vNIC configuration from the hypervisor. This command will be deprecated in a future release.

clear rbscp

To reset and restart a Rate Based Satellite Control Protocol (RBSCP) tunnel, use the **clearrbscp** command in privileged EXEC mode.

clear rbscp [**tunnel** *tunnel-number*]

Syntax Description

tunnel	(Optional) Resets and restarts the RBSCP tunnel interface specified in the *tunnel-number*argument. If a tunnel interface is not specified, all RBSCP tunnels are reset and restarted. • *tunnel-number* --Number of the tunnel interface in the range from 0 to 2147483647.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The **clearrbscp**command resets the tunnel interface to its initial state and this clears RBSCP statistical information. Use this command for troubleshooting issues with RBSCP tunnels.

Examples

The following example shows how to clear the RBSCP statistics. A **showrbscpstatistics** command is issued first to display the current RBSCP counters for tunnel interface 0. The **clearrbscp**command is then entered to reset and restart tunnel interface 0. All the counters for tunnel interface 0 are reset to zero. A final **showrbscpstatistics** command is issued to show that all the counters, except those counters that show the packets sent since the clearing, are reset to zero.

```
Router# show rbscp statistics tunnel 0
Tunnel0 is up, line protocol is up
RBSCP protocol statistics:
  Init FWD-TSNs sent 15, received 11
  TUNNEL-UPs sent 10, received 5
  CLOSEDs sent 3, received 2
  TSNs sent 40, resent 2, lost by sender 1
  TSNs received 36 (duplicates 2)
  FWD-TSNs sent 144 (heartbeats 2)
  FWD-TSNs received 120 (ignored 1)
  FWD-TSNs caused 3 packet drops, 0 whole window drops
  SACKs sent 10, received 6 (ignored 1)
  Recovered with RTX 1
  Received with delay 2
  Most released at once 5
  Failed sends into the: tunnel 1, network 0
  Dropped due to: excess delay 0, tmit queue full 0
  Max on any queue: num packets: 12, num bytes: 0
  Max outstanding: 0
Router# clear rbscp tunnel 0
Tunnel0: cleared statistics
Router# show rbscp statistics tunnel 0
Tunnel0 is up, line protocol is up
RBSCP protocol statistics:
  Init FWD-TSNs sent 0, received 0
```

```
TUNNEL-UPs sent 0, received 0
CLOSEDs sent 0, received 0
TSNs sent 0, resent 0, lost by sender 0
TSNs received 0 (duplicates 0)
FWD-TSNs sent 26 (heartbeats 0)
FWD-TSNs received 0 (ignored 0)
FWD-TSNs caused 0 packet drops, 0 whole window drops
SACKs sent 0, received 0 (ignored 0)
Recovered with RTX 0
Received with delay 0
Most released at once 0
Failed sends into the: tunnel 0, network 0
Dropped due to: excess delay 0, tmit queue full 0
Max on any queue: num packets: 0, num bytes: 0
Max outstanding: 0
```

Related Commands

Command	Description
show rbscp	Displays RBSCP state and statistical information.

clear service-module serial

To reset an integrated CSU/DSU, use the **clearservice-moduleserial**command in privileged EXEC mode.

clear service-module serial *number*

Syntax Description

number	Number of the serial interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command only in severe circumstances (for example, when the router is not responding to a CSU/DSU configuration command).

This command terminates all DTE and line loopbacks that are locally or remotely configured. It also interrupts data transmission through the router for up to 15 seconds. The software performs an automatic software reset in case of two consecutive configuration failures.

The CSU/DSU module is not reset with the **clearinterface** command.

Caution If you experience technical difficulties with your router and intend to contact customer support, refrain from using this command. This command erases the router's past CSU/DSU performance statistics. To clear only the CSU/DSU performance statistics, issue the **clearcounters**command.

Examples

The following example show how to reset the CSU/DSU on a router:

```
Router# clear service-module serial 0
```

Related Commands

Command	Description
clear counters	Clears the interface counters.
test service-module	Performs self-tests on an integrated CSU/DSU serial interface module, such as a 4-wire, 56/64-kbps CSU/DSU.

clear top counters interface report

To clear the TopN reports, use the **cleartopcountersinterfacereport** command in privileged EXEC mode.

clear top counters interface report *number*

Syntax Description

number	(Optional) Number of ports to be displayed; valid values are from 1 to 5000 physical ports.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Ethernet, Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet ports only. LAN ports on the OSMs are also supported.

The **cleartopinterfacereport** command clears all the completed reports. It does not clear the pending TopN reports. When you specify a report number, the TopN task is cleared regardless of its status.

Examples

This example shows how to clear all TopN tasks:

```
Router# clear top counters interface report 1000

04:00:06: %TOPN_COUNTERS-5-DELETED: TopN report 1 deleted by the console
04:00:06: %TOPN_COUNTERS-5-DELETED: TopN report 2 deleted by the console
04:00:06: %TOPN_COUNTERS-5-DELETED: TopN report 3 deleted by the console
04:00:06: %TOPN_COUNTERS-5-DELETED: TopN report 4 deleted by the console1/24/
Router#
```

This example shows the output if you attempt to clear a pending TopN task:

```
Router# clear top counters interface report 4

04:52:12: %TOPN_COUNTERS-5-KILLED: TopN report 4 killed by the sattili onvty0 (9.10.69.9)
Router#
```

Related Commands

Command	Description
collect top counters interface	Lists the TopN processes and specific TopN reports.
show top counters interface report	Displays TopN reports and information.

clock

To configure the port clocking mode for the 1000BASE-T transceivers, use the **clock** command in interface configuration mode. To return to the default settings,use the **no** form of this command.

clock {**auto** | **active** [**prefer**] | **passive** [**prefer**]}
no clock

Syntax Description

auto	Enables the automatic-clock configuration.
active	Enables the active operation.
prefer	(Optional) Negotiates the specified mode with the far end of the link.
passive	Enables the passive operation.

Command Default

auto

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on the 1000BASE-T transceivers only.

If the clock mode of the near end of a link does not match the clock mode of the far end, the line protocol does not come up.

The active and passive clock status is determined during the auto negotiation process before the transmission link is established.

The **clock** command supports the following configurations:

- **auto** --Auto negotiates with the far end of the link but preference is given to the active-clock switch.
- **active** --Uses a local clock to determine transmitter-operation timing.
- **passive** --Recovers the clock from the received signal and uses the recovered clock to determine transmitter-operation timing.
- **active prefer** --Auto negotiates with the far end of the link but preference is given to the active-clock switch.
- **passive prefer** --Auto negotiates with the far end of the link but preference is given to the passive-clock switch.

Enter the **show running-config interface** command to display the current clock mode.

Enter the **show interfaces** command to display the clock mode that is negotiated by the firmware.

Examples

This example shows how to enable the active-clock operation:

```
Router(config-if)# clock active
Router(config-if)#
```

Related Commands

Command	Description
show interfaces	Displays traffic that is seen by a specific interface.
show running-config interface	Displays the status and configuration of the module or Layer 2 VLAN.

clock destination

To specify the IP address of a Precision Time Protocol clock destination, use the **clockdestination** command in interface configuration mode. To remove a clock destination configuration, use the **no** form of this command.

clock destination *clock-ip-address*
no clock destination *clock-ip-address*

Syntax Description

clock-ip-address	IP address of the clock destination.

Command Default

No default behavior or values.

Command Modes

Clock port configuration (config-ptp-port)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

If the clock port is set to primary mode with unicast and negotiation is disabled, you can only configure a single destination. If the clock port is set to primary mode with unicast negotiation, you do not need to use this command because the device uses negotiation to determine the IP address of PTP subordinate devices.

Examples

The following example shows how to configure a PTP clock destination:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# clock-port masterPort master
Device(config-ptp-port)# clock destination 192.168.1.2
Device(config-ptp-port)# end
```

Related Commands

Command	Description
clock source	Specifies a PTP clock source.

clock mode

To configure the clock mode of a serial circuit emulation (CEM) channel, use the **clockmode** command in CEM configuration mode. To reset the clock mode to its default, use the **no** form of this command.

clock mode {**normal** | **split**}
no clock mode

Syntax Description

normal	Specifies normal mode, in which the DCE, whether it is a CEM over IP (CEoIP) data port or the external data device, provides both the receive clock and the transmit clock to the DTE.
split	Specifies split mode, in which the DCE, whether it is a CEoIP data port or the external device, provides the receiver clock to the DTE and the DTE provides the transmit clock to the DCE.

Command Default

The serial CEM channel clock defaults to normal mode.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command applies only to serial ports.

Examples

The following example shows how to configure the CEM clock for normal mode.

```
Router(config-cem)# clock mode normal
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clock rate	Configures the clock rate of a serial port.
clock source	Configures the clock source of a serial port.
show cem	Displays CEM statistics.

clock rate through cut-through

clock rate

To configure the clock rate for the hardware connections on serial interfaces such as network interface modules (NIMs) and interface processors to an acceptable bit rate, use the **clockrate** command in interface configuration mode. To remove the clock rate if you change the interface from a DCE to a DTE device, use the **no** form of this command. Using the **no** form of this command on a DCE interface sets the clock rate to the hardware-dependent default value.

clock rate *bps*
no clock rate

Syntax Description

bps	Desired clock rate, in bits per second: **1200**, **2400**, **4800**, **960**0, **19200**, **38400**, **56000**, **64000**, **72000**, **125000**, **148000**, **250000**, **500000**, **800000**, **1000000**, **1300000**, **2000000**, **4000000**, or **8000000** For the synchronous serial port adapters (PA-8T-V35, PA-8T-X21, PA-8T-232, and PA-4T+), a nonstandard clock rate can be used. You can enter any value from 300 to 8000000 bps. The clock rate you enter is rounded (adjusted), if necessary, to the nearest value that your hardware can support except for the following standard rates: **1200**, **2400**, **4800**, **960**0, **14400**, **19200**, **28800**, **38400**, **56000**, **64000**, **128000**, or **2015232**.

Command Default

No clock rate is configured.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
11.3	This command was modified to include nonstandard clock rates for the PA-8T-V35, PA-8T-X21, PA-8T-232, and PA-4T+ synchronous serial port adapters.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Cable Length

Be aware that the fastest speeds might not work if your cable is too long, and that speeds faster than 148,000 bits per second are too fast for EIA/TIA-232 signaling. It is recommended that you only use the synchronous serial EIA/TIA-232 signal at speeds up to 64,000 bits per second. To permit a faster speed, use EIA/TIA-449 or V.35.

Synchronous Serial Port Adapters

For the synchronous serial port adapters (PA-8T-V35, PA-8T-X21, PA-8T-232, and PA-4T+) on Cisco 7200 series routers, and on second-generation Versatile Interface Processors (VIP2s) in Cisco 7500 series routers, the clock rate you enter is rounded (if needed) to the nearest value that your hardware can support. To display the clock rate value for the port adapter, use the **showrunning-config**command.

If you plan to netboot your router over a synchronous serial port adapter interface and have a boot image prior to Cisco IOS Release 11.1(9)CA that does not support nonstandard (rounded) clock rates for the port adapters, you must use one of the following standard clock rates:

- **1200**
- **2400**
- **4800**
- **9600**
- **19200**
- **38400**
- **56000**
- **64000**

Examples

The following example shows how to set the clock rate on the first serial interface to 64,000 bps:

```
Router(config)# interface serial 0
Router(config-if)# clock rate 64000
```

The following example shows how to set the clock rate on a synchronous serial port adapter in slot 5, port 0 to 1,234,567 bps. In this example, the clock rate is adjusted to 1,151,526 bps.

```
Router(config)# interface serial 5/0
Router(config-if)# clock rate 1234567
%Clockrate rounded to nearest value that your hardware can support.
```

The following example shows how to determine the exact clock rate that the serial interface was rounded to by using the**showrunning-config** command.

```
Router# show running-config
Building configuration...
.
.
.
!
interface Serial5/0
 no ip address
 clockrate 1151526
!
.
.
.
```

clock rate (interface ATM)

To configure the clock rate between a WAN interface card (WIC) and the serial communication controllers (SCCs) that are used by the WIC, use the **clockrate** command in interface ATM configuration mode. To disable the clock rate setting, use the **no** form of this command.

clock rate [{**aal2** | **aal5**}] *clock-rate-value*
no clock rate [{**aal2** | **aal5**}] *clock-rate-value*

Syntax Description

aal2	(Optional) Specifies the ATM adaptation layer 2 (AAL2) clock rate.
aal5	(Optional) Specifies the ATM adaptation layer 5 (AAL5) clock rate.
clock-rate-value	**Clock rate value, which can be changed as follows:** • **aal2 --ForCisco1700seriesrouters,theminimumvalueforasymmetricdigitalsubscriberline(ADSL)a** **For Cisco 2600 and Cisco 3600 series routers, the minimum value for ADSL and G.SHDSL is for ADSL and G.SHDSL is 2.6 Mbps for both mainboard slots and network modules** . To make full use of the 2.3 Mbps bandwidth for Voice over ATM (VoATM) nonswitched trunk calls AAL2 clock rate as 2.6 Mbps. We recommend, however, that you keep the ADSL SCC clock rate for AAL2 at the default value of **Note** You should change the AAL2 default value on Cisco 2600 and Cisco 3600 series router for AAL2 should remain at 1 Mbps for ADSL and G.SHDSL. • **aal5** --For Cisco 1700 series routers, the minimum value for ADSL and G.SHDSL is 4 Mbps. For Cisco 2600 and Cisco 3600 series routers, the minimum value for ADSL and G.SHDSL is 1 Mb G.SHDSL is 2.6 Mbps for both mainboard slots and network modules. **Note** If you configure a clock rate that exceeds the maximum limit, the configuration will fai

Command Default

No clock rate is set

Command Modes

Interface ATM configuration

Command History

Release	Modification
12.2(8)YN	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T for the following platforms: Cisco 1721, Cisco 2610XM-2651XM, Cisco 2691, and Cisco 3660.

Usage Guidelines

The communication between digital subscriber line (DSL) WICs and a host in a router occurs through a device called the SCC. If a host wants to forward data or send any control traffic to a DSL WIC, it uses SCCs. In the same way, if a DSL WIC wants to forward incoming data from a line to the host, it also uses SCCs. Each DSL WIC installed in the router uses two SCCs. One SCC (SCC-A) is used for AAL5 data traffic, and the other SCC (SCC-B) is used for AAL2 and control traffic. The speed at which the SCC transfers data between a host and a WIC depends on the clock rate with which it has been configured. You can configure this clock rate on the basis of the DSL line rate. Even though the DSL upstream and downstream line rate may vary, the clock rate between the SCC and the DSL WIC is the same for both the transmitting and receiving direction. That is, the communication between the SCC and the DSL WIC is synchronous. Therefore, you need to configure only one clock rate for an SCC that will be used for both transmitting and receiving between an SCC and a DSL WIC.

We always recommend that you configure the SCC clock rate slightly higher than the DSL line rate to accommodate overhead between the SCC and the DSL WIC. For an asynchronous DSL WIC (for example, ADSL), the SCC clock rate depends on either the downstream or the upstream line rate, whichever is the maximum rate. For a synchronous DSL WIC (for example, G.SHDSL), the bandwidth for upstream and downstream is the same. Therefore, the SCC clock rate configuration can be based on either the upstream or the downstream line rate.

Because the maximum line rate for G.SHDSL is 2.312 Mbps, the default SCC clock rate of 2.6 Mbps for AAL5 and 1 Mbps for AAL2 should be sufficient. However, for ADSL, the clock rate may need to be configured on the basis of the current line rate. If AAL2 is used for voice traffic, the AAL2 SCC must be configured to the appropriate clock rate: 1 Mbps for ADSL and 2.6 Mbps for G.SHDSL.

The maximum data rate between an SCC and a DSL WIC depends primarily on the maximum clock rate that the SCC can support. For example, on the Cisco 2600 series mainboard, which supports two DSL WICs, the total SCC clock rate that can be configured for both WICs is 8 Mbps. Therefore, if only one DSL WIC is present on the mainboard, AAL5 and AAL2 clock rates can be configured to 7 Mbps and 1 Mbps, respectively. If two DSL WICs are supported on the mainboard, the total of 8 Mbps should be distributed among the four SCCs.

Network module SCCs also pose similar limitations. That is, on the Cisco 2600 series, the total clock rate for all four SCCs is 8 Mbps. The maximum AAL5 clock rate that may be configured on a network module is 5.3 Mbps. On the Cisco 1700 series, the maximum configurable SCC clock rate for both AAL5 and AAL2 is 8 Mbps.

If the clock rate is not configured, the SCC is reset to the default values.

The clock rate can be configured independently for each SCC. To verify the clock rate setting, use the **showrunning-config** command.

Examples

The following example shows how to set the clock rate to 2 Mbps for AAL5 and to 1.3 Mbps for AAL2 for a Cisco 2600 or Cisco 3600 series router:

```
Router (config)# interface atm1/0
Router (config-if)# no ip address
Router (config-if)# no atm ilmi-keepalive
Router (config-if)# pvc 6/65
Router (config-if)# clock rate aal5 2000000
Router (config-if)# clock rate aal2 1300000
Router (config-if)# vbr-nrt 640 640 128
Router (config-if)# tx-ring-limit 3
```

Related Commands

Command	Description
show running-config	Displays the current configuration.

clock rate (interface serial)

To configure the clock rate for the hardware connections on serial interfaces, such as network interface modules (NIMs) and interface processors, to an acceptable bit rate, use the **clockrate** command in interface configuration mode or Circuit Emulation Module (CEM) configuration mode. To remove the clock rate if you change the interface from a DCE to a DTE device, use the **no** form of this command. Using the **no** form of this command on a DCE interface sets the clock rate to the hardware-specific default value.

clock rate {**line***rate*}
no clock rate

Syntax Description

line	Specifies that the clock source is the network. **Note** This keyword is not supported on CEM serial interfaces.
rate	Desired clock rate, in bits per second (bps): **1200**, **2400**, **4800**, **9600**, **19200**, **38400**, **56000**, **64000**, **72000**, **125000**, **148000**, **250000**, **500000**, **800000**, **1000000**, **1300000**, **2000000**, **4000000**, or **8000000** For some synchronous serial port adapters a nonstandard clock rate can be used. Refer to the hardware documentation for specific supported Lvalues. You can enter any value from 300 to 8000000 bps. The clock rate you enter is rounded (adjusted), if necessary, to the nearest value that your hardware can support except for the following standard rates: **1200**, **2400**, **4800**, **9600**, **14400**, **19200**, **28800**, **38400**, **56000**, **64000**, **128000**, or **2015232**.

Command Default

No clock rate is configured.

Command Modes

Interface configuration CEM configuration in Circuit Emulation Module (CEM)

Command History

Release	Modification
10.0	This command was introduced.
11.3	This command was modified to include nonstandard clock rates for the PA-8T-V35, PA-8T-X21, PA-8T-232, and PA-4T+ synchronous serial port adapters.
12.3(2)T	This command was modified to include the **line** keyword.
12.4(5)M	The value range for the *rate* argument was updated to support additional baud rates of 300, 600, 1792K, and 1920K bps on CEM Network Modules.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Using the **no** form of this command on a DCE interface sets the clock rate to the hardware-dependent default value.

Cable Length

Be aware that the fastest speeds might not work if your cable is too long and that speeds faster than 148,000 bits per second are too fast for EIA/TIA-232 signaling. It is recommended that you use the synchronous serial EIA/TIA-232 signal at speeds up to 64,000 bits per second only. To permit a faster speed, use EIA/TIA-449 or V.35.

Synchronous Serial Port Adapters

For the synchronous serial port adapters (PA-8T-V35, PA-8T-X21, PA-8T-232, and PA-4T+) on Cisco 7200 series routers and on second-generation Versatile Interface Processors (VIP2s) in Cisco 7500 series routers, the clock rate that you enter is rounded (if needed) to the nearest value that your hardware can support. To display the clock rate value for the port adapter, use the **showrunning-config**command.

If you plan to boot from a network (TFTP) server over a synchronous serial port adapter interface and have a boot image prior to Cisco IOS Release 11.1(9)CA that does not support nonstandard (rounded) clock rates for the port adapters, you must use one of the following standard clock rates:

1200, 2400, 4800, 9600, 19200, 38400, 56000, 64000

CEM Network Modules

The following clock rates are supported on CEM Network Modules:

200, 300, 400, 600, 800, 1200, 1800, 2400, 3200, 3600, 4800, 6400, 7200, 8000, 9600, 12000, 12800, 14400, 16000, 16800, 19200, 24000, 28800, 32000, 38400, 48000, 56000, 57600, 64000, 76800, 84000, 96000, 112000, 115200, 128000, 144000, 168000, 192000, 224000, 230400, 256000, 288000, 336000, 384000, 448000, 512000, 672000, 768000, 772000, 896000, 1024000, 1152000, 1344000, 1536000, 1544000, 1792000, 1920000, 2048000

Examples

Network as Clock Source Example

The following example shows how to set the clock rate to use the network as the clock source:

```
Router(config)# interface serial 0
Router(config-if)# clock rate line
```

Clock Rate on Synchronous Serial Port Example

The following example shows how to set the clock rate on a synchronous serial port adapter in slot 5, port 0 to 1,234,567 bps. In this example, the clock rate is adjusted to 1,151,526 bps.

```
Router(config)# interface serial 5/0
Router(config-if)# clock rate 1234567
%Clockrate rounded to nearest value that your hardware can support.
```

Clock Rate Rounded on Serial Enterface Example

The following example shows how to determine the exact clock rate that the serial interface was rounded to by using the**showrunning-config** command.

```
Router# show running-config
Building configuration...
.
```

```
.
.
!
interface Serial5/0
 no ip address
 clockrate 1151526
!
```

CEM Channel Example

show running-config	Displays the current configuration.
show cem	Displays circuit emulation statistics.

clock rate network-clock

To configure the network clock rate (speed) for serial ports 0 or 1 in DCE mode, use the **clockratenetwork-clock** command in interface configuration mode. To cancel the network clock rate value, use the no form of this command.

clock rate network-clock *rate*
no clock rate network-clock *rate*

Syntax Description

rate	Network clock rate, in kbps per second. The range is from 56 to 2048. The value entered should be a multiple of the value set for the **network-clockbase-rate** command. There is no default rate.

Command Default

No clock rate is set.

Command Modes

Interface configuration

Command History

Release	Modification
11.3(1)MA	This command was introduced on the Cisco MC3810 multiservice access concentrator.

Usage Guidelines

This command uses a synchronized clock on the serial port. The use of this command allows the clock on the serial port to be synchronized with the clock source of controller T1 0.

To configure the clock rate for a serial port in DTE mode, use the **clockrateline** command.

Examples

The following example shows how to configure the clock rate on serial port 1 in DCE mode:

```
Router(config)# interface serial 1
Router(config-if)# clock rate network-clock 2048
```

Related Commands

Command	Description
clock rate line	Configures the line clock rate for serial ports 0 or 1 in DTE mode.
clock source (MC3810)	Specifies the clock source of a DS1 link on the Cisco MC3810 multiservice access concentrator.
network-clock base-rate	Configures the network clock base rate for universal I/O serial ports 0 and 1 on the Cisco MC3810 multiservice concentrator.

clock recovered adaptive/differential cem

To associate the clock recovered ID to the CEM group use the clock recovered adaptive or differential **cem** command in recovered clock mode

This command is also applicable to Cisco ASR 900 Series Routers.

clock recovered *clock id* **adaptive cem** *cem group no* *port-no*

clock recovered *clock id* **differential cem** *cem group no* *port-no*

Command Default

None

Command Modes

Recovered clock mode

Command History

Release	Modification
XE 3.18SP	This command was integrated into the Cisco NCS 4200 Series
XE Everest 16.5.1	This command is introduced on the Cisco ASR 900 Series Routers.

Usage Guidelines

This command is used to associate the clock recovered ID to the CEM group.

The following example shows how to associate the clock recovered ID to the CEM group.

```
recovered-clock 0 3
 clock recovered 1 adaptive cem 0 1
```

The following example shows how to associate the clock recovered ID to the CEM group.

```
recovered-clock 0 3
 clock recovered 1 differential cem 0 1
```

Related Commands

Table 7:

Command	Description
recovered-clock	Configures an associated clock ID with the corresponding CEM circuit.

clock source

To configure the clock source of a DS1 link, enter the **clocksource** command in interface configuration, controller configuration, or ATM interface configuration mode. To restore the default **line** setting, use the **no** form of this command.

clock source {**line** | **internal** | **loop-timed**}
no clock source

Syntax Description

line	Specifies that the T1/E1 link uses the recovered clock from the line. This is the default.
internal	Specifies that the T1/E1 link uses the internal clock from the interface.
loop-timed	Specifies that the T1/E1 interface takes the clock from the Rx (line) and uses it for Tx.

Command Default

The default value is **line**.

Command Modes

Interface configuration

Controller configuration for the Cisco MC3810 multiservice access concentrator.

ATM interface configuration for the Cisco 2600 and 3600 series routers.

Command History

Release	Modification
10.3	This command was introduced.
11.1 CA	This command was modified to support the E1-G.703/G.704 serial port adapter, PA-E3 serial port adapters, and Cisco 7200 series routers.
11.3 MA	This command was introduced as a controller configuration command for the Cisco MC3810.
12.0(5)T and 12.0(5)XK	The command was introduced as an ATM interface configuration command for the Cisco 2600 and 3600 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command sets clocking for individual T1/E1 links.

Make sure that you specify the clock source correctly for each link, even if you are planning to specify that a certain link will provide clocking for all the links in an IMA group. Because links may be taken in and out of service, requiring that the system select another link for common clocking, any link in an IMA group may provide the common clock.

If the ATM interface is part of an IMA group, you can use the **loop-timed** keyword to specify that the clock source is the same as the IMA group clock source.

Examples

On a Cisco 2600 or 3600 series router, the following example specifies an internal clock source for the link:

```
Router(config)# interface atm 0/2
Router(config-if)# clock source internal
```

Related Commands

Command	Description
ima clock-mode	Sets the transmit clock mode for an ATM IMA group.

clock source(10GE)

To specify the clock source of a 10 Gigabit Ethernet (GE) line card, use the **clocksource** command in interface configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

clock source {**internal** | **line** | **loop**}
no clock source {**internal** | **line** | **loop**}

Syntax Description

internal	Uses the internal clock. This is the default.
line	Recovers the clock from the line.
loop	Uses local loop timing.

Command Default

The default is internal.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced for the 7600-ES+ITU-2TG and 7600-ES+ITU-4TG.

Usage Guidelines

When the clock source is internal, the port receive (Rx) clock is not eligible as the system clock source. The port transmit (Tx) clock is synchronized to the system clock.

When the clock source is line, the port Rx clock is eligible as the system clock source. The port Tx clock is synchronized to the system clock.

When the clock source is loop, the port Rx clock is not eligible as the system clock source. The port Tx clock is synchronized to its own Rx clock.

Examples

The following example shows how to specify line timing as the clock source:

```
Router(config)# interface TenGigabitEthernet 1/1
Router(config-if)# clock source line
```

The following example shows how to specify the internal clock on the interface provided by the 7600-ES+ITU-2TG or the 7600-ES+ITU-4TG:

```
Router(config)# interface TenGigabitEthernet 1/1
```

Router(config-if)# **clocksourceinternal**

Related Commands

Command	Description
network-clock select	Selects a source for the network clock.
show network-clocks	Displays the current configured and active network clock sources.

Command	Description
show platform hardware network-clocks	Displays network clocks for an ES+ line card.

clock source (AS5200)

To select the clock source for the time-division multiplexing (TDM) bus in a Cisco AS5200 access server, use the **clocksource** command in interface configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

clock source {**line** {**primary** | **secondary**} | **internal**}
no clock source line {**primary** | **secondary**}

Syntax Description

line	Clock source on the active line.
primary	Primary TDM clock source.
secondary	Secondary TDM clock source.
internal	Selects the free running clock (also known as internal clock) as the clock source.

Command Default

The primary TDM clock source is from the T1 0 controller.

The secondary TDM clock source is from the T1 1 controller.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in 12.2S-Family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

To use the clocking coming in from a T1 line, configure the **clocksourcelineprimary** command on the T1 interface that has the most reliable clocking. Configure the **clocksourcelinesecondary** command on the T1 interface that has the next best known clocking. With this configuration, the primary line clocking is backed up to the secondary line if the primary clocking shuts down.

Examples

The following example configures the Cisco AS5200 access server to use T1 controller 0 as the primary clock source and T1 controller 1 as the secondary clock source:

```
Router(config)# controller t1 0
Router(config-controller)# clock source line primary
Router(config)# controller t1 1
Router(config-controller)# clock source line secondary
```

clock source (CEM)

To configure the clock source of a circuit emulation (CEM) network module port, use the **clocksource** command in CEM configuration mode or controller configuration mode. To return to the default clock source, use the **no** form of this command.

Cisco NM-CEM-4SER
clock source {**internal** | **loop** | **adaptive**}
no clock source {**internal** | **loop** | **adaptive**}

Cisco NM-CEM-4TE1
clock source {**internal** | **line** | **adaptive** *channel-number* [{**closed-loop** | **open-loop** | **coarse**}]}
no clock source {**internal** | **line** | **adaptive** *channel-number* [{**closed-loop** | **open-loop** | **coarse**}]}

Cisco NCS4200 Series
clock source {**internal** | **line** | **recovered**}
no clock source {**internal** | **line** | **recovered**}

Syntax Description

internal	Specifies that the clocks provided by the port to the attached CPE are derived from the router's TDM bus backplane clock (if one exists in the router) or from the onboard oscillator on the network module. This is the default clock source for a Cisco NM-CEM-4SER. For Cisco NCS 4200 Series, internal is the default clock source for channelized mode.
loop	(Cisco NM-CEM-4SER network module only) Specifies that the clock provided by the port to the attached CPE is derived from the clock received on the same port from the attached CPE.
line	(Cisco NM-CEM-4TE1 network module only) Specifies that the port transmit clock is derived from receive clock on the same port. This is the default clock source for a Cisco NM-CEM-4TE1. For Cisco NCS 4200 Series, line is the default clock source for un-channelized mode.
adaptive	Specifies that the clocks provided by the port to the attached CPE are locally synthesized on the basis of the average data content of the local dejitter buffer.
channel-number	(Cisco NM-CEM-4TE1 network module only) Number of the channel whose dejitter buffer is to be used to synthesize the transmit clock of the port.
closed-loop	(Optional; Cisco NM-CEM-4TE1 network module only) Specifies that the adaptive clock algorithm enhancements are used to improve the adaptive clock accuracy. The same clock must be used in both directions for the closed loop mode. This keyword is supported in Cisco IOS Release 12.4(2)T and later releases.
open-loop	(Optional; Cisco NM-CEM-4TE1 network module only) Specifies that some of the adaptive clock algorithm enhancements are used but the clocks do not have to be the same in both directions. This is the default. This keyword is supported in Cisco IOS Release 12.4(2)T and later releases.

coarse	(Optional; Cisco NM-CEM-4TE1 network module only) Specifies that the original adaptive clock algorithm without the enhancements is used. This keyword is supported in Cisco IOS Release 12.4(2)T and later releases.
recovered	Specifies the recovered clock number. This applies the recovered clock from a CEM interface on a T1/E1 Controller.

Command Default

The clock source defaults to **internal**.

The clock source defaults to **line**

Command Modes

CEM configuration

Controller configuration

Controller configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.4(2)T	The **closed-loop**, **open-loop**, and **coarse** keywords were added.
XE 3.18SP	This command was integrated in Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated in Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

When clock source **internal** is specified, the clocks provided by the network module are derived from either of the following source:

- The router's backplane TDM clock frequency (in any router equipped with a TDM backplane bus)
- The master oscillator on the network module (in any router not equipped with a TDM backplane bus)

When the **adaptive** keyword is specified, the clocks provided by the network module are derived from the same source as in the clock source **internal** case. However, the derived frequency is further adjusted up or down on the basis of the measured average fill of the egress dejitter buffer of the connection. If the dejitter buffer is perceived to be slowly filling, the frequency is adjusted slightly upward. If the dejitter buffer is perceived to be slowly depleting, the frequency is adjusted slightly downward.

Cisco NM-CEM-4SER

When the **loop** keyword is specified, the clock provided by the NM-CEM-4SER is the same as the clock provided to the NM-CEM-4SER from the attached CPE. The specification of clock source **loop** is only valid when the **clockmodesplit** command is specified. The **clockmode** command is used only during configuration of the NM-CEM-4SER.

Cisco NM-CEM-4TE1

In Cisco IOS Release 12.4(2)T, the adaptive clocking algorithm is enhanced to provide better adaptive clock accuracy. Three new keywords are used to specify the preferred mode:

- **closed-loop** --Specifies the closed loop mode. Taking advantage of the fact that a T1 or E1 link uses the same clock in both directions, the adaptive clock algorithm enhancements are used to improve the adaptive clock accuracy. The same clock must be used in both directions for the closed loop mode, and both ends of the CEM must be running a Cisco IOS release that supports the enhanced adaptive clock algorithm. Use the closed loop mode when clock accuracy is required, the master clock from the customer premises equipment (CPE) is of good quality, and the clocks are the same in both directions of the T1 or E1 link.

Note Do not use the closed loop mode in applications where the clocks are different for the two directions of the T1 or E1 link.

- **open-loop** --Specifies the open loop mode. Some of the adaptive clock algorithm is used, but this mode does not require the clocks to be the same in both directions. This mode is compatible with previous Cisco IOS releases and is the default mode if no keyword is specified. Use the open loop mode when the master clock from the CPE is of good quality, but the clocks are not the same in both directions of the T1 or E1 link.
- **coarse** --Specifies the coarse mode. The coarse mode uses the original adaptive clock algorithm and is used when the stability of the master clock derived from the CPE is not guaranteed. This mode is compatible with previous Cisco IOS releases.

Examples

The following example shows how to configure the clock source for the serial CEM network module, NM-CEM-4SER:

```
Router(config-cem)# clock source loop
```

The following example shows how to configure the clock source for the T1/E1 CEM network module, NM-CEM-4TE1:

```
Router(config-controller)# clock source adaptive 6
```

The following example shows how to configure the clock source for an NM-CEM-4TE1 using the closed-loop mode to improve the adaptive clock accuracy:

```
Router(config-controller)# clock source adaptive 5 closed-loop
```

The following example shows how to configure the clock source for the T1 or T3 CEM network module:

```
Router(config-controller)# clock source recovered 1
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clock mode	Configures the clock mode on an NM-CEM-4SER network module.
show cem	Displays CEM channel statistics.

clock source (controller)

To set the T1 line clock source, use the **clock source** command in controller configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

Cisco 4400 Integrated Services Routers

clock source [{**line** {**primary** | **secondary**} | **internal** | **network**}]

no clock source

Cisco 7200 and Cisco 7500 Series Routers

clock source [{**line** {**primary** | **secondary**} | **internal**}]

no clock source

Cisco 10000 Series Router

clock source [{**line** | **internal**}]

no clock source

Syntax Description

line	(Optional) Specifies that the interface will clock its transmitted data from a clock recovered from the line's receive data stream. This is the default.
primary	Specifies the source of primary line clocking. The default primary time-division multiplexing (TDM) clock source is from the T0 controller.
secondary	Specifies the source of secondary line clocking. The default secondary TDM clock source is from the T1 controller.
internal	(Optional) Specifies that the interface will clock its transmitted data from its internal clock.
network	(Optional) Specifies that the master clock is from the module's TDM switch. This is required for voice applications.

Command Default

Cisco 4400 Integrated Services Routers

The default clock source is line.

Cisco 7200 and Cisco 7500 Series Routers

The default clock source is line. The default primary TDM clock source is from the T0 controller. The default secondary TDM clock source is from the T1 controller. The default clock for the interface's transmitted data is from a clock recovered from the line's receive data stream from the PA-T3 serial port adapter.

Cisco 10000 Series Router

The default clock source is internal.

Command Modes

Controller configuration

Command History

Release	Modification
10.3	This command was introduced.

Release	Modification
11.1CA	This command was modified to include the T3 serial port adapter and PA-T3 serial port adapter.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 3.9S	This command was modified to include the **network** keyword.

Usage Guidelines

This command is available on Cisco 4000, Cisco 4400 ISR, Cisco 7000 series, Cisco 7200 series, Cisco 7500 series, and Cisco 10000 series routers. A T3 interface on a PA-T3 serial port adapter can clock its transmitted data either from its internal clock or from a clock recovered from the line's receive data stream.

Clocking on a T1 Line

To use the clocking coming in from a T1 line, configure the **clock source line primary** command on the controller that has the most reliable clocking. Configure the **clock source line secondary** command on the controller that has the next best known clocking. With this configuration, the primary line clocking is backed up to the secondary line if the primary clocking shuts down.

Cisco 10000 Series Router

The clock source cannot be specified as line on both ends of the connection.

Cisco 4400 ISR Series

The following example sets the master clock to the TDM switch:

```
Device(config)# controller t1 0/1/0
Device(config-controller)# clock source network
```

Cisco 7200

The following example shows how to configure the Cisco 7200 to use the T0 controller as the primary clocking source and the T1 controller as the secondary clocking source:

```
C7200(config)# controller t1 0
C7200(config-controller)# clock source line primary
C7200(config-controller)# exit
C7200(config)# controller t1 1
C7200(config-controller)# clock source line secondary
```

Cisco 10000 Series Router

The following example instructs the controller to use a line clock source:

```
Device(config)# controller dsx3 4/0/6
Device(config-controller)# clock source line
```

Related Commands

Command	Description
framing	Selects the frame type for the T1 or E1 data line.
linecode	Selects the line code type for T1 or E1 line.

clock source (CT3IP)

To specify where the clock source is obtained for use by the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **clocksource** command in controller configuration mode. To restore the default clock source, use the **no** form of this command.

clock source {**internal** | **line** | **loop-timed**}
no clock source

Syntax Description

internal	Specifies that the internal clock source is used. This is the default.
line	Specifies that the network clock source is used.
loop-timed	Decouples the controller clock from the system-wide clock set with the **network-clock-select** command. The loop-timed clock enables the Digital Voice Module (DVM) to connect to a PBX and to connect the Multiflex Trunk Module (MFT) to a central office when both the PBX and the central office function as DCE clock sources. This situation assumes that the PBX also takes the clocking from the central office, thereby synchronizing the clocks on the DVM and the MFT.

Command Default

The internal clock source is used.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not specify the **clocksource**command, the default internal clock source is used by the CT3IP.

You can also set the clock source for each T1 channel by using the **t1clocksource** controller configuration command.

Note This command replaces the **posinternal-clock** command.

Examples

The following example sets the clock source for the CT3IP to line:

```
Router(config)# controller t3 9/0/0
Router(config-controller)# clock source line
```

Related Commands

Command	Description
network-clock-select	Specifies selection priority for the clock sources.
t1 clock source	Specifies where the clock source is obtained for use by each T1 channel on the CT3IP in Cisco 7500 series routers.

clock source (interface)

To control the clock from which a G.703-E1 interface, an E1-G.703/G.704 serial port adapter, or a PA-E3 serial port adapter clocks its transmitted data, use the **clocksource** command in interface configuration mode. To restore the default clock source, use the **no** form of this command.

Cisco ASR 901 Series Aggregation Services Routers
clock source {**line** | **internal** | **loop**}
no clock source

Cisco AS5300 Access Servers
clock source {**line** {**primary** | **secondary**} | **internal**}
no clock source line {**primary** | **secondary**}

Cisco ASR 901 Series Aggregation Services Routers
clock source {**line** | **internal** | **loop**}
no clock source

Syntax Description

line	Specifies that the interface will clock its transmitted data from a clock recovered from the line's receive data stream. This is the default.
internal	Specifies that the interface will clock its transmitted data from its internal clock.
primary	Specifies the primary time-division multiplexing (TDM) clock source.
loop	Specifies that the system clock-selection process selects the clock source line as the interface. For the transmit (Tx) clock, the interface uses the clock source received on the same interface.
loop	Specifies that the system clock-selection process selects the clock source line as the interface. For the transmit (Tx) clock, the interface uses the clock source received on the same interface.

Command Default

Cisco 7000, Cisco 7200, and Cisco 7500 Series

The clock source is obtained from the receive data stream of the line.

Cisco AS5300 Access Servers

The primary TDM clock source is from the T0 controller. The secondary TDM clock source is from the T1 controller.

Cisco ASR 901 Series Aggregation Services Routers

The default clock source is internal.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced for the Cisco 4000 series, Cisco 7000 series w ith RSP7000, and Cisco 7500 series routers with the G.703 E1 interface.

Release	Modification
11.1 CA	This command was implemented on the TDM bus in a Cisco AS5200 or Cisco AS5300 access server and was modified to support the E1-G.703/G.704 serial port adapter, PA-E3 serial port adapters, and Cisco 7200 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers. The **loop** keyword was added.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers. The **loop** keyword was added.

Usage Guidelines

Cisco 7000, Cisco 7200, and Cisco 7500 Series

A G.703-E1 interface , E1-G.703/G.704 serial port adapter, or a PA-E3 serial port adapter can clock its transmitted data from either its internal clock or from a clock recovered from the line’s receive data stream.

Cisco AS5300 Access Servers

To use the clocking coming in from a T1 line, configure the **clocksourcelineprimary** command on the controller that has the most reliable clocking. Configure the **clocksourcelinesecondary** command on the controller that has the next best known clocking. With this configuration, the primary line clocking is backed up to the secondary line if the primary clocking shuts down.

Examples

Cisco 7000, Cisco 7200, and Cisco 7500 Series

The following example shows how to configure the G.703-E1 interface to clock its transmitted data from its internal clock:

```
Router(config)# interface serial 0/1
Router(config-if)# clock source internal
```

Cisco ASR 901 Series Aggregation Services Routers

The following example shows how to use an internal clock source:

```
Router(config-if)# clock source internal
```

Cisco ASR 901 Series Aggregation Services Routers

The following example shows how to use an internal clock source:

```
Router(config-if)# clock source internal
```

clock source (J1 controller)

To configure the clock source for a J1 controller, use the clock source command in controller configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

clock source {**line** | **internal**}
no clock source

Syntax Description

line	The controller recovers the external clock from the line and provides the recovered clock to the internal (system) clock generator. The line value is the default clock source.
internal	The controller synchronizes itself to the internal (system) clock.

Command Default

Clock source is line for the J1 controller.

Command Modes

Controller configuration

Command History

Release	Modification
11.1 T	This command was introduced.
12.2(8)T	The command was introduced as a J1 controller configuration command for the Cisco 2600 and Cisco 3600 series.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If multiple network modules are present in the router, then each J1 controller must be given a separate priority by configuration of the network-clock-select command. The controller having the highest priority will drive the internal clock.

Examples

The following example configures the clock source for line:

```
Router(config)# controller j1 3/0
Router(config-controller)# clock source line
```

Related Commands

Command	Description
network-clock-select	Sets the selection priority for a clock source.

clock source (MC3810)

To specify the clock source of a DS1 link on the Cisco MC3810 multiservice access concentrator, use the **clocksource** command in controller configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

clock source {**line** | **internal** | **loop-timed**}
no clock source

Syntax Description

line	Specifies that the DS1 link uses the recovered clock. The line value is the default clock source used when the Multiflex Trunk (MFT) is installed.
internal	Specifies that the DS1 link uses the internal clock. The internal value is the default clock source used when the Digital Voice Module (DVM) is installed.
loop-timed	Specifies that the T1/E1 controller will take the clock from the Rx (line) and use it for Tx. This setting decouples the controller clock from the system-wide clock set with the **network-clock-select** command. The loop-timed clock enables the DVM to connect to a PBX and to connect the MFT to a central office when both the PBX and the central office function as DCE clock sources. This situation assumes that the PBX also takes the clocking from the central office, thereby synchronizing the clocks on the DVM and the MFT.

Command Default

Line (when the MFT is installed) Internal (when the DVM is installed)

Command Modes

Controller configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in 12.2S-Family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to Voice-over-Frame Relay, Voice-over-ATM, and Voice-over-HDLC on the Cisco MC3810.

Note You cannot configure the clock source to the line setting for both T1/E1 controllers at the same time.

Examples

The following example configures the clock source for the MFT to internal, and the clock source for the DVM line on a Cisco MC3810 multiservice access concentrator:

```
Router(config)# controller T1 0
Router(config-controller)# clock source internal
Router(config)# controller T1 1
Router(config-controller)# clock source line
```

clock source (SONET controller)

To specify the clock source of a SONET controller, use the **clocksource** command in controller configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

clock source {**internal** | **line** | **loop**}
no clock source

Syntax Description

internal	Specifies that the clock source uses the internal clock provided by the Route Switch Controller (RSC). This is the default.
line	Specifies that the clock source uses the primary system clock from the optical line and the recovered clock will go through the RSC phased locked loop (PLL) circuitry. Can be used when one or more STM-1 cards are installed.
loop	Specifies that the clock source uses the primary system clock from the optical line and the same recovered clock is used in the transmit (tx) direction without going through the RSC PLL circuitry. Can be used when only one STM-1 card is installed.

Command Default

Internal

Command Modes

Controller configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to specify line timing as the clock source on a SONET controller of an STM-1 card in physical slot number 2 on a Cisco AS5850:

```
Router(config)# controller sonet 2/0
Router(config-controller)# clock source line
```

clock source (T1 E1 controller)

To set clocking for individual T1 or E1 links, use the **clocksource** command in controller configuration mode. To return to the default, use the **no** form of this command.

clock source {**line** [{**primary** | **bits** | **independent**}] | **internal** [**independent**] | **free-running**}
no clock source

Syntax Description

line	Specifies that the phase-locked loop (PLL) on this controller derives its clocking from the external source to which the controller is connected, which is generally the telephone company central office (CO).
primary	(Optional) Specifies that the PLL on this controller derives its clocking from the external source to which the controller is connected. This option also puts a second port, which is generally connected to the PBX, into looped-time mode. Both ports are configured with line, but only the port connected to the external source is configured with primary.
bits	(Optional) Specifies that the controller will derive clocking from the Building Integrated Timing Supply (BITS).
independent	(Optional) Specifies that the port can operate on an independent clocking domain. Before this capability was added, on a 2-port VWIC-MFT, if both ports were configured as **clocksourceline**, the 2-port was really looped, which meant that it was getting the clock from the first port. With independent clocking mode, this dependency no longer exists, so the keyword **independent** means that both ports can be independently clocked.
internal	Specifies that the clock is generated from the T1 or E1 controller's internal PLL.
free-running	Specifies a free-running clock derived from the oscillator on the motherboard, which is used only for testing and back-to-back connections.

Command Default

The default is **line**.

Command Modes

Controller configuration

Command History

Release	Modification
12.2(2)XB	This command was introduced in controller configuration mode for Cisco 2600 series and Cisco 3660 routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(15)T	This command was implemented on the Cisco 2691 and the Cisco 3700 series.
12.3(4)XD	The **bits** keyword was added.
12.3(7)T	The **bits** keyword was integrated into Cisco IOS Release 12.3(7)T.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T and the **independent**keyword was added.

Usage Guidelines

For a detailed discussion of clock sources on individual ports, refer to "Clock Sources on Digital T1/E1 Voice Ports" in the Voice Configuration Library at the following URL: http://www.cisco.com/en/US/products/ps6441/prod_configuration_guide09186a0080565f8a.html

Examples

The following example shows the router providing clock source to two controllers:

```
Router(config)# controller E1 1/0
Router(config-controller)# framing crc
Router(config-controller)# linecoding hdb3
Router(config-controller)# clock source internal
Router(config-controller)# ds0-group timeslots 1-15 type e&m-wink-start
!
Router(config)# controller E1 1/1
Router(config-controller)# framing esf
Router(config-controller)# linecoding b8zs
Router(config-controller)# clock source internal
Router(config-controller)# ds0-group timeslots 1-15 type e&m-wink-start
```

The following example shows the digital voice hardware receiving clocking for the PLL from E1 1/0 and using this clock as a reference to clock E1 1/1. If controller E1 1/0 fails, the PLL internally generates the clock reference to drive E1 1/1.

```
Router(config)# controller E1 1/0
Router(config-controller)# framing crc
Router(config-controller)# linecoding hdb3
Router(config-controller)# clock source line
Router(config-controller)# ds0-group timeslots 1-15 type e&m-wink-start
!
Router(config)# controller E1 1/1
Router(config-controller)# framing crc4
Router(config-controller)# linecoding hdb3
Router(config-controller)# clock source internal
Router(config-controller)# ds0-group timeslots 1-15 type e&m-wink-start
```

The following example shows the router being configured to receive clocking from the BITS.

```
Router(config)# network-clock-participate slot 1
Router(config)# network-clock-select 1 E1 1/1
Router(config)# controller E1 1/1
Router(config-controller)# clock source line bits
```

Related Commands

Command	Description
controller	Configures a T1 or E1 controller and enters controller configuration mode.

clock source (T1 E1 interface)

To configure the clock source of a DS1 link, use the **clocksource** command in interface configuration or ATM interface configuration mode. To restore the default line setting, use the **no** form of this command.

clock source {**line** | **internal** | **loop-timed**}
no clock source

Syntax Description

line	Specifies that the T1/E1 link uses the recovered clock from the line. This is the default.
internal	Specifies that the T1/E1 link uses the internal clock from the interface.
loop-timed	Specifies that the T1/E1 interface takes the clock from the Rx (line) and uses it for Tx.

Command Default

line

Command Modes

Interface configuration ATM interface configuration for the Cisco 2600 and Cisco 3600 series routers

Command History

Release	Modification
10.3	This command was introduced.
11.1CA	This command was modified to support the E1-G.703/G.704 serial port adapter, PA-E3 serial port adapters, and Cisco 7200 series routers.
11.3MA	This command was introduced as a controller configuration command for the Cisco MC3810.
12.0(5)XK	The command was introduced as an ATM interface configuration command for the Cisco 2600 and Cisco 3600 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command sets clocking for individual T1/E1 links.

Make sure that you specify the clock source correctly for each link, even if you are planning to specify that a certain link will provide clocking for all the links in an IMA group. Because links may be taken in and out of service, requiring that the system select another link for common clocking, any link in an IMA group may provide the common clock.

If the ATM interface is part of an IMA group, you can use the **loop-timed** keyword to specify that the clock source is the same as the IMA group clock source.

Examples

On a Cisco 2600 or Cisco 3600 series router, the following example specifies an internal clock source for the link:

```
Router(config)# interface atm 0/2
Router(config-if)# clock source internal
```

Related Commands

Command	Description
ima clock-mode	Sets the transmit clock mode for an ATM IMA group.

clock source (T3 E3 controller)

To specify where the clock source is obtained for use by a T3 or E3 controller, use the **clocksource** command in controller configuration mode. To restore the default clock source, use the no form of this command.

clock source {**internal** | **line**}
no clock source

Syntax Description

internal	Specifies that the internal clock source is used. This is the default for T3.
line	Specifies that the network clock source is used. This is the default for E3.

Command Default

The internal clock source is used for T3 controllers. The line clock source is used for E3 controllers.

Command Modes

Controller configuration

Command History

Release	Modification
12.2(11)YT	This command was introduced on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

If you do not specify the clock source command, the default clock source is used.

Configure the **clocksourceline** command if your telephone company or the remote data service unit provides the master clock of the T3 or E3 connection.

Configure the **clocksourceinternal** command if your router provides the master clock of the T3 or E3 connection.

Note For a back-to-back connection between two T3 or E3 network modules, one controller must be configured for internal clocking while the other controller must be configured for line clocking.

Examples

The following example shows how to set the clock source to line:

```
Router(config)# controller t3 1/0
Router(config-controller)# clock source line
```

Related Commands

Command	Description
controller	Configures a T1 or E1 controller and enters controller configuration mode.

clock switchover

To specify the input lead state change that triggers the clock switching over from line to internal or from internal to line, use the clock switchover command in Data Circuit Terminating Equipment (DCE) split mode. To disable the command's effect, use the **no** form of this command.

clock switchover {**rts** | **dtr** | **ll** | **rl**} {**off** | **on**}
no clock switchover {**rts** | **dtr** | **ll** | **rl**} {**off** | **on**}

Syntax Description

off | on	On - clock switches over to internal clock when lead state is on; clock switches over to the CPE-provided clock when lead state is off. Default value. Off - clock switches over to internal clock when lead state is off; clock switches over to the CPE-provided clock when lead state is on.

Command Default

The default state is on.

Command Modes

DCE split mode (off / on).

Command History

Release	Modification
12.4(20)YA	This command was introduced.
12.4(22)T	This command is integrated into Cisco IOS Release 12.4(22)T.

Usage Guidelines

You can use the clock switchover command to switch the clock source over to internal clock. This is to provide continuity of the CEM channel when disruption of the RxC cable from the CPE occurs.

Examples

The following example shows how the clock switchover <input_lead> <off | on > command is used to check the input lead state for the clock switchover feature:

```
Router(mode-prompt
)# clock switchover <dtr> <off | on>
```

clock-port

To specify the clocking mode of a Precision Time Protocol clock port, enter clock port configuration mode using the **clock-port** command in the PTP clock configuration mode. To remove a clocking mode configuration, use the **no** form of this command.

clock-port *name* {**slave** | **master**}[{**profile g8265.1**}]
no clock-port *name* {**slave** | **master**}

Syntax Description

name	Specifies a name for the clock port.
slave	Sets the clock port to PTP subordinate mode; the port exchanges timing packets with a PTP primary device.
master	Sets the clock port to PTP primary mode; the port exchanges timing packets with PTP subordinate devices.
profile g8265.1	(Optional) Sets the clock to use the ITU-T G.8265.1 recommendations for establishing PTP sessions, determining the best primary clock, handling synchronization status message (SSM), and mapping PTP classes.

Command Default

This command is disabled by default.

Command Modes

PTP clock configuration (config-ptp-clk)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
Cisco IOS Release 3.8S	The **profile g8265.1** keyword was added on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

This command defines a new clock port and enters clock port configuration mode.

Cisco IOS XE Release 3.8S introduces support for telecom profiles, which allow you to configure a clock that uses the ITU-T G.8265.1 recommendations for establishing PTP sessions, determining the best primary clock, handling SSM, and mapping PTP classes.

Examples

The following example shows how to configure a PTP clock port:

```
Device> enable
Device# configure terminal
Device# ptp clock boundary domain 0
Device(config-ptp-clk)# clock-port slave slaveport
Device(config-ptp-port)# clock source 8.8.8.1
Device(config-ptp-port)# sync limit 1
Device(config-ptp-port)# announce timeout 4
```

```
Device(config-ptp-port)# delay-req interval 2
Device(config-ptp-port)# end
```

Related Commands

Command	Description
ptp clock	Creates a PTP clock instance.

cmt connect

To start the processes that perform the connection management (CMT) function and to allow the ring on one fiber to be started, use the **cmtconnect** command in user EXEC or privileged EXEC mode.

cmt connect [**fddi** [{*port* | *slot/port*}] [{**phy-a** | **phy-b**}]]

Syntax Description

fddi	(Optional) Identifies this as a FDDI interface.
port	(Optional) Port number . Refer to the appropriate hardware manual for slot and port information.
slot	(Optional) Slot n umber. Refer to the appropriate hardware manual for slot and port information.
phy-a	(Optional) Selects Physical Sublayer A.
phy-b	(Optional) Selects Physical Sublayer B.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In normal operation, the FDDI interface is operational once the interface is connected and configured. The **cmtconnect** command allows the operator to start the processes that perform the CMT function.

The **cmtconnect** command is not needed in the normal operation of FDDI; this command is used mainly in interoperability tests.

This command does not have a **no** form. To stop the CMT processes, use the **cmtdisconnect** command.

Examples

The following examples demonstrate use of the **cmtconnect** command for starting the CMT processes on the FDDI ring.

The following command starts all FDDI interfaces:

```
Router# cmt connect fddi
```

The following command starts both fibers on FDDI interface unit 0:

```
Router# cmt connect fddi 0
```

The following command on the Cisco 7200 series or Cisco 7500 series starts both fibers on FDDI interface unit 0:

```
Router# cmt connect fddi 1/0
```

The following command starts only Physical Sublayer A on FDDI interface unit 0:

```
Router# cmt connect fddi 0 phy-a
```

Related Commands

Command	Description
cmt disconnect	Stops the CMT processes.

cmt disconnect

To stop the processes that perform the connection management (CMT) function and to allow the ring on one fiber to be stopped, use the **cmtdisconnect** command in user EXEC or privileged EXEC mode.

cmt disconnect [**fddi** [{*port* | *slot*/*port*}] [{**phy-a** | **phy-b**}]]

Syntax Description

fddi	(Optional) Identifies this as a FDDI interface.
port	(Optional) Port n umber. Refer to the appropriate hardware manual for slot and port information.
slot	(Optional) Slot number. Refer to the appropriate hardware manual for slot and port information.
phy-a	(Optional) Selects Physical Sublayer A.
phy-b	(Optional) Selects Physical Sublayer B.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In normal operation, the FDDI interface is operational once the interface is connected and configured, and is turned on using the **noshutdown** command in interface configuration mode. The **cmtdisconnect** command allows the operator to stop the processes that perform the CMT function and allow the ring on one fiber to be stopped.

The **cmtdisconnect** command is not needed in the normal operation of FDDI; this command is used mainly in interoperability tests.

This command does not have a **no** form. To start the CMT processes, use the **cmtconnect** command.

Examples

The following examples demonstrate use of the **cmtdisconnect** command for stopping the CMT processes on the FDDI ring.

The following command stops all FDDI interfaces:

```
Router# cmt disconnect fddi
```

The following command stops both fibers on FDDI interface unit 0:

```
Router# cmt disconnect fddi 0
```

The following command on the Cisco 7200 series or Cisco 7500 series stops both fibers on FDDI interface unit 0:

```
Router# cmt disconnect fddi 1/0
```

The following command stops only Physical Sublayer A on the FDDI interface unit 0. This command causes the FDDI media to go into a wrapped state so that the ring will be broken.

```
Router# cmt disconnect fddi 0 phy-a
```

The following command on the Cisco 7500 series stops only Physical Sublayer A on FDDI interface unit 0 in slot 1. This command causes the FDDI media to go into a wrapped state so that the ring will be broken.

```
Router# cmt disconnect fddi 1/0 phy-a
```

Related Commands

Command	Description
cmt connect	Starts the CMT processes.

compress

To configure software compression for Link Access Procedure, Balanced (LAPB), PPP, and High-Level Data Link Control (HDLC) encapsulations, use the **compress** command in interface configuration mode. To disable compression, use the **no** form of this command.

compress {**predictor** | **stac**}
no compress {**predictor** | **stac**}

Cisco VIP2 Cards
compress {**predictor** | **stac** [{**distributed** | **software**}]}
no compress {**predictor** | **stac** [{**distributed** | **software**}]}

Cisco 7200 Series and Cisco 7500 Series
compress {**predictor** | **stac** [{**csa** *slot* | **software**}]}
no compress {**predictor** | **stac** [{**csa** *slot* | **software**}]}

PPP Encapsulation
compress [{**predictor** | **stac** | **mppc** [**ignore-pfc**]}]
no compress [{**predictor** | **stac** | **mppc** [**ignore-pfc**]}]

Syntax Description

predictor	Specifies that a predictor compression algorithm will be used on LAPB and PPP encapsulation. Compression is implemented in the software installed in the router's main processor.
stac	Specifies that a Stacker (LZS) compression algorithm will be used on LAPB, HDLC, and PPP encapsulation. For all platforms except Cisco 7200 series and platforms that support the Virtual Interface Processor 2 (VIP2), compression is implemented in the software installed in the router's main processor. On Cisco 7200 series and on VIP2s in Cisco 7500 series, specifying the **compressstac** command with no options causes the router to use the fastest available compression method for PPP encapsulation only: • If the router contains a compression service adapter (CSA), compression is performed in the CSA hardware (hardware compression). • If a CSA is not available, compression is performed in the software installed on the VIP2 (distributed compression). • If a VIP2 is not available, compression is performed in the router's main processor (software compression).
distributed	(Optional) Specifies that compression is implemented in the software that is installed in a VIP2. If the VIP2 is not available, compression is performed in the router's main processor (software compression).
software	(Optional) Specifies that compression is implemented in the Cisco IOS software installed in the router's main processor.
csa *slot*	(Optional) Specifies the CSA to use for a particular interface.

mppc	(Optional) Specifies that the Microsoft Point-to-Point Compression (MPPC) compression algorithm be used.
ignore-pfc	(Optional) Specifies that the protocol field compression flag negotiated through Link Control Protocol (LCP) will be ignored.

Command Default

Compression is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
11.3P	The following keywords were added: • **distributed** • **software** • **csa** *slot*
11.3T	The following keywords were added: • **mppc** • **ignore-pfc**
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Note This command replaces the**compresspredictor** command.

Usage Guidelines

Point-to-Point Compression

Compression reduces the size of frames through lossless data compression. You can configure point-to-point software compression for all LAPB, PPP, and HDLC encapsulations. The compression algorithm used is a predictor algorithm (the RAND compression algorithm), which uses a compression dictionary to predict what the next character in the frame will be.

End-point devices must be configured to use the same compression method (predictor, Stacker or MPPC).

HDLC encapsulations supports the Stacker compression algorithm. PPP and LAPB encapsulations support both predictor and Stacker compression algorithms.

MPPC Compression

The **compress** command using the **mppc** and **ignore-pfc** options support compression between Cisco routers and access servers and Microsoft clients, such as Windows 95 and Windows NT. MPPC implements an LZ-based compression algorithm that uses a compression dictionary to compress PPP packets. The **ignore-pfc** keyword instructs the router to ignore the protocol field compression flag negotiated by LCP. For example, the standard protocol field value for IP is 0x0021 when compression is disabled and 0x21 when compression is enabled. When the **ignore-pfc** option is enabled, the router will continue to use the uncompressed value (0x0021). Using the **ignore-pfc** option is helpful for some asynchronous driver devices that use an uncompressed protocol field (0x0021), even though the pfc is negotiated between peers. If protocol rejects are displayed when the **debugpppnegotiation** command is enabled, setting the **ignore-pfc** option may remedy the problem.

HDLC Encapsulations

For HDLC encapsulations, you can specify a Stacker compression algorithm by using the **stac** keyword. PPP and LAPB encapsulations support both predictor and Stacker compression algorithms.

Public Data Network Connections

Compression requires that both ends of the serial link be configured to use compression. You should never enable compression for connections to a public data network.

Cisco 7200 and Cisco 7500 Series

Using CSA hardware compression on Cisco 7200 series routers and Cisco 7500 series routers removes the compression and decompression responsibilities from the VIP2 or the main processor installed in the router. By using the **compressstac** command, the router determines the fastest compression method available on the router.

On Cisco 7200 series routers and Cisco 7500 series routers, hardware compression on the compression service adapter (CSA) is supported for PPP links. When using hardware compression on Cisco 7200 series routers with multiple CSAs, you can optionally specify which CSA is used by the interface to perform compression. If no CSA is specified, the router determines which CSA is used. On Cisco 7500 series routers, the router uses the CSA on the same VIP2 as the interface.

System Performance

Caution When compression is performed in software installed in the router's main processor, it might affect system performance significantly. We recommend that you disable compression if the CPU load exceeds 40 percent. To display the CPU load, use the **showprocesscpu** EXEC command.

If the majority of your traffic is already compressed files, we recommend that you not use compression. If the files are already compressed, the additional processing time spent in attempting unsuccessfully to compress them again will slow system performance.

The table below provides general guidelines for deciding which compression type to select.

Table 8: Compression Guidelines

Situation	Compression Type to Use
Bottleneck is caused by the load on the router.	Predictor
Bottleneck is the result of line bandwidth or hardware compression on the CSA is available.	Stacker
Most files are already compressed.	None

Software compression makes heavy demands on the router's processor. The maximum compressed serial line rate depends on the type of Cisco router that you are using and which compression algorithm you specify.

The table below shows a summary of the compressed serial line rates for software compression. The maximums shown in the table below apply to the “combined” serial compressed load on the router. For example, a Cisco 4000 series router could handle four 64-kbps lines using Stacker compression or one 256-kbps line. These maximums also assume that there is very little processor load on the router aside from compression. Lower these numbers when the router is required to do other processor-intensive tasks.

Table 9: Combined Compressed Serial Line Rates (Software Compression)

Compression Method	Cisco 1000 Series	Cisco 3000 Series	Cisco 4000 Series	Cisco 4500 Series	Cisco 4700 Series	Cisco 7000 Family
Stacker (kbps)	128	128	256	500	T1	256
Predictor (kbps)	256	256	500	T1	2xT1	500

Hardware compression can support a combined line rate of 16 Mbps.

Cisco recommends that you do not adjust the maximum transmission unit (MTU) for the serial interface and the LAPB maximum bits per frame (N1) parameter.

Note The best performance data compression algorithms adjust their compression methodology as they identify patterns in the data. To prevent data loss and support this adjustment process, the compression algorithm is run over LAPB to ensure that everything is sent in order, with no missing data and no duplicate data.

Note For information on configuring Frame Relay compression, refer to the “Configuring Frame Relay” chapter in the *CiscoIOSWide-AreaNetworkingConfigurationGuide*.

Examples

The following example enables hardware compression and PPP encapsulation on serial interface 3/1/0.

```
Router(config)# interface serial 3/1/0
Router(config-if)# encapsulate ppp
Router(config-if)# compress stac
```

The following example enables predictor compression on serial interface 0 for a LAPB link:

```
Router(config)# interface serial 0
Router(config-if)# encapsulation lapb
Router(config-if)# compress predictor
Router(config-if)# mtu 1509
Router(config-if)# lapb n1 12072
```

The following example enables Stacker compression on serial interface 0 for a LAPB link. This example does not set the MTU size and the maximum bits per frame (N1); we recommend that you do not change those LAPB parameters for Stacker compression:

```
Router(config)# interface serial 0
Router(config-if)# encapsulation lapb
Router(config-if)# compress predictor
```

The following example configures BRI interface 0 to perform MPPC:

```
Router(config)# interface BRI0
Router(config-if)# ip unnumbered ethernet0
Router(config-if)# encapsulation ppp
Router(config-if)# isdn spid1 5551234
Router(config-if)# dialer map ip 172.21.71.74 5551234
Router(config-if)# dialer-group 1
Router(config-if)# compress mppc
```

The following example configures asynchronous interface 1 to implement MPPC and ignore the protocol field compression flag negotiated by LCP:

```
Router(config)# interface async1
Router(config-if)# ip unnumbered ethernet0
Router(config-if)# encapsulation ppp
Router(config-if)# async default routing
Router(config-if)# async dynamic routing
Router(config-if)# async mode interactive
Router(config-if)# peer default ip address 172.21.71.74
Router(config-if)# compress mppc ignore-pfc
```

Related Commands

Command	Description
encapsulation	Sets the encapsulation method used by the interface.
encapsulation x25	Specifies operation of a serial interface as an X.25 device.
exec	Allows an EXEC process on a line.
show compress	Displays compression statistics.
show processes	Displays information about the active processes.

compress mppc

To configure compression using the Microsoft Point-to-Point Compression (MPPC) algorithm on your data compression Advanced Interface Module (AIM) for the Cisco 2600 series router, use the **compressmppc**command in interface configuration mode. To disable MPPC compression, use the **no** form of this command.

compress mppc
no compress mppc

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The MPPC compression algorithm is used to exchange compressed information with a Microsoft NT remote access server.

When configuring PPP on a serial interface, you can use hardware compression on the data compression AIM daughter card for MPPC if one is installed; otherwise you can use software compression.

Examples

The following example shows how to configure the data compression AIM daughtercard for MPPC:

```
Router(config-if)# encapsulate ppp
Router(config-if)# compress mppc
```

Related Commands

Command	Description
clear aim	Clears data compression AIM registers and resets the hardware.
compress stac caim	Specifies the exact hardware compression resource preferred.
encapsulation	Sets the encapsulation method used by the interface.
show compress	Displays compression statistics.
show pas caim	Displays debug information about the data compression AIM daughtercard.
show processes	Displays information about the active processes.

compress stac caim

To specify the hardware compression, use the **compressstaccaim**command in interface configuration mode. To disable compression, use the **no** form of this command.

compress stac caim *interface-number*
no compress stac caim *interface-number*

Syntax Description

interface-number	Interface on which compression is enabled. AIM interfaces begin with 0.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.0(1)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Hardware Compression

If the router contains a data compression Advanced Interface Module (CAIM), compression is performed in the CAIM hardware.

Using hardware compression in the AIM frees the main processor of the router for other tasks. You can also configure the router to use the Compression Port Module to perform compression by using the distributed option or to use the router's main processor by using the software option. If the Compression Port Module compression is performed in the main processor of the router.

Software Compression

If the CAIM is not available, compression is performed in the main processor of the router.

When compression is performed by the software installed in the router's main memory, system performance might be affected significantly. It is recommended that you disable compression in the main processor if the router CPU load exceeds 40 percent. To display the CPU load, use the show process cpu command in EXEC mode.

Examples

The following example specifies that hardware compression should be activated for CAIM interface 0:

```
Router(config-if)# encapsulation ppp
Router(config-if)# compress stac caim 0
```

Related Commands

Command	Description
clear aim	Clears data compression AIM registers and resets the hardware.
encapsulation	Sets the encapsulation method used by the interface.
show compress	Displays compression statistics.
show pas caim	Displays debug information about the data compression AIM daughtercard.
show process cpu	Displays information about the active processes on the router.

connect (module)

To create a connection between two Gigabit Ethernet (GE) enhanced network modules (ENMs) or between the GE port on an installed small-form-factor-pluggable (SFP) module and a GE ENM, or between the GE port on a switch module (SM) and another SM GE port, on a Cisco 2900 series (Cisco 2901 ISRs do not support the HIMI backplane feature.), 3800 series, or 3900 series Integrated Services Router (ISR), use the **connect** command in global configuration mode. To deactivate a connection between two GE modules on a Cisco 3800 series router, use the **no** form of this command.

connect *connection-name* **module** **module1** **channel-id1** **module** **module2** **channel-id2**
no **connect** *connection-name*

To create a dedicated connection between two GE ENMs, or between the GE port on an SFP module and a GE ENM, or between the GE port on a SM and another SM GE port, for the purpose of sending data on a specified VLAN on a Cisco 3900 series or 2900 series (Cisco 2901 ISRs do not support vlan connect in configuring the HIMI backplane feature.), use the **connect** command in global configuration mode with the **vlan***vlan-id* syntax. To deactivate a connection between two GE interfaces on a Cisco 3900 series router, 2900 series (Cisco 2901 ISRs do not support vlan connect in configuring the HIMI backplane feature.), use the **no** form of this command.

connect *connection-name* **module** **module1** **vlan** **vlan-id** **module** **module2**
no **connect** *connection-name*

Syntax Description

connection-name	Unique name for this connection.
module *module1* *channel-id1*	First of the two GE interfaces on the router between which a connection will be created. • Use the *module1* argument to identify the GE port number. Use the syntax **GigabitEthernet***slot/port* , where *slot* is the slot number in which the ENM resides, or 0 for the router onboard SFP GE port, and *port* is either the ENM port number or 0 for the router onboard SFP GE port. The following interfaces are valid: • • On the Cisco 3825 and Cisco 3845 routers, the GE port in an installed SFP module • On the Cisco 3825 router, GE interfaces in ENM slots 1 and 2 • On the Cisco 3845 router, GE interfaces in ENM slots 2 and 4 • On the Cisco 2900 (Cisco 2901 ISRs do not support the HIMI backplane feature.) series and the Cisco 3900 series routers, all interfaces and slots are permissible providing your SM and ISM supports the HIMI backplane feature. • Use the *channel-id1* argument to indicate the channel identifier on the interface slots of *module1*. On Cisco 3800 series routers, there is only one channel identifier, so this value must be 0.

module *module2* *channel-id2*	Second half of the two GE interfaces on the router between which a connection will be created. • Use the *module2* argument to identify the GE port number. Use the syntax **GigabitEthernet***slot/port* , where *slot* is the slot number in which the ENM resides, or 0 for the onboard SFP GE port, and *port* is either the ENM port number or 0 for the onboard SFP GE port. • Use the *channel-id2* argument to indicate the channel identifier on the interface slots of *module2*. On Cisco 3800 series and Cisco 3900 series routers, there is only one channel identifier, so this value must be 0.
module *module1* **vlan** vlan-id **module***module2*	Specified vlan on two GE interfaces on the router. **Note** On the Cisco 2900 series (Cisco 2901 ISRs do not support vlan connect in configuring the HIMI backplane feature.) and Cisco 3900 series routers, if your ISM or SM supports the HIMI backplane and VLAN connection, the module interconnection between the GE port (with the exception of onboard GE ports) on any slot is permitted at any given time.

Command Default

There is no connection between GE ENMs.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(2)T	This command was introduced.
15.0(1)M	This command was modified to support the Cisco 3900 series and 2900 series (Cisco 2901 ISRs do not support the HIMI backplane feature.) ISR release.

Usage Guidelines

To create a connection between two GE modules on a Cisco 2900 (Cisco 2901 ISRs do not support the HIMI backplane feature.), 3800, and 3900 series routers using the High-Speed Intrachassis Module Interconnect (HIMI) feature, use the **connect***connection-name***module** module1 channel-id1 **module** module2 channel-id2 command in global configuration mode:

Connections can be only established as follows:

- Between the GE port in an installed small-form-factor pluggable (SFP) module on the Cisco 3825 and Cisco 3845 routers
- Between GE interfaces in NME slots 1 and 2 on the Cisco 3825 router
- Between GE interfaces in NME slots 2 and 4 on the Cisco 3845 router

Note A module interconnection between the GE port on an SFP module and an ENM slot or an ENM-to-ENM cross-connection on the Cisco 3800 series routers is permitted at any time, but both types of connections cannot exist at the same time.

Note Connections between the onboard RJ-45 GE ports and ENM slots are not supported.

To create a connection between two GE SMs, to send data on a specified VLAN, on a VLAN on a Cisco 2900 (Cisco 2901 ISRs do not support the HIMI backplane feature.), and 3900, use the connect command with the with the **vlan***vlan-id* syntax.

If the **connect** command is successfully executed, the router enters connection configuration mode, which is designated by the "config-module-conn" prompt. Once the router is in connection configuration mode, the commands shown in the table below can be issued.

Table 10: Connection Configuration Mode Commands

Command	Description
default	Sets a command to its default values. Has no effect on the **connect** command functionality.
exit	Exits connection configuration mode. After you exit connection configuration mode, the actual connection establishment phase starts.
shutdown	Shuts down the connection. This command effectively deactivates the connection.
no	Negates a command or sets it to default. The **noshutdown** command reactivates a previously shut down connection.

To establish a connection, after entering connection configuration mode, issue the **exit** command to return to configuration mode. The connection will be established after you leave connection configuration mode.

Examples

The following example illustrates the creation of a connection between the onboard port GigabitEthernet0/0 and port GigabitEthernet4/0, which resides in ENM slot 4:

```
Router(config)# connect connection1 module GigabitEthernet0/0 0 module GigabitEthernet4/0
0
Router(config-module-conn)# exit
```

The following example shows the creation of a VLAN connection which is named VLAN 10 and a second VLAN connection which is named VLAN 5.

```
Router(config)# connect connection1 module gi2/0 vlan 10 module gi3/0
Router(config-module-conn)# connect connection2 module gi3/0 vlan 5 module gi4/0
Router(config-module-conn)# exit
```

Related Commands

Command	Description
show connection	Displays the status of interworking connections.

constellation

To configure the constellation for the global navigation satellite system (GNSS) module on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers, use the **constellation** command in the gnss mode. To remove the constellation configuration, use the **no** form of this command.

constellation {**auto** | **beidou** | **galileo** | **glonass** | **gps** | **qzss**}
no constellation {**auto** | **beidou** | **galileo** | **glonass** | **gps** | **qzss**}

Syntax Description

auto	Enables auto locking to an available constellation.
beidou	Enables detection and locking to the BeiDou constellation. **Note** BeiDou and GLONAS constellations cannot be enabled simultaneously. **Note** If the `auto` option is used, BeiDou will not be part of the selected constellations.
galileo	Enables detection and locking to the Galileo constellation.
glonas	Enables detection and locking to the GLONAS constellation.
gps	Enables detection and locking to the GPS constellation.
qzss	Enables detection and locking to the QZSS constellation.

Command Default

No default behavior or values.

Command Modes

GNSS configuration (config-gnss)

Command History

Release	Modification
IOS-XE 3.17	This command was introduced on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers.

Usage Guidelines

BeiDou and GLONAS constellations cannot be enabled simultaneously. Also, if the **auto** option is used, BeiDou will not be part of the selected constellations.

Irrespective of configured constellation, initially the GPS constellation is used for the Self-Survey mode and the GNSS module switches to using the configured constellation in over-determined mode.

Examples

The following example shows how to configure the constellations:

```
Router# configure terminal
Router(config)# gnss slot r0
Router(config-gnss)# constellation auto
```

Related Commands

Command	Description
gnss	Configures the GNSS on the router.
1pps	Configures the pulse per second from the GNSS module.
anti-jam	Enables or disables the anti-jam mode on the GNSS module.
default	Resets the device to its default state.
exit	Exists the GNSS sub mode.

control-lead sampling-rate

To configure the sampling rate of input control leads, use the **control-leadsampling-rate** command in CEM configuration mode.

control-lead sampling-rate *rate*

Syntax Description

rate	Integer that specifies the number of samples per second. Range is from 0 to 20. Default is 0.

Command Default

The input control lead sampling rate defaults to 0 (no sampling).

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command applies only to serial channels. This command does not have a **no** form; to disable control-lead sampling, set the *rate* argument to 0.

Examples

The following example shows how to configure the ingress control-lead sampling rate to 20 samples per second on a serial CEM port.

```
Router(config-cem)# control-lead sampling-rate 20
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
control-lead state	Specifies the state of an output control lead.
show cem	Displays CEM channel statistics.

control-lead state

To specify the state of an output control lead, use the **control-leadstate** command in CEM configuration mode. The choice of output lead depends on whether the port is DCE or DTE.

control-lead state {**active** | **fail**} **output-lead** {**on** | **off** | **follow**} [{**local** | **remote**} *follow-lead*]

Syntax Description

active	Active template configuration.
fail	Failed template configuration.
output-lead	Specifies the name of the output control lead. The choice of the control lead depends on whether the port is DCE or DTE.
on	Activates the lead.
off	Deactivates the lead.
follow	Specifies the control lead state to follow.
local	(Optional) Specifies a local lead state.
remote	(Optional) Specifies a remote lead state.
follow-lead	(Optional) Specifies the local or remote input control lead for this control lead to follow. The choice of the control lead depends on whether the port is DCE or DTE.

Command Default

The default Active template that is activated depends on whether the port is DCE or DTE. The default Fail template deactivates all signals. The table below shows the various control-lead default states.

Table 11: Control-Lead Default States

Lead Number	DCE Name	DTE Name	Active Default	Fail Default
1	CTS	RTS	On	Off
2	DSR	DTR	On	Off
3	DCD	--	On	Off
4	--	LL	Off	--
5	TM	--	On	Off
6	RI	RL	Off	Off

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The state of each output control lead may be specified to assume a constant level (on or off) or to change on the basis of the state of any input control lead, either at the local data port or at the remote data port.

This command applies only to serial ports. This command does not have a **no** form; to disable the control lead, specify the **off** keyword.

Examples

The following example shows how to specify the state of an output control lead.

```
Router(config-cem)# control-lead state active cts on
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
control-lead sampling-rate	Configures the sampling rate of input control leads.
show cem	Displays CEM channel statistics.

controller

To configure a T1, E1, J1, or BITS controller and enter controller configuration mode, use the **controller** command in global configuration mode.

Cisco 2600 and 3600 Series Routers
controller {**t1** | **e1** | **j1**} *slot/port*

Cisco 7200 Series and Cisco 7500 Series Routers
controller {**bits** | **t1** | **e1** | **shdsl**} *slot/port/subslot-number/port-number*

Cisco AS5300 Access Servers
controller {**t1** | **e1**} *number*

Cisco ASR 901 Series Aggregation Services Routers
controller {**bits** | **t1** | **e1** | **shdsl**} *slot/port/subslot-number/port-number*

Cisco ASR 901 Series Aggregation Services Routers
controller {**bits** | **t1** | **e1** | **shdsl**} *slot/port/subslot-number/port-number*

Syntax Description

shdsl	T1 controller.
e1	E1 controller.
j1	J1 controller.
slot / port	Backplane slot number and port number on the interface. Refer to your hardware installation manual for the specific values and slot numbers.
port-number	Network processor module (NPM) number, in the range 0 through 2.
dial-shelf	Dial shelf chassis in the Cisco AS5800 access server that contains the interface card.
/ *t3-port*	T3 port number. The only valid value is 0.
port-number	Port number of the controller. Valid numbers are 0 and 1. A forward slash mark (/) is required between the slot argument and the port argument.
port-number	Port number of the controller. Valid numbers are 0 and 1. A forward slash mark (/) is required between the slot argument and the port argument.
port-number	Port number of the controller. Valid numbers are 0 and 1. A forward slash mark (/) is required between the slot argument and the port argument.
port-number	Port number of the controller. Valid numbers are 0 and 1. A forward slash mark (/) is required between the slot argument and the port argument.
port-number	Port number of the controller. Valid numbers are 0 and 1. A forward slash mark (/) is required between the slot argument and the port argument.

Command Default

No T1, E1, or J1 controller is configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
10.0	This command was introduced.
10.3	The **e1** keyword was added.
12.0(3)T	Support was added for dial shelves on Cisco AS5800 access servers.
12.2(7)XO	The **j1**keyword was added for the Cisco 2600 and Cisco 3600 series.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers. The **bits** and **shdsl** keywords and the *subslot-number* and *port-number* arguments were added.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers. The **bits** and **shdsl** keywords and the *subslot-number* and *port-number* arguments were added.

Usage Guidelines

T1 or E1 Fractional Data Lines

This command is used in configurations where the router or access server is intended to communicate with a T1 or E1 fractional data line. Additional parameters for the T1 or E1 line must be configured for the controller before the T1 or E1 circuits can be configured by means of the **interface** global configuration command.

To view the status of the controllers use the **showcontrollers** command.

Examples

Cisco 7500 Series Router As a T1 Controller

The following example configures the MIP in slot 4, port 0 of a Cisco 7500 series router as a T1 controller:

```
Router(config)# controller t1 4/0
Router(config-controller)#
```

Cisco AS5800 Access Server with Dial Shelf

The following example configures the T1 controller in shelf 1, slot 0, port 0:

```
Router(config)# controller t1 1/0/0:1
Router(config-controller)#
```

Cisco 3660 As a J1 Controller

The following example configures the Cisco IOS interface card in slot 3, port 0 of a Cisco 3660 as a J1 controller:

```
Router(config)# controller j1 3/0
Router(config-controller)#
```

Related Commands

Command	Description
bert abort	Resets the T1 or E1 controller.
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller (for ISDN PRI, CAS, or robbed-bit signaling).
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller (for ISDN PRI, CAS, or robbed-bit signaling).
show controllers content-engine	Displays information about the E1 links supported by the NPM (Cisco 4000) or MIP (Cisco 7500 series).
show controllers j1	Displays information about the J1 link.
show controllers j1	Displays information about the J1 link.
show controllers t1	Displays the total number of calls and call durations on a T1 controller.

controller dsl

To configure the digital subscriber line (DSL) controller and enter controller configuration mode, use the **controllerdsl** command in global configuration mode. This command does not have a **no** form.

controller dsl *slot/port*

Syntax Description

slot	Slot number of the DSL controller. Valid numbers are 0 and 1.
/ *port*	Port number of the DSL controller. Valid numbers are 0 and 1. The slash mark (/) is required between the *slot* argument and the *port*argument.

Command Default

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

This command is used to enter controller configuration mode for the controller in the specified slot and port. If the controller is present, it is automatically set to a default set of values, including customer premises equipment (CPE) mode and annex A.

The central office (CO) and CPE sides of the link must be configured the same in order for a connection to be made. This command is available only when the WIC-1SHDSL-V2 is installed.

Examples

The following example shows how to enter DSL controller configuration mode on the controller in slot 1 and port 0:

```
Router(config)# controller dsl
 1/0
Router(config-controller)#
```

Related Commands

Command	Description
controller shdsl	Configures the controller status.
debug xdsl application	Displays status of the xDSL if the DSL does not activate as expected.
debug xdsl driver	Displays status when the drivers are downloaded and installed.

Command	Description
debug xdsl eoc	Displays the contents of the embedded operations channel messages.
debug xdsl error	Displays the errors of xDSL process and firmware.
show controller dsl	Displays the DSL controller status and the controller number.

controller dwdm

To configure a Dense Wavelength-Division Multiplexing (DWDM) controller, use the **controllerdwdm**command in global configuration mode. This command does not have a no form.

controller dwdm *slot/port*

Syntax Description

slot/port	Number of the chassis slot that contains the interface, where: • slot--Chassis slot number. • /port--Port number.

Command Default

No default behavior or values

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Examples

The following example shows how to configure a DWDM controller in slot 3:

```
Router(config)# controller dwdm 3/1
```

Related Commands

Command	Description
g709 fec	Configures the FEC for the DWDM controller.
g709 odu threshold	Configures thresholds for selected ODU BER alarms.
g709 otu threshold	Configures thresholds for selected OTU BER alarms.
no g709 odu report	Disables the logging of selected ODU alarms.
no g709 otu report	Disables the logging of selected OTU alarms.
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.
show platform dwdm alarm history	Displays platform DWDM alarm history.
transport-mode	Configures a transport mode.

controller e3

To configure an E3 controller and enter controller configuration mode, use the **controllere3**command in global configuration mode.

controller e3 *slot/port*

Syntax Description

slot/port	Number of the slot and port being configured. Refer to the appropriate hardware manual for slot and port information. The slash mark is required.

Command Default

No E3 controller is configured.

Command Modes

Global configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE Everest 16.5.1	This command was integrated into Cisco ASR 900 Series Routers and Cisco NCS 4200 Series.

Examples

The following example shows the E3 controller configured in slot 0, port 0:

```
Router(config)# controller e3 0/0
Router(config-controller)#
```

Related Commands

Command	Description
controller t3	Configures a T3 controller and enters controller configuration mode.
show controllers e3	Displays information about E3 controllers.
show controllers t3	Displays information about T3 controllers.

controller mediatype

Use this command to configure MediaType controller.

mode sonet *slot* / *bay* / *port*

Syntax Description

Syntax Description:

slot	Physical slot number of the interface
bay	Bay of the interface
port	Mediatype port number

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on the NCS 4200 Series.
XE Everest 16.5.1	This command was integarted into the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

This command is used to configure the Mediatype controller mode. Configure the Mediatype controller mode before configuring SONET controller and T3 controller.

Examples

The following example shows how to configure Mediatype controller mode:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
end
```

The following example shows how to set up port on the T3 interface module:

```
enable
configure terminal
controller MediaType 0/4/0
mode t3
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

controller protection-group

Use this command to configure protection group controller.

controller protection-group *group id*

Syntax Description

Syntax Description:

group id	Identifier of the interface

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	This command was introduced into the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

The parameters used for protection group controller are executed after using this command.

Examples

The following example shows how to configure protection group:

```
enable
configure terminal
protection-group 401 type STS48c
controller protection group 401
type STS48c
cem-group 19001 cep
end
```

Related Commands

Command	Description
show protection-group	Verifies the protection group configuration.

controller sdh

Use this command to configure a SDH controller and enter controller configuration mode.

controller sdh *slot* /*bay* /*port*

Syntax Description

Syntax Description

slot	Physical slot number. The slot is always 0 for Cisco NCS 4200 Series.
bay	Physical sub-slot or bay number. The range is 0-5.
port	SDH port number. The port number is always 0 because only one STM-1 port is supported per interface. The slash mark is required.
stm1 number	The STM number ranges from 1 to 4.

Command Default

The default port is 0.

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

This command does not have a **no** form because the SDH controller is created automatically when the STM-1 trunk card is detected.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm 4
aug mapping au-4
au-4 1
mode vc4
cem-group 100 cep
end
```

Related Commands

Command	Description
show running configuration	Verifies controller SDH configuration.

controller sonet

To configure a SONET controller and enter controller configuration mode, use the **controllersonet** command in global configuration mode.

controller sonet *slot/port*

For Cisco NCS 4200 Series

controller sonet *slot/subslot/port*

Syntax Description

bay	Identifies the bay where the VCoP SSFP is inserted. On NCS4200 series bay value is 0 always.
slot	Physical slot number. The slot number is in a range either from 0 to 5 or 8 to 13, depending on the slot in which the STM-1 card resides. The slot is always 0 for Cisco NCS 4200 Series.
/subslot	Physical sub-slot number. The range for sub-slot is 0-5.
/port	SONET port number. The port number is always 0 because only one STM-1 port is supported per interface. The slash mark is required. The range of port number for Cisco NCS 4200 Series is 8-14.

Command Default

port : 0

Command Modes

Global configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series and Cisco ASR 920 Routers.

Usage Guidelines

This command does not have a **no** form because the SONET controller is created automatically when the STM-1 trunk card is detected by the Cisco AS5850. Use this command to specify which slot number the STM-1 card is plugged into and to configure different attributes under controller configuration mode.

Examples

The following example shows how to specify that the SONET controller is in slot number 2:

```
Router(config)# controller sonet 2/0
Router(config-controller)#
```

Examples

The following example shows how to specify that the SONET controller for Cisco NCS 4200 Series in slot number 0, sub-slot 0, and port as 8:

```
Router(config)# controller SONET 0/0/8
Router(config-controller)#
```

Related Commands

Command	Description
show controllers sonet	Displays information about SONET controllers.

controller sonet-acr

To configure a SONET Access Circuit Redundancy (ACR) virtual controller, and to enter the controller configuration mode, use the **controller sonet-acr** command in global configuration mode.

controller sonet-acr *controller unit number*

Syntax Description

controller unit number	Specifies the controller unit number. The range is 1 to 255.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
15.1(01)S	This command was introduced on the Cisco 7600 routers.

Usage Guidelines

The **controller sonet-acr**commandis used to configure channelized ATM, IMA and CEM timeslots. Before you begin the SONET ACR virtual controller configuration, ensure that you configure the APS group ACR and APS working by using the **aps group acr** *acr-group number*and **aps working** *circuit number* commandsrespectively.

Examples

This example shows how to configure the **controller sonet-acr**:

```
Router(config)# Controller sonet 4/1/0
Router(config-controller)# aps group acr 1
Router(config-controller)# aps working 1
```

The above commands on the physical controller helps in creating a virtual sonet-acr controller

```
Router(config)#
controller sonet-acr 21
```

Related Commands

Command	Description
sts-1	Configures the Synchronous Transport Signal (level)-1 in the SONET hierarchy.
vtg	Configures the (CESoPSN) CEM group.
mode vt-15	Configures the path operation mode.

controller t1/e1

To configure a T1or E1 controller and enter controller configuration mode, use the **controller** command in global configuration mode.

controller t1/**e1** *slot*/*bay*/*port*

Syntax Description

t1	Specifies T1 controller
e1	Specifies E1 controller
slot	Specifies the slot number of the interface.
bay	Specifies the bay number of the interface.
port	Specifies the port number of the interface.

Command Default

No T1 or E1controller is configured.

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18SP	This command was introduced for Cisco NCS 4200 Series Routers.
XE Everest 16.5.1	This command is implemented on Cisco NCS 4200 Series and Cisco ASR 903 Series Router.

Usage Guidelines

This command is used in configurations where the router or access server is intended to communicate with a T1 or E1 fractional data line. Additional parameters for the T1 or E1 line must be configured for the controller before the T1 or E1 circuits can be configured by means of the **interface** global configuration command.

Examples

The following example shows how to configure T1 controller in slot 0, bay 1, port 1:

```
Router(config)# controller t1 0/1/1
Router(config-controller)#
```

Examples

The following example shows how to configure E1 controller in slot 0, bay 1, port 1:

```
Router(config)# controller e1 0/1/1
Router(config-controller)#
```

Related Commands

Command	Description
show controller t1/e1	Displays the total number of calls and call durations on a T1/E1 controller.

controller t3

To configure the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers or the CT3 feature board in Cisco AS5800 access servers, use the **controllert3** command in global configuration mode. To delete the defined controller, use the **no** form of this command.

Cisco 7500 Series
controller t3 *slot*/*port-adapter*/*port*
no controller t3 *slot*/*port-adapter*/*port*

Cisco AS5800 Access Server
controller t3 *dial-shelf*/*slot*/*t3-port*
no controller t3 *dial-shelf*/*slot*/*t3-port*

Cisco NCS 4200 Series
controller t3 *slot*/*sub-slot*/*port*
no controller t3 *slot*/*sub-slot*/*port*

Syntax Description

slot	Number of the slot being configured. Refer to the appropriate hardware manual for slot and port information./
/ *port-adapter*	Number of the port adapter being configured. Refer to the appropriate hardware manual for information about port adapter compatibility.
/ *port*	Number of the port being configured. Refer to the appropriate hardware manual for slot and port information.
dial-shelf	Dial shelf chassis in the Cisco AS5800 access server containing the CT3 interface card.
/ *slot*	Location of the CT3 interface card in the dial shelf chassis.
/ *sub-slot*	Sub-slot location of the T3 interface card in the dial shelf chassis.
/ *t3-port*	T3 port number. The only valid value is 0.

Command Default

No T3 controller is configured.

No default behavior or values.

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
11.3	This command was introduced.
12.0(3)T	This command was implemented on the Cisco AS5800 access server.
XE 3.18SP	This command was implemented on the Cisco NCS 4200 Series.

Release	Modification
XE Everest 16.5.1	This command was implemented on the Cisco NCS 4200 Series and Cisco ASR 920 Routers.

Usage Guidelines

This command is used to configure the CT3IP and the 28 T1 channels. After the T1 channels are configured, continue to configure each T1 channel as a serial interface by using the **interfaceserial**global configuration command

Examples

Cisco 7500 Series

The following example configures the CT3IP in slot 3:

```
Router(config)# controller t3 3/0/0
```

Cisco AS5800 Access Server

The following example configures the T3 controller in shelf 3, slot 0, port 0 and T1 time slot 1:

```
Router(config)# controller t3 3/0/0
```

Cisco NCS 4200 Series

The following example configures the T3 controller in slot 0, sub-slot 4, and port 40:

```
Router(config)# controller t3 0/4/40
```

Related Commands

Command	Description
controller	Configures a T1, E1, or J1 controller and enters controller configuration mode.
interface	Specifies a serial interface created on a channelized E1 or channelized T1 controller (for ISDN PRI, CAS, or robbed-bit signaling).

copy flash lex

To download an executable image from Flash memory on the core router to a LAN Extender, use the **copyflashlex** command in privileged EXEC mode.

copy flash lex *number* **copy flash lex command**

Syntax Description

number	Number of the LAN Extender interface to which to download an image from Flash memory.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in 12.2S-Family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you attempt to download a version of the software older than what is currently running on the LAN Extender, a warning message is displayed.

This command does not have a **no** form.

Examples

The following example copies the executable image *namexx* to LAN Extender interface 0:

```
Router# copy flash lex 0
Name of file to copy? namexx
Address of remote host [255.255.255.255] <cr>
writing namexx !!!!!!!!!!!!!!!!!!!!!!!!!copy complete
```

Related Commands

Command	Description
copy tftp lex	Downloads an executable image from a TFTP server to a LAN Extender.

copy tftp lex

To download an executable image from a TFTP server to the LAN Extender, use the **copytftplex** command privileged EXEC mode.

copy tftp lex *number* **copy tftp lex command**

Syntax Description

number	Number of the LAN Extender interface to which to download an image.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco IOS Mainline or Technology-based (T) releases. It may continue to appear in 12.2S-Family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you attempt to download a version of the software older than what is currently running on the LAN Extender, a warning message is displayed.

This command does not have a not form.

Examples

The following example copies the file *namexx* from the TFTP server:

```
Router# copy tftp lex 0
Address or name of remote host (255.255.255.255]? 10.108.1.111
Name of file to copy? namexx
OK to overwrite software version 1.0 with 1.1 ?[confirm] YLoading namexx from
10.108.13.111!!!!!!!!!!!!!!!!!!!!!!!!!
[OK - 127825/131072 bytes]
Successful download to LAN Extender
```

crc

To set the length of the cyclic redundancy check (CRC), use the**crc** command in interface configuration mode. To set the CRC length to the default value, use the **no** form of this command.

crc commandcrc *size-in-bits*
no crc

Syntax Description

size-in-bits	CRC size in bits. Valid values are 16 and 32. The default is 16.

Command Default

16 bits

32 bits

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

All interfaces use a 16-bit CRC by default, but also support a 32-bit CRC. CRC is an error-checking technique that uses a calculated numeric value to detect errors in transmitted data. The designators 16 and 32 indicate the length (in bits) of the frame check sequence (FCS). A CRC of 32 bits provides more powerful error detection, but adds overhead. Both the sender and receiver must use the same setting.

CRC-16, the most widely used CRC rate throughout the United States and Europe, is used extensively with WANs. CRC-32 is specified by IEEE 802 and as an option by some point-to-point transmission standards. It is often used on Switched Multimegabit Data Service (SMDS) networks and LANs.

Examples

The following example enables the 32-bit CRC on serial interface 3/0:

```
Router(config)# interface serial 3/0
Router(config-if)# crc 32
```

crc bits 5

To enable generation of CRC5 (per ITU Recommendation G.704 and G.703) to improve data integrity, use the **crcbits5**command in interface configuration mode. To disable this function, use the **no** form of this command.

crc bits 5 commandcrc bits 5
no crc bits 5

Syntax Description

This command has no arguments or keywords.

Command Default

CRC5 checking is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.1 CA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is available for the JT2 6.3-MHz serial port adapter (PA-2JT2) on the second-generation Versatile Interface Processor (VIP2), in Cisco 7500 series routers, and in Cisco 7000 series routers with the Cisco 7000 series Route Switch Processor (RSP7000) and the Cisco 7000 series Chassis Interface (RSP7000CI).

This command is useful for checking data integrity while operating in framed mode. CRC5 provides additional protection for a frame alignment signal under noisy conditions. For data transmission at JT2 (6.312 Mbps), the G.704 standard suggests 5 bits CRC. Refer to ITU Recommendation G.704 for a definition of CRC5.

You can also use the **crc** command to set the CRC size for the High-Level Data Link Control (HDLC) controllers.

Examples

The following example enables CRC5 generation on the PA-2JT2 port adapter and also sets the CRC size to 32 bits:

```
Router(config)# interface serial 0/0
Router(config-if)# crc 32
Router(config-if)# crc bits 5
```

Related Commands

Command	Description
crc	Sets the length of the CRC.

crc4

To enable generation of CRC4 (per ITU Recommendation G.704 and G.703) to improve data integrity, use the **crc4**command in interface configuration mode. To disable this function, use the **no** form of this command.

crc4
no crc4crc4 command

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
11.1 CA	This command was implemented on the Cisco 7200 series router and the E1-G.703/G.704 serial port adapter.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to the Cisco 7200 series, Cisco 7000 series, and Cisco 7500 series routers. This command is supported on the Fast Serial Interface Processor (FSIP) and the E1-G.703/G.704 serial port adapter.

This command is useful for checking data integrity while operating in framed mode. CRC4 provides additional protection for a frame alignment signal under noisy conditions. For data transmission at E1 (2.048 Mbps), the G.704 standard suggests 4 bits CRC. Refer to CCITT Recommendation G.704 for a definition of CRC4.

You can also use the **crc** command to set the CRC size for the High-Level Data Link Control (HDLC) controllers.

Examples

The following example enables CRC4 generation on the E1-G.703/G.704 serial port adapter and also sets the CRC size to 32 bits:

```
Router(config)# interface serial 0/0
Router(config-if)# crc 32
Router(config-if)# crc4
```

Related Commands

Command	Description
crc	Sets the length of the CRC.

crc-threshold

To define a severely errored second (SES) by specifying the number of cyclic redundancy check (CRC) errors that occur in one second, use the **crc-threshold** command in controller configuration mode. To return to the default value, use the **no** form of this command.

crc-threshold *value*
no crc-threshold

Syntax Description

value	Number of CRC errors in one second that results in the second being declared a severely errored second (SES). Range is from 0 to 3000. Default is 320.

Command Default

A default SES is defined by a value of 320 CRC errors per second.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

On a T1 port, this command applies only if extended super frame (ESF) framing is used because the super frame (SF) (also known as D4) frame structure does not include any CRC protection.

This command does not apply to an E1 port.

Examples

The following example shows how to set the CRC threshold at 512 CRC errors in one second.

```
Router(config-controller)# crc-threshold 512
```

ctunnel mode

To transport IPv4 and IPv6 packets over Connectionless Network Service (CLNS) tunnel (CTunnel), use the **ctunnelmode** command in interface configuration mode. To return the ctunnel to the default **cisco** mode, use the **no** form of this command.

ctunnel mode [{**gre** | **cisco**}]
no ctunnel mode

Syntax Description

gre	(Optional) Sets the ctunnel mode to Generic Routing Encapsulation (GRE) for transporting IPv6 packets over the CLNS network.
cisco	(Optional) Returns the ctunnel mode to the default cisco.

Command Default

Cisco encapsulation tunnel mode is the default.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.2(25)S	This command was integrated into Cisco IOS Release 12.2(25)S.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

GRE tunneling of IPv4 and IPv6 packets through CLNS-only networks enables Cisco ctunnels to interoperate with networking equipment from other vendors. This feature provides compliance with RFC 3147, Generic Routing Encapsulation over CLNS Networks, which should allow interoperation between Cisco equipment and that of other vendors. in which the same standard is implemented.

RFC 3147 specifies the use of GRE when tunneling packets. The implementation of this feature does not include support for GRE header fields such as those used to specify checksums, keys, or sequencing. Any packets received which specify the use of these features will be dropped.

The default ctunnel mode continues to use the standard Cisco encapsulation. Both ends of the tunnel must be configured with the same mode for it to work. If you want to tunnel ipv6 packets you must use the new gre mode.

Examples

The following example configures a CTunnel from one router to another and shows the CTunnel destination set to 49.0001.1111.1111.1111.00. The ctunnel mode is set to gre to transport IPv6 packets.

```
interface ctunnel 301
 ipv6 address 2001:0DB8:1111:2222::2/64
```

```
ctunnel destination 49.0001.1111.1111.1111.00
ctunnel mode gre
```

Related Commands

Command	Description
clns routing	Enables routing of CLNS packets.
ctunnel destination	Specifies the destination for the CTunnel.
debug ctunnel	Displays debug messages for the IP over a CLNS Tunnel feature.
interface ctunnel	Creates a virtual interface to transport IP over a CLNS tunnel.
ip address	Sets a primary or secondary IP address for an interface.

cut-through

To configure the interfaces on the PA-12E/2FE port adapter to use cut-through switching technology between interfaces within the same bridge group, use the **cut-through**command in interface configuration mode. To return each interface to store-and-forward switching, use the **no**form of this command.

cut-through [{**receive** | **transmit**}]
no cut-through

Syntax Description

receive	(Optional) Selects cut-through switching technology on received data.
transmit	(Optional) Selects cut-through switching technology on transmitted data.

Command Default

Store-and-forward switching technology (that is, no cut-through)

Command Modes

Interface configuration

Command History

Release	Modification
11.2P	This command was introduced.’
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Cut-through mode allows switched packets to be transmitted after 64 bytes are received. The transmission of the packets can start before the end of the packet arrives. This reduces the time spent in the switch, but allows packets to be transmitted with bad cyclical redundancy checks (CRCs), because the transmission is initiated before the CRC is received or checked. Store-and-forward mode waits for the entire packet to be received before that packet is forwarded, but will check the CRC before starting transmission.

The PA-12E/2FE port adapter offloads Layer 2 switching from the host CPU by using store-and-forward or cut-through switching technology between interfaces within the same VLAN on the PA-12E/2FE port adapter. The PA-12E/2FE port adapter supports up to four VLANs (bridge groups).

Examples

The following example configures interface 3/0 for cut-through switching:

```
Router(config)#
 interface fastethernet 3/0
Router(config-if)#
 bridge-group 10
Router(config-if)#
 cut-through
Router(config-if)#
 no shutdown
Router(config-if)# exit
```

D through E

data-protection

To enable data protection for a circuit emulation (CEM) channel, use the **data-protection**command in CEM configuration mode. To disable data protection, use the **no** form of this command.

data-protection
no data-protection

Syntax Description

This command has no arguments or keywords.

Command Default

Data protection is disabled for a CEM channel.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Examples

The following example demonstrates how to enable data protection.

```
Router(config-cem)# data-protection
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
show cem	Displays CEM channel statistics.

data-strobe

To specify an input control lead to be monitored as an indicator of valid data, use the **data-strobe** command in CEM configuration mode. To disable the monitoring of an input control lead, use the **no** form of this command.

data-strobe **input-lead** {**on** | **off**}
no **data-strobe**

Syntax Description

input-lead	Specifies the input lead. The choice of leads depends on whether the port is DCE or DTE.
on	Enables packet creation when the lead is asserted.
off	Enables packet creation when the lead is deactivated.

Command Default

No input control lead is monitored.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Any input control signal on a serial data port may be configured as a "data strobe" to indicate to the NM-CEM-4SER network module whether ingress data on the port should be encapsulated for transmission or ignored. If the **data-strobe** command is specified with the **on** keyword, data packets are created and sent when the input lead is asserted. If the data strobe is off (either intentionally or as a result of the failure of the customer premises equipment [CPE]), no data packets are created, and this results in preservation of bandwidth in the IP network.

This command applies only to serial ports.

Examples

The following example demonstrates how to specify that packets are to be created and sent to the far end only when the DTR input control lead is asserted.

```
Router(config-cem)# data-strobe dtr on
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
control-lead sampling rate	Configures the sampling rate of input control leads.
control-lead state	Specifies the state of an output control lead.
show cem	Displays CEM channel statistics.

dce-terminal-timing enable

To prevent phase shifting of the data with respect to the clock when running the line at high speeds and long distances, use the **dce-terminal-timingenable** command in interface configuration mode. If serial clock transmit external (SCTE) terminal timing is not available from the DTE, use the **no**form of this command; the DCE will use its own clock instead of SCTE from the DTE.

dce-terminal-timing enable
no dce-terminal-timing enable

Syntax Description

This command has no arguments or keywords.

Command Default

The DCE uses its own clock.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

On the Cisco 4000 router, you can specify the serial Network Interface Module timing signal configuration. When the board is operating as a DCE and the DTE provides terminal timing (SCTE or TT), the **dce-terminal-timingenable** command causes the DCE to use SCTE from the DTE.

Examples

The following example shows how to prevent phase shifting of the data with respect to the clock:

```
Router(config)# interface serial 0
Router(config-if)# dce-terminal-timing enable
```

debug l2protocol-tunnel

To configure the debugging option of Layer 2 Protocol Tunneling (L2PT), use the **debugl2protocol-tunnel** command in EXEC mode.

debug l2protocol-tunnel [{**error** | **event** | **misc** | **packet**}]

Syntax Description

error	(Optional) Displays L2PT errors.
event	(Optional) Displays L2PT events.
misc	(Optional) Displays L2PT miscellaneous.
packet	(Optional) Displays L2PT activities.

Command Default

If you do not specify a debugging option, all options are enabled.

Command Modes

User EXEC (>)

Command History

Release	Modification
15.2(2)T	This command was introduced.

Examples

The following example shows how to debug the **l2protocol-tunnel** command:

```
Router# debug l2protocol-tunnel error
```

Related Commands

Command	Description
l2protoco-tunnel	Enables Layer 2 protocol tunneling for CDP, STP, or VTP packets on an interface.
show l2protocol-tunnel	Displays information about L2PT ports.

debug platform link-dc

To display debugging messages for the link daughter card, use the **debugplatformlink-dc**command in privileged EXEC mode. To disable debugging output, use the **no** form of this command.

debug platform link-dc {**dwdm** | **interface** | **interrupt** | **netclk** | **serdes** | **transceiver** | **wanphy**}
no debug platform link-dc {**dwdm** | **interface** | **interrupt** | **netclk** | **serdes** | **transceiver** | **wanphy**}

Syntax Description

dwdm	OTN G.709/DWDM driver debug information.
interface	Interface driver debug information.
interrupt	Interrupt debug information.
netclk	Network clocking debug information.
serdes	Physical layer (PHY) and SerDes debug information.
transceiver	Pluggable optics module information.
wanphy	WAN PHY driver debug information.

Command Default

Debugging is not enabled.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD	This command was introduced. **Note** This command applies only to the Cisco 7600 Series Ethernet Services Plus (ES+) line card on the Cisco 7600 series router.
12.2(33)SRD1	This command added the dwdm and wanphy keywords.

Usage Guidelines

Use this command with the remote command command or the attach command in privileged EXEC mode.

Examples

The following examples show the output for both the debug platform link-dc tranceiver command and the debug platform link-dc interrupt command. Notice that the show platform hardware transceiver command shows the status for the port.

```
Router# remote command module 1 debug platform link-dc tranceiver
Link-DC transceiver debugging is on
Router# remote command module 1 debug platform link-dc interrupt
Link-DC interrupt debugging is on
Router# remote command module 1 show debug
x40g subsystem:
  Link-DC transceiver debugging is on
  Link-DC interrupt debugging is on
Router# remote command module 1 show platform hardware transceiver status 1
Show status info for port 1:
```

```

Related Commands

Command	Description
show platform hardware transceiver	Displays transceiver information on a port.

debug platform network-clock

To debug issues related to the network clock, such as alarms, out-of-resource (OOR), and active-standby sources not selected correctly, use the debug platform network-clock command in the privileged EXEC mode. To disable debugging, use the **no**no form of this command. .

debug platform network-clock
no debug platform network-clock

Command Default

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.2	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.

Examples

The following example shows how to debug the network clock:

```
Router(config)# debug platform network-clock
```

debug platform software ucse

To debug the Cisco UCS E-Series Server platform software and display debug messages, use the **debug platform software ucse** command in privileged EXEC mode. To disable debug, use the **no** form of this command.

debug platform software ucse {**all** | **error** | **normal**}
no debug platform software ucse {**all** | **error** | **normal**}

Syntax Description

all	Displays all platform debug messages.
error	Displays error debug messages.
normal	Displays normal debug messages.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).

Usage Guidelines

After you use the **debug platform software ucse all** command, use the appropriate **ucse** command to display debug messages.

Examples

The following example shows how to display debug messages for the **ucse subslot imc password-reset** command:

```
Router# debug platform software ucse all
Router#
Router# ucse subslot 2/0 imc password-reset
 ucse2/0/0
Password reset command sent.
Router#
 IMC ACK: UCSE password reset successful for IMC
 ACK received for UCSE: Password Reset Command
```

debug snmp tunnel-mib

To enable the debugging for configuring the IP Tunnel Management Information Base (MIB) through Simple Network Management Protocol (SNMP), use the **debugsnmptunnel-mib** command in privileged EXEC mode. To disable debugging, use the **no** form of this command.

debug snmp tunnel-mib
no debug snmp tunnel-mib

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRB	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
12.2(33)SB1	This command was integrated into Cisco IOS Release 12.2(33)SB1.
12.2(44)SG	This command was integrated into Cisco IOS Release 12.2(44)SG.
Cisco IOS Release XE 2.1	This command was integrated into Cisco IOS Release XE 2.1.

Usage Guidelines

Use the **debugsnmptunnel-mib** command to verify whether a tunnel is created or deleted.

Examples

The following is sample output from the **debugsnmptunnel-mib** command. The output shows that a tunnel is created through SNMP.

```
Router# debug snmp tunnel-mib
SNMP TUNNEL-MIB debugging is on
k_tunnelInetConfigEntry_get: Entering
k_tunnelInetConfigEntry_get: Exact search
tim_client_tunnel_endpoint_data_get: Entering
tim_client_tunnel_endpoint_data_get: Exact search
tim_client_tunnel_endpoint_data_get: No element found
k_tunnelInetConfigEntry_get: Client service failed
k_tunnelInetConfigEntry_test: Entering
k_tunnelInetConfigEntry_test: Completed
k_tunnelInetConfigEntry_set: Entering
tim_client_tunnel_endpoint_data_get: Entering
tim_client_tunnel_endpoint_data_get: Exact search
tim_client_tunnel_endpoint_data_get: No element found
k_tunnelInetConfigEntry_set: Calling tunnel create
tim_client_tunnel_create: Entering
tim_client_tunnel_create: Completed
```

default (CEM)

To reset channel options to their default values, use the **default**command in CEM configuration mode.

default {**data-protection** | **dejitter-buffer** | **idle-pattern** | **ip dscp** | **ip tos** | **ip precedence** | **payload-compression** | **payload-size** | **signaling**}

Syntax Description

data-protection	Resets data protection to its default value.
dejitter-buffer	Resets the dejitter buffer to its default value.
idle-pattern	Resets the idle pattern to its default value.
ip dscp	Resets the IP differentiated services code point (DSCP) field to its default value.
ip tos	Resets the IP type of service (ToS) field to its default value.
ip precedence	Resets the IP precedence field to its default value.
payload-compression	Resets payload compression to its default value.
payload-size	Resets payload size to its default value.
signaling	Resets signaling to its default value.

Command Default

The CEM channel options are set at their configured values.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced for CEM configuration mode.

Examples

The following example demonstrates how to reset CEM channel data protection to its default value.

```
Router(config-cem)# default data-protection
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
data-protection	Enables data protection.
dejitter-buffer	Configures the dejitter buffer size.
idle-pattern	Defines the idle pattern that the channel transmits when it goes down.
payload-compression	Enables payload compression.

Command	Description
payload-size	Configures the payload size.
show cem	Displays CEM channel statistics.
signaling	Enables CAS signaling.

default interface

To reset the configuration of an interface back to its default values, use the **default**command in global configuration mode.

default *interface-type* *interface-number*

Syntax Description

interface-type	Type of interface. The interface types that are available to be reset to their default values will vary depending on the available interface types on the networking device and the Cisco IOS release that is installed on the device. Not all possible interface types are documented here. • **async** --Reconfigures the specified async interface to its default value. • **atm** --Reconfigures the specified ATM interface to its default value. • **bvi** --Reconfigures the specified bridge-group virtual interface to its default value. • **dialer** --Reconfigures the specified dialer interface to its default value. • **ethernet** --Reconfigures the specified Ethernet interface to its default value. • **fastethernet** --Reconfigures the specified Fast Ethernet interface to its default value. • **fddi** --Reconfigures the specified FDDI interface to its default value. • **gigabitethernet** --Reconfigures the specified Gigabit Ethernet interface to its default value. • **group-async** --Reconfigures the specified group async interface to its default value. • **loopback** --Reconfigures the specified loopback interface to its default value. • **null** --Reconfigures the specified null interface to its default value. • **pos** --Reconfigures the specified Packet over SONET (POS) interface to its default value. • **serial** --Reconfigures the specified serial interface to its default value. • **tunnel** --Reconfigures the specified tunnel interface to its default value.
interface-number	Number of the interface, slot, router shelf, unit, port, or port adaptor if appropriate for the interface type. Slash marks may be required between elements of this argument.

Command Default

Existing interface configuration values are not reset.

Command Modes

Global configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **default** command is a general-purpose command that is not limited to interfaces; it resets defaults based on the command name that follows it. Use the **default**(interface) command when you need to remove any configuration for a specified interface and reset the interface to its default values.

Examples

The following example demonstrates how to reset serial interface 0 to its default values.

```
Router(config)# default serial 0
```

Related Commands

Commands	Description
interface	Enters interface configuration mode.

define interface-range

To create an interface-range macro, use the **define interface-range** command in global configuration mode. To remove an interface-range macro, use the **no** form of this command.

define interface-range *macro-name interface-range*

Syntax Description

macro-name	Name of the interface-range macro.
interface-range	Type of interface range. • For a list of valid values, see the "Usage Guidelines" section.

Command Default

Interface-range macro is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(14)SX	This command was introduced.
12.2(17d)SXB	This command was integrated into Cisco IOS XE Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

- The **define interface-range** command applies a particular configuration on multiple interfaces and creates multiple logical, and sub interfaces.
- An interface range macro name can comprise up to 32 characters.
- An interface range for a macro can accept a maximum of five ranges. However, the subinterface range for a macro accepts only one range.
- An interface range cannot span slots.
- Use the *interface-type slot/first-interface last-interface* format to enter the interface range.
- Valid values for the *interface-type* argument are as follows:
  - **atm** —Supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2
  - **ethernet**
  - **fastethernet**
  - **ge-wan** —Supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2
  - **gigabitethernet**
  - **loopback**
  - **port-channel** *interface-number* —Valid values are from 1 to 256
  - **pos** —Supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2

- **tengigabitethernet**
- **tunnel**
- **vlan** *vlan-id* —Valid values are from 1 to 4094

Examples

The following example shows how to create a multiple-interface macro:

```
Device(config)# define interface-range macro1 ethernet 1/2 - 5, fastethernet 5/5 - 10
```

The following example shows how to create multiple loopback interfaces:

```
Device(config)# define interface-range loopback1-10
```

Related Commands

Command	Description
interface range	Executes a command on multiple ports at the same time.

dejitter-buffer

To configure the size of the dejitter buffer, use the **dejitter-buffer** command in CEM configuration mode. To restore the dejitter buffer to its default size, use the **no** form of this command.

dejitter-buffer *size*
no dejitter-buffer

Syntax Description

size	Size, in milliseconds, of the dejitter buffer. The range is from 5 to 500. The default is 60. For Cisco ASR 901 Series Aggregation Services Routers, the range is from 4 to 500; the default is 4.

Command Default

The dejitter buffer defaults to 60 milliseconds. For Cisco ASR 901 Series Aggregation Services Routers, the default is 4.

Command Modes

CEM configuration

Command History

Release	Modification
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Examples

The following example shows how to set the dejitter buffer to 200 milliseconds.

```
Router(config-cem)# dejitter-buffer 200
```

The following example shows how to specify the size of the dejitter buffer to 10 milliseconds on the Cisco ASR 901 Series Aggregation Services Router:

```
Router# configure terminal
Router(config)# interface cem 0/0
Router(config-if)# no ip address
Router(config-if)# cem 0
Router(config-if-cem)# dejitter-buffer 10
Router(config-if-cem)# xconnect 10.10.10.10 200 encapsulation mpls
Router(config-if-cem-xconn)# exit
Router(config-if-cem)# exit
Router(config-if)# exit
Router(config)# exit
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
clear cem	Clears CEM channel statistics.
clear cem	Clears CEM channel statistics.

Command	Description
show cem	Displays CEM channel statistics.

delay-asymmetry

To perform the PTP asymmetry readjustment on a PTP node to compensate for the delay in the network, use the **delay-asymmetry** command in the PTP clock configuration mode. To revert to default setting, use the **no** form of this command.

delay-asymmetry *asymmetry_compensation_offset*
no delay-asymmetry *asymmetry_compensation_offset*

Syntax Description

asymmetry_compensation_offset	Asymetry value of the clock that defines if a one way delay of forward or reverse path occurs.Value ranges from -500000000 to 500000000 nanoseconds.

Command Default

The default asymmetry offset value is zero.

Command Modes

PTP Clock Configuration (for default Telecom profile), Clock-Port Configuration (for G8275.1 Telecom profile)

Command History

Release	Modification
Cisco IOS XE Gibraltar 16.10.1	This command was introduced.

Usage Guidelines

The asymmetry compensation offset value can be configured on default, G8275.1 Telecom profile.

The following example demonstrates how to configure the delay asymmetry for ports with default Telecom profile.

```
Router# configure terminal
Router(config)#ptp clock
Router(config-ptp-clk)#clock-port sla slave
Router(config-ptp-port)#clock source 1.1.1.1 delay-asymmetry 300 nanoseconds
```

The following example demonstrates how to configure the delay asymmetry for ports with G8275.1 Telecom profile.

```
Router# configure terminal
Router(config)#ptp clock
Router(config-ptp-clk)#clock-port sla slave
Router(config-ptp-port)#delay-asymmetry 500
```

Related Commands

Command	Description
ptp clock	Creates a Precision Time Protocol clock and specifies the clock mode.
clock-port	Specifies the clocking mode of a Precision Time Protocol clock port.

delay (interface)

To set a delay value for an interface, use the **delay** command in interface configuration mode. To restore the default delay value, use the **no** form of this command.

delay *tens-of-microseconds*
no delay

Syntax Description

tens-of-microseconds	Integer that specifies the delay in tens of microseconds for an interface or network segment. To see the default delay, use the **showinterfaces** command.

Command Default

Default delay values may be displayed with the **showinterfaces**EXEC command.

Command Modes

Interface configuration (config-if) Virtual network interface (config-if-vnet)

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 3.2S	This command was modified. Support was added for this command in virtual network interface configuration mode.

Examples

The following example shows how to set a delay of 30,000 microseconds on serial interface 3:

```
Router(config)# interface serial 3
Router(config-if)# delay 3000
```

Related Commands

Command	Description
show interfaces	Displays the statistical information specific to a serial interface.

delay-req interval

To specify a recommended interval for Precision Time Protocol member devices to send delay request messages, use the **delay-reqinterval** command in PTP clock port configuration mode. To remove a delay request interval configuration, use the **no** form of this command.

delay-req interval *interval-value* **unicast**
no delay-req interval *interval-value* **unicast**

Syntax Description

interval-value	Specifies the length of the interval for delay request messages. The intervals are set using log base 2 values, as follows: • 4--1 packet every 16 seconds • 3--1 packet every 8 seconds • 2--1 packet every 4 seconds • 1--1 packet every 2 seconds • 0--1 packet every second • -1--1 packet every 1/2 second, or 2 packets per second • -2--1 packet every 1/4 second, or 4 packets per second • -3--1 packet every 1/8 second, or 8 packets per second • -4--1 packet every 1/16 seconds, or 16 packets per second. • -5--1 packet every 1/32 seconds, or 32 packets per second. • -6--1 packet every 1/64 seconds, or 64 packets per second. The recommended value is -6.
unicast	(Optional) Specifies that the device send PTP delay request messages using unicast mode.

Command Default

The default value is -4 (16 packets per second).

Command Modes

PTP clock-port configuration (config-ptp-port)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

This configuration is only required when an interface is in PTP subordinate mode.

Examples

The following example shows how to use the **delay-req** command:

```
Router# configure terminal
Router(config)# ptp clock ordinary domain 0
```

```
Router(config-ptp-clk)# clock-port slaveport slave
Router(config-ptp-port)# delay-req interval 2 unicast
Router(config-ptp-port)# end
```

Related Commands

Command	Description
clock-port	Specifies the mode of a PTP clock port.

description (controller)

To add a description to an E1 or T1 controller or the Channelized T3 Interface Processor (CT3IP) in Cisco 7500 series routers, use the **description**command in controller configuration mode. To remove the description, use the **no**form of this command.

description *string*
no **description**

Syntax Description

string	Comment or description (up to 80 characters) to help you remember what is attached to an interface.

Command Default

No description is added.

Command Modes

Controller configuration

Command History

Release	Modification
10.3	This command was introduced.
11.3	This command was modified to include the CT3IP controller.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **description** command is meant solely as a comment to be put in the configuration to help you remember what certain controllers are used for. The description affects the CT3IP and Multichannel Interface Processor (MIP) interfaces only and appears in the output of the **showcontrollere1**, **showcontrollert1,showcontrollert3**, and**showrunning-config**EXEC commands.

Examples

The following example shows how to add a description for a 3174 controller:

```
Router(config)# controller t1
Router(config-controller)# description 3174 Controller for test lab
```

Related Commands

Command	Description
show controllers e1	Displays information about the E1 links supported by the NPM (Cisco 4000) or MIP (Cisco 7500 series).
show controllers t1	Displays information about the T1 links.
show controllers t3	Displays information about the CT3IP on Cisco 7500 series routers.

description (interface configuration)

To add a description to an interface configuration, use the **description** command in interface configuration mode. To remove the description, use the **no**form of this command.

description *string*
no description

Syntax Description

string	Comment or a description to help you remember what is attached to this interface. This string is limited to 238 characters.

Command Default

No description is added.

Command Modes

Interface configuration

Command History

Release	Modification
9.21	This command was introduced.

Usage Guidelines

The **description** command is meant solely as a comment to be put in the configuration to help you remember what certain interfaces are used for. The description appears in the output of the following EXEC commands:**morenvram:startup-config**, **showinterfaces**, and**moresystem:running-config**

Examples

The following example shows how to add a description for a T1 interface:

```
interface serial 0
 description Fractional T1 line to remote office -- 128 kbps
```

Related Commands

Command	Description
more nvram:startup-config	Displays the startup configuration file contained in NVRAM or specified by the CONFIG_FILE environment variable.
more system:running-config	Displays the running configuration.
show interfaces	Displays statistics for all interfaces configured on the router or access server.

diagnostic level

To turn on power-on diagnostic tests for the network service engines (NSEs) installed in a Cisco 7300 series router, use the **diagnostic level** command in privileged EXEC configuration mode. There is no **no** form of this command.

diagnostic level {**power-on** | **bypass**}

Syntax Description

power-on	Power-on diagnostic tests are performed at system bootup on the NSEs.
bypass	No diagnostic tests are performed. This is the default.

Command Default

No diagnostic tests are performed.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(10)EX2	This command was introduced.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2 S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to enable power-on diagnostic tests to run on the installed NSEs of a Cisco 7300 series router when the system is booted. It is recommended that you issue this command only if you are experiencing problems with an NSE and are planning on rebooting the router. Issuing this command causes an increase in the boot time.

Examples

The following example shows how to enable diagnostic power-on tests:

```
diagnostic level power-on
```

The following sample output shows the output that is displayed upon system bootup after a power cycle or router crash:

```
.
.
.
System Power On Diagnostics
DRAM Size ....................128 MB
Testing DRAM..................Passed
Level2 Cache .................Present
Testing Level2 Cache (256  KB)Passed
Level3 Cache .................Present
Testing Level3 Cache (1024 KB)Passed
System Power On Diagnostics Complete
```

Note This output is displayed when the system is booting, not when the command is issued.

Related Commands

Command	Description
debug redundancy	Enables NSE redundancy debugging.
show c7300	Displays the types of cards (NSE and line cards) installed in a Cisco 7300 series router.
show redundancy (7300)	Displays redundancy information for the active and standby NSEs.

dial-tdm-clock

To configure the clock source and priority of the clock source used by the time-division multiplexing (TDM) bus on the dial shelf of the Cisco AS5800, use the **dial-tdm-clock** command in global configuration mode. To return the clock source and priority to the default values, use the **no** form of this command.

dial-tdm-clock priority *number* {**external** {**e1** | **t1**} [**120ohm**] | **freerun** | **trunk-slot** *slot* **port** *port*} [**line** {**0** | **1**}]
no dial-tdm-clock priority *number* {**external** {**e1** | **t1**} [**120ohm**] | **freerun** | **trunk-slot** *slot* **port** *port*} [**line** {**0** | **1**}]

Syntax Description

priority *number*	Specifies the priority of the clock source. The range is from 1 to 50. Priority 1 is the highest priority, and 50 is the lowest.
external	Specifies the priority of an external clock source. The external clock source is connected to the front panel of the Dial Shelf Controller (DSC) card.
e1 | **t1**} [**120ohm**]	Specifies priority of the E1 (2.048 MHz) or T1 (1.54 MHz) external clock source. The default value of the external coaxial cable impedance is 75 ohm. Specify the **120ohm**option if a 120 ohm coaxial cable is connected.
freerun	Specifies the priority of the local oscillator clock source.
trunk-slot *slot*	Specifies the priority of the trunk card to provide the clock source. The slot number is from 0 to 5 (these are the only slots capable of providing clock sources).
port *port*	Specifies the controller number on the trunk used to provide the clock source. The port number is from 0 to 28. The T1 and E1 trunk cards each have 12 ports. The T3 trunk card has 28 ports.
line {**0** | **1**	(Optional) Specifies the optical port. If the physical optical port is 0, the**line** value is also 0.

Command Default

If no clock sources are specified, the software selects the first available good clock source on a trunk port.

Command Modes

Global configuration

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(15)T	The **line** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The TDM bus in the backplane on the dial shelf must be synchronized to the T1/E1 clocks on the trunk cards. The DSC card on the dial shelf provides hardware logic to accept multiple clock sources as input and use one of them as the primary source to generate a stable, PPL synchronized output clock. The input clock can be any of the following sources:

- Trunk port in slots 0 through 5 (up to 12 can be selected (two per slot)
- An external T1 or E1 clock source fed directly through a connector on the DSC card
- A free running clock from an oscillator in the clocking hardware on the DSC card

The clock commands are listed in the configuration file with the highest priority listed first.

If the current primary clock source is good, specifying another clock source of higher priority does not cause the clock source to switch to the higher priority clock source. The new higher priority clock source is used as a backup clock source. This prevents switching of the clock source as you enter multiple dial-tdm-clock priority configuration commands in random order. Also, it is important not to disturb the existing clock source as long as it is good. To force the new higher priority clock source to take over from a currently good primary clock source, configure the new clock source and use the **no** dial-tdm-clock priority command to remove the current primary clock source.

To display the current primary and backup clocks along with their priorities, use the **showdial-shelfclocks**EXECcommand.

Examples

In the following example, an external clock source is set at priority 1 and the trunk card in slot 4, port 1 is set at priority 5:

```
Router(config)# dial-tdm-clock priority 1 external t1
Router(config)# dial-tdm-clock priority 5 trunk-slot 4 port 1
Router(config)# exit
```

Related Commands

Command	Description
show dial-shelf	Displays information about the dial shelf, including clocking information.

dot1q tunneling ethertype

To define the Ethertype field type used by peer devices when implementing Q-in-Q VLAN tagging, use the **dot1qtunnelingethertype**command in interface configuration mode. To remove the VLAN tag Ethertype, use the **no** form of this command.

no dot1q tunneling ethertype{*0x88A8 0x9100 0x9200*}
no dot1q tunneling ethertype

Syntax Description

0x88A8 |0x9100|0x9200	Type of Ethertype field.

Command Default

The Ethertype field used by peer devices when implementing Q-in-Q VLAN tagging is 0x8100.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.3(7)XI1	This command was implemented on the Cisco 10000 series routers.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
Cisco IOS XE Release 2.2	This command was integrated into Cisco IOS XE Release 2.2.

Usage Guidelines

Use the **dot1qtunnelingethertype** command if the peer switching devices are using an Ethertype field value of 0x9100 or 0x9200. All Cisco switching devices use the default Ethertype field value of 0x88A8. The Cisco 10000 series router also supports the 0x9200 Ethertype field value.

Note On the Cisco 10000 series router, the Ethertype field for the outer VLAN ID can be changed, but the Ethertype field for the inner VLAN ID cannot be changed.

This command is used with the IEEE 802.1Q-in-Q VLAN Tag Termination feature in which double VLAN tagging is configured using the **encapsulationdot1q** command. 802.1Q double tagging allows a service provider to use a single VLAN to support customers who have multiple VLANs.

Examples

The following example shows how to configure an Ethertype field as 0x9100:

```
Router(config
)
# interface gigabitethernet 1/0/0
Router(config
-if)#
 dot1q tunneling ethertype 0x9100
```

The following example shows how to configure an Ethertype field as 0x9200 on a Cisco 10000 series router:

```
Router(config)# interface gigabitethernet 1/0/0
Router(config-if)# dot1q tunneling ethertype 0x9200
```

Related Commands

Command	Description
encapsulation dot1q	Enables 802.1Q encapsulation of traffic on a specified subinterface or range of subinterfaces.
interface	Configures an interface and enters interface configuration mode.

down-when-looped

To configure an interface to inform the system that it is down when loopback is detected, use the **down-when-looped**command in interface configuration mode.

down-when-looped

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is valid for High-Level Data Link Control (HDLC) or PPP encapsulation on serial and High-Speed Serial Interface (HSSI) interfaces.

This command does not have a **no** form.

Note

- This command cannot be enabled when default speed or 1000BaseT advertisement is enabled on the GMII interface.
- 1000BaseT advertisement cannot be configured when down-when-looped is enabled.

Backup Interfaces

When an interface has a backup interface configured, it is often desirable that the backup interface be enabled when the primary interface is either down or in loopback. By default, the backup is enabled only if the primary interface is down. By using the **down-when-looped** command, the backup interface will also be enabled if the primary interface is in loopback.

Testing an Interface with the Loopback Command

If testing an interface with the loopback command, or by placing the DCE into loopback, the **down-when-looped** command should not be configured; otherwise, packets will not be transmitted out the interface that is being tested.

Examples

The following example shows how to configure interface serial 0 for HDLC encapsulation. The interface is then configured to let the system know that it is down when in loopback mode.

```
Router(config)# interface serial0
```

```
Router(config-if)# encapsulation hdlc
Router(config-if)# down-when-looped
```

Related Commands

Command	Description
backup interface	Configures an interface as a secondary or dial backup interface.
loopback (E3 controller)	Diagnoses equipment malfunctions between an interface and a device.

ds0-group (J1 controller)

To configure channelized J1 time slots, use the**ds0-group**commandincontroller configuration mode. To remove the DS0 group, use the**no** form of this command.

ds0-group *ds0-group-no* **timeslots** *timeslot-list* **type** *external-signaling*
no ds0-group *ds0-group-no* **timeslots** *timeslot-list* **type** *external-signaling*

Syntax Description

ds0-group-no	Specifies the DS0 group number.
timeslots *timeslot-list*	Specifies the DS0 time slot range of values from 1 to 31 for J1 interfaces. Time slot 16 is reserved for signaling.
type *external-signaling*	Specifies that the signaling traffic comes from an outside source. The signaling method selection for type depends on the connection that you are making.

Command Default

No DS0 group is defined.

Command Modes

Controller configuration

Command History

Release	Modification
11.2	This command was originally the **cas-group** command.
12.0(1)T	The **cas-group** command was introduced for the Cisco 3600 series.
12.0(5)XE	The command was renamed**ds0-group** on the Cisco AS5300 and on the Cisco 2600 and Cisco 3600 series.
12.0(7)T	The command was integrated into the Cisco IOS Release 12.0(7)T.
12.2(8)T	The command was introduced as a J1 configuration command for the Cisco 2600 and Cisco 3600 series.

Usage Guidelines

The ds0-group command replaces the existing cas-group command. Making the command generic allows flexibility and scalability. It is not restricted to channel associated signaling (CAS) or channel bundling.

The **ds0-group** command automatically creates a logical voice port that is numbered as follows on Cisco 2600 and Cisco 3600 series routers: *slot*/*port***:***ds0-group-no*. Although only one voice port is created for each group, applicable calls are routed to any channel in the group.

Examples

The following example is sample output from the **showcontrollersj1**command on the Cisco 3660 series after channelized J1 time slots have been configured:

```
Router(config-controller)# ds0-group 1 timeslots 1-15,17-31 type e&m-wink-start

Router(config-controller)# end
Router# show controllers j1
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(1), cp
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(2), cp
```

```
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(3), cp
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(4), cp
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(5), cp
*Mar  1 03:12:26.259: %LINK-3-UPDOWN: Interface recEive and transMit3/0:0(6), cp

```

Related Commands

Command	Description
ds0 busyout	Busyouts one or more signal level 0s (DS0s).

dsl-group

To create and configure a digital subscriber line (DSL) group, and enter config-controller-dsl-group mode, or to automatically configure an ATM group, use the **dsl-group**command in configuration controller mode. To disable the DSL group, use the **no** form of this command.

dsl-group [**pairs**] [{[*number*] **pairs** *link-number* | **auto** [{**default** | **exit** | **no** | **shdsl** {**4-wire** | **annex**}}]}] [**efm-bond**]
no dsl-group [**pairs**] [{[*number*] **pairs** *link-number* | **auto** [{**default** | **exit** | **no** | **shdsl** {**4-wire** | **annex**}}]}] [**efm-bond**]

Syntax Description

pairs	(Optional) Defines the DSL wire pairs.
number	(Optional) DSL group number. The DSL group number can be one of the following numbers: • 0 • 1
efm-bond	(Optional) Defines the DSL group as Ethernet First Mile (EFM) group bonding group.

link-number	(Optional) Link number of the pair. Link number options are limited to one of the following choices, based on the hardware interface and the desired DSL group: **HWIC-4SHDSL-E** EFM-bond DSL Group • 0 • 1 • 2 • 3 • Any combination of the numbers 0, 1, 2, and 3 1-Pair DSL Group • 0 • 1 • 2 • 3 In the case of 1-pair DSL group (2-wire), only one pair needs to be configured. **HWIC-4SHDSL** IMA DSL Group • 0 • 1 • 2 • 3 • Any combination of the numbers 0, 1, 2, and 3

	M-Pair DSL Group • 0-1 • 0-2 • 0-3 2-Pair DSL Group • 0-1 • 2-3 1-Pair DSL Group • 0 • 1 • 2 **HWIC-2SHDSL** DSL Group 0 • 0 • 0-1 DSL Group 1 • 1
auto	(Optional) Automatically assigns the Central Office's (CO) wire configuration to an ATM DSL group on the Customer Premise Equipment (CPE).
default	(Optional) Sets a command to the default values.
exit	(Optional) Exits DSL group command mode.
no	(Optional) Negates a command or set its defaults.
shdsl	(Optional) Configures the symmetric g.shdsl.
4-wire	(Optional) Configures the 4-wire symmetric g.shdsl.
annex	(Optional) Configures the annex symmetric g.shdsl.

Command Default

No DSL group is defined or automatically configured.

Command Modes

Configuration controller (config-controller)

Configuration controller DSL group (config-controller-dsl-group)

Command History

Release	Modification
12.4(15)T	This command was introduced for the Cisco HWIC-4SHDSL and HWIC-2SHDSL running on the Cisco 1841 router and the Cisco 2800 and 3800 series access routers.
15.1(1)T	This command was modified to support automatic configuration of Cisco HWIC-4SHDSL and HWIC-2SHDSL running on the Cisco 1841 router and the Cisco 2800 and 3800 series access routers. Added **dsl-grouppairs***link-number* [**efm-bond**] for the Cisco HWIC-4SHDSL-E.
15.1(1)T1	This command was modified. The auto configuration options **default**,**exit**,**no**, and **shdsl**were added to the dsl-group.

Usage Guidelines

Use the **dsl-group** command in configuration controller mode to define the DSL group, and manually configure the DSL group from configuration controller DSL group mode. Use the **dsl-groupauto** command to automatically adopt the Central Office (CO) wire configuration on an ATM DSL group. Use the **dsl-grouppairs** to define the DSL group as Ethernet First Mile (EFM) group bonding group.

Note Automatic configuration is not supported on IMA groups.

Automatic configuration is limited to only one DSL group and ATM interface. After a group is automatically configured, no other group can be created. All manually created groups must be deleted before creating an automatic configuration group.

Examples

The following example shows how to use the dsl-group command to create an IMA-DSL group and enter configuration controller DSL group mode:

```
Router(config-controller)# dsl-group 1 pairs 0-1 ima
Router(config-controller-dsl-group)#
Sep 14 13:15:40.285:%HWIC_SHDSL-5-DSLGROUP_UPDOWN: SHDSL 0/2/0 dsl-group(1) state changed
to down.
Sep 14 13:15:42.285:%LINK-3-UPDOWN: Interface ATM0/2/IMA1, changed state to down
Sep 14 13:15:43.285:%LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/2/IMA1, changed
state to down
```

The following example shows how to use the dsl-group auto command to automatically adopt the Central Office (CO) configuration on an ATM group:

```
Router(config-controller)# dsl-group auto
Router(config-controller-dsl-group-auto)#
*May 14 18:56:33.136: %HWIC_SHDSL-5-DSLGROUP_UPDOWN: SHDSL 0/0/0 dsl-group(0) state changed
 to down.
*May 14 18:56:35.136: %LINK-3-UPDOWN: Interface ATM0/0/0, changed state to down
*May 14 18:56:36.136: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/0/0,
changed state to down
```

The following example shows how to configure a single-pair DSL group and enters the configuration controller DSL group mode:

```
Router(config-controller)# dsl-group pairs 0
Router(config-controller-dsl-group)#
```

The following example shows how to create a 4-pair EFM bonding group:

```
Router(config-controller)# dsl-group pairs 0-3 efm-bond
Router(config-controller-dsl-group)#
```

Related Commands

Command	Description
controller shdsl	Configures a controller for SHDSL mode and enters configuration controller mode.
ima group	Defines physical links as IMA group members.
ima group clock-mode	Sets the clock mode for an IMA group.
ima link	Defines physical links in an IMA group.
shdsl 4-wire mode enhanced	Defines the SHDSL to use enhanced mode in a 2-pair DSL group.
shdsl annex	Defines the SHDSL G.991.2 standard.
shdsl rate	Defines the SHDSL rate.
show controller shdsl	Displays the status of the controller that is configured for SHDSL mode.

dsl-mode shdsl symmetric annex

To specify the operating mode of the digital subscriber line (DSL) controller, use the **dsl-mode shdsl symmetric annex**command in controller configuration mode.

To specify the line coding type of the DSL controller, use the **dsl-mode shdsl symmetric annex coding**command in controller configuration mode. To return the DSL to the default Annex A, use the **no** form of the command.

dsl-mode shdsl symmetric annex mode [**coding type**]
no dsl-mode shdsl symmetric annex mode [**coding type**]

Syntax Description

mode	Sets the DSL operating mode. The valid values are: • **a** : Supports Annex A of the G.991.2 standard for North America. This is the default. • **b** : Supports Annex B of the G.991.2 standard for Europe. • **a-b** : Supports Annex A or B. For CPE mode only. Not supported in CO mode. Selected when the line trains. • **a-b-anfp** : Supports Annex A or B-ANFP. For CPE mode only. Not supported in CO mode. Selected when the line trains. • **b-anfp** : Supports Annex B-ANFP. • f: Supports Annex F, 2-wire mode, line 0 only. • f-g: Supports Annex F-G, 2-wire mode, line 0 only. • g: Supports Annex G, 2-wire mode, line 0 only.
coding	TCPAM line coding.
Type	The valid values are: • 16bit-TCPAM: Sets the line coding to16 bit-TCPAM. • 32bit-TCPAM: Sets the line coding to 32 bit-TCPAM. • AUTO-TCPAM: Detects the central office coding type.

The annex defaults to A for North America.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(4)XG	This command was integrated into the Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.

Release	Modification
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series, Cisco 3631, and Cisco 3700 series routers.
12.3(11)T	Support for the following additional annex parameters was integrated into Cisco IOS Release 12.3(11)T to support Cisco 1700, Cisco 2600, Cisco 2800, Cisco 3700, and Cisco 3800 series routers: • **b** • **a-b** • **a-b-anfp** • **b-anfp**
12.3(14)T	This command was implemented on Cisco 1800 series routers.
12.4(15)T	Support for the following additional annex parameters was integrated into Cisco IOS Release 12.X(X)T to support Cisco to support Cisco 1700, Cisco 2600, Cisco 2800, Cisco 3700, and Cisco 3800 series routers: • f • f-g • g
12.4(20)T	Support for **coding** *type* parameters was added.

Usage Guidelines

This command is used to configure the DSL controller interface to operate in a specified DSL mode and to set regional operating parameters. The **shdsl** keyword is used to set the mode to SHDSL and configures multirate, high-speed DSL per ITU G.991.2. The **symmetric** keyword configures the controller to symmetric mode. The **annex** keyword configures the controller to use regional operating parameters. The regional operating parameters default to North America. The coding keyword configures the controller Trellis Encoded Pulse Amplitude Modulation (TCPAM) line coding type.

Examples

The following example displays the use of the **controller dsl 0/0**commandto configure the controller in the router configured on the central office (CO) side. Use the **dsl-mode shdsl symmetric annex b**command to configure the controller for multirate, high-speed DSL with symmetric mode for European operating parameters.

```
Router# configure terminal

Router(config)# controller dsl 0/0
Router(config-controller)# line-term co
Router(config-controller)# dsl-mode shdsl symmetric annex b
Router(config-controller)# mode atm
Router(config-controller)#
00:22:07: %CONTROLLER-5-UPDOWN: Controller DSL 0/0, changed state to down
Router(config-controller)# line-mode 4-wire
00:23:25: %CONTROLLER-5-UPDOWN: Controller DSL 0/0, changed state to up
00:23:31: %LINK-3-UPDOWN: Interface ATM0/0, changed state to up
00:23:32: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/0, changed state to up
```

The following example uses the **dsl-mode shdsl symmetric annex command to configure the controller for 2-wire line 0, annex F, AUTO-TCPAM line coding.**

```
Router> enable
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# controller dsl 0
Router(config-controller)# line-mode 2-wire line-zero
Router(config-controller)# dsl-mode shdsl symmetric annex f coding ?
 16bit-TCPAM  16bit-TCPAM line coding
 32bit-TCPAM  32bit-TCPAM line coding
 AUTO-TCPAM   AUTO-TCPAM line coding
Router(config-controller)# dsl-mode shdsl symmetric annex f coding auto-tcpam
Router(config-controller)#
Router#
```

Related Commands

Command	Description
controller dsl	Configures the DSL controller.

dsu bandwidth

To specify the maximum allowable bandwidth used by a T3 or E3 controller or the PA-T3 and PA-E3 port adapters, use the **dsubandwidth**command in interface configuration mode. To return to the default bandwidth, use the **no** form of this command.

dsu bandwidth *kbps*
no dsu bandwidth

Syntax Description

kbps	Maximum bandwidth, in kbps. Range is from 22 to 44736. Default values are as follows: • 34,010 for E3 or PA-E3 • 44,210 for T3 • 44,736 for PA-T3 • 34,368 kbps for E3 on a Cisco_10000 Series Router • 44,210 kbps for T3 on a Cisco_10000 Series Router

Command Default

34,010 kbps

44,210 kbps

44,736 kbps

34,368 kbps for E3

44,210 kbps for T3

Command Modes

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Local and Remote Bandwidths

The local interface configuration must match the remote interface configuration. For example, if you reduce the maximum bandwidth to 16,000 on the local port, you must also do the same on the remote port.

The **dsubandwidth**command reduces the bandwidth by padding the E3 and T3 frame.

Verifying DSU Bandwidth

To verify the data service unit (DSU) bandwidth configured on the interface, use the show interfaces serial user EXEC command.

G.751 Framing

When G.751 framing is used, DSU bandwidth can be used to select a payload subrate from 34,010 kbps down to 22 kbps. Before framing bypass can be used, a DSU bandwidth of 34,010 kbps must be configured.

Continuous Range of Bandwidth

Even though Cisco_IOS software allows you to configure a continuous range of bandwidths in subrate modes, vendors support bandwidths only in quantums (for example, in an E3 digital link, bandwidth must be in multiples of 358 kbps). Therefore, the software sets the user-configured bandwidth to the closest vendor-supported bandwidth. Use the show interfaces serial slot/port command to display the actual bandwidth that is configured.

Subrates

The user-configured subrate mode, subrate bandwidth, actual subrate bandwidth configured, and scramble configuration are displayed near the end of the show interfaces serial command output.

DSU Modes and Vendor-Supported Bandwidths

The following table shows DSU modes and vendor-supported bandwidths.

Mode	DSU	Bandwidth Range	Bandwidth Multiples
0	Digital Link or Cisco	358-34,010 kbps for E3 300-44,210 kbps for T3	358 kbps 300.746 kbps
1	ADC Kentrox T3/E3 IDSU	1000-34,010 kbps for E3 1500-44,210 kbps for T3	500 kbps 500 kbps
2	Larscom Access T45	3100-44,210 kbps	3158 kbps
3	Adtran T3SU 300	75-44,210 kbps	75.186 kbps
4	Verilink HDM 2182	1500-44,210 kbps	1579 kbps

Examples

The following example sets the maximum allowable DSU bandwidth to 16,000 kbps on interface 1/0/0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# dsu bandwidth 16000
```

The following example shows the user-configured subrate bandwidth and the actual configured subrate bandwidth as displayed in the output of the show interfaces serial command:

```
Router# show interfaces serial
Serial1/0 is up, line protocol is up
```

```
  Hardware is DSXPNM Serial
  MTU 1500 bytes, BW 44210 Kbit, DLY 20000 usec,
     reliability 253/255, txload 1/255, rxload 1/255
  Encapsulation HDLC, crc 16, loopback not set
  Keepalive not set
  DTR is pulsed for 0 seconds on reset, Restart-Delay is 1637167 secs
  Last input 04:59:04, output 04:59:04, output hang never

show interfaces serial	Displays information that is specific to the interface hardware.

dsu mode

To specify the interoperability mode used by a T3 or E3 controller or the PA-T3 and PA-E3 port adapters, use the **dsumode**command in interface configuration mode. To return to the default mode, use the **no** form of this command.

dsu mode {**0** | **1** | **2** | **3** | **4**}
no dsu mode

Cisco 10000 Series Router
dsu mode {**adtran** | **cisco** | **digital-link** | **kentrox** | **larscom** | **verilink-highbit** | **verilink-lowbit**}
no dsu mode

Syntax Description

0	Sets the interoperability mode to 0. This is the default. • Specify mode 0 to connect an E3 controller to another E3 controller or to a Digital Link data service unit (DSU) DL3100. • Specify mode 0 to connect a PA-E3 port adapter to another PA-E3 port adapter or to a DL3100. • Specify mode 0 to connect a PA-T3 port adapter to another PA-T3 port adapter or to a DL3100.
1	Sets the interoperability mode to 1. Specify mode 1 to connect an E3 or T3 controller or a PA-E3 or PA-T3 port adapter to a Kentrox DSU.
2	Sets the interoperability mode to 2. Specify mode 2 to connect a T3 controller or a PA-T3 port adapter to a Larscom DSU.
3	Sets the interoperability mode to 3. Specify mode 3 to connect a T3 controller to an Adtran T3SU 300.
4	Sets the interoperability mode to 4. Specify mode 4 to connect a T3 controller to a Verilink HDM 2182.
adtran	Connects a T3 interface to an Adtran DSU.
cisco	Connects an E3 or T3 interface to a Cisco DSU.
digital-link	Connects an E3 or T3 interface to a Digital Link DSU.
kentrox	Connects an E3 or T3 interface to a Kentrox DSU.
larscom	Connects a T3 interface to a Larscom DSU.
verilink-highbit	Connects a T3 interface to a Verilink High Bit DSU.
verilink-lowbit	Connects a T3 interface to a Verilink Low Bit DSU.

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for E3 and T3 controllers: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Scrambling Support in DSU Mode 1

DSU mode 1 refers to Kentrox mode. If DSU mode is used on a T3 serial interface and the bandwidth is greater than or equal to 35,000 bits per second (bps), the scrambling option is not supported. Likewise, if DSU mode 1 is used for an E3 serial interface and the bandwidth is greater than or equal to 24,510 bps, scrambling is not supported.

Match Local and Remote DSU Configurations

The local interface configuration must match the remote interface configuration. For example, if you define the DSU interoperability mode as 1 on the local port, you must also do the same on the remote port.

Know the DSU Type

You must know what type of DSU is connected to the remote port to determine if it interoperates with an E3 or T3 controller or a PA-E3 or PA-T3 port adapter. The **dsumode** command enables and improves interoperability with other DSUs.

Verify DSU Mode

To verify the DSU mode configured on the interface, use the **showcontrollersserial** or **showinterfacesserial** user EXEC commands.

Cisco 10000 Series Router

Only Cisco, Digital Link, and Kentrox DSUs are supported on E3 interfaces.

Examples

Setting DSU Mode

The following example sets the DSU mode to 1 on interface 1/0/0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# dsu mode 1
```

Serial Interface in DSI Mode 1

The following example shows the configuration for a serial interface configured in DSU mode 1. The bandwidth is set higher than that supported by the Kentrox firmware allows for scrambling. therefore, the scrambling option is not supported in this configuration.

```
Router(config
)#
 interface serial 1/0/0
Router(config-if)# mtu 4474
Router(config-if)# ip address 192.168.93.114 255.255.255.252
Router(config-if)# ip mtu 4470
Router(config-if)# dsu mode 1
Router(config-if)# dsu bandwidth 44210
```

Cisco 10000 Series Router

The following example sets the DSU mode to cisco:

```
Router(config)# interface serial 1/0/0
Router(config-if)# dsu mode cisco
```

Related Commands

Command	Description
show controllers	Displays information about the controllers.
show interfaces	Displays statistics for all interfaces configured on the router.

dte-invert-txc

To invert the transmit external clock (TXC) signal received from the DCE when the device is operating as a DTE, use the **dte-invert-txc** command in interface configuration mode. If the DCE accepts serial clock transmit external (SCTE) signal when the device is operating as a DTE, use the **no** form of this command.

dte-invert-txc
no dte-invert-txc

Syntax Description

This command has no arguments or keywords.

Command Default

The TXC signal is not inverted.

Command Modes

Interface configuration

Command History

Release	Modification
9.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command if the DCE cannot receive SCTE from the DTE, the data is running at high speeds, and the transmission line is long. The **dte-invert-txc** command prevents phase shifting of the data with respect to the clock.

On the Cisco 4000 series, you can specify the serial Network Processor Module timing signal configuration. When the board is operating as a DTE, the **dte-invert-txc** command inverts the TXC clock signal it gets from the DCE that the DTE uses to transmit data.

If the DCE accepts SCTE from the DTE, use **nodte-invert-txc**.

Examples

The following example inverts the TXC on serial interface 0:

```
Router(config)# interface serial 0
Router(config-if)# dte-invert-txc
```

duplex

To configure the duplex operation on an interface, use the **duplex** command in interface configuration mode. To return to the default configuration, use the **no** form of this command.

duplex {**full** | **half** | **auto**}
no duplex

Syntax Description

full	Specifies full-duplex operation.
half	Specifies half-duplex operation.
auto	Enables autonegotiation. The interface automatically operates at half-duplex or full-duplex mode depending on environmental factors, such as the type of media and the transmission speeds for the peer routers, hubs, and switches used in the network configuration.

Command Default

Half-duplex mode is enabled.

For the 4-port 10/100 Fast Ethernet Shared Port Adapter (SPA) and the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router, autonegotiation is enabled. The command is set to **auto**.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.2(10)P	This command was introduced.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(14)SX	This command was implemented on the Supervisor Engine 720.
12.2(17d)SXB	This command was integrated into Cisco IOS Release 12.2 SXB.
12.2(20)S2	This command was implemented on the 4-port 10/100 Fast Ethernet SPA and the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.
15.2(02)SA	This command was implemented on the Cisco ME 2600X Series Ethernet Access Switches.

Usage Guidelines

To use the autonegotiation capability (that is, to automatically detect speed and duplex modes), you must set both the **speed** command and the **duplex** command to **auto**.

Cisco Cloud Services Router 1000V Series

Cisco Cloud Services Router 1000V Series does not support the **duplex** command.

Duplex Options and Interfaces

The table below lists the supported command options by interface type.

Table 12: Supported Duplex Command Options

Interface Type	Supported Syntax	Default Setting	Usage Guidelines
10/100-Mbps module	**duplex** [**half** | **full**]	See the "Usage Guidelines" column.	Run the **no duplex auto** command to set the speed to **auto**. If the speed is set to **10** or **100**, without configuring the duplex setting, the duplex is set to **half**.
100-Mbps fiber modules	**duplex** [**half** | **full**]	**half**	
Gigabit Ethernet interfaces	**duplex full**	**full**	
10-Mbps ports	**duplex** [**half** | **full**]	**half**	

If the transmission speed on a 16-port RJ-45 Gigabit Ethernet port is set to 1000, the duplex mode is set to full. If the transmission speed is changed to 10 or 100, the duplex mode stays at half duplex. You must configure the correct duplex mode when the transmission speed is changed to 10 or 100 from 1000.

Gigabit Ethernet is full duplex only. You cannot change the mode on Gigabit Ethernet ports.

When manually configuring the interface speed to either 10 or 100-Mbps, you should also configure the duplex mode on the interface.

Caution Changing the interface speed and duplex mode configuration might shut down and reenable the interface during reconfiguration.

4-Port 10/100 Fast Ethernet SPA and 2-Port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 Router

The **duplex** command is applied to the SPA interfaces that use the RJ-45 media. Gigabit Ethernet interfaces using fiber media support full-duplex mode only and use the **negotiation** command to enable and disable autonegotiation.

To enable the autonegotiation capability on an RJ-45 interface, you must set either the **speed** command or the **duplex** command to **auto**. The default configuration is that both commands are set to **auto**.

Note For the Cisco AS5300, the **duplex** {**full** | **half** | **auto**} command syntax replaces the **duplex** commands—**half-duplex** and **full-duplex**. Cisco 7600 series routers can automatically negotiate the interface speed and the duplex mode only if one of the connected interfaces are configured to **auto**.

The table below describes the interface behavior for different combinations of the **duplex** and **speed** command settings. The specified **duplex** command configured with the specified **speed** command produces the resulting system action.

If you specify both **duplex** and **speed** settings other than **auto** on an RJ-45 interface, autonegotiation is disabled for the interface.

Note If you need to force an interface port to operate with certain settings and, therefore, need to disable autonegotiation, you must be sure that the remote link is configured with compatible link settings for proper transmission including the support of flow control on the link.

Note Every interface on a 4-port 10/100 Fast Ethernet SPA supports transmission of pause frames to stop packet flow when the Modular Services Card (MSC) is full. You cannot disable flow control for an interface on the 4-port 10/100 Fast Ethernet SPA. Hence, the flow control support is not configurable, but it is advertised during autonegotiation. If you disable autonegotiation, you must be sure that the remote device is configured to support flow control because flow control is automatically enabled for all interfaces on the 4-port 10/100 Fast Ethernet SPA.

Table 13: Relationship Between duplex and speed Commands

duplex Command	speed Command	Resulting System Action
duplex auto	**speed auto**	Autonegotiates both speed and duplex modes. The interface advertises the capability for the following link settings: • 10 Mbps and half duplex • 10 Mbps and full duplex • 100 Mbps and half duplex • 100 Mbps and full duplex • 1000 Mbps and half duplex • 1000 Mbps and full duplex
duplex auto	**speed 10** or **speed 100** or **speed 1000**	Autonegotiates the duplex mode. The interface advertises the capability for the configured speed with the capability for both half-duplex or full-duplex mode. For example, if the **speed 100** command is configured with **duplex auto**, then the interface advertises the following capability: • 100 Mbps and half duplex • 100 Mbps and full duplex

duplex Command	speed Command	Resulting System Action
duplex half or **duplex full**	**speed auto**	Autonegotiates the speed. The interface advertises the capability for duplex mode for Fast Ethernet interfaces at a speed of 10-Mbps and 100-Mbps, and Gigabit interfaces at 10-Mbps, 100-Mbps, and 1000-Mbps. For example, if the **duplex full** command is configured with the **speed auto** command, then the interface advertises the following capability: • 10 Mbps and full duplex • 100 Mbps and full duplex • 1000 Mbps and full duplex (Gigabit Ethernet interfaces only)
duplex half	**speed 10**	Forces 10-Mbps speed and the half-duplex operation, and disables autonegotiation on the interface.
duplex full	**speed 10**	Forces a speed of 10-Mbps and the full-duplex operation, and disables autonegotiation on the interface.
duplex half	**speed 100**	Forces a speed of 100-Mbps and the half-duplex operation, and disables autonegotiation on the interface.
duplex full	**speed 100**	Forces a speed of 100-Mbps and the full-duplex operation, and disables autonegotiation on the interface.
duplex half	**speed 1000**	Forces a speed of 1000-Mbps and the half-duplex operation, and disables autonegotiation on the interface (Gigabit Ethernet only).
duplex full	**speed 1000**	Forces a speed of 1000-Mbps and the full-duplex operation, and disables autonegotiation on the interface (Gigabit Ethernet only).

Examples

The following example shows how to configure a full-duplex operation on a Cisco AS5300 router:

```
Device(config)# interface fastethernet 0
Device(config-if)# duplex full
```

The following example shows how to specify the advertisement of only half-duplex support and either 10-Mbps or 100-Mbps capability during autonegotiation for the second interface (port 1) on the SPA located in the bottom subslot (1) of the MSC that is installed in slot 2 of the Cisco 7304 router:

```
Device# configure terminal
Device(config)# interface fastethernet 2/1/1
Device(config-if)# duplex half
Device(config-if)# speed auto
```

With this configuration, the interface advertises the following capabilities during autonegotiation:

- 10 Mbps and half duplex
- 100 Mbps and half duplex

Note Flow control support is always advertised when autonegotiation is enabled.

Related Commands

Command	Description
interface	Configures an interface and enters interface configuration mode.
interface fastethernet	Selects a particular Fast Ethernet interface for configuration.
interface gigabitethernet	Selects a particular Gigabit Ethernet interface for configuration.
show controllers	Displays information that is specific to the hardware on a module.
show controllers fastethernet	Displays Fast Ethernet interface information, transmission statistics, and errors, and the applicable MAC destination address and VLAN filtering tables.
show controllers gigabitethernet	Displays Gigabit Ethernet interface information, transmission statistics, and errors, and the applicable MAC destination address and VLAN filtering tables.
show interfaces	Displays traffic that is seen by a specific interface.
show interfaces fastethernet	Displays information about Fast Ethernet interfaces.
show interfaces gigabitethernet	Displays information about Gigabit Ethernet interfaces.
speed	Sets the port speed for a Fast Ethernet interface.

dxi interface-dfa

To specify a map command for a point to point serial interface, use the Data Exchange Interface (dxi) command **dxiinterface-dfa** in interface configuration mode. To deletct the map command, use the **no** form of this command.

dxi interface-dfa *vpi-number vci* [{**snap** | **mux**}]
no dxi interface-dfa *vpi-number vci*

Syntax Description

vpi-number	ATM network virtual path identifier (VPI) of the permanent virtual circuit (PVC), in the range from 0 to 15. The VPI is a 4-bit field in the header of the ATM DXI frame. The VPI value is unique only on a single interface, not throughout the ATM network, because it has local significance only. Both *vpi* and *vci* cannot be specified as 0; if one is 0, the other cannot be 0.
vci	ATM network virtual channel identifier (VCI) of this PVC, in the range from 0 to 63. The VCI is a 6-bit field in the header of the ATM DXI frame. The VCI value is unique only on a single interface, not throughout the ATM network, because it has local significance only. Both *vpi* and *vci* cannot be specified as 0; if one is 0, the other cannot be 0.
snap	(Optional) LLC/SNAP encapsulation based on the protocol used in the packet. This keyword defines a PVC that can carry multiple network protocols. This is the default.
mux	(Optional) Enables multiplex (mux) encapsulation.

Command Default

No map command is specified.

Command Modes

Interface configuration

Command Default

No map definition is established.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.4	This command was integrated into Cisco IOS Release 12.4.

Examples

The following example shows how to specify a map command.

```
Router(config)# interface serial 1
Router(config-if)# dxi interface-dfa 10
```

Related Commands

Command	Description
encapsulation atm-dxi	Enables ATM-DXI encapsulation.

Command	Description
dxi pvc	Configures multiprotocol or single protocol AMT-Data Exchange Interface (dxi) encapsulation.
dxi map	Maps a protocol address to a given virtual path identifier (VPI) and virtual channel identifier (VCI).
show dxi pvc	Displays the PVC statistics for a serial interface.
smds dxi	Enables Data Exchange Interface (dxi) version 2.2 support.

dxi pvc	Configures multiprotocol or single protocol AMT-Data Exchange Interface (dxi) encapsulation.

dxs3mode

To define the controller type as an E3 or T3 controller, use the dxs3mode command in controller configuration mode. To remove the controller, use the no form of this command.

dxs3mode [{**e3** | **t3**}]
no dxs3mode [{**e3** | **t3**}]

Syntax Description

e3	(Optional) Defines an E3 controller.
t3	(Optional) Defines a T3 controller.

Command Default

t3

Command Modes

Controller configuration

Command History

Release	Modification
12.2S	This command was introduced.

Examples

The following example defines a T3 controller:

```
Router(config
)
# controller dsx3 2/0/0
Router(config
-controller)
# dsx3mode t3
```

Related Commands

Command	Description
description	Adds a description to identify particulars about a controller.

e2-clockrate

To configure serial interface 0 for E2 (8 MHz full duplex) and to shut down the other three serial interfaces (1 to 3), use the **e2-clockrate** command in interface configuration mode. To disable the full duplex E2, use the **no** form of this command.

e2-clockrate
no e2-clockrate

Syntax Description

This command has no arguments or keywords.

Command Default

All interfaces are running.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was integrated into Cisco IOS Release 12.0(3)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **e2-clockrate** command is an interface configuration command and is seen only with **interfaceserial0**. When this command is used, serial interface 0 supports speeds up to E2 (8 MHz full duplex) and the other three serial interfaces (1 to 3) are put in the "shutdown" state. Also, running this command displays the following warning message:

```
Serial interface 0 is configured to support E2 rates and serial ports "1-3" are moved to
shutdown state
.
```

Examples

The following example shows sample display output for the **e2-clockrate** EXEC command.

```
Router(config-if)#
e2-clockrate
Interface Serial 0 is configured to support clockrates up to E2 (8Mbps)
Interfaces serial 1-3 will not be operational
```

Related Commands

Command	Description
clock rate	Configures the clock rate for the hardware connections on serial interfaces such as NIMs and interface processors to an acceptable bit rate.

early-token-release

To enable early token release on Token Ring interfaces, use the **early-token-release** command in interface configuration mode. To disable this function, use the **no** form of this command.

early-token-release
no early-token-release

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Early token release is a method whereby the Token Ring interfaces can release the token back onto the ring immediately after transmitting, rather than waiting for the frame to return. This feature helps increase the total bandwidth of the Token Ring.

The Token Ring Interface Processor (TRIP) on the Cisco 7500 series routers and the Token Ring adapters on the Cisco 7200 series routers all support early token release.

Examples

The following example enables the use of early token release on Token Ring interface 1:

```
Router(config)# interface tokenring 1
Router(config-if)# early-token-release
```

The following example enables the use of early token release on the Token Ring interface processor in slot 4 on port 1 on the Cisco 7500 series routers:

```
Router(config)# interface tokenring 4/1
Router(config-if)# early-token-release
```

efm-grp

The efm-grp command is used to perform the necessary link operations (add, delete, and shutdown) of a single link after the creation of efm-bonding group. To perform the link operations in the efm-grp command, enter the config-controller-dsl-group mode. Use the no form of the command to shut down the related command.

efm-grp [{**add** | **delete** | **shutdown**}] **link** *link number*
no efm-grp [{**add** | **delete** | **shutdown**}] *link link number*

Syntax Description

link number	Designates the pairs link number.
add	Adds a link to the efm-bonding group.
delete	Deletes a link from the efm-bonding group
shutdown	Shuts down a link in the efm-bonding group.

Command Default

No default behavior or values.

Command Modes

Config-controller-dsl-group (config-controller-dsl-group)

Command History

Release	Modification
15.1(1)T	This command was introduced.

Usage Guidelines

This command is used to add, delete, or shutdown a link in the efm-bond.

Examples

The following example shows how **efm-grp** command is used.

```
Router(config-controller-dsl-group)# efm-grp ?
add       Add a link to the EFM Bonding group
delete    Delete a link from the EFM Bonding group
shutdown  Shutdown a link in the EFM Bonding group
Router(config-controller-dsl-group)# efm-grp add ?
link  EFM Bonding group link configuration

Router(config-controller-dsl-group)# efm-grp add link ?
<0-3>  Link pair number
```

Related Commands

Command	Description
controller shdsl	Configures a controller for SHDSL mode and enters config-controller mode.
shdsl annex	Defines the SHDSL G.991.2 standard.
shdsl rate	Defines the SHDSL rate.
show controller shdsl	Displays the status of the controller that is configured for SHDSL mode.

eigrp interface

Note Effective with Cisco IOS Release 15.0(1)M, the **eigrp interface**command is replaced by the **dampening-change** command and the **dampening-interval** command. See the **dampening-change** and **dampening-interval**commands for more information.

To set a threshold value to minimize hysteresis in a router-to-radio configuration, use the **eigrp interface** command in interface configuration mode. To reset the hysteresis threshold to the default value, use the **no** form of this command.

eigrp *vmi-interface-number* **interface** [**dampening-change** *value*] [**dampening-interval** *value*]
no eigrp *vmi-interface-number* **interface** [**dampening-change** *value*] [**dampening-interval** *value*]

Syntax Description

vmi-interface-number	The number assigned to the VMI interface.
dampening-change *value*	(Optional) Value used to minimize the effect of frequent routing changes in router-to-radio configurations. Percent interface metric must change to cause update. Value range is 1 to 100.
dampening-interval *value*	(Optional) Specifies the time interval in seconds to check the interface metrics at which advertising of routing changes occurs. The default value is 30 seconds. Value range is 1 to 65535.

Command Default

Default for change-based dampening is 50 percent of the computed metric.

Default for interval-based dampening is 30 seconds.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.4(15)XF	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.
15.0(1)M	This command was replaced. This command was replaced by the **dampening-change**command and the **dampening-interval** command.

Usage Guidelines

This command advertises routing changes for EIGRP traffic only.

The REPLY sent to any QUERY will always contain the latest metric information. Exceptions which will result in immediate UPDATE being sent:

- A down interface
- A down route
- Any change in metric which results in the router selecting a new next hop

Change-based Dampening

The default value for the change tolerance will be 50% of the computed metric. It can be configured in the range from 0 to 100 percent. If the metric change of the interface is not greater (or less) than the current metric plus or minus the specified amount, the change will not result in a routing change, and no update will be sent to other adjacencies.

Interval-based Dampening

The default value for the update intervals is 30 seconds. It can be configured in the range from 0 to 64535 seconds. If this option is specified, changes in routes learned though this interface, or in the interface metrics, will not be advertised to adjacencies until the specified interval is met. When the timer expires, any changes detected in any routes learned through the interface, or the metric reported by the interfaces will be sent out.

Examples

Change-based Dampening Example

The following example sets the threshold to 50 percent tolerance routing updates involving VMI interfaces and peers:

```
interface vmi1
 ip address 10.2.2.1 255.255.255.0
 ipv6 address 2001:0DB1:2::1/96
 ipv6 enable
 eigrp 1 interface dampening-change 50
 physical-interface Ethernet0/0
```

Interval-based Dampening Example

The following example sets the interval to 30 seconds at which updates occur for topology changes that affect VMI interfaces and peers:

```
interface vmi1
 ip address 10.2.2.1 255.255.255.0
 ipv6 address 2001:0DB1:2::1/96
 ipv6 enable
 eigrp 1 interface dampening-interval 30
 physical-interface Ethernet0/0
```

Related Commands

Command	Description
debug vmi	Displays debugging output for virtual multipoint interfaces (VMIs)
interface vmi	Creates a virtual multipoint interface (VMI) that can be configured and applied dynamically.

emulation-mode

To configure Configuration Circuit Emulation (CEM), use the emulation-mode command in unidirectional mode.

emulation-mode {**bidirectional** | **unidirectional** {**rx** | **tx**}}
no emulation-mode

Syntax Description

rx	When the CEM is in rx-only mode, there is no data transmitted by that CEM. The CEM status shows "active (rx-only)".
tx	The CEM in tx-only mode does not receive any data. There is no data sent to the IP side and the received data is silently dropped at the CEM. The CEM status shows "active (tx-only)".

Command Default

Default mode is unidirectional mode.

Command Modes

Configuration CEM mode (emulation-mode).

Command History

Release	Modification
12.4(20)YA	This command was introduced.

Usage Guidelines

You can use the emulation-mode command to configure the CEM in unidirectional mode. Once configured, traffic will flow only in that direction through the CEM channel. The CEM status will show as "active (rx-only)" or "active (tx-only)" depending on the configuration. To disable the command's effect, use the **no** form of this command.

Examples

The following example shows how the command configures the traffic in unidirectional mode:

```
Router(config-cem
)# emulation-mode unidirectional tx
```

The following example shows how the command configures the traffic in bidirectional mode:

```
Router(config-cem
)# emulation-mode bidirectional
```

encapsulation

To set the encapsulation method used by the interface, use the **encapsulation** command in interface configuration mode. To remove the encapsulation, use the **no** form of this command.

encapsulation *encapsulation-type*
no encapsulation *encapsulation-type*

Syntax Description

encapsulation-type	Encapsulation type; one of the following keywords: • **atm-dxi** -- ATM Mode-Data Exchange Interface. • **bstun** --Block Serial Tunnel. • **dot1q** *vlan-id* [**native**]--Enables IEEE 802.1q encapsulation of traffic on a specified subinterface in VLANs. The *vlan-id* argument is a virtual LAN identifier. The valid range is from 1 to 1000. The optional **native** keyword sets the PVID value of the port to the *vlan-id* value. • **frame-relay** --Frame Relay (for serial interface). • **hdlc** -- High-Level Data Link Control (HDLC) protocol for serial interface. This encapsulation method provides the synchronous framing and error detection functions of HDLC without windowing or retransmission. This is the default for synchronous serial interfaces. • **isl** *vlan-id* --Inter-Switch Link (ISL) (for VLANs). • **lapb** --X.25 Link Access Procedure, Balanced. Data link layer protocol (LAPB) DTE operation (for serial interface). • **ppp** -- PPP (for serial interface). • **sde** *said* --IEEE 802.10. The *said* argument is a security association identifier. This value is used as the VLAN identifier. The valid range is from 0 to 0xFFFFFFFE. • **sdlc** --IBM serial Systems Network Architecture (SNA). • **sdlc-primary** --IBM serial SNA (for primary serial interface) . • **sdlc-secondary** --IBM serial SNA (for secondary serial interface). • **slip** --Specifies Serial Line Internet Protocol (SLIP) encapsulation for an interface configured for dedicated asynchronous mode or dial-on-demand routing (DDR). This is the default for asynchronous interfaces. • **smds** --Switched Multimegabit Data Services (SMDS) (for serial interface). • **ss7** --Sets the encapsulation type to SS7 and overrides the serial interface objects high-level data link control (HDLC) default.

Command Default

The default depends on the type of interface. For example, synchronous serial interfaces default to HDLC and asynchronous interfaces default to SLIP.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
10.3	The **sde** keyword was added to support IEEE 802.10
11.1	The **isl** keyword was added to support the Interswitch Link (ISL) Cisco protocol for interconnecting multiple switches and routers, and for defining virtual LAN (VLAN) topologies.
11.3(4)T	The **tr-isltrbrf-vla**n keyword was added to support TRISL, a Cisco proprietary protocol for interconnecting multiple routers and switches and maintaining VLAN information as traffic goes between switches.
12.0(1)T	The **dot1q** keyword was added to support IEEE 8021q standard for encapsulation of traffic on a specified subinterface in VLANs.
12.1(3)T	The **native** keyword was added.
12.2(11)T	This command was modified to include the **ss7** keyword in support of integrated signaling link terminal capabilities.
12.2(13)T	Support for IPv6 was added.
12.3(2)T	The **tr-isltrbrf-vla**n keyword was removed because support for the TRISL protocol is no longer available in Cisco IOS software.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
Cisco IOS XE Release 2.5	This command was updated. It was integrated into Cisco IOS XE Release 2.5.

Usage Guidelines

SLIP and PPP

To use SLIP or PPP, the router or access server must be configured with an IP routing protocol or with the **iphost-routing** command. This configuration is done automatically if you are using old-style **slipaddress** commands. However, you must configure it manually if you configure SLIP or PPP via the **interfaceasync** command.

On lines configured for interactive use, encapsulation is selected by the user when they establish a connection with the **slip** or **ppp** EXEC command.

IP Control Protocol (IPCP) is the part of PPP that brings up and configures IP links. After devices at both ends of a connection communicate and bring up PPP, they bring up the control protocol for each network protocol that they intend to run over the PPP link such as IP or IPX. If you have problems passing IP packets and the **showinterface** command shows that line is up, usethe**negotiations** command to see if and where the negotiations are failing. You might have different versions of software running, or different versions of PPP, in which case you might need to upgrade your software or turn off PPP option negotiations. All IPCP options as listed in RFC 1332, *PPP Internet Protocol Control Protocol (IPCP)* , are supported on asynchronous lines. Only Option 2, TCP/IP header compression, is supported on synchronous interfaces.

PPP echo requests are used as keepalive packets to detect line failure. The **nokeepalive** command can be used to disable echo requests. For more information about the **nokeepalive** command, refer to the chapter “IP Services Commands” in the *CiscoIOSIPCommandReference,Volume1of4:AddressingandServices*and to thechapter“Configuring IP Services” in the *CiscoIOSIPConfigurationGuide*.

To use SLIP or PPP, the Cisco IOS software must be configured with an IP routing protocol or with the **iphost-routing** command. This configuration is done automatically if you are using old-style **slipaddress** commands. However, you must configure it manually if you configure SLIP or PPP via the **interfaceasync** command.

Note Disable software flow control on SLIP and PPP lines before using the **encapsulation** command.

SS7

The SS7 encapsulation command is new with the Integrated SLT feature and is available only for interface serial objects created by the channel-group command. For network access server (NAS) platforms, the encapsulation for channel group serial interface objects defaults to HDLC. You must explicitly set the encapsulation type to SS7 to override this default.

When encapsulation is set to SS7, the encapsulation command for that object is no longer available. A serial SS7 link is deleted only when its associated dial feature card (DFC) card is removed. As with existing Cisco 26xx-based SLTs, you do not need to specify whether the SS7 link is to be used as an A-link or an F-link.

By itself this command does not select the correct encapsulation type. Therefore, once created, you must set the encapsulation type to the new SS7 value, as well as assign a session channel ID to the link at the serial interface command level. The configuration on a digital SS7 link can be saved (no shutdown) only when its encapsulation is successfully set to SS7 and it has been assigned a channel identifier.

VLANs

Do not configure encapsulation on the native VLAN of an IEEE 802.1q trunk without the **native** keyword. (Always use the **native** keyword when the *vlan-id* is the ID of the IEEE 802.1q native VLAN.)

For detailed information on use of this command with VLANs, refer to the *Cisco IOS Switching Services Configuration Guide* and the *Cisco IOS Switching Services Command Reference* .

Examples

The following example shows how to reset HDLC serial encapsulation on serial interface 1:

```
Router(config)# interface serial 1
Router(config-if)# encapsulation hdlc
```

The following example shows how to enable PPP encapsulation on serial interface 0:

```
Router(config)# interface serial 0
Router(config-if)# encapsulation ppp
```

The following example shows how to configure async interface 1 for PPP encapsulation:

```
Router(config)# interface async 1
Router(config-if)# encapsulation ppp
```

To learn more about the virtual serial interface and check SS7 encapsulation, enter the show interfaces serial *slot/trunk:channel-group* command in privileged EXEC mode, as in the following example:

```
Router# show interfaces serial 7/3:1
Serial7/3:1 is up, line protocol is down
 Hardware is PowerQUICC Serial
 MTU 1500 bytes, BW 1544 Kbit, DLY 20000 usec,
  reliability 255/255, txload 4/255, rxload 1/255
 Encapsulation SS7 MTP2, loopback not set
 Keepalive set (10 sec)
 Last input never, output 00:00:00, output hang never
 Last clearing of "show interface" counters 03:53:40
 Queueing strategy: fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 26000 bits/sec, 836 packets/sec
  0 packets input, 0 bytes, 0 no buffer
  Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
  0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
  11580159 packets output, 46320636 bytes, 0 underruns
  0 output errors, 0 collisions, 1 interface resets
  0 output buffer failures, 0 output buffers swapped out
  2 carrier transitions
  DCD=up DSR=down DTR=down RTS=down CTS=down
```

Related Commands

Command	Description
channel-group	Assigns a channel group and selects the DSO time slots desired for SS7 links.
encapsulation x25	Specifies operation of a serial interface as an X.25 device.
keepalive	Sets the keepalive timer for a specific interface.
ppp	Starts an asynchronous connection using PPP.
ppp authentication	Enables CHAP or PAP or both and specifies the order in which CHAP and PAP authentication are selected on the interface.
ppp bap call	Sets PPP BACP call parameters.
slip	Starts a serial connection to a remote host using SLIP.

end (satellite initial configuration)

To exit satellite initial configuration mode, save any new or changed parameters, and reset the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **end** command in satellite initial configuration mode.

end

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **end** command is identical to the **exit** command in satellite initial configuration mode.

When you enter the **exit** or **end** command to exit satellite initial configuration mode, the system automatically saves any changed parameters to the NM-1VSAT-GILAT network module nonvolatile memory and resets the NM-1VSAT-GILAT network module.

Examples

The following example shows what appears when you enter the **end** or **exit**command after changing one or more initial configuration parameters:

```
Router(sat-init-config)# end

Applying changed parameters to the satellite module.
Parameter update succeeded.  Module is now resetting.
Router#
```

The following example shows what appears when you enter the **end** or **exit** command when no parameters have been changed:

```
Router(sat-init-config)# end

Router#
```

Related Commands

Command	Description
apply	Saves new or changed satellite initial configuration parameters and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
exit (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

equipment loopback

To run loopbacks in conjunction with remote equipment, use the **equipmentloopback**command in controller configuration mode. To terminate the loopback, use the no form of this command.

equipment [{**customer** | **network**}] **loopback**
no **equipment** [{**customer** | **network**}] **loopback**

Syntax Description

customer	(Optional) Enables the line card to respond to remote T3 loopback commands from the remote T3 equipment.
network	(Optional) Causes the line card to ignore remote T3 loopback commands.

Command Default

No default behavior or values.

Command Modes

Controller configuration

Command History

Release	Modification
12.2S	This command was introduced

Examples

The following example configures an equipment network loopback:

```
Router(config
)
# controller t3 1/0/0
Router(config
-controller)
# equipment network loopback
```

Related Commands

Command	Description
loopback	Enables controller loopbacks.

errdisable detect cause

To enable error-disable detection, use the **errdisable detect cause** command in global configuration mode. To disable error-disable detection, use the **no** form of this command.

errdisable detect cause {**all** | **bpduguard** | **dtp-flap** | **l2ptguard** | **link-flap** | **packet-buffer-error** | **pagp-flap** | **rootguard** | **udld**}
no errdisable detect cause {**all** | **bpduguard** | **dtp-flap** | **l2ptguard** | **link-flap** | **pagp-flap** | **rootguard** | **udld**}

Syntax Description

all	Specifies error-disable detection for all error-disable causes.
bpduguard	Specifies detection for the Bridge Protocol Data Unit (BPDU)-guard error-disable cause.
dtp-flap	Specifies detection for the Dynamic Trunking Protocol (DTP)-flap error-disable cause.
l2ptguard	Specifies detection for the Layer 2 Protocol Tunneling guard error-disable cause.
link-flap	Specifies detection for the link flap error-disable cause.
packet-buffer-error	Causes the packet buffer error to error-disable the affected port.
pagp-flap	Specifies detection for the Port Aggregation Protocol (PAgP)-flap error-disable cause.
rootguard	Specifies detection for the root-guard error-disable cause.
udld	Specifies detection for the Unidirectional Link Detection (UDLD) error-disable cause.

Command Default

Error-disable detection is enabled for all causes.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(14)SX	This command was modified. Support was added for the Supervisor Engine 720.
12.2(17b)SXA	This command was modified. The **packet-buffer-error** keyword was added.
12.2(17d)SXB	This command was modified. Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

> **Note** Entering the **no errdisable detect cause packet-buffer-error** command allows you to detect the fault that triggers a power cycle of the affected module.

A cause (bpduguard, dtp-flap, link-flap, pagp-flap, root-guard, udld) is defined as the reason why the error-disable state occurred. When a cause is detected on an interface, the interface is placed in an error-disable state (an operational state that is similiar to the link-down state).

You must enter the **shutdown** and then the **no shutdown** commands to recover an interface manually from the error-disable state.

Examples

The following example shows how to enable error-disable detection for the Layer 2 protocol-tunnel guard error-disable cause:

```
Router(config)#
errdisable detect cause l2ptguard
```

Related Commands

Command	Description
show errdisable detect	Displays the error-disable detection status.
show interfaces status	Displays the interface status or a list of interfaces in an error-disable state on LAN ports only.
shutdown	Disables an interface.

errdisable recovery

To configure recovery mechanism variables, use the **errdisable recovery** command in global configuration mode. To return to the default state, use the **no** form of this command.

errdisable recovery {**cause** {**all** | **arp-inspection** | **bpduguard** | **channel-misconfig** | **dhcp-rate-limit** | **dtp-flap** | **gbic-invalid** | **l2ptguard** | **link-flap** | **pagp-flap** | **psecure-violation** | **security-violation** | **rootguard** | **udld** | **unicast-flood**} | **interval** *seconds*}
no errdisable recovery {**cause** {**all** | **arp-inspection** | **bpduguard** | **channel-misconfig** | **dhcp-rate-limit** | **dtp-flap** | **gbic-invalid** | **l2ptguard** | **link-flap** | **pagp-flap** | **psecure-violation** | **security-violation** | **rootguard** | **udld** | **unicast-flood**} | **interval** *seconds*}

Syntax Description

cause	Enables error-disable recovery from a specific cause.
all	Enables the recovery timers for all error-disable causes.
arp-inspection	Enables error-disable recovery from an Address Resolution Protocol (ARP) inspection cause.
bpduguard	Enables the recovery timer for the Bridge Protocol Data Unit (BPDU)-guard error-disable cause.
channel-misconfig	Enables the recovery timer for the channel-misconfig error-disable cause.
dhcp-rate-limit	Enables the recovery timer for the Dynamic Host Configuration Protocol (DHCP)-rate-limit error-disable cause.
dtp-flap	Enables the recovery timer for the Dynamic Trunking Protocol (DTP)-flap error-disable cause.
gbic-invalid	Enables the recovery timer for the Gigabit Interface Converter (GBIC)-invalid error-disable cause.
l2ptguard	Enables the recovery timer for the Layer 2 Protocol Tunneling (L2PT) error-disable cause.
link-flap	Enables the recovery timer for the link-flap error-disable cause.
pagp-flap	Enables the recovery timer for the Port Aggregation Protocol (PAgP)-flap error-disable cause.
psecure-violation	Enables the recovery timer for the psecure-violation error-disable cause.
security-violation	Enables the automatic recovery of ports that were disabled because of 802.1X security violations.
rootguard	Enables the recovery timer for the root-guard error-disable cause.
udld	Enables the recovery timer for the Unidirectional Link Detection (UDLD) error-disable cause.
unicast-flood	Enables the recovery timer for the unicast-flood error-disable cause.

interval *seconds*	Specifies the time, in seconds, to recover from a specified error-disable cause. The range is from 30 to 86400. The default interval is 300.

Command Default

The recovery mechanisms are disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(14)SX	This command was modified. This command was implemented on the Supervisor Engine 720.
12.2(17d)SXB	This command was modified. This command was implemented on the Supervisor Engine 2.
12.2(18)SXD	This command was modified. The **arp-inspection** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

A cause (bpduguard, channel-misconfig, dhcp-rate-limit, dtp-flap, l2ptguard, link-flap, pagp-flap, psecure-violation, security-violation, rootguard, udld, or unicast-flood) is defined as the reason why the error-disable state occurred. When a cause is detected on an interface, the interface is placed in an error-disable state (an operational state that is similar to the link-down state). If you do not enable error-disable recovery for the cause, the interface stays in the error-disable state until a shutdown and no shutdown occur. If you enable recovery for a cause, the interface is brought out of the error-disable state and allowed to retry operation once all the causes have timed out.

You must enter the **shutdown** command and then the **no shutdown** command to manually recover an interface from the error-disable state.

Note A separate line is required each time you want to enter the **errdisable recovery cause** command to add a new reason for recovery; each new reason does not get appended to the original single line. This means you must enter each new reason separately.

Examples

This example shows how to enable the recovery timer for the BPDU-guard error-disable cause:

```
Router(config)#
 errdisable recovery cause bpduguard
```

This example shows how to set the recovery timer to 300 seconds:

```
Router(config)#
 errdisable recovery interval 300
```

Related Commands

Command	Description
show errdisable recovery	Displays the information about the error-disable recovery timer.
show interfaces status	Displays the interface status or a list of interfaces in an error-disabled state on LAN ports only.
shutdown	Disables an interface.

error throttling

To stop receiving error data packets on multiple channel groups configured on all interfaces on the T1 controller of a channelized T3 port adapter or on the E1 controller of a channelized E3 port adapter, use the **errorthrottling** command in controller configuration mode. To continue receiving error data packets on all channels on the T1 or E1 controller, use the no form of this command.

error throttling
no error throttling

Syntax Description

This command has no arguments or keywords.

Command Default

The **errorthrottling** command is enabled by default on a T3 or a E3 port adapter.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(19c)	This command was introduced.
15.0(1)M3	This command was modified. This command can be enabled on E1 controllers.
12.2(33)SRD5	This command was integrated into Cisco IOS Release 12.2(33)SRD5.

Usage Guidelines

Use the **showcontrollerst3** command or **showcontrollerse3** command to display whether the current router configuration has error throttling enabled or disabled.

The **errorthrottling** command disables the T1 or E1 level clock in order to stop receiving error data packets on a T1 or E1 controller.

When a T1 or a E1 has multiple channel groups configured over it, error throttling affects all the channels on a T1 or a E1. If any single interface receives a burst of errors, over a short duration, such as 400 errors in 100 milliseconds (ms), the T1 or E1 clock is turned off for a period of 100 ms. When there is a high rate of errors, the error rate is likely to continue for a long duration of time. Using error throttling to stop receiving the error data packets reduces wasteful processing and discarding of error packets.

The **noerrorthrottling** command allows all the error data packets to be processed, dropped, and accounted for on a T1 or a E1 controller. When the error rate is high, the CPU can become overloaded.

When the **noerrorthrottling** command is used to configure a T3 or a E3 port, the configuration applies to all of the 28 associated T1 or E1 channels.

Examples

The following example enables error throttling by disabling the T1 clock in order to stop receiving error data packets on a T1 controller:

```
Router(config-controller)# error throttling
```

The following example uses the **showcontrollerst3** command to display partial output showing that error throttling is enabled on the T1 controller:

```
Router# show controllers t3 2/1/0
```

```
T3 2/1/0 is down.  Hardware is 2CT3 single wide port adapter
  CT3 H/W Version: 0.2.2, CT3 ROM Version: 1.0, CT3 F/W Version: 2.5.1
  FREEDM version: 1, reset 0 resurrect 0
  Applique type is Channelized T3
  Transmitter is sending remote alarm.
  Receiver has loss of signal.
  FEAC code received: No code is being received
  Framing is M23, Line Code is B3ZS, Clock Source is Internal
  Rx-error throttling on T1's ENABLED
  .
```

The following example uses the **showcontrollerse3** command to display partial output showing that error throttling is enabled on the E1 controller:

```
Router# show controller e3 5/0
*Mar 14 21:19:06.795: %SYS-5-CONFIG_I: Configured from console by console
E3 5/0 is up.
  CE3 H/W Version : 3.1.0, CE3 ROM Version : 1.1, CE3 F/W Version : 1.2.1
  Applique type is Channelized E3
  Total available channels 128, used 4
  No alarms detected. Line Code is HDB3, Clock Source is Line.
  Rx-error throttling on E1's ENABLED
  Data in current interval (564 seconds elapsed):
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation
     0 P-bit Err Secs, 0 P-bit Severely Err Secs
     0 Severely Err Framing Secs, 0 Unavailable Secs
     0 Line Errored Secs, 0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
E3 5/0 E1 1
  No alarms detected.
  Framing is crc4, Clock Source is line, National bits are 0x1F.
  Data in current interval (565 seconds elapsed):
     0 Line Code Violations, 0 Path Code Violations
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs
     0 Unavail Secs
E3 5/0 E1 2
  No alarms detected.
  Framing is crc4, Clock Source is line, National bits are 0x1F.
```

Related Commands

Command	Description
show controllers e3	Displays information about E3 links, and displays hardware and software driver information for the E3 controller.
show controllers t3	Displays information about T3 links, and displays hardware and software driver information for the T3 controller.

esmc mode ql-disabled

To disable the Ethernet synchronization message channel (ESMC) on an interface, use the **esmc mode ql-disabled**command in interface configuration mode. To remove the quality level (QL) disabled mode and get back to the default ql-enabled mode, use the **no** form of this command.

esmc mode ql-disabled
no esmc mode ql-disabled

Syntax Description

This command has no arguments or keywords.

Command Default

The ESMC mode is ql-enabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2) SNI	This command was introduced in Cisco ASR 901 Aggregation Services Router.
Cisco IOS XE Release 3.8S	This command was integrated into Cisco IOS XE Release 3.8S.

Usage Guidelines

You can use the **esmc modeql-disabled** command only if a synchronous Ethernet (SyncE) capable interface is installed on the device. When this command is used no QL ESMC packets are sent during network clock synchronization.

Examples

The following example shows how to enable ESMC process:

```
Device(config-if)# esmc mode ql-disabled
```

Related Commands

Command	Description
esmc process	Enables the ESMC process in a device.
show esmc	Displays the enabled ESMCs in a device.
show interfaces accounting	Displays the number of packets of each protocol type that have been sent through all configured interfaces.

esmc process

To enable the Ethernet synchronization message channel (ESMC) process in a router, use the **esmc process**command in global configuration mode. To disable the process, use the **no** form of this command.

esmc process
no esmc process

Syntax Description

This command has no arguments or keywords.

Command Default

The ESMC process is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2) SNI	This command was introduced in Cisco ASR 901 Aggregation Services Router.
Cisco IOS XE Release 3.8S	This command was integrated into Cisco IOS XE Release 3.8S.

Usage Guidelines

You can use the **esmc process** command only if a synchronous Ethernet (SyncE) capable interface is installed on the device. ESMC is the communication channel for conveying clock information in SyncE. You can use the ESMC process in a SyncE to synchronize the clock frequency over an Ethernet port.

Examples

The following example shows how to enable ESMC process:

```
Device(config)# esmc process
```

Related Commands

Command	Description
esmc mode ql-disabled	Disables the ESMC on an interface.
show esmc	Displays the enabled ESMCs in a device.
show interfaces accounting	Displays the number of packets of each protocol type that have been sent through all configured interfaces.

exit (satellite initial configuration)

To exit satellite initial configuration mode, save any new or changed parameters, and reset the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **exit** command in satellite initial configuration mode.

exit

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **exit**command is identical to the **end** command in satellite initial configuration mode.

When you enter the **exit** or **end** command to exit satellite initial configuration mode, the system automatically saves any changed parameters to the NM-1VSAT-GILAT network module nonvolatile memory and resets the NM-1VSAT-GILAT network module.

Examples

The following example shows what appears when you enter the **exit** or **end**command after changing one or more initial configuration parameters:

```
Router(sat-init-config)# exit

Applying changed parameters to the satellite module.
Parameter update succeeded.  Module is now resetting.
Router#
```

The following example shows what appears when you enter the **exit** or **end**command when no parameters have been changed:

```
Router(sat-init-config)# exit

Router#
```

Related Commands

Command	Description
apply	Saves new or changed satellite initial configuration parameters and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
end (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

F through H

fabric buffer-reserve

To reserve ASIC buffers, use the **fabricbuffer-reserve** command. in global configuration mode. To return to the default settings, use the **no** form of this command.

fabric buffer-reserve [{**high** | **low** | **medium***value*}]
[**default**] **fabric buffer-reserve queue**
no fabric buffer-reserve

Syntax Description

high	(Optional) Reserves the high (0x5050) ASIC buffer spaces.
low	(Optional) Reserves the low (0x3030) ASIC buffer spaces.
medium	(Optional) Reserves the medium (0x4040) ASIC buffer spaces.
value	(Optional) 16-bit value; valid values are from 0x0 to 0x5050.
default	(Optional) Specifies the default queue setting.
queue	Specifies the queue setting for the buffer reserve.

Command Default

The default settings are as follows:

- Buffer reserve is set to 0x0.
- Two queues.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(18)SXF	This command was changed to add the **queue** keyword.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Note Use this command only under the direction of Cisco TAC.

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

The **fabricbuffer-reservequeue**command is supported on Cisco 7600 series routers that are configured with the following modules:

- WS-X6748-GE-TX
- WS-X6724-SFP

- WS-X6748-SFP
- WS-X6704-10GE

Entering the **defaultfabricbuffer-reservequeue** command is the same as entering the **fabricbuffer-reservequeue** command.

You can enter the **fabricbuffer-reserve** command to improve the system throughput by reserving ASIC buffers.

This command is supported on the following modules:

- WS-X6704-10GE
- WS-X6748-SFP
- WS-X6748-GE-TX
- WS-X6724-SFP

Examples

This example shows how to reserve the high (0x5050) ASIC buffer spaces:

```
Router(config)# fabric buffer-reserve high
Router(config)#
```

This example shows how to reserve the low (0x3030) ASIC buffer spaces:

```
Router(config)# fabric buffer-reserve low
Router(config)#
```

fabric clear-block

To enable the clear-block congestion control for the fabric channels, use the **fabricclear-block** command in global configuration mode. To disable the clear-block congestion control for the fabric channels, use the **no** form of this command.

fabric clear-block
no fabric clear-block

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(17d)SXB1	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Note Do not enter the **fabricclear-block**command unless TAC advises you to do so.

This command is supported only with Supervisor Engine 720 hardware revision 4.0 and later releases.

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

Examples

This example shows how to enable the clear-block congestion control for the fabric channels:

```
Router(config)# fabric clear-block
Router(config)#
```

This example shows how to disable the clear-block congestion control for the fabric channels:

```
Router(config)# no fabric clear-block
Router(config)#
```

fabric error-recovery fabric-switchover (virtual switch)

To enable a supervisor engine switchover when excessive fabric synchronization errors are detected on the fabric-enabled module, use the **fabricerror-recoveryfabric-switchover** command in global configuration mode. To disable the supervisor engine switchover for excessive fabric synchronization errors, use the **no** form of this command.

fabric switch *num* **error-recovery fabric-switchover**
no fabric switch *num* **error-recovery fabric-switchover**

Syntax Description

switch *num*	Specifies the switch number; valid values are 1 and 2.

Command Default

Excessive fabric synchronization errors initiate a supervisor engine switchover, and the configuration is not saved to the configuration file.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXH1	Support for this command was introduced.

Usage Guidelines

When a fabric-capable switching module has fabric errors, a supervisor engine switchover is initiated.

You can use the **nofabricerror-recoveryfabric-switchover** command to avoid the supervisor engine switchover. This command does not perform the supervisor engine switchover but powers down the module that is experiencing the excessive fabric errors. This command is saved to the configuration file.

Examples

The following example shows how to enable a supervisor engine switchover when excessive fabric synchronization errors are detected on the fabric-enabled module:

```
Router(config)# fabric switch 2 error-recovery fabric-switchover
Router(config)#
```

The following example shows how to disable a supervisor engine switchover when excessive fabric synchronization errors are detected on the fabric-enabled module:

```
Router(config)# no fabric switch 2 error-recovery fabric-switchover
Router(config)#
```

Related Commands

Command	Description
show fabric	Displays the information about the crossbar fabric .

fabric lcd-banner

To specify the message-of-the-day (MOTD) banner for display on the Switch Fabric Module, use the **fabriclcd-banner** command in global configuration mode. To delete the MOTD banner, use the **no** form of this command.

fabric lcd-banner *d message d*
no fabric lcd-banner

Syntax Description

d	Delimiting character; see the "Usage Guidelines" section for additional guidelines.
message	Message text; see the "Usage Guidelines" section for additional guidelines.

Command Default

No MOTD banner is specified.

Command Modes

Global configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2 only.

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32

You cannot use the delimiting character in the banner message. The delimiter is a character of your choice--a pound sign (#), for example.

You can replace tokens with the corresponding configuration argument.

Follow this command with one or more blank spaces and a delimiting character of your choice. Then enter one or more lines of text, terminating the message with the second occurrence of the delimiting character.

This MOTD banner is useful for displaying messages that affect all users (such as impending system shutdowns).

When you connect to the router, the MOTD banner appears before the login prompt. After you successfully log in to the router, the EXEC banner or incoming banner is displayed, depending on the type of connection. For a reverse Telnet login, the incoming banner is displayed. For all other connections, the router displays the EXEC banner.

To customize the banner, use tokens in the form $(token) in the message text. Tokens display current Cisco IOS configuration arguments, such as the router's hostname and IP address.

The table below describes the command tokens.

Table 14: Command Tokens

Token	Information Displayed in the Banner
$(hostname)	Displays the router's hostname.

$(domain)	Displays the router's domain name.
$(line)	Displays the VTY or TTY (async) line number.
$(line-desc)	Displays the description that is attached to the line.

Examples

This example shows how to set a MOTD banner for display on the Switch Fabric Module LCD display; the pound sign (#) is used as a delimiting character:

```
Router(config)# fabric lcd-banner#
Building power will be off from 7:00 AM until 9:00 AM this coming Tuesday.
#
```

This example shows how to set a MOTD banner; the percent sign (%) is used as a delimiting character:

```
Router(config)# fabric lcd-banner%
Enter TEXT message.  End with the character '%'.
You have entered $(hostname).$(domain) on line $(line) ($(line-desc)) %
```

When the MOTD banner is executed, you see the following (notice that the $(token) syntax is replaced by the corresponding configuration argument):

```
You have entered company.ourdomain.com on line 5 (Dialin Modem)
```

Related Commands

Command	Description
banner exec	Specifies and enables a message to be displayed when an EXEC process is created.
banner incoming	Defines and enables a banner to be displayed when there is an incoming connection to a terminal line from a host on the network.
banner login	Defines and enables a customized banner to be displayed before the username and password login prompts.
banner slip-ppp	Allows customization of the banner that is displayed when a SLIP or PPP connection is made.
exec-banner	Reenables the display of EXEC and MOTD banners on the specified line or lines.
motd-banner	Enables the display of MOTD banners on the specified line or lines.

fabric required

To prevent the Cisco 7600 series routers from coming online without a Switch Fabric Module, use the **fabricrequired**command in global configuration mode. To allow the Cisco 7600 series routers to come up without a Switch Fabric Module, use the **no** form of this command.

fabric required
no fabric required

Syntax Description

This command has no arguments or keywords.

Command Default

A Switch Fabric Module is not required.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

If you enter the **fabricrequired** command, when you remove or power down the last Switch Fabric Module, all modules except the supervisor engine, power down. When you insert or power on the first Switch Fabric Module, the modules that were previously powered down power up if the Switch Fabric Module configuration is not in conflict with other configurations.

If you enter the **nofabricrequired** command, the modules will also power on if a Switch Fabric Module is not present and the configuration allows for it.

Examples

This example shows how to prevent the Cisco 7600 series routers from coming online without a Switch Fabric Module:

```
Router(config)#
fabric required
Router(config)#
```

This example shows how to allow the Cisco 7600 series routers to come up without a Switch Fabric Module:

```
Router(config)#
no fabric required
Router(config)#
```

Related Commands

Command	Description
show fabric	Displays the information about the crossbar fabric.

fabric switching-mode allow

To enable various switching modes in the presence of two or more fabric-enabled switching modules, use the **fabricswitching-modeallow** command in global configuration mode. To disable the settings, use the **no** form of this command.

fabric switching-mode allow {**bus-mode** | **dcef-only** | **truncated** [**threshold** [*mod*]]}
no fabric switching-mode allow {**bus-mode** | **truncated** [**threshold**]}

Syntax Description

bus-mode	Specifies a module to run in bus mode.
dcef-only	Allows switching in distributed Cisco Express Forwarding (dCEF)-only mode.
truncated	Specifies a module to run in truncated mode.
threshold *mod*	(Optional) Specifies the number of fabric-enabled modules for truncated switching mode; see the "Usage Guidelines" section for additional information.

Command Default

The truncated mode is disabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was modified. This command supports the Supervisor Engine 2.
12.2(18)SXD1	This command was modified. The **dcef-only** keyword was added on the Supervisor Engine 2.
12.2(18)SXE	This command was modified. Support for OIR performance enhancement and the **dcef-only** keyword was added on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was modified. This command was introduced on the Supervisor Engine 720-10GE.

Usage Guidelines

This command is not supported on Catalyst 6500 or Cisco 7600 series routers that are configured with a Supervisor Engine 32.

Ethernet ports are not disabled when this command is entered on a Supervisor Engine 720-10GE. This command is also supported with Supervisor Engine 720 starting with Release 12.2(33)SXI2. However, prior to Release 12.2(33)SXI2, if all the installed switching modules have Distributed Forwarding Cards (DFCs), enter the **fabricswitching-modeallowdcef-only** command to disable the Ethernet ports on both supervisor engines. Entering this command ensures that all modules are operating in dCEF-only mode and simplifies switchover to the redundant supervisor engine.

With a Supervisor Engine 2 and Release 12.2(18)SXD1 and later releases, if all the installed switching modules have DFCs, enter the **fabricswitching-modeallowdcef-only** command to disable the Ethernet ports on the redundant supervisor engine. Entering this command ensures that all modules are operating in dCEF-only mode.

Note The **fabricswitching-modeallowdcef-only** command is accepted only in stateful switchover (SSO) redundancy mode.

Bus mode--Supervisor engines use this mode for traffic between nonfabric-enabled modules and for traffic between a nonfabric-enabled module and a fabric-enabled module. In this mode, all traffic passes between the local bus and the supervisor engine bus.

dCEF-only--Supervisor engines, both active and redundant, operate as nonfabric-capable modules with their uplink ports relying on the Policy Feature Card (PFC) on the active supervisor engine for all forwarding decisions. For the Supervisor 720-10G, the uplink ports on both the active and standby routers will remain active. If all other modules are operating in dCEF-only mode, module Online Insertion and Removal (OIR) is nondisruptive.

Note The system message “PSTBY-2-CHUNKPARTIAL: Attempted to destroy partially full chunk, chunk 0xB263638, chunk name: MET FREE POOL” is displayed on the Supervisor Engine if both the **fabricswitching-modeallowdcef-only** and **ipv6mfibhardware-switchinguplink** commands are configured. The router will ignore the command configured last.

Truncated mode--Supervisor engines use this mode for traffic between fabric-enabled modules when there are both fabric-enabled and nonfabric-enabled modules installed. In this mode, line cards send a truncated version of the traffic (the first 64 bytes of the frame) over the Catalyst bus.

Compact mode--Supervisor engines use this mode for all traffic when only fabric-enabled modules are installed. In this mode, a compact version of the Desktop Bus (DBus) header is forwarded over the Catalyst bus, which provides the best possible centralized forwarding performance.

A fabric-enabled module has an additional connection directly to the switch fabric. Fabric-enabled modules forward packets in compressed mode, where only the header is sent to the Supervisor Engine and the full packet is forwarded directly from one line card to another.

To prevent use of nonfabric-enabled modules or to prevent fabric-enabled modules from using bus mode, enter the **nofabricswitching-modeallowbus-mode** command.

Caution Entering the **nofabricswitching-modeallowbus-mode** command removes power from any nonfabric-enabled modules that are installed.

The **fabricswitching-modeallow** c ommand affects Supervisor engines that are configured with a minimum of two fabric-enabled modules.

You can enter the **fabricswitching-modeallowtruncated** command to unconditionally allow truncated mode.

You can enter the **nofabricswitching-modeallowtruncated** command to allow truncated mode if the threshold is met.

You can enter the **nofabricswitching-modeallowbus-mode**command to prevent any module from running in bus mode.

To return to the default truncated-mode threshold, enter the **nofabricswitching-modeallowtruncatedthreshold** command.

The valid value for *mod*is the threshold value.

Examples

The following example shows how to specify truncated mode:

```
Router(config)#
fabric switching-mode allow truncated
```

Related Commands

Command	Description
ipv6 mfib hardware-switching uplink	Configures MFIB hardware switching for IPv6 multicast packets on a global basis.
show fabric	Displays the information about the crossbar fabric.

fabric switching-mode force bus-mode

To force fabric-enabled modules into bus switching mode, use the**fabricswitching-modeforcebus-mode** command in global configuration mode. To power cycle the module to truncated mode, use the **no** form of this command.

fabric switching-mode force bus-mode
no fabric switching-mode force bus-mode

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXD5	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 32.

This command applies to the following modules:

- WS-SVC-FWM-1-K9--Firewall Services Module
- WS-SVC-IDS2-BUN-K9--Intrusion Detection Service Module 2
- WS-SVC-MWAM-1--Multiprocessor WAN Application Module
- WS-SVC-NAM-1--Network Analysis Module 1
- WS-SVC-NAM-2--Network Analysis Module 2
- WS-SVC-PSD-1--Persistent Storage Device Module
- WS-SVC-SSL-1-K9--SSL Module
- WS-SVC-WLAN-1-K9--Wireless LAN Service Module

After you enter the **fabricswitching-modeforcebusmode** or the **nofabricswitching-modeforcebusmode**command, the fabric-enabled service modules power cycle immediately. The mode change occurs as the modules come up after the power cycle.

Examples

This example shows how to force fabric-enabled modules into flow-through switching mode:

```
Router(config)#
fabric switching-mode force bus-mode
Router(config)#
```

Related Commands

Command	Description
show fabric	Displays the information about the crossbar fabric.

fabric timer

To set the drop counter time-stamp and peak-utilization poll time in seconds, use the **fabrictimer**command in global configuration mode. To remove the drop counter time-stamp and peak-utilization poll time, use the **no** form of this command.

fabric timer *seconds*
no fabric timer *seconds*

Syntax Description

seconds	Poll time in seconds for drop counter time-stamps and peak-utilization. Valid values are from 1 to 1800.

Command Default

The internal default timer is set to 15 seconds.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(14)SXF	This command was introduced on the Catalyst 6500 series switch.
12.2(5)SRB	This command was implemented on the Supervisor Engine 720.

Examples

The following example shows how to set the drop counter time-stamp and peak-utilization poll time to 200 seconds:

```
Router(config)#
fabric timer 200
```

Related Commands

Command	Description
show fabric	Displays the information about the crossbar fabric.

facility-alarm

To configure threshold temperatures for minor, major, and critical alarms, use the **facility-alarm** command in global configuration mode. To disable alarms for the threshold and reset the threshold to the default value, use the no form of this command.

Cisco 10000 Series Router

facility-alarm {**core-temperature** | **outlet-temperature**} {**major** | **minor** | **critical**} [*temperature*]

no facility-alarm {**core-temperature** | **outlet-temperature**} {**major** | **minor** | **critical**} [*temperature*]

Cisco 7200 Series Router

facility-alarm {**core-temperature** | **intake-temperature**} *temperature*

Syntax Description

core-temperature	Specifies that the alarm applies to the temperature of the internal core of the router. The temperature sensor close to the router's processor measures the core temperature.
outlet-temperature	Specifies that the alarm applies to the air flow temperature. **Note** This keyword is valid only on the Cisco 10000 series router for the PRE3.
major [*temperature*	Specifies the alarm threshold temperature threshold in degrees C. The default value is 53 degrees C. Major alarms affect several subscribers that connect to the reporting node.
minor [*temperature*	Specifies the alarm threshold temperature threshold in degrees C. The default value is 45 degrees C. Minor alarms affect a single or small number of subscribers who connect to the reporting node.
critical [*temperature*	Specifies the alarm threshold temperature threshold in degrees C. The default value is 85 Celsius C. Critical alarms affect most or all subscribers that connect to the reporting node.
temperature	Temperature threshold in degrees C. The range is 30 to 70 degrees C.

Command Default

If the command is not enabled, the default values are set.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(17)SL	This command was introduced on the Cisco 10000 series router.
12.2(16)BX	This command was introduced on the PRE2.
12.2(31)SB2	This command was introduced on the PRE3 for the Cisco 10000 series router.

Release	Modification
15.0(1)M	This command was integrated into a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

You can configure explicit threshold temperatures to override the defaults for major, minor, and critical alarms. Temperature thresholds for each alarm type and location are automatically set based on determined values that vary depending on the number and type of boards inserted in the chassis. In addition to the automatically set thresholds, you can set thresholds for minor and major temperature alarms. You can also disable the minor and major temperature alarms. You cannot, however, change the threshold for or disable critical alarms.

Cisco 10000 Series Router

On the PRE2, use the **facility-alarmcore-temperature** command. On the PRE3, use the **facility-alarmoutlet-temperature** command.

The default value for a threshold temperature depends on the performance routing engine (PRE) installed in the router as the following describes:

- Major alarm
  - PRE2--The default value is 53.
  - PRE3--The default value is 58.
- Minor alarm
  - PRE2--The default value is 45.
  - PRE3--The default value is 50.
- Critical alarm
  - PRE2--The default value is 85.
  - PRE3--The default value is 85.

Examples

The following example sets a threshold temperature of 53 for major alarms on the PRE2:

```
Router> enable
Router# config terminal
Router(config)# facility-alarm core-temperature major 53
```

The following example sets a threshold temperature of 50 for minor alarms on the PRE3:

```
Router> enable
Router# config terminal
Router(config)# facility-alarm core-temperature minor 50
```

Related Commands

Command	Description
clear facility-alarm	Clears alarm conditions and resets the alarm contacts.
show facility-alarm status	Displays the current major, minor, and critical alarm status, if any, and displays the configuration of the alarm thresholds.

facility-alarm critical exceed-action shutdown

To allow automatic router shutdown, use the facility-alarm critical exceed-action shutdown command in global configuration mode. To disable automatic router shutdown, use the **no** form of this command.

facility-alarm critical exceed-action shutdown
no facility-alarm critical exceed-action shutdown

Syntax Description

This command has no arguments or keywords.

Command Default

Automatic router shutdown is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

If the facility-alarm critical exceed-action shutdown command is enabled, the router performs an automatic shutdown under the following conditions:

- The internal temperature of the router or a power supply exceeds the temperature threshold.
- The voltage of an AC or DC power supply is out of tolerance.

Examples

The following example enables automatic router shutdown:

```
Router(config)# facility-alarm critical exceed-action shutdown
```

Related Commands

Command	Description
show facility-alarm	Displays the status of a generated alarm.

facility-alarm detect

To turn on the facility alarms, use the **facility-alarmdetect** command in global configuration mode. To turn off the alarm, use the **no** form of this command.

facility-alarm detect {**controller** *controller slot-number* | **interface** *type number* | **rps** | **temperature** | **fan**}
no facility-alarm detect {**controller T1** *slot-number* | **interface** *type number* | **rps** | **temperature** | **fan**}

Syntax Description

controller	Specifies the facility alarm for controllers.
controller slot-number	Specifies the controller. The controller can be one of the following: • **E1** --The range of the slot value is from 1 to 7 and the range of the port is from 0 to 7. • **T1** --The range of the slot value is from 1 to 7 and the range of the port is from 0 to 7. • **T3** --The range of the slot value is from 1 to 7.
interface	Specifies the facility alarm for interfaces.
type	Interface type. For more information, use the question mark (?) online help function.
number	Interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (?) online help function.
rps	Specifies the facility alarm for the redundant power supply (RPS).
temperature	Specifies the facility alarm for the environmental monitor temperature.
fan	Specifies the facility alarm for the environmental monitor fans.

Command Default

The facility alarm is turned off.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M on the Cisco 5400-XM series routers.

Usage Guidelines

Facility alarms monitor the following failure events:

- CT1/CE1/CT3 controller down
- Interface down
- RPS failure

- Trunk card failure

Cisco IOS software polls every second to detect the failure events that you have configured and turns on the alarm when any one of the failure events is detected. By default, the facility alarm is off. Users have to configure a facility alarm command to enable monitoring of the failure conditions.

Examples

The following example shows how to turn on the facility alarm for RPS:

```
Router(config)# facility-alarm detect rps
```

Related Commands

Command	Description
show facility-alarm	Displays the status of a generated alarm.

factory-reset all

To erase all the user-configured data, use the **factory-reset all** command in EXEC mode:

factory-reset all

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Modes

EXEC mode

Command History

Release	Modification
Cisco IOS XE Bengaluru Release 17.6.1	This command was introduced on ASR 900, ASR 920, and NCS 4200 platforms.

Usage Guidelines

The command erases the following data:

- All writable file systems and personal data
- OBFL logs
- User data and startup configuration
- ROMMON variables
- User credentials
- License information

Examples

The following example shows the configuration of the command:

```
Router>enable
Router>factory-reset all
```

factory-reset keep-licensing-info

To erase all the user-configured data except the licensing information, use the **factory-reset keep-licensing-info** command in EXEC mode:

factory-reset keep-licensing-info

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Modes

EXEC mode

Command History

Release	Modification
Cisco IOS XE Bengaluru Release 17.6.1	This command was introduced on ASR 900, ASR 920, and NCS 4200 platforms.

Usage Guidelines

This command erases the following user-configured data:

- All writable file systems and personal data
- OBFL logs
- User data and startup configuration
- ROMMON variables
- User credentials

Examples

The following example shows the configuration of the command:

```
enable
factory-reset keep-licensing-info
```

factory-reset all secure 3-pass

To erase all data using the the National Industrial Security Program Operating Manual (DoD 5220.22-M) Wiping Standard, use the **factory-reset all secure 3-pass-DoD 5220-22-M** command in EXEC mode:

factory-reset all-secure 3-pass-DoD 5220-22-M

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Modes

EXEC mode

Command History

Release	Modification
Cisco IOS XE Bengaluru Release 17.6.1	This command was introduced on ASR 900, ASR 920, and NCS 4200 platforms.

Usage Guidelines

The commands erases the following data

- All writable file systems and personal data using the the National Industrial Security Program Operating Manual (DoD 5220.22-M) Wiping Standard:
- OBFL logs
- User data and startup configuration
- ROMMON variables
- User credentials
- License information

Examples

The following example shows the configuration of the command:

```
enable
factory-reset all-secure 3-pass
DoD 5220-22-M
```

fddi burst-count

To allow the FCI card to preallocate buffers to handle bursty FDDI traffic (for example, Network File System [NFS] bursty traffic), use the **fddiburst-count** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi burst-count *number*
no fddi burst-count

Syntax Description

number	Number of preallocated buffers in the range from 1 to 10. The default is 3.

Command Default

3 buffers

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command applies to the FCI card only.

Note The microcode software version should *not* be 128.45 or 128.43.

Examples

The following example sets the number of buffers to 5:

```
Router(config)# interface fddi 0
Router(config-if)# fddi burst-count 5
```

fddi c-min

To set the C-Min timer on the pulse code modulation (PCM), use the **fddic-min** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi c-min *microseconds*
no fddi c-min

Syntax Description

microseconds	Sets the timer value, in microseconds. The default is 1600.

Command Default

1600 microseconds

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command applies to the processor connection management (CMT) only. You need extensive knowledge of the PCM state machine to tune this timer. Use this command when you run into PCM interoperability problems.

Examples

The following example sets the C-Min timer to 2000 microseconds:

```
Router(config)# interface fddi 0
Router(config-if)# fddi c-min 2000
```

Related Commands

Command	Description
fddi tb-min	Sets the TB-Min timer in the PCM.
fddi tl-min-time	Controls the TL-Min time (the minimum time to transmit a PHY line state before advancing to the PCM state, as defined by the X3T9.5 specification).
fddi t-out	Sets the t-out timer in the PCM.

fddi cmt-signal-bits

To control the information transmitted during the connection management (CMT) signaling phase, use the **fddicmt-signal-bits**command in interface configuration mode.

fddi cmt-signal-bits *signal-bits* [{**phy-a** | **phy-b**}]

Syntax Description

signal-bits	A hexadecimal number preceded by 0x; for example, 0x208. The FDDI standard defines 10 bits of signaling information that must be transmitted, as follows: • bit 0--Escape bit. Reserved for future assignment by the FDDI standards committee. • bits 1 and 2--Physical type, as defined in the first table below. • bit 3--Physical compatibility. Set if topology rules include the connection of a physical-to-physical type at the end of the connection. • bits 4 and 5--Link confidence test duration; set as defined in the second table below. • bit 6--MAC available for link confidence test. • bit 7--Link confidence test failed. The setting of bit 7 indicates that the link confidence was failed by the Cisco end of the connection. • bit 8--MAC for local loop. • bit 9--MAC on physical output.
phy-a	(Optional) Selects Physical Sublayer A. The default is 0x008 (hexadecimal) or 00 0000 1000 (binary). Bits 1 and 2 are set to 00 to select Physical A. Bit 3 is set to 1 to indicate “accept any connection.”
phy-b	(Optional) Selects Physical Sublayer B. The default is 0x20c (hexadecimal) or 10 0000 1100 (binary). Bits 1 and 2 are set to 10 to select Physical B. Bit 3 is set to 1 to indicate “accept any connection.” Bit 9 is set to 1 to select MAC on output. The normal data flow on FDDI is input on Physical A and output on Physical B.

Command Default

- **phy-a** is set to 0x008 (hexadecimal) or 00 0000 1000 (binary). Bits 1 and 2 are set to 00 to select Physical A. Bit 3 is set to 1 to indicate “accept any connection.”
- **phy-b** is set to 0x20c (hexadecimal) or 10 0000 1100 (binary). Bits 1 and 2 are set to 10 to select Physical B. Bit 3 is set to 1 to indicate “accept any connection.” Bit 9 is set to 1 to select MAC on output. The normal data flow on FDDI is input on Physical A and output on Physical B.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If neither the **phy-a** nor **phy-b** keyword is specified, the signal bits apply to both physical connections.

> **Caution** Use of the **fddicmt-signal-bits** configuration command is *not* recommended under normal operations. This command is used when debugging specific CMT implementation issues.

The table below lists the physical types.

Table 15: FDDI Physical Type Bit Specifications

Bit 2	Bit 1	Physical Type
0	0	Physical A
1	0	Physical B
0	1	Physical S
1	1	Physical M

The table below lists the duration bits.

Table 16: FDDI Link Confidence Test Duration Bit Specification

Bit 5	Bit 4	Test Duration
0	0	Short test (default 50 milliseconds)
1	0	Medium test (default 500 milliseconds)
0	1	Long test (default 5 seconds)
1	1	Extended test (default 50 seconds)

This command does not have a **no** form.

Examples

The following example sets the CMT signaling phase to signal bits 0x208 on both physical connections:

```
Router(config)# interface fddi 0
Router(config-if)# fddi cmt-signal-bits 0x208
```

fddi duplicate-address-check

To enable the duplicate address detection capability on the FDDI interface, use the **fddiduplicate-address-check** command in interface configuration mode. To disable this function, use the **no** form of this command.

fddi duplicate-address-check
no fddi duplicate-address-check

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you use this command, the Cisco IOS software will detect a duplicate address if multiple stations are sharing the same MAC address. If the software finds a duplicate address, it will shut down the interface.

Examples

The following example enables duplicate address checking on the FDDI interface:

```
Router(config)# interface fddi 0
Router(config-if)# fddi duplicate-address-check
```

fddi encapsulate

To specify encapsulating bridge mode on the CSC-C2/FCIT interface card, use the **fddiencapsulate** command in interface configuration mode. To turn off encapsulation bridging and return the FCIT interface to its translational, nonencapsulating mode, use the **no**form of this command.

fddi encapsulate
no fddi encapsulate

Syntax Description

This command has no arguments or keywords.

Command Default

By default, the FDDI interface uses the SNAP encapsulation format defined in RFC 1042, *Standard for the Transmission of IP Datagrams Over IEEE 802 Networks* . It is not necessary to define an encapsulation method for this interface when using the CSC-FCI interface card.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **nofddiencapsulate** command applies only to CSC-C2/FCIT interfaces, because the CSC-FCI interfaces are always in encapsulating bridge mode. The CSC-C2/FCIT interface card fully supports transparent and translational bridging for the following configurations:

- FDDI to FDDI
- FDDI to Ethernet
- FDDI to Token Ring

The **fddiencapsulate** command puts the CSC-C2/FCIT interface into encapsulation mode when doing bridging. In transparent mode, the FCIT interface interoperates with earlier versions of the CSC-FCI encapsulating interfaces when performing bridging functions on the same ring.

Caution Bridging between dissimilar media presents several problems that can prevent communications from occurring. These problems include bit-order translation (or usage of MAC addresses as data), maximum transfer unit (MTU) differences, frame status differences, and multicast address usage. Some or all of these problems might be present in a multimedia bridged LAN and might prevent communication from taking place. These problems are most prevalent when bridging between Token Rings and Ethernets or between Token Rings and FDDI nets. This is because of the different way Token Ring is implemented by the end nodes.

The following protocols have problems when bridged between Token Ring and other media: Novell IPX, DECnet Phase IV, AppleTalk, VINES, XNS, and IP. Furthermore, the following protocols may have problems when bridged between FDDI and other media: Novell IPX and XNS. We recommend that these protocols be routed whenever possible.

Examples

The following example sets FDDI interface 1 on the CSC-C2/FCIT interface card to encapsulating bridge mode:

```
Router(config)# interface fddi 1
Router(config-if)# fddi encapsulate
```

fddi frames-per-token

To specify the maximum number of frames that the FDDI interface transmits per token capture, use the **fddiframes-per-token** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi frames-per-token *number*
no fddi frames-per-token

Syntax Description

number	Maximum number of frames to transmit per token capture. Valid values are from 1 to 10. The default is 3.

Command Default

3 frames

Command Modes

Interface configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Changing the value will increase or decrease the maximum number of frames that the FDDI interface can transmit when it receives a token. Increasing the value does not necessarily mean more frames will be transmitted on each token capture. This is heavily dependent on the traffic load of the specific interface.

When the interface captures a token, it transmits all of the frames that are queued in the interface’s transmit ring, up to a maximum value specified by the**fddiframes-per-token** command.

If there are no frames ready for transmission, the token is passed on, and no frames are transmitted. If there are less than the **fddiframes-per-token**valuein the transmit ring, all frames in the transmit ring are transmitted before the token is passed on. If there are more than the **fddiframes-per-token**value in the transmit ring, the specified value is transmitted before the token is passed on. The remaining frames in the transmit ring remain queued until the token is captured again.

Examples

The following example shows how to configure the FDDI interface to transmit four frames per token capture:

```
Router(config-if)# fddi frames-per-token 4
```

fddi smt-frames

To enable the Station Management (SMT) frame processing capability on the FDDI, use the **fddismt-frames** command in interface configuration mode. To disable this function and prevent the Cisco IOS software from generating or responding to SMT frames, use the **no** form of this command.

fddi smt-frames
no fddi smt-frames

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **no** form of this command to turn off SMT frame processing for diagnosing purposes. Use the **fddismt-frames** command to reenable the feature.

Examples

The following example disables SMT frame processing:

```
Router(config)# interface fddi 0
Router(config-if)# no fddi smt-frames
```

fddi tb-min

To set the TB-Min timer in the physical connection management (PCM), use the **fdditb-min** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi tb-min *milliseconds*
no fddi tb-min

Syntax Description

milliseconds	Number, in milliseconds, that sets the TB-Min timer value. The range is from 0 to 65535. The default is 100.

Command Default

milliseconds : 100

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command applies to the processor connection management (CMT) only. Use this command when you run into PCM interoperability problems.

Note You need extensive knowledge of the PCM state machine to tune this timer.

Examples

The following example shows how to set the TB-Min timer to 200 ms:

```
Router(config)# interface fddi 0
Router(config-if)# fddi tb-min 200
```

Related Commands

Command	Description
fddi c-min	Sets the C-Min timer on the PCM.
fddi tl-min-time	Controls the TL-Min time (the minimum time to transmit a PHY line state before advancing to the PCM state, as defined by the X3T9.5 specification).
fddi t-out	Sets the t-out timer in the PCM.

fddi tl-min-time

To control the TL-Min time (the minimum time to transmit a Physical Sublayer, or PHY line state, before advancing to the next physical connection management [PCM] state, as defined by the X3T9.5 specification), use the **fdditl-min-time** command in interface configuration mode.

fddi tl-min-time *microseconds*

Syntax Description

microseconds	Number, in microseconds, that specifies the time used during the connection management (CMT) phase to ensure that signals are maintained for at least the value of TL-Min so that the remote station can acquire the signal. The range is from 0 to 4294967295. The default is 30.

Command Default

microseconds : 30

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Interoperability tests have shown that some implementations of the FDDI standard need more than 30 microseconds to sense a signal.

This command does not have a **no** form.

Examples

The following example changes the TL-Min time from 30 microseconds to 100 microseconds:

```
Router(config)# interface fddi 0
Router(config-if)# fddi tl-min-time 100
```

The following example changes the TL-Min time from 30 microseconds to 100 microseconds on a Cisco 7500 series router:

```
Router(config)# interface fddi 3/0
Router(config-if)# fddi tl-min-time 100
```

Related Commands

Command	Description
fddi c-min	Sets the C-Min timer on the PCM.
fddi t-out	Sets the t-out timer in the PCM.

fddi token-rotation-time

To control ring scheduling during normal operation and to detect and recover from serious ring error situations, use the **fdditoken-rotation-time** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi token-rotation-time *microseconds*
no fddi token-rotation-time

Syntax Description

microseconds	Number, in microseconds, that specifies the token rotation time (TRT). The range is from 4000 to 165000. The default is 5000.

Command Default

microseconds : 5000

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The FDDI standard restricts the allowed time to be greater than 4000 microseconds and less than 165,000 microseconds. As defined in the X3T9.5 specification, the value remaining in the TRT is loaded into the token holding timer (THT). Combining the values of these two timers provides the means to determine the amount of bandwidth available for subsequent transmissions.

Examples

The following example sets the rotation time to 24,000 microseconds:

```
Router(config)# interface fddi 0
Router(config-if)# fddi token-rotation-time 24000
```

The following example sets the rotation time to 24,000 microseconds on a Cisco 7500 series router:

```
Router(config)# interface fddi 3/0
Router(config-if)# fddi token-rotation-time 24000
```

fddi t-out

To set the timeout timer in the physical connection management (PCM), use the **fddit-out** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi t-out *milliseconds*
no fddi t-out

Syntax Description

milliseconds	Number, in milliseconds, that sets the timeout timer. The range is from 0 to 65535. The default is 100.

Command Default

milliseconds : 100

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command applies to the processor connection management (CMT) only. Use this command when you run into PCM interoperability problems.

Note You need extensive knowledge of the PCM state machine to tune this timer.

Examples

The following example sets the timeout timer to 200 ms:

```
Router(config)# interface fddi 0
Router(config-if)# fddi t-out 200
```

Related Commands

Command	Description
fddi c-min	Sets the C-Min timer on the PCM.
fddi tb-min	Sets the TB-Min timer in the PCM.
fddi tl-min-time	Controls the TL-Min time (the minimum time to transmit a PHY line state before advancing to the PCM state, as defined by the X3T9.5 specification).

fddi valid-transmission-time

To change the transmission valid timer (TVX) interval, use the**fddivalid-transmission-time** command in interface configuration mode. To revert to the default value, use the **no** form of this command.

fddi valid-transmission-time *microseconds* **fddi valid-transmission-time command**
no fddi valid-transmission-time

Syntax Description

microseconds	Number, in microseconds, that specifies the TVX interval. The range is from 2500 to 2147483647. The default is 2500.

Command Default

microseconds : 2500

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to recover from a transient FDDI ring error by setting a longer transmission timer interval.

Examples

The following example shows how to change the transmission timer interval to 3000 microseconds:

```
Router(config)# interface fddi 0
Router(config-if)# fddi valid-transmission-time 3000
```

The following example shows how to change the transmission timer interval to 3000 microseconds on Cisco 7000 series routers or Cisco 7200 series routers:

```
Router(config)# interface fddi 3/0
Router(config-if)# fddi valid-transmission-time 3000
```

fdl

To set the Facility Data Link (FDL) exchange standard for CSU controllers or to set the FDL exchange standard for a T1 interface that uses the Extended Super Frame (ESF) framing format, use the **fdl** command in interface configuration mode. To disable FDL support or to specify that there is no ESF FDL, use the **no** form of this command.

Cisco 2600 Series and Cisco 3600 Series Routers
fdl {**att** | **ansi** | **all** | **none**}
no fdl {**att** | **ansi** | **all** | **none**}

Cisco 10000 Series Router
fdl {**att** | **ansi**}
no fdl {**att** | **ansi**}

Syntax Description

att	Specifies AT&T technical reference 54016 for ESF FDL exchange support.
ansi	Specifies ANSI T1.403 for ESF FDL exchange support.
all	Specifies both AT&T technical reference 54016 and ANSI T1.403 for ESF FDL exchange support.
none	Specifies that there is no support for ESF FDL exchange.

Command Default

ANSI T1.403 for ESF FDL exchange support

Command Modes

Interface configuration

Command History

Release	Modification
11.3	This command was introduced.
12.0(5)XK	The **none** keyword was added, and the **both** keyword was changed to **all**.
12.0(5)T	The **none** keyword was added, and the **both** keyword was changed to **all**.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is available only for T1 links. This command sets the standard to be followed for FDL messaging through a 4-kbps out-of-band channel that a service provider uses to check for errors on the facility.

You must use the same FDL exchange standard as your service provider. If the setting is not correct, the link might not come up. You can configure a different standard on each T1 interface.

> **Note**
> When using a multiport T1 ATM IMA network module on a Cisco 2600 series or Cisco 3600 series router, ESF framing and binary eight zero substitution (B8ZS) line encoding are supported. When using a multiport E1 ATM IMA network module on a Cisco 2600 series or Cisco 3600 series router, CRC4 multiframe framing and HDB3 line encoding are supported. These are the parameters specified by the ATM Forum, and they cannot be changed.

Examples

Cisco 2600 and Cisco 3600 Series Routers

The following example shows how to specify the ANSI standard and the AT&T standard for FDL exchange:

```
Router(config)# interface atm 0/2
Router(config-if)# fdl all
```

Cisco 10000 Series Router

The following example shows how to specify the AT&T standard for FDL exchange:

```
Router(config)# interface atm 1/0/0
Router(config-if)# fdl att
```

flowcontrol

To configure a port to send or receive pause frames, use the **flowcontrol** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

flowcontrol {**send** | **receive**} {**desired** | **off** | **on**}
no flowcontrol {**send** | **receive**} {**desired** | **off** | **on**}

Syntax Description

send	Specifies that a port sends pause frames.
receive	Specifies that a port processes pause frames.
desired	Obtains predictable results regardless of whether a remote port is set to **on**, **off**, or **desired**.
off	Prevents a local port from receiving and processing pause frames from remote ports or from sending pause frames to remote ports.
on	Enables a local port to receive and process pause frames from remote ports or send pause frames to remote ports.

Command Default

Flow control is disabled.

Flow-control defaults depend upon port speed. The defaults are as follows:

- Gigabit Ethernet ports default to **off** for receive and **desired** for send.
- Fast Ethernet ports default to **off** for receive and **on** for send.
- On the 24-port 100BASE-FX and 48-port 10/100 BASE-TX RJ-45 modules, the default is **off** for receive and **off** for send.
- You cannot configure how WS-X6502-10GE 10-Gigabit Ethernet ports respond to pause frames. WS-X6502-10GE 10-Gigabit Ethernet ports are permanently configured to respond to pause frames.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was implemented on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

The **send** and **desired** keywords are supported on Gigabit Ethernet ports only.

Pause frames are special packets that signal a source to stop sending frames for a specific period of time because the buffers are full.

Gigabit Ethernet ports on the Catalyst 6500 series switches and on the Cisco 7600 series routers use flow control to inhibit the transmission of packets to the port for a period of time; other Ethernet ports use flow control to respond to flow-control requests.

If a Gigabit Ethernet port receive buffer becomes full, the port transmits a “pause” packet that tells remote ports to delay sending more packets for a specified period of time. All Ethernet ports (1000 Mbps, 100 Mbps, and 10 Mbps) can receive and act upon “pause” packets from other devices.

You can configure non-Gigabit Ethernet ports to ignore received pause frames (disable) or to react to them (enable).

When used with the **receive**keyword, the **on** and **desired** keywords have the same result.

All the Gigabit Ethernet ports on the Catalyst 6500 series switches and the Cisco 7600 series routers can receive and process pause frames from remote devices.

To obtain predictable results, follow these guidelines:

- Use **sendon** only when remote ports are set to **receiveon** or **receivedesired**.
- Use **sendoff** only when remote ports are set to **receiveoff** or **receivedesired**.
- Use **receiveon** only when remote ports are set to **sendon** or **senddesired**.
- Use **sendoff** only when remote ports are set to **receiveoff** or **receivedesired**.

Examples

These examples show how to configure the local port to not support any level of flow control by the remote port:

```
Router# configure terminal

Router(config)# interface GigabitEthernet1/9 10.4.9.157 255.255.255.0

Router(config-if)# flowcontrol receive off
Router(config-if)# flowcontrol send off
```

Related Commands

Command	Description
show interfaces flowcontrol	Displays flow-control information.

frame-relay

To configure Frame Relay payload compression for each Frame Relay port, use the **frame-relay**command in interface configuration mode. To terminate this form of payload compression over Frame Relay, use the **no** form of this command.

frame-relay payload-compression frf9 stac caim [*element-number*]
no frame-relay payload-compression

Syntax Description

payload-compression	Packet-by-packet payload compression, using the Stacker method.
frf9 stac	Enables FRF.9 compression using the Stacker method. If the router contains a data compression Advanced Interface Module (AIM) for the Cisco 2600 series router, compression is performed in the hardware (hardware compression). If the compression Advanced Interface Module (CAIM) is not available, compression is performed in the software installed on the main processor of the router (software compression).
caim *element-number*	Enable the data compression AIM hardware compression daughtercard to do compression, at the element numbered beginning with 0 and incrementing to include all possible elements.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.0(2)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **frame-relaypayload-compression** command to enable or disable payload compression on a point-to-point interface or subinterface. Use the **frame-relaymap** command to enable or disable payload compression on a multipoint interface or subinterface.

Shut down the interface before changing encapsulation types. Although this is not required, shutting down the interface ensures the interface is reset for the new encapsulation.

Examples

The following example shows Frame Relay configured to use payload compression with the frf9 stac algorithm for CAIM hardware compression, using the installed data compression AIM daughtercard as the compression source:

```
Router(config-if)# frame-relay payload-compression frf9 stac caim 0
```

Related Commands

Command	Description
compress stac caim	Specifies the exact hardware compression resource preferred.
encapsulation frame-relay	Enables Frame Relay encapsulation.
frame-relay interface-dlci	Assigns a DLCI to a specified Frame Relay subinterface on the router or access server.
frame-relay map	Defines mapping between a destination protocol address and the DLCI used to connect to the destination address.
show compress	Displays compression statistics.

framing

To select the frame type for the T1 or E1 data line, use the **framing** command in controller configuration mode.

T1 Lines
framing commandframing {**sfadm** | **esfadm**}

E1 Lines
framing {**crc4adm** | **pcm30adm** | **clear e1**}

Syntax Description

sfadm	Specifies super frame for the T1 channel.
esfadm	Specifies extended super frame for the T1 channel.
crc4adm	Specifies CRC4 framing mode for the E1 channel.
pcm30adm	Specifies CRC4 disabled framing mode for the E1 channel.
clear e1	Specifies clear-e1 framing mode for the E1 channel.

Command Default

Extended super frame (esf) for a T1 line CRC4 disabled framing (pcm30adm) for an E1 line

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.0(5)XE	The command was enhanced as an ATM interface configuration command.
12.0(7)XE1	This command was implemented on the Cisco 7100 series routers.
12.0(11)S	This command was integrated into Cisco IOS Release 12.0(11)S.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command in configurations in which the router or access server is intended to communicate with T1 or E1 fractional data lines. The service provided determines which framing type is required for your T1 or E1 circuit.

This command does not have a **no** form.

Examples

The following example selects extended super frame as the T1 frame type:

```
Router(config)# controller t1 4/0
Router(config-controller)# framing esfadm
```

Related Commands

Command	Description
lbo	Specifies the distance of the cable from the routers to the network equipment.
linecode	Selects the line code type for a T1 or E1 line.

framing (CEM)

To specify the framing format of a circuit emulation (CEM) T1 or E1 port, use the **framing** command in controller configuration mode. To reset the framing format of the port to its default value, use the **no** form of this command.

T1 Port
framing {**sf** | **esf** | **unframed**}
no framing

E1 Port
framing {**crc4** | **no-crc4** | **unframed**}
no framing

Syntax Description

sf	Specifies that the T1 port framing format is set to super frame (SF) format, also commonly known as D4 framing format.
esf	Specifies that the T1 port framing format is set to extended super frame (ESF) format. This is the default for a T1 line.
crc4	Specifies that the E1 port framing format is set to the G.704 standard with the optional CRC4 mechanism defined in time slot 0 enabled. This is the default for a E1 line. For Cisco NCS 4200 Series, crc4 is the default framing mode for E1 interface module.
no-crc4	Specifies that the E1 port framing format is set to the G.704 standard with the optional CRC4 mechanism defined in time slot 0 disabled.
unframed	Specifies that no framing structure is sought (on the ingress data stream) or imposed (on the egress data stream) on the T1 or E1 port. For Cisco NCS 4200 Series, unframed is the default framing mode for T1 interface module.

Command Default

The framing format of a T1 line defaults to **esf**. The framing format of an E1 line defaults to **crc4**. If an unframed CEM channel is created on the port using the **cem-group** command, no framing structure is sought or imposed.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(7)T	This command was introduced to support circuit emulation.
XE 3.18SP	This command was integrated in the Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated in the Cisco NCS 4200 Series and Cisco ASR 903 Series Router.

Usage Guidelines

Framing must be configured to match the framing format used by the attached equipment.

In order to change a line between unframed and any framed mode, you must first delete the CEM channels defined in the line.

Examples

The following example shows how to set the framing format of a CEM T1 port to be super frame format.

```
Router(config-controller)# framing
 sf
```

The following example shows how to set the framing format of a CEM E1 port to the G.704 standard with the optional CRC4 mechanism defined in time slot 0 disabled.

```
Router(config-controller)# framing no-crc4
```

Examples

The following example shows how to set the framing format of a CEM T1 port for Cisco NCS 4200 Series.

```
Router(config-controller)# framingunframed
```

Examples

The following example shows how to set the framing format of a CEM E1 port for Cisco NCS 4200 Series and Cisco ASR 903 Series Router.

```
Router(config-controller)# framingcrc4
```

Related Commands

Command	Description
cem-group	Creates CEM channels on T1 or E1 ports.

framing (E3 controller)

To specify the type of framing used by the E3 controller, use the **framing**command in controller configuration mode. To restore the default framing type, use the **no** form of this command.

framing {**bypass** | **g751**}
no framing

Syntax Description

bypass	Specifies that G.751 framing be bypassed.
g751	Specifies G.751 as the E3 framing type. This is the default.

Command Default

G.751 framing

Command Modes

Controller configuration

Command History

Release	Modification
11.1 CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for E3: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

If you do not specify the framing command, the default, **g751**, is used by the E3 controller to automatically determine the framing type received from the far-end equipment.

Configure framing as G.751 when the E3 connection terminates remotely on a Digital Link or Kentrox data service unit (DSU), or when needing a subrate on an E3 connection between two T3 or E3 network modules.

Note The local interface configuration must match the remote interface, or DSU, configuration.

When G.751 framing is used, DSU bandwidth can be used to select a payload subrate from 34,010 kbps down to 22 kbps.

When framing bypass is used, DSU bandwidth of 34,010 kbps must be configured.

When G.751 framing is used, configuring the scramble command can prevent some payload data from being mistakenly interpreted as G.751 framing bits by switches placed between the DSUs. By default, the no scramble command is configured.

When framing bypass is used, the no scramble command must be configured.

When G.751 framing is used, bit 11 of the G.751 frame is reserved for national use and is set to 1 by default. Configure national bit 1 only when required for interoperability with your telephone company.

Examples

The following example shows the framing for the E3 controller set to bypass:

```
Router(config)# controller e3 1/0
Router(config-controller)# framing bypass
```

Related Commands

Command	Description
scramble	Specifies the type of framing used by the T1 channels on the CT3IP in Cisco 7500 series routers.

framing (SONET)

To select the frame type of the frame received on an optical line, use the **framing**command in controller configuration mode.

framing {**sonet** | **sdh**}

Syntax Description

sonet	Specifies the framing type as SONET.
sdh	Specifies the framing type as Synchronous Digital Hierarchy (SDH).

Command Default

SONET is the default for the PA-MC-STM-1 port adapter. SDH is the default for the STM-1 trunk card.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T and support was added for the STM-1 trunk card on the Cisco AS5850 platform.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
XE Everest 16.5.1	This command was introduced on the Cisco ASR 920 Routers and Cisco NCS 4200 Series.

Usage Guidelines

Use this command to configure the framing type of the SONET controller. The PA-MC-STM-1 port adapter supports both the SONET and SDH framing modes. The STM-1 trunk feature card on the Cisco AS5850 supports only SDH framing.

This command does not have a **no** form.

Examples

The following example shows how to configure the framing type on a SONET controller of an STM-1 card in physical slot number 2 on a Cisco AS5850:

```
Router(config)# controller sonet 2/0
Router(config-controller)# framing sonet
```

Related Commands

Command	Description
show controllers sonet	Displays information about SONET controllers.

framing (T1 E1 controller)

To select the frame type for the T1 or E1 data line, use the **framing** command in controller configuration mode. To return to the default, use the **no** form of the command.

T1 Lines
framing {**sf** | **esf**}

E1 Lines
framing {**crc4** | **no-crc4**} [**australia**]

T1 Shared Port Adapter
framing {**sf** | **esf**}
no framing {**sf** | **esf**}

E1 Shared Port Adapter
framing {**crc4** | **no-crc4** | **unframed**}
no framing {**crc4** | **no-crc4** | **unframed**}

Syntax Description

sf	Specifies super frame as the T1 frame type. This is the default.
esf	Specifies extended super frame as the T1 frame type.
crc4	Specifies CRC4 as the E1 frame type. This is the default for Australia.
no-crc4	Specifies CRC4 disabled as the E1 frame type.
unframed	Specifies unframed mode.
australia	(Optional) Specifies the E1 frame type used in Australia.

Command Default

sf on a T1 line

crc4 on an E1 line

Command Modes

Controller configuration

Command History

12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on a Cisco 7600 series router and Catalyst 6500 series switch.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.1(2)SNH	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

Use this command in configurations in which the router or access server is intended to communicate with T1 or E1 fractional data lines. The service provider determines the framing type required for your T1/E1 circuit.

To return to the default mode on a T1/E1 SPA, use the **no** form of this command. This command does not have a **no** form for other T1/E1 lines.

Examples

The following example selects extended super frame as the T1 frame type:

```
Router(config-controller)# framing esf
```

Related Commands

Command	Description
cablelength	Specifies the distance of the cable from the routers to the network equipment.
linecode	Selects the linecode type for T1 or E1 line.

framing (T3 controller)

To choose framing mode on a T3 port, use the **framing**command in controller configuration mode. To return to the default mode, use the no form of this command.

T3 Controllers
framing {**c-bit** | **m23**}
no framing

Channelized T3 Shared Port Adapters and the Cisco 7500 Series Routers with CT3IP Port Adapter
framing {**c-bit** | **m23** | **auto-detect**}
no framing

Syntax Description

auto-detect	Specifies detection of the framing type that it receives from the far-end equipment.
c-bit	Specifies that C-bit framing is used as the T3 framing type.
m23	Specifies that M23 framing is used as the T3 framing type.

Command Default

c-bit (for the 2-Port and 4-Port Channelized T3 SPA and most T3 controllers)

auto-detect (for the CT3IP in a Cisco 7500 series router)

Command Modes

Controller configuration

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for T3: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on a Cisco 7600 series router or Catalyst 6500 series switch.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can set the framing for each T1 channel by using the **t1framing**controller configuration command.

Cisco 7500 Series Routers with CT3IP Port Adapter

Because the CT3IP supports the Application Identification Channel (AIC) signal, the setting for the framing might be overridden by the CT3IP firmware.

Examples

The following example sets the framing mode on a T3 interface.

```
Router# configure terminal
Router(config)# controller t1 6/0/0
Router(config-controller)# framing m23
```

The following example sets the framing for the CT3IP to C-bit:

```
Router(config)# controller t3 9/0/0
Router(config-controller)# framing c-bit
```

Related Commands

Command	Description
controller	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller	Displays controller configuration.
t1 framing	Specifies the type of framing used by the T1 channels.

framing (T3-E3 interface)

To choose framing mode on a T3 or E3 port, use the **framing**command in interface configuration mode. To return to the default mode, use the no form of this command.

PA-T3 and T3 Shared Port Adapters
framing {**bypass** | **c-bit** | **m13**}
no framing {**bypass** | **c-bit** | **m13**}

PA-E3 and E3 Shared Port Adapters
framing {**bypass** | **g751** | **g832**}
no framing {**bypass** | **g751** | **g832**}

Syntax Description

bypass	Bypasses DS3 framing mode.
c-bit	Enables DS3 C-bit framing mode.
m13	Enables DS3 M13 framing mode.
g751	Enables E3 G.751 framing mode.
g832	Enables E3 G.832 framing mode. The g832 keyword is not supported on Cisco 7304 routers with the 4-Port Clear Channel T3/E3 SPA.

Command Default

T3: C-bit framing

E3: g751 framing

Command Modes

Interface configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on a Cisco 7600 series router and Catalyst 6500 series switch. The **g832** keyword option was added to the command.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The default framing is described in the ITU-T Recommendation G.751.

Note The International Telecommunication Union Telecommunication Standardization Sector (ITU-T) carries out the functions of the former Consultative Committee for International Telegraph and Telephone (CCITT).

When the framing mode is **bypass**, the T3 frame data is not included in the T3 frame, just the data.

When the framing mode is **bypass**, the E3 frame data is not included in the E3 frame, just the data.

If you use the **bypass** keyword, scrambling must be set to the default (disabled), the DSU mode must be set to the default (0), and the DSU bandwidth must be set to the default (44736).

The g832 keyword is not supported on Cisco 7304 routers with the 2-Port and 4-Port Clear Channel T3/E3 SPA.

Examples

The following example sets the framing mode to bypass on interface 1/0/0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# framing bypass
```

Related Commands

Command	Description
show controller serial	Displays serial line statistics.

full-duplex

To specify full-duplex mode on full-duplex single-mode and multimode port adapters, use the **full-duplex**command in interface configuration mode. To restore the default half-duplex mode, use the **no** form of this command.

full-duplex
no full-duplex

Syntax Description

This command has no arguments or keywords.

Command Default

Half-duplex; a Fast Ethernet Interface Processor (FEIP), and serial interfaces that are configured for bisynchronous tunneling

Autonegotiation

Command Modes

Interface configuration

Command History

Release	Modification
11.1	This command was introduced.
11.3	This command was modified to include information on FDDI full-duplex, single-mode, and multimode port adapters.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command if the equipment on the other end is capable of full-duplex mode.

This command specifies full-duplex mode on full-duplex single-mode and multimode port adapters available on the following networking devices:

- Cisco 7200 series routers
- Second-generation Versatile Interface Processors (VIP2s) in Cisco 7500 series routers
- FEIP ports
- Serial interface ports that uses bisynchronous tunneling

Refer to the *CiscoProductCatalog* for hardware compatibility information and for specific model numbers of port adapters.

To enable half-duplex mode, use the **nofull-duplex** or **half-duplex** command.

Note For the Cisco AS5300, the **duplexfull**| **halfauto**} command replaces the **full-duplex** and **half-duplex** commands. You will get the following error messages if you try to use the **full-duplex** and **half-duplex** commands on a Cisco AS5300: Router(config)# **interfacefastethernet0** Router(config-if)# **full-duplex** Please use duplex command to configure duplex mode Router(config-if)# Router(config-if)# **half-duplex** Please use duplex command to configure duplex mode

Support for This Command

Use the question mark (?) command to find out which port adapters support this command. If the interface does not support full-duplex, an informational message displayed, and no changes are made to the interface. To determine if the interface supports full-duplex, use the **showinterfaces**command. For example, the following message is displayed if the interface does not support full-duplex:

```
% interface does not support full-duplex.
```

Use on FDDI

Full-duplex on the FDDI full-duplex port adapters allows an FDDI ring with exactly two stations to transform the ring into a full-duplex, point-to-point topology. For the interface to operate in full-duplex mode, there must be only two stations on the ring, the two stations must be capable of operating in full-duplex mode, and both stations must complete a full-duplex autoconfiguration protocol. There is no FDDI token in full-duplex mode. Refer to the *CiscoProductCatalog* for specific model numbers of port adapters.

Full-duplex autoconfiguration protocol allows an FDDI station to dynamically and automatically operate in either half-duplex (or ring) or full-duplex mode, and ensures that the stations fall back to ring mode when a configuration change occurs, such as a third station joining the ring.

After booting the router, the FDDI stations begin operation in half-duplex mode. While the station performs the full-duplex autoconfiguration protocol, the station continues to provide data-link services to its users. Under normal conditions, the transition between half-duplex mode and full-duplex mode is transparent to the data-link users. The data-link services provided by full-duplex mode are functionally the same as the services provided by half-duplex mode.

If you change the full-duplex configuration (for example, from disabled to enabled) on supported interfaces, the interface resets.

Cisco 10000 Series Router

The Fast Ethernet line card responds only to 802.3x pause frames from another device when it autonegotiates the duplex mode (the default). The line card does not support 802.3x flow control when you manually set half-duplex or full-duplex mode.

Examples

Cisco 7200 Series Router

The following example configures full-duplex mode on the Cisco 7200 series routers:

```
Router(config)# interface fastethernet 0/1
Router(config-if)# full-duplex
```

Full-Duplex Binary Synchronous

The following example specifies full-duplex binary synchronous communications (Bisync) mode:

```
Router(config)# interface serial 0
Router(config-if)# encapsulation bstun
Router(config-if)# full-duplex
```

Full-Duplex on FDDI Interface

The following example enables full-duplex mode on FDDI interface 0:

```
Router(config)# interface fddi 0/1/0
Router(config-if)# full-duplex
```

Related Commands

Command	Description
half-duplex	Specifies half-duplex mode on an SDLC interface or on the FDDI full-duplex, single-mode port adapter and FDDI full-duplex, multimode port adapter on the Cisco 7200 series and Cisco 7500 series routers.
interface	Configures an interface type and enters interface configuration mode.
interface fastethernet	Selects a particular Fast Ethernet interface for configuration.
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller (for ISDN PRI, CAS, or robbed-bit signaling).
show interfaces	Displays statistics for all interfaces configured on the router or access server.
show interfaces fddi	Displays information about the FDDI interface.

g709 disable

To disable the ITU-T G.709 wrapper, use the **g709 disable** command in DWDM configuration mode. To enable the ITU-T G.709 wrapper, use the **no** form of this command.

g709 disable

no g709 disable

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Default

The G.709 wrapper is enabled.

Command Modes

DWDM configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series router.

Usage Guidelines

To display the G.709 alarms and counters, use the**show controller dwdm g709** command.

Examples

The G.709 wrapper is enabled by default. The following example shows how to disable the G.709 wrapper on an interface:

```
enable
configure terminal
controller dwdm 0/0/0
g709 disable
end
```

If you have disabled the G.709 wrapper using the **g709 disable** command, use the **no g709 disable** command to re-enable it, as shown in the following example:

```
enable
configure terminal
controller dwdm 0/0/0
no g709 disable
end
```

Related Commands

Command	Description
show controller dwdm	Displays DWDM controller configuration.

g709 fec

To configure the forward error correction (FEC) mode for the DWDM controller, use the **g709fec**command in controller configuration mode. To return to the default state, use the **no** form of this command.

g709 fec {**disable** | **enhanced** | **standard**}
no g709 fec

Syntax Description

disable	Disables FEC.
enhanced	Enables enhanced FEC mode.
standard	Enables standard FEC mode.

Command Default

Standard FEC mode is enabled by default.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Usage Guidelines

The **g709fec** command can be used only when the DWDM controller is in the shutdown state.

Standard FEC is the default mode; therefore, if you use the **nog709fec** command, standard FEC is used.

Examples

The following example shows how to configure standard FEC mode on a DWDM controller:

```
Router(config)# controller dwdm 1/3
Router(config-controller)# g709 fec standard
```

Related Commands

Command	Description
controller dwdm	Configures a DWDM controller.
g709 odu threshold	Configures thresholds for selected ODU BER alarms.
g709 otu threshold	Configures thresholds for selected OTU BER alarms.
no g709 odu report	Disables the logging of selected ODU alarms.
no g709 otu report	Disables the logging of selected OTU alarms.
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.
transport-mode	Configures a transport mode.

g709 odu report

To enable the logging of selected optical channel data unit (ODU) alarms to the console for a DWDM controller, use the **g709odureport**command in controller configuration mode. To disable logging, use the no form of this command.

g709 odu report {**ais** | **bdi** | **lck** | **oci** | **pm-tca** | **ptim** | **sd-ber** | **sf-ber** | **tim**}
no g709 odu report {**ais** | **bdi** | **lck** | **oci** | **pm-tca** | **ptim** | **sd-ber** | **sf-ber** | **tim**}

Syntax Description

ais	Alarm indication signal reporting status.
bdi	Backward defect indication reporting status.
lck	Upstream connection locked reporting status.
oci	Open connection indication error reporting status.
pm-tca	Path monitoring BER TCA reporting status.
ptim	Payload type identifier mismatch reporting status.
sd-ber	Sets PM BER in excess of SD threshold reporting status.
sf-ber	Sets PM BER in excess of SF threshold reporting status.
tim	Sets Trace Identifier Mismatch reporting status.

Command Default

Logging is enabled for all keywords.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Usage Guidelines

This command can be used only when the DWDM conroller is in the shutdown state.

Examples

The following example shows how to enable ODU reporting for OCI:

```
Router(config)# controller dwdm 1/2
Router(config-controller)# g709 odu report oci
```

Related Commands

Command	Description
controller dwdm	Configures a DWDM controller.
g709 fec	Configures the FEC for the DWDM controller.
g709 odu threshold	Configures thresholds for selected ODU BER alarms.

Command	Description
g709 otu threshold	Configures thresholds for selected OTU BER alarms.
show controller dwdm	Displays G.709 alarms, alerts, and counters.
show platform dwdm alarm history	Displays platform DWDM alarm history.

g709 odu overhead tti

To configure the Trail Trace Identifier (TTI) level for an Optical Channel Data Unit (ODU), use the **g709oduoverheadtti**command in DWDM configuration mode. To return to the default, use the **no** form of this command.

g709 odu overhead tti {**expected** | **sent**} {**ascii** | **hex**} *tti-string*
no g709 odu overhead tti {**expected** | **sent**} {**ascii** | **hex**} *tti-string*

Syntax Description

expected	Configures the expected TTI string.
sent	Configures the transmit TTI string.
ascii	Indicates that the string is in ASCII format.
hex	Indicates that the string is in hexidecimal format.
tti-string	The TTI level string. You can configure the TTI level string in ASCII string format or hexadecimal format. The ASCII text string can be a maximum of 64 characters. The hexadecimal string length must be an even number and can be a maximum of 128 bytes.

Command Default

No TTI level string is configured.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(2)S	This command was introduced on the Cisco 7600 Router.

Usage Guidelines

To display the TTI strings, use the **showcontrollerdwdmg709** command.

Examples

The following example shows how to configure the expected TTI string:

```
Router(config)# controller dwdm 0/1/0/0
Router(config-dwdm)# g709 odu overhead tti expected ascii test_odu_5678
```

Related Commands

Command	Description
show controller dwdm	Displays optical parameters, G.709 alarms and counters, and register and module information for a DWDM controller.

g709 odu threshold

To configure thresholds for selected optical channel data unit (ODU) bit error rate (BER) alarms, use the **g709oduthreshold**command in controller configuration mode. To return to the default state, use the **no** form of this command.

g709 odu threshold {**pm-tca** **bit-error-rate** | **sd-ber** **bit-error-rate** | **sf-ber** **bit-error-rate**}
no g709 odu threshold {**pm-tca** **bit-error-rate** | **sd-ber** **bit-error-rate** | **sf-ber** **bit-error-rate**}

Syntax Description

pm-tca	Sets the path monitoring threshold crossing alert threshold.
sd-ber	Sets the signal degrade bit error rate (BER) threshold.
sf-ber	Sets the signal failure BER threshold.
bit-error-rate	Specifies the BER threshold value in the range from 3 through 9. The threshold value is interpreted as a negative exponent of 10 when determining the bit error rate. For example, a value of 5 implies a bit error rate of 10 to the minus 5. The default BER threshold value is 6.

Command Default

sd-ber: 6

sf-ber: 3

pm-tca: 3

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Usage Guidelines

This command can be used only when the DWDM controller is in the shutdown state.

Examples

The following example shows how to set the signal fail BER rate to 5:

```
Router(config)# controller dwdm 1/2
Router(config-controller)# g709 odu threshold sf-ber 5
```

Related Commands

Command	Description
controller dwdm	Configures a DWDM controller.
g709 fec	Configures the FEC for the DWDM controller
g709 otu threshold	Configures thresholds for selected OTU BER alarms.
no g709 odu report	Disables the logging of selected ODU alarms.
no g709 otu report	Disables the logging of selected OTU alarms.

Command	Description
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.
transport-mode	Configures a transport mode.

g709 otu report

To enable the logging of selected optical channel transport unit (OTU) alarms to the console for a DWDM controller, use the **g709otureport**command in controller configuration mode. To disable logging, use the no form of this command.

g709 otu report {**ais** | **bdi** | **iae** | **lof** | **lom** | **los** | **sm-tca** | **tim** | **sd-ber** | **sf-ber**}
no g709 otu report {**ais** | **bdi** | **iae** | **lof** | **lom** | **los** | **sm-tca** | **tim** | **sd-ber** | **sf-ber**}

Syntax Description

ais	Alarm indication signal reporting status.
bdi	Backward defect indication reporting status.
iae	Incoming alignment error reporting status.
lof	OTU loss of frame reporting status.
lom	Loss of multiple frame reporting status.
los	Loss of signal reporting status.
sm-tca	Section monitoring BER TCA reporting status.
tim	Trace identifier mismatch reporting status.
sd-ber	SM BER is in excess of the SD BER threshold
sf-ber	SM BER is in excess of the SF BER threshold

Command Default

Reporting is enabled for all keywords.

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.
XE 3.18SP	This command was introduced on the Cisco NCS 4200 Series router.

Usage Guidelines

This command can be used only when the DWDM controller is in the shutdown state.

Examples

The following example shows how to enable OTU reporting for IAE:

```
Router(config)# controller dwdm 1/2
Router(config-controller)# g709 otu report iae
```

Related Commands

g709 otu threshold	Configures thresholds for selected OTU BER alarms.
no g709 odu report	Disables the logging of selected ODU alarms.
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.
show platform dwdm alarm history	Displays platform DWDM alarm history.
transport-mode	Configures a transport mode.

g709 otu threshold

To configure thresholds for selected optical channel transport unit (OTU) bit error rate (BER) alarms, use the **g709otuthreshold**command in controller configuration mode. To return to the default state, use the **no** form of this command.

g709 otu threshold sm-tca| sd-ber| sf-ber bit-error-rate
no g709 otu threshold sm-tca| sd-ber| sf-ber bit-error-rate

Syntax Description

sm-tca	Sets the Section Monitoring Threshold Crossing Alert threshold.
sd-ber	Sets the Signal Degrade Bit Error rate threshold.
sf-ber	Sets the Signal Failure Bit Error Rate threshold.
bit-error-rate	Sets the BER threshold value in the range from 3 through 9. The threshold value is interpreted as a negative exponent of 10 when determining the bit error rate. For example, a value of 5 implies a bit error rate of 10 to the minus 5. The default BER threshold value is 3.

Command Default

bit-error-rate: 3

Command Modes

Controller configuration (config-controller)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.
XE 3.18 SP	This command was introduced on the Cisco NCS 4200 Series router.

Usage Guidelines

This command can be used only when the DWDM controller is in the shutdown state.

Examples

The following example shows how to set the Section Monitoring Threshold Crossing Alert threshold to 5:

```
Router(config)# controller dwdm 1/2
Router(config-controller)# g709 otu threshold sm-tca 5
```

Related Commands

Command	Description
controller dwdm	Configures a DWDM controller.
g709 fec	Configures the FEC for the DWDM controller.
g709 odu threshold	Configures thresholds for selected ODU BER alarms.
no g709 odu report	Disables the logging of selected ODU alarms.
no g709 otu report	Disables the logging of selected OTU alarms.

Command	Description
show controller dwdm	Displays ITU-T G.709 alarms, alerts, and counters.
transport-mode	Configures a transport mode.

g709 tti-processing enable

To configure Trail Trace Identifier (TTI), use the **g709 tti-processing enable** command in the controller configuration mode.

g709 tti-processing enable {*odu* | *otu*}

Syntax Description

Syntax Description

odu	Configures TTI for selected ODU alarm.
otu	Configures TTI for selected OTU alarm.

Command Modes

Controller configuration

Command History

Release	Modification
15.6(02)SP	Support for this command was introduced on NCS 4200 Series router.

Usage Guidelines

The interface goes down in case of OTU TIM or ODU TIM alarms.

Examples

The following example shows how to enter CEM interface parameters:

```
enable
configure terminal
controller dwdm 0/4/1
shutdown
g709 tti-processing enable odu
no shutdown
end
```

Related Commands

Command	Description
clear controller dwdm	Displays the DWDM controller configuration.

gnss

To enable the global navigation satellite system (GNSS) module on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers, use the **gnss** command in the global configuration mode.

gnss slot {*r0r1*}

Syntax Description

slot	Specifies the slot information.
r0	Indicates route processor slot 0.
r1	Indicates route processor slot 1.

Command Default

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
IOS-XE 3.17	This command was introduced on the Cisco ASR 903, Cisco ASR 907, and the Cisco ASR 920 routers.

Usage Guidelines

This command enables the GNSS module on the router. However, you must execute the **no shutdown** command after the **gnss** command to ensure that the interface is administratively up.

Examples

The following example shows how to enable the GNSS module and enter the GNSS mode:

```
Router# configure terminal
Router(config)# gnss slot r0
Router(config-gnss)# no shutdown
```

Related Commands

Command	Description
1pps	Configures the pulse per second from the GNSS module.
anti-jam	Enables or disables the anti-jam mode on the GNSS module.
constellation	Configures the GNSS module based on the specified satellite constellations.
default	Resets the device to its default state.
exit	Exists the GNSS sub mode.
no	Negates the command or sets the value of the command to its default values.
shutdown	Enables GNSS module.

gtp

To enables Enhanced Wireless Access Gateway (EWAG) General packet radio service (GPRS) Tunneling Protocol (GTP) and enter EWAG GTP configuration mode, use the **gtp** command in global configuration mode.

gtp

Syntax Description

This command does not contain any keywords or arguments.

Command Default

This command has no defaults.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.8S	This command was introduced.

Examples

The following example shows how to enable GTP and configure parameters of an access point.

```
Device(config)# gtp
Device(config-gtp)# n3-request 3
Device(config-gtp)# interval t3-response 30
Device(config-gtp)# information-element rat-type wlan
Device(config-gtp)# interface local GigabitEthernet0/0/0
WARNING: same interface has already been configured
Device(config-gtp)# apn 1
Device(config-gtp-apn)#  apn-name starent.com
Device(config-gtp-apn)#  ip address ggsn 10.1.2.1
Device(config-gtp-apn)#  dns-server 10.1.2.1
Device(config-gtp-apn)#  dhcp-server 10.10.197.1
Device(config-gtp-apn)#  dhcp-lease 6000
Device(config-gtp-apn)#  tunnel mtu 1500
Device(config-gtp-apn)# end
```

Related Commands

Command	Description
apn	Configures an ASCII regular expression string to be matched against the APN for GPRS load balancing.
apn-name	Configures access point name.
debug gtp	Debugs information related to EWAG GTP.

Command	Description
dns-server	Specifies the DNS IP servers available to a DHCP client.
dhcp-server	Specifies a primary (and backup) DHCP server to allocate IP addresses to MS users entering a particular PDN access point.
dhcp-lease	Configures DHCP lease time in seconds.
interval (EWAG)	Configures message intervals.
information-element	Configures information elements.
interface (EWAG)	Configure EWAG interface.
ip address ggsn	Configures GGSN IP address.
n3-request	Specifies the maximum number of times that the quota server attempts to send a signaling request to the CSG.
show gtp	Displays information related to EWAG GTP.
tunnel mtu	Configures GTP tunnel parameters.

half-duplex

To specify half-duplex mode on an Synchronous Data Link Control (SDLC) interface or on the FDDI full-duplex, single-mode port adapter and FDDI full-duplex, multimode port adapter on the Cisco 7200 series and Cisco 7500 series routers, use the **half-duplex** command in interface configuration mode. To reset the interface to full-duplex mode, use the **no** form of this command.

half-duplex
no half-duplex

Syntax Description

This command has no arguments or keywords.

Command Default

Full-duplex mode is the default mode on an SDLC interface, the FDDI full-duplex, single-mode port adapter and FDDI full-duplex, multimode port adapter on the Cisco 7200 series and Cisco 7500 series routers.

Command Modes

Interface configuration

Command History

Release	Modification
11.1	This command was introduced.
11.3	This command was modified to include information on FDDI full-duplex, single-mode, and multimode port adapters.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

SDLC Interfaces

The **half-duplex** command is used to configure an SDLC interface for half-duplex mode and is used on a variety of port adapters. Use the question mark (?) command to find out which port adapters support this command.

Note The **half-duplex**command replaces the **sdlchdx** and **media-typehalf-duplex** commands.

Note For the Cisco AS5300, the **duplexfullhalfauto**} command replaces the **full-duplex** and **half-duplex** commands. You will get the following error messages if you try to use the **full-duplex** and **half-duplex** commands on a Cisco AS5300: Router(config)# **interfacefastethernet0** Router(config-if)# **full-duplex** Please use duplex command to configure duplex mode Router(config-if)# Router(config-if)# **half-duplex** Please use duplex command to configure duplex mode

Enabling Full-Duplex Mode

To enable full-duplex mode, use the **nohalf-duplex**or**full-duplex**commands.

Note The **media-typehalf-duplex** command exists in Cisco IOS Release 11.0(5). As of Release 11.0(6), the keyword **half-duplex** was removed from the **media-type** command. In Release 11.0(6), the functionality for specifying half-duplex mode is provided by the**half-duplex** command.

Port Adapters

Refer to the *CiscoProductCatalog* for specific model numbers of port adapters.

Examples

The following example configures an SDLC interface for half-duplex mode:

```
Router(config-if)# encapsulation sdlc-primary
Router(config-if)# half-duplex
```

Related Commands

Command	Description
full-duplex	Specifies full-duplex mode on full-duplex single-mode and multimode port adapters.

half-duplex controlled-carrier

To place a low-speed serial interface in controlled-carrier mode, instead of constant-carrier mode, use the **half-duplexcontrolled-carrier**command in interface configuration mode. To return the interface to constant-carrier mode, use the **no** form of this command.

half-duplex controlled-carrier
no half-duplex controlled-carrier

Syntax Description

This command has no arguments or keywords.

Command Default

Constant-carrier mode, where Data Carrier Detect (DCD) is held constant and asserted by the DCE half-duplex interface.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies only to low-speed serial DCE interfaces in half-duplex mode. Configure a serial interface for half-duplex mode by using the **half-duplex** command. Refer to the *CiscoProductCatalog* for specific model numbers of networking devices which support serial interfaces.

Controlled-carrier operation means that the DCE interface has DCD deasserted in the quiescent state. When the interface has something to transmit, it asserts DCD, waits a user-configured amount of time, then starts the transmission. When the interface has finished transmitting, it waits a user-configured amount of time and then deasserts DCD.

Examples

The following examples place the interface in controlled-carrier mode and then back into constant-carrier operation.

This example shows changing to controlled-carrier mode from the default of constant-carrier operation:

```
Router(config)# interface serial 2
Router(config-if)# half-duplex controlled-carrier
```

This example shows changing to constant-carrier operation from controlled-carrier mode:

```
Router(config)# interface serial 2
Router(config-if)# no half-duplex controlled-carrier
```

Related Commands

Command	Description
half-duplex	Specifies half-duplex mode on an SDLC interface or single-mode and multimode port adapters.
half-duplex timer	Tunes half-duplex timers.
physical-layer	Specifies the mode of a slow-speed serial interface on a router as either synchronous or asynchronous.

half-duplex timer

To tune half-duplex timers, use the **half-duplextimer** command in interface configuration mode. To return to the default parameter values, use the **no** form of this command.

half-duplex timer {**cts-delay** *value* | **cts-drop-timeout** *value* | **dcd-drop-delay** *value* | **dcd-txstart-delay** *value* | **rts-drop-delay** *value* | **rts-timeout** *value* | **transmit-delay** *value*}
no half-duplex timer {**cts-delay** *value* | **cts-drop-timeout** *value* | **dcd-drop-delay** *value* | **dcd-txstart-delay** *value* | **rts-drop-delay** *value* | **rts-timeout** *value* | **transmit-delay** *value*}

Syntax Description

cts-delay *value*	Specifies the delay introduced by the DCE interface from the time it detects the Request to Send (RTS) to the time it asserts Clear to Send (CTS) in response. The range is dependent on the serial interface hardware. The default **cts-delay** value is 0 ms.
cts-drop-timeout *value*	Determines the amount of time a DTE interface waits for CTS to be deasserted after it has deasserted RTS. If CTS is not deasserted during this time, an error counter is incremented to note this event. The range is from 0 to 1,140,000 ms (1140 seconds). The default **cts-drop-timeout** value is 250 ms.
dcd-drop-delay *value*	Applies to DCE half-duplex interfaces operating in controlled-carrier mode (see the **half-duplexcontrolled-carrier** command). This timer determines the delay between the end of transmission by the DCE and the deassertion of Data Carrier Detect (DCD). The range is from 0 to 4400 ms (4.4 seconds). The default **dcd-drop-delay** value is 100 ms.
dcd-txstart-delay *value*	Applies to DCE half-duplex interfaces operating in controlled-carrier mode. This timer determines the time delay between the assertion of DCD and the start of data transmission by the DCE interface. The range is from 0 to 1,140,000 ms (1140 seconds). The default **dcd-txstart-delay** value is 100 ms.
rts-drop-delay *value*	Specifies the time delay between the end of transmission by the DTE interface and deassertion of RTS. The range is from 0 to 1,140,000 ms (1140 seconds). The default **rts-drop-delay** value is 3 ms.
rts-timeout *value*	Determines the number of milliseconds the DTE waits for CTS to be asserted after the assertion of RTS before giving up on its transmission attempt. If CTS is not asserted in the specified amount of time, an error counter is incremented. The range is dependent on the serial interface hardware. The default **rts-timeout** value is 3 ms.
transmit-delay *value*	Specifies the number of milliseconds a half-duplex interface will delay the start of transmission. In the case of a DTE interface, this delay specifies how long the interface waits after something shows up in the transmit queue before asserting RTS. For a DCE interface, this dictates how long the interface waits after data is placed in the transmit queue before starting transmission. If the DCE interface is in controlled-carrier mode, this delay shows up as a delayed assertion of DCD. This timer enables the transmitter to be adjusted if the receiver is a little slow and is not able to keep up with the transmitter. The range is from 0 to 4400 ms (4.4 seconds). The default**transmit-delay** value is 0 ms.

Command Default

The default **cts-delay** value is 0 ms. The default **cts-drop-timeout** value is 250 ms. The default **dcd-drop-delay** value is 100 ms. The default **dcd-txstart-delay** value is 100 ms. The default **rts-drop-delay** value is 3 ms. The default **rts-timeout** value is 3 ms. The default**transmit-delay** value is 0 ms.

Command Modes

Interface configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Tuning Half-Duplex Timers

The **half-duplextimer** command is used to tune half-duplex timers. With these timer tuning commands you can adjust the timing of the half-duplex state machines to suit the particular needs of their half-duplex installation.

You can configure more than one option using this command, but each option must be specified as a separate command.

Note The **half-duplextimercts-delay** command replaces the **sdlccts-delay** command. The **half-duplextimerrts-timeout** command replaces the **sdlcrts-timeout** command.

Value Ranges

The range of values for the **cts-delay** and **rts-timeout** keywords are dependent on the serial interface hardware.

Examples

The following example set the cts-delay timer to 10 ms and the transmit-delay timer to 50 ms:

```
Router(config)# interface serial 2
Router(config-if)# half-duplex timer cts-delay 10
Router(config-if)# half-duplex timer transmit-delay 50
```

Related Commands

Command	Description
half-duplex controlled-carrier	Places a low-speed serial interface in controlled-carrier mode, instead of constant-carrier mode.
physical-layer	Specifies the mode of a slow-speed serial interface on a router as either synchronous or asynchronous.

history (interface)

To enable an interface to maintain utilization history, use the **history** command in interface configuration mode. To disable an interface, use the **no** form of this command.

history {**bps** | **pps**} [*filter*]
no history

Syntax Description

bps	Maintains history in bits per second.
pps	Maintains history in packets per second.
filter	(Optional) Interface counters. See the table below for details. Any number of counters can be used.

Command Default

Interface utilization history is not maintained.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)XNE	This command was introduced.

Usage Guidelines

Once interface history is configured, the interface history histograms can be displayed using the **show interface history** command.

Some of the interface counters are interface-type-specific and cannot be specified unless they apply to the specific interface type being configured. Once interface history is configured, counters cannot be added or removed without first removing the interface history configuration.

Significant processor memory is allocated to maintain the history information. For example, if two counters are monitored, then approximately 4KB are used for the rate and counter history. If 20 counters are monitored, then approximately 19KB are used.

The table below lists the interface counter options for the **history (interface)** command.

Table 17: Interface Counter Options For Interface History

Interface Counter	Description
all	Includes all interface counters in the history.
babbles	Includes the Ethernet output babbles in the history.
crcs	Includes CRC counter in the history.
deferred	Includes the deferred Ethernet output in the history.
dribbles	Includes dribble counter in the history.
excessive-collisions	Includes Ethernet excessive output collisions in the history.
flushes	Includes flushes counter in the history.

Interface Counter	Description
frame-errors	Includes frame errors in the history.
giants	Includes giants counter in the history.
ignored	Includes ignored counter in the history.
input-broadcasts	Includes input broadcasts in the history.
input-drops	Includes input drops in the history.
input-errors	Includes input errors in the history.
interface-resets	Includes interface resets in the history.
late-collisions	Includes Ethernet late output collisions in the history.
lost-carrier	Includes Ethernet output lost carrier in the history.
multi-collisions	Includes Ethernet multiple output collisions in the history.
multicast	Includes Ethernet input multicast in the history.
no-carrier	Includes Ethernet output no-carrier in the history.
output-broadcasts	Includes output broadcasts in the history.
output-buffer-failures	Includes output buffer failures in the history.
output-buffers-swapped-out	Includes output buffers swapped out in the history.
output-drops	Includes output drops in the history.
output-errors	Includes output errors in the history.
output-no-buffer	Includes output no buffer in the history.
overruns	Includes overruns in the history.
pause-input	Includes Ethernet input pause in the history.
pause-output	Includes Ethernet output pause in the history.
runts	Includes runts in the history.
single-collisions	Includes Ethernet single output collisions in the history.
throttles	Includes throttles in the history.
underruns	Includes underruns in the history.
unknown-protocol-drops	Includes unknown protocol drops in the history.
watchdog	Includes Ethernet output watchdog in the history.

Examples

The following example shows how to configure the interface history command to maintain interface utilization history in bits per second (bps) and also the input-drop history:

```
Device(config-if)# history bps input-drops
```

Related Commands

Command	Description
show interface history	Displays information on the interface utilization.

hold-queue

To limit the length of the IP output queue on an interface, use the **hold-queue** command in interface configuration or template configuration mode. To restore the default values, use the **no** form of this command.

hold-queue *length* {**in** | **out**}
no hold-queue *length* {**in** | **out**}

Syntax Description

length	Integer that specifies the maximum number of packets in the queue. The range of valid values is from 0 to 65535.
in	Specifies the input queue. The default is 75 packets. For asynchronous interfaces, the default is 10 packets.
out	Specifies the output queue. The default is 40 packets. For asynchronous interfaces, the default is 10 packets.

Command Default

Input hold-queue limit is 75 packets. Output hold-queue limit is 40 packets. Asynchronous interfaces default is 10 packets.

Command Modes

Interface configuration (config-if)

Template configuration (config-template)

Command History

Release	Modification
10.0	This command was introduced.
11.1	The **nohold-queue**command was added.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.
15.1(2)T	This command was modified. The *length* argument was added to the **no** form of the command.
15.2(2)E	This command was integrated into Cisco IOS Release 15.2(2)E. This command is supported in template configuration mode.
Cisco IOS XE Release 3.6E	This command was integrated into Cisco IOS XE Release 3.6E. This command is supported in template configuration mode.

Usage Guidelines

Defaults

The default limits for this command prevent a malfunctioning interface from consuming an excessive amount of memory. There is no fixed upper limit to a queue size.

Back-to-Back Routing Updates

The default of 10 packets allows the Cisco IOS software to queue a number of back-to-back routing updates. This is the default for asynchronous interfaces only; other media types have different defaults.

Hold Queues and Priority Queueing

- The hold queue stores packets received from the network that are waiting to be sent to the client. Cisco recommends that the queue length not exceed10 packets on asynchronous interfaces. For most other interfaces, queue length should not exceed 100.
- The input hold queue prevents a single interface from flooding the network server with too many input packets. Further input packets are discarded if the interface has too many input packets outstanding in the system.
- If you are using priority output queueing, the length of the four output queues is set using the **priority-list** global configuration command. The **hold-queue** command cannot be used to set an output hold queue length in this situation.
- For slow links, use a small output hold-queue limit to prevent storing packets at a rate that exceeds the transmission capability of the link.
- For fast links, use a large output hold-queue limit. A fast link may be busy for a short time (and require the hold queue) but can empty the output hold queue quickly when capacity returns.
- You can display the current hold-queue setting and the number of packets that are discarded because of hold-queue overflows by using the **showinterfaces** command in user EXEC mode.

Caution Increasing the hold queue can have detrimental effects on network routing and response times. For protocols that use seq/ack packets to determine round-trip times, do not increase the output queue. Dropping packets instead informs hosts to slow down transmissions to match available bandwidth. This is generally better than having duplicate copies of the same packet within the network (which can happen with large hold queues).

Note When you use the **no** form of the **hold-queue** command, the *length* value (maximum number of packets in the queue) need not necessarily be the same as the configured value.

Examples

The following example shows how to set a small input queue on a slow serial line:

```
Router(config)# interface serial 0
Router(config-if)# hold-queue 30 in
```

The following example shows how to set an input value in an interface template:

```
Device# configure terminal
Device(config)# template user-template1
Device(config-template)# hold-queue 30 in
Device(config-template)# end
```

Cisco uBR10012 Universal Broadband Router

The following example shows how to modify the input hold queue on a Gigabit Ethernet SPA:

```
Router# configure terminal

Router(config)#interface GigabitEthernet3/0/0
Router(config-if)#hold-queue 30 in
```

Related Commands

Command	Description
priority-list	Establishes queueing priorities based on the protocol type.
show interfaces	Displays statistics for all interfaces configured on the router or access server.

hssi external-loop-request

To allow the router to support a CSU/DSU that uses the loopback circuit (LC) signal to request a loopback from the router, use the **hssiexternal-loop-request** command in interface configuration mode. To disable this function, use the **no** form of this command.

hssi external-loop-request
no hssi external-loop-request

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The HSA applique on the High-Speed Serial Interface (HSSI) contains an LED that indicates the loopback circuit A (LA), loopback circuit B (LB), and LC signals that are transiting through the devices. The CSU/DSU uses the LC signal to request a loopback from the router. The CSU/DSU may want to do this so that its own network management diagnostics can independently check the integrity of the connection between the CSU/DSU and the router.

Use this command to enable a two-way, internal, and external loopback request on the HSSI from the CSU/DSU.

Caution If your CSU/DSU does not support this function, it should not be enabled on the router. Not enabling this function prevents spurious line noise from accidentally tripping the external loopback request line, which would interrupt the normal data flow.

Examples

The following example enables a CSU/DSU to use the LC signal to request a loopback from the router:

```
Router(config-if)# hssi external-loop-request
```

hssi internal-clock

To convert the High-Speed Serial Interface (HSSI) into a clock master, use the **hssiinternal-clock** command in interface configuration mode. To disable the clock master mode, use the **no** form of this command.

hssi internal-clock
no hssi internal-clock

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command in conjunction with the HSSI null-modem cable to connect two Cisco routers together with HSSI. You must configure this command at both ends of the link, not just one.

Note HSSI network module provides full-duplex connectivity at SONET OC-1/STS-1 (51.840 Mhz), T3 (44.736 MHZ), and E3 (34.368 MHz) rates in conformance with the EIA/TIA-612 and EIA/TIA-613 specifications. The actual rate of the interface depends on the external data service unit (DSU) and the type of service to which it is connected.

Examples

The following example shows how to convert the HSSI interface into a clock master:

```
Router(config-if)# hssi internal-clock
```

hub

To enable and configure a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router, use the **hub** command in global configuration mode.

hub ethernet *number port* [*end-port*]

Syntax Description

ethernet	Indicates that the hub is in front of an Ethernet interface.
number	Hub number, starting with 0. Because there is only one hub, this number is 0.
port	Port number on the hub. On the Cisco 2505 router, port numbers range from 1 to 8. On the Cisco 2507 router, port numbers range from 1 to 16. If a second port number follows, then this port number indicates the beginning of a port range.
end-port	(Optional) Last port number of a range.

Command Default

No hub ports are configured.

Command Modes

Global configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command does not have a **no** form.

Examples

The following example enables port 1 on hub 0:

```
Router# hub ethernet 0 1
Router(config-hub)# no shutdown
```

The following example enables ports 1 through 8 on hub 0:

```
Router# hub ethernet 0 1 8
Router(config-hub)# no shutdown
```

Related Commands

Command	Description
shutdown (hub)	Shuts down a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

hw-module boot

To specify the boot options for the module through the power management bus control register, use the **hw-moduleboot** command in privileged EXEC mode.

hw-module module *num* **boot** [*value*] {**config-register** | **eobc** | **flash** *image* | **rom-monitor**}

Syntax Description

module *num*	Specifies the number of the module to apply the command.
boot *value*	(Optional) Literal value for the module's boot option; valid values are from 0 to 15. See the “Usage Guidelines” section for additional information.
config-register	Boots using the module’s config-register value.
eobc	Boots using an image downloaded through EOBC.
flash *image*	Specifies the image number in the module’s internal Flash memory for the module’s boot option; valid values are 1 and 2.
rom-monitor	Stays in ROM-monitor mode after the module resets.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The valid values for the **boot***value* argument are as follows:

0--Specifies the module’s config-register value.

1--Specifies the first image in the Flash memory.

2--Specifies the second image in the Flash memory.

3--Stays in ROM-monitor mode after the module reset.

4--Specifies the download image through EOBC.

Examples

This example shows how to reload the module in slot 6 using the module’s config-register value:

```
Router# hw-module module 1 boot config-register
Router#
```

This example shows how to reload the module in slot 3 using an image downloaded through EOBC:

```
Router# hw-module module 1 boot eobc
Router#
```

Related Commands

Command	Description
showmodule	Displays the module status and information for all modules in the chassis.

hw-module energywise level

> **Note** Effective with Cisco IOS Releases 15.1(1)T and 15.0.1M(2), the **hw-moduleenergywiselevel** command is not available in Cisco IOS software. For more information, see the Cisco 3900 Series, 2900 Series, and 1900 Series Software Configuration Guide .

To set the energywise level on the service module (SM), internal service module (ISM), or packet voice/data module (PVDM), use the **hw-moduleenergywiselevel**command in privileged EXEC mode.

hw-module *module-type* *slot-number* **energywise** **level** *level*

Syntax Description

module-type	Specifies the type of module.
slot-number	Specifies the slot, and if applicable, the sub slot number for the module.
energywise level	Specifies the power level for each module.
level	0-10. 0 will shut the power. Any number between 1 to 10 will turn the power on.

Command Default

The energywise level is 10.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Use the **hw-moduleenergywiselevel**command in privileged EXEC mode to set the energywise level on the SM, ISM, or PVDM on your router. Specify the slot, and if applicable, the sub slot number for the module.

The energywise levelsupported for the module is specified by the module. The following table provides a definition for each energywise level:

Energywise Level	Definition
0	Shut
1	Hibernate
2	Sleep
3	Standby
4	Ready
5	Low
6	Frugal

Energywise Level	Definition
7	Medium
8	Reduced
9	High
10	Full

Note When the router reboots, the energywise level is set to energywise level 10 and will remain at energywise level 10 till a different energywise level is applied.

Examples

The following example shows how to set the energywise level at shut on an SM in slot 1.

```
Router#hw-module
sm 1
 energywise level
0
```

The following example shows how to set the energywise level at full on an SM in slot 1.

```
Router#hw-module
sm 1
 energywise level
10
```

Related Commands

Command	Description
show environment	To display temperature, voltage, fan, and power supply information, use the **showenvironment** command in user EXEC or privileged EXEC mode.
show platform hw-module-power	To display the energywise levels supported on the module, and the current and previous energywise level on the router, use the show platform hw-module-power command in user EXEC or privileged EXEC mode.

hw-module fan-tray version

To set the fan-type (high or low power) version, use the **hw-modulefan-trayversion**command in privileged EXEC mode.

hw-module fan-tray version [{**1** | **2**}]

Syntax Description

1 | 2	(Optional) Specifies the version number; see the “Usage Guidelines” section for additional information.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Before you install a high-capacity fan tray, enter the **hw-modulefan-trayversion2** command to check for configuration problems, such as power-supply compatbility and power sufficiency. If there are no problems, a message is displayed to change the fan tray from version 1 to version 2. At this point, you can remove the old fan tray and quickly insert the new high-capacity fan tray.

The **hw-modulefan-trayversion2** command aplies to Cisco 7600 series routers configured with a Supervisor Engine 2. This command is not required in systems configured with a Supervisor Engine 720 or a Supervisor Engine 32.

This command is supported on the following chassis:

- WS-C6506
- WS-C6509
- WS-C6509-NEB/OSR7609

Set the version to **2** before installing higher power fan trays.

Set the version to **1** before downgrading to lower power fan trays.

Command confirmation does not change the fan power consumption or cooling capacity. It updates the backplane IDPROM. The new values take effect the next time that you insert a fan.

When you execute the command, the software checks the configurations and prompts for confirmation. Any illegal configurations (such as power-supply incompatibility) result in a warning being displayed and a command failure.

Examples

This example shows how to set the fan type for lower power fan trays:

```
Router#
hw-module fan-tray version 1
```

Related Commands

Command	Description
show environment cooling	Displays information about the cooling parameter.

hw-module interface als restart

To request a restart pulse when Automatic Laser Shutdown (ALS) restart mode is configured as manual, use the **h**w-module interface TenGigabitEthernet als restart command in Privileged EXEC mode.

hw-module interface TenGigabitEthernet slot/port als restart

Syntax Description

slot/port	Number of the chassis slot that contains the interface, where:
	• slot--Chassis slot number.
	• /port--Port number.
	  • For a 7600-ES+ITU-2TG, the valid values for the port are 1, 2.
	  • For a 7600-ES+ITU-4TG, the valid values for the port are 1, 2, 3, 4.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series router.

Examples

The following example shows how to request an ALS restart pulse for the Ten Gigabit Ethernet interface on slot 6 port number 2:

```
Router# hw-module interface TenGigabitEthernet 6/2 als restart
```

Related Commands

Command	Description
als	Enables the ALS mode.
als restart mode	Selects the ALS restart mode.
als restart pulse	Select the ALS pulse mode.
show als	Displays ALS status.
show controller dwdm	Displays G.709 alarms, alerts, and counters.
transport-mode	Configures a transport mode.

hw-module main-cpu qa error-recovery

To enable the recovery mechanism for a QA error condition on a Cisco 7500 series router, use the **hw-modulemain-cpuqaerror-recovery** command in global configuration mode. To disable the recovery mechanism for a QA error condition, use the **no** form of this command.

hw-module main-cpu qa error-recovery
no hw-module main-cpu qa error-recovery

Syntax Description

This command has no arguments or keywords.

Command Default

In Cisco IOS Release 12.0(24)S1, the recovery mechanism for a QA error condition is disabled; in all other releases, it is enabled.

Command Modes

Global configuration

Command History

Release	Modification
12.1(19)E	This command was introduced.
12.0(24)S1	This command was integrated into Cisco IOS Release 12.0(24)S1.
12.2(15)T5	This command was integrated into Cisco IOS Release 12.2(15)T5.
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)S.
12.0(26)S	This command was integrated into Cisco IOS Release 12.0(26)S.
12.3(6)	This command was integrated into Cisco IOS Release 12.3(6).

Usage Guidelines

QA errors are sometimes seen in heavy traffic situations and may indicate a hardware failure or a software bug. In the case of a hardware failure, a Versatile Interface Processor (VIP) or a Route Switch Processor (RSP) must be replaced. It is possible, however, to recover from a QA error and not see another error for months. When the same buffer header is present in two different queues, the QA ASIC goes into an error condition and triggers a QA error interrupt. The QA error interrupt causes the RSP to dump the QA diagnostics and perform a cbus complex during which all the line cards are reloaded. Although the duplicate buffer header condition does not always indicate a hardware failure, the downtime of up to 300 seconds creates a real problem in the network.

The **hw-modulemain-cpuqaerror-recovery** command has been created to enable a recovery mechanism for a QA error by allowing the router to remove the duplicate buffer header from the queue that shows the problem and requeue the buffer header. By using the QA error recovery, the downtime is reduced to less than one second under lab conditions. Three QA errors caused by buffer headers are permitted before the router performs a cbus complex and reloads all the line cards.

After three QA errors caused by duplicate queued buffer headers occur, the cbus complex is initiated and the line cards reload. Other QA errors, such as a null buffer header on any queue, can occur. Recovery is not possible in these cases, and the QA error triggers a cbus complex and subsequent line-card reloads. The QA error condition is specific to the Cisco 7500 series routers.

Examples

The following example shows how to enable the QA error recovery mechanism when a Cisco IOS Release 12.0(24)S1 image is used on a Cisco 7500 series router. In all other supported releases, the QA error recovery mechanism is enabled by default.

```
Router(config)# hw-module main-cpu qa error-recovery
```

Related Commands

Command	Description
show controllers cbus	Displays information about the cBus controller card.

hw-module mode

To configure the interface module from 10G to 5G mode, use the **hw-module mode** command in global configuration mode.

hw-module *slot* / *bay PID***mode** *mode*

Use the following command to disable the eight unused odd ports (1, 3, 5, 7, 9, 11, and 15) of A900-IMA8CS1Z-M interface modules within the slots of Cisco N560-RSP4 and Cisco N560-RSP4-E routers:

hw-module *slot 0-15* **im-mode** *1*

Syntax Description

Syntax Description:

slot	Physical slot number of the interface
bay	Bay of the interface
PID	Part number of the interface modules
mode	Option to select the mode of the interface module
mode	Selected mode of the Interface Module, for example 5G_CEM.

Command Default

Default is 10G mode

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.5.1	This command was introduced into the Cisco NCS 4200 Series, NCS 560 Series, and Cisco ASR 900 Series Routers.

Usage Guidelines

We recommend that you remove all the configurations before configuring 5G mode for the interface module. Do not use the **mode** keyword if you want to configure 10G mode.

Note Only 4-port-only mode is supported on the 8-port 10 Gigabit Ethernet Interface Module (8x10GE) interface module.

Examples

The following example shows how to configure configure 5G mode from 10G mode:

```
enable
configure terminal
platform hw-module configuration
hw-module 0 / 3 PID mode 5G_CEM
end
```

The following example shows the configuration of 8-port 10 Gigabit Ethernet Interface Module (8x10GE) interface module:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# platform hw-module configuration
Router(conf-plat-hw-conf)# hw-module 0/3 A900-IMA8Z mode ?
  4-ports-only  Four Ports

Router(conf-plat-hw-conf)#hw-module 0/3 A900-IMA8Z mode 4-ports-only

Interface configs would be defaulted before mode change?? [yes/no]: yes
```

Related Commands

Command	Description
show running-config | include mode	Verifies if the interface module is configured in 5G mode.

hw-module oversubscription

To administratively disable the oversubscribed ports (3, 4, 7, and 8) on a module, use the **hw-moduleoversubscription** command. Use the **no** form of this command to enable the oversubscribed ports.

hw-module module *num* **oversubscription**
no hw-module module *num* **oversubscription**

Syntax Description

module *num*	Applies the command to a specific module.

Command Default

Oversubscription is enabled by default.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)ZY	Support for this command was introduced (Cisco 76700 series router).
12.2(18)SXF5	Support for this command was intruduced (Catalyst 6500 series switch).

Usage Guidelines

This command is supported on the WS-X6708-10G-3C and the WS-X6708-10G-3CXL modules only.

When you disable the oversubscribed ports, the port is put into shutdown mode. In this mode, you cannot enter the **noshut** command on the disabled ports. If you attempt to enter the **noshut** command on the disabled ports, this message appears:

```
The current module is operating in non-oversubscription mode. To utilise this interface,
enable oversubscription mode for the module.
```

When you enter the **showinterfaces** command on the disabled ports, the output displays “disabled for performance” to distinguish between the normal port shutdown and the shutdown for performance.

Examples

This example shows how to administratively disable the oversubscribed ports on a module:

```
Router #
hw-module module 3 oversubscription
Router #
```

This example shows how to administratively enable the oversubscribed ports on a module:

```
Router #
no hw-module module 3 oversubscription
Router #
```

Related Commands

Command	Description
show interfaces	Displays traffic that is seen by a specific interface.

hw-module power-supply power-cycle

To power cycle the power supplies, use the **hw-modulepower-supplypower-cycle**command in privileged EXEC mode.

hw-module power-supply {**1** | **2**} **power-cycle**

Syntax Description

1 | **2**	Specifies the power supply to power cycle.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

If you have redundant power supplies and you power cycle one of the power supplies, only that power supply is power cycled. If you power cycle both power supplies, the system goes down and comes back up in 10 seconds.

If you only have one power supply and you power cycle that power supply, the system goes down and comes back up in 10 seconds.

This command works only on routers with an 8700 watt power supply.

Examples

This example shows how to power cycle a power supply:

```
Router# hw-module power-supply 2 power-cycle
Power-cycling the power supply may interrupt service.
Proceed with power-cycling? [confirm]
Power-cycling power-supply 1
22:10:23: %C6KPWR-SP-2-PSFAIL: power supply 1 output failed.
22:10:25: %C6KENV-SP-4-PSFANFAILED: the fan in power supply 1 has failed
22:10:33: %C6KPWR-SP-4-PSOK: power supply 1 turned on.
22:10:33: %C6KENV-SP-4-PSFANOK: the fan in power supply 1 is OK
Router#
```

hw-module pxf stall-monitoring

To enable the parallel express forwarding (PXF) stall monitor on the Cisco 10000 series router, and configure the default threshold values for resetting the line card (LC) and the Hyper Transport Data Protocol (HTDP), use the **hw-modulepxfstall-monitoring**command in the global configuration mode. To disable the PXF stall monitor, use the **no** form of this command.

hw-module pxf stall-monitoring [{**HT-Reset** *threshold-value* | **LC-Reset** *threshold-value*}]
no hw-module pxf stall-monitoring [{**HT-Reset** *threshold-value* | **LC-Reset** *threshold-value*}]

Syntax Description

HT-Reset *threshold-value*	Specifies the threshold value for HTDP reset. The valid value ranges from 4 to 6. By default, the threshold value is set to 3.
LC-Reset *threshold-value*	Specifies the threshold value for LC reset. The valid value ranges from 4 to 6. By default, the threshold value is set to 3.

Command Default

None

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)XNE	This command was introduced.

Usage Guidelines

Initially, use the **hw-modulepxfstall-monitoring**command to enable the PXF stall monitor on the Cisco 10000 series router. Then use the **hw-modulepxfstall-monitoring**command again, to configure the threshold values of LC and HTDP reset.

Examples

The following example shows how to enable the PXF stall monitor, and configure the threshold values of LC and HTDP reset, using the **hw-modulepxfstall-monitoring**command.

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# hw-module pxf stall-monitoring
Router(config)# hw-module pxf stall-monitoring HT-Reset 5
Router(config)# hw-module pxf stall-monitoring LC-Reset 4
```

Related Commands

Command	Description
show pxf stall-monitoring	Displays the current configuration and the operating status of the PXF stall monitor.

hw-module reset

To reset a module by turning the power off and then on, use the **hw-module reset** command in privileged EXEC mode.

hw-module module *num* **reset**

Syntax Description

module *num*	Applies the command to a specific module; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS 12.2(31)SB2.

Usage Guidelines

The *num* argument designates the module number. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

Examples

This example shows how to reload a specific module:

```
Router#
hw-module module 3 reset
```

hw-module sec-cpu reset

To reset and reload the standby Route Switch Processor (RSP) with the specified Cisco IOS image and to execute the image, use the **hw-modulesec-cpureset** command in privileged EXEC mode.

hw-module sec-cpu reset

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(16)ST	This command was introduced.
12.0(19)ST1	This command was enabled in privileged EXEC mode.
12.0(22)S	This command was integrated into Cisco IOS Release 12.0(22)S.
12.2(4)XF	This command was integrated into Cisco IOS Release 12.2(4)XF on the Cisco uBR10012 router.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3BC	This command was integrated into Cisco IOS Release 12.3BC.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Before using this command, you must use the **hw-moduleslotimage**global configuration command to specify a high availability Cisco IOS image to run on the standby RSP. After the high availability image is loaded in the active RSP, use the **hw-modulesec-cpureset** command to reset and reload the standby RSP with the specified Cisco IOS image and to execute the image. To load the standby RSP with the default micro-IOS software contained in the active RSP image instead of a high availability Cisco IOS image, use the **no** form of the **hw-moduleslotimage** command followed by the **hw-modulesec-cpureset**command.

Examples

The following example shows a Cisco 7513 router with the standby RSP loaded in slot 7. The standby RSP is reset and reloaded with the rsp-pv-mz high availability Cisco IOS image. Both RSPs have slot 0 flash memory cards.

```
Router(config)# hw-module slot 7 image slot0:rsp-pv-mz
Router(config)# end
Router# hw-module sec-cpu reset
```

Related Commands

Command	Description
hw-module slot image	Specifies a high availability Cisco IOS image to run on an active or standby RSP.

hw-module shutdown

To shut down the module, use the **hw-module shutdown** command in privileged EXEC mode.

hw-module module *num* **shutdown**

Syntax Description

module *num*	Applies the command to a specific module; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on the SSL Services Module and the NAM.

If you enter the hw-module **shutdown**command to shut down the module, you will have to enter the no power enable module command and the **power enable module** command to restart (power down and then power up) the module.

Examples

This example shows how to shut down and restart the module:

```
Router# hw-module module 3 shutdown
Router# no power enable module 3
Router# power enable module 3
```

hw-module simulate link-up

To enable softlink on a specified module, use the **hw-modulesimulatelink-up**command in privileged EXEC mode. For information on disabling softlink, refer to the "Usage Guidelines" section.

hw-module module *num* **simulate link-up**

Syntax Description

module *num*	Applies the command to a specific module; see the "Usage Guidelines" section for valid values.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(18)SXD	Support for this command was introduced on the Supervisor Engine 720 and the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Ethernet modules only.

To disable softlink on a module, you must perform one of the following procedures:

- Enter the **shutdown** and then the **noshutdown**commands on all the ports on the module.
- Enter the **hw-modulereset**command.

When you apply this command to a module, the port LEDs on the module will glow green and simulate a link-up condition. This command can be used for testing interface configurations without cabling to the interface.

The *num* argument designates the module number. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

Examples

This example shows how to enable softlink on a module:

```
Router# hw-module module 3 simulate link-up
Router#
```

Related Commands

Command	Description
hw-module reset	Resets a module by turning the power off and then on.

hw-module slot

T o enable the router shelf to restart a stopped Dial Shelf Controller (DSC) card, to stop a DSC card, or to cause a shutdown, reset, or reload of any specified dial shelf feature board, use the **hw-moduleslot**command in privliged EXEC mode and global configuration mode.

hw-module slot *shelf-id/slot-number* {**reload** | **reset** | **shutdown** {**powered** | **unpowered**} [**dual-wide**] | **start** | **stop**}

Syntax Description

shelf-id	Number of the dial shelf. The default number for the dial shelf is 1.
/ *slot-number*	Number of the slot in the shelf where the target feature board or DSC is installed. If the **start** or **stop** keyword is used, the slot number must be either 12 or 13, because these keywords apply only to DSCs.
reload	Enables a remote reload of an individual feature board without having to use manual online insertion and removal (OIR).
reset	Resets a feature board.
shutdown	Shuts down a feature board.
powered	Shuts down the DSC and all of its interfaces and leaves them in an administratively down state with power enabled.
unpowered	Shuts down the DSC and all of its interfaces and leaves them in an administratively down state without power.
dual-wide	(Optional) Specifies the dual-wide port adapter (PA).
start	Restarts the specified DSC.
stop	Stops the specified DSC.

Command Default

Shuts down the DSC and all of its interfaces and leaves them in an administratively down state with power enabled.

Command Modes

Global configuration (config) Privileged EXEC (#)

Command History

Release	Modification
11.3(6)AA	The **hw-module** command was introduced.
12.1	• The **hw-module** command was expanded to become the **hw-moduleslot**command. • The **reload** keyword was added to enable a remote reload of a feature board.
12.3(2)T	The**reset**and **shutdown** keywords were added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SB	This command's behavior was modified on the Cisco 10000 series router for the PRE3 and PRE4, and the **reload** option was introduced on the router.
15.0(1)M	This command was modified. The command became available in global configuration mode. The **powered**, **unpowered**, and **dual-wide** keywords were added.

Usage Guidelines

The **stop** form of this command is issued from the router shelf console instead of by pressing the attention (ATTN) button on the target DSC. Confirmation of when the start or stop took place is displayed. Warnings are issued and confirmation input is required if a **stop** command will result in a loss of service when backup functionality is not available.

When a DSC card is stopped, removed, and then reinstalled, there is no need to restart the card (whether the card is the original or a replacement) because a freshly installed card reboots as the backup DSC automatically. However, if a DSC is stopped, either by using the ATTN button or by issuing the **hw-moduleslotstop** command, it must be restarted by using the **start** form of the same command, or the DSC must be removed and reinstalled in order to reboot.

Press the ATTN button on the DSCs to shut down a card manually before removing the card. This is equivalent to issuing an **hw-moduleslot** command for that card at the router command prompt. Use the ATTN button to shut down the card before it is swapped out or tested in place, or to restart it, if the card has not been removed after having been shut down.

Tip The **hw-module** slot *shelf-id*/*slot-number***reload** form of this command is useful for simulating an OIR event in the case of a feature board failure when physical access to the feature board card is restricted.

Entering the **hw-module** slot *shelf-id*/*slot-number***reload**command initiates the feature board reload process through power cycling. The **hw-module** slot *shelf-id*/*slot-number***reload** command cannot be used to reload DSCs.

Use the **reset** form of this command to reset the specified feature card and drop all active calls.

Use the **shutdown** form of this command to shut down the specified feature card and drop all active calls.

Cisco 10000 Series Router Usage Guidelines,

In Cisco IOS Release 12.2(33)SB, when you enter the **hw-moduleslot***slot-number***reset** command, the software asks you to confirm the command.

In Cisco IOS Release 12.2(31)SB, the software does not ask you to confirm the **hw-moduleslot***slot-number***reset** command.

Examples

The following example shows how to stop the DSC in slot 13 and start the other DSC in slot 12 (which was previously stopped):

```
Router# hw-module slot 1/13 stop
Router# hw-module slot 1/12 start
```

The following example shows how to reload the dial shelf feature board in slot 6:

```
Router# hw-module slot 1/6 reload
```

The following example shows how to reset the card in slot 3:

```
Router# hw-module slot 1/3 reset
```

The following example shows how to shut down the PRE card located in slot 3:

```
Router# hw-module slot 1/3 shutdown powered
```

Related Commands

Command	Description
debug redundancy	Displays information used for troubleshooting dual (redundant) DSC cards.
show redundancy	Displays current or historical status and related information on dual (redundant) DSC cards.

hw-module slot (6500)

To enable ports on a module, use the **hw-moduleslot** command. To disable ports on a module, use the **no** form of this command.

hw-module slot *num* {**clear-block** | **oversubscription**} [**port-group** *num*]
no hw-module slot *num* {**clear-block** | **oversubscription**} [**port-group** *num*]

Syntax Description

slot *num*	Applies the command to a specific module.
clear-block	Drops the packets that are destined for jammed ports and continues delivering the packets for other ports.
oversubscription	Administratively disables the oversubscribed ports on a module. To enable oversubscription, use the **no** form of this command.
port-group *num*	(Optional) Applies the command to a specific port group on the module. The range depends on the module type.

Command Default

The default settings are as follows:

- Clear block is enabled by default.
- Oversubscription is enabled by default.

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXF5	Support for this command was introduced (Catalyst 6500 series switch).
12.2(33)SXH1	Support for these keywords and arguments were introduced: • clear-block [port-group *num* • oversubscription [port-group *num*
12.2(33)SXH2	This command was changed to support the following modules: • WS-X6716-10G-3C • WS-X6716-10G-3CXL

Usage Guidelines

This command is supported on the following modules:

- WS-X6708-10G-3C--The port-group *num* and the clear-block keywords and argument are not supported.
- WS-X6708-10G-3CXL--The port-group *num* and the clear-block keywords and argument are not supported.
- WS-X6716-10G-3C

- WS-X6716-10G-3CXL

When you disable the oversubscribed ports, the port is put into shutdown mode. In this mode, you cannot enter the **noshut** command on the disabled ports. If you enter the **noshut** command on the disabled ports, this message appears:

```
The current module is operating in non-oversubscription mode. To utilise this interface,
enable oversubscription mode for the module.
```

When you enable oversubscription for a port group, the port group is in mux mode. When you disable oversubscription, the port group is in transparent mode. When a group is in transparent mode, the first port in the group retains its administrative status and the remaining three ports are administratively shut down. You cannot enter the **shut**, and then the **noshut** commands on the disabled ports. You can enter the **shut**, and then the **noshut** commands on the enabled port in the group.

The port-group mappings for the WS-X6716-10G-3C and the WS-X6716-10G-3CXL modules are as follows:

- Group 1--Ports 1 to 4. Port 1 is enabled in transparent mode.
- Group 2--Ports 5 to 8. Port 5 is enabled in transparent mode.
- Group 3--Ports 9 to 12. Port 9 is enabled in transparent mode.
- Group 4--Ports 13 to 16. Port 13 is enabled in transparent mode.

For the WS-X6716-10G-3C and the WS-X6716-10G-3CXL modules in transparent mode, ports 2, 3, 4, 6, 7, 8, 10, 11, 12, 14, 15, 16 are disabled.

If you specify a slot number without a group number, all four groups are put into transparent/mux mode.

You cannot put the port group into oversubscription mode when any port in the port group is configured as a virtual switch link (VSL). A warning message is displayed asking you to disable the VSL link before changing to oversubscription mode.

When you enter the **showinterfaces** command on the disabled ports, the output displays “disabled for performance” to distinguish between the normal port shutdown and the shutdown for performance.

Each 4-port group shares a common packet queue. If head-of-line blocking is enabled and one port of the four ports receives a pause frame, all packets are blocked behind this packet until the packet is delivered to the flow-controlled port. You can enter the **hw-moduleslot**clear-block [port-group *num*] command to drop the packets that are destined for the jammed port and continue to deliver the packets for other ports.

Examples

This example shows how to administratively disable the oversubscribed ports on a module:

```
Router#
no hw-module slot 3 oversubscription
Router#
```

This example shows how to administratively disable the oversubscribed ports on a specific port group:

```
Router#
no hw-module slot 3 oversubscription port-group 4
Router#
```

This example shows how to administratively enable the oversubscribed ports on a module:

```
Router#
hw-module slot 3 oversubscription
Router#
```

This example shows how to drop the packets that are destined for the jammed port and continue to deliver the packets for other ports:

```
Router#
hw-module slot 3 clear-block port-group 4
Router#
```

Related Commands

Command	Description
show interfaces	Displays traffic that is seen by a specific interface.
show hw-module slot	Displays information for a SPA interface processor (SIP) or other module.

hw-module slot (7300)

To prepare a line card, MSC, or PCI port adapter carrier card for online removal, use the**hw-moduleslot** command in privileged EXEC mode.

hw-module slot *slot-number* {**stop** | **start**}

Syntax Description

slot-number	Specifies the slot number of the line card, MSC, or PCI port adapter carrier card.
stop	Stops traffic, turns on the OIR LED, shuts down all interfaces, and deactivates the line card, MSC, or PCI port adapter carrier card.
start	Restarts the line card and shuts off the OIR LED, putting the hardware back online.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was enabled on the Cisco 7304 router.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2(18)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **hw-moduleslot***slot-number***stop**command to stop traffic, turn on the green OIR LED, and shut down all interfaces to remove a line card, MSC, or PCI port adapter carrier card from the Cisco 7304 router without disrupting data flow. You should not remove hardware while traffic is still running.

The **stop** keyword stops traffic through interfaces and deactivates the hardware. When the OIR LED turns green, the hardware has been deactivated and can be physically removed.

The **hw-moduleslot***slot-number***start**command restarts the line card, MSC, or PCI port adapter carrier card and shuts off the OIR LED, putting the card back online.

Use the **hw-moduleslot***slot-number***start**command if you issue the **hw-moduleslot***slot-number***stop** command, did not remove the hardware, and now want to reactivate it. If you remove and then reinsert the hardware, the hardware restarts without this command.

This command cannot be used for online removal of SPAs. For online removal of SPAs, use the **hw-modulesubslot** command.

You can also use thiscommand to restore a line card, MSC, or PCI port adapter carrier card that has been deactivated due to some failure.

> **Note** Line cards, MSCs, and PCI port adapter carrier cards are automatically initialized after being inserted or after a system bootup. You do not need to issue the**hw-moduleslot***slot-number***start** command.

Examples

The following example shows how to deactivate the line card, MSC, or PCI port adapter carrier card in slot 2. After entering this command and the green OIR LED turns on, you can remove the hardware and insert a new piece of hardware:

```
Router# hw-module slot 2 stop
```

The following example shows how to reactivate a line card, MSC, or PCI port adapter carrier card in slot 2. You only need to enter this command if you enter the **hw-moduleslot** *slot-number***stop** command but do not remove the hardware and instead want to restart the hardware.

```
Router# hw-module slot 2 start
```

Related Commands

Command	Description
hw-module subslot	Prepares a SPA for online removal.
show c7300	Displays the types of cards (NSE and line cards) installed in a Cisco 7304 router.
show diag	Displays hardware information for any slot or the chassis.
show c7300 errorlog	Displays error information on a Cisco 7304 series router.
show platform errorlog	Displays error information for any installed card.

hw-module slot (7600)

To enable ports on a module, use the **hw-module slot** command in global configuration mode. To disable the ports, use the **no** form of this command.

hw-module slot *slot-number* {**memory test full** | **oversubscription** | **pos** | **process-max-time** *number-of-seconds* | **rate-limit** {**fsol_rate** *fsol-rate* | **punt_rate** *punt-packet-rate*} | **srp** | **subslot** *subslot-number* **only** | **mp-recovery-enable** | **ipv6-hbh-rl** *rate* }
no hw-module slot *slot-number* {**memory test full** | **oversubscription** | **pos** | **process-max-time** *number-of-seconds* | **rate-limit** {**fsol_rate** *fsol-rate* | **punt_rate** *punt-packet-rate*} | **srp** | **subslot** *subslot-number* **only** | **mp-recovery-enable** | **ipv6-hbh-rl** *rate* }

Syntax Description

slot-number	Chassis slot number.
memory	Specifies the memory settings of a module.
test	Specifies the memory options available for testing.
full	Performs a complete memory test on the Lower Circuit (LC).
oversubscription	Administratively disables the oversubscribed ports on a module.
pos	Converts a module to packet-over-SONET (POS) mode.
process-max-time	Specifies the maximum time for which the process runs before it stops the processor.
number-of-seconds	Number of milliseconds before the processor suspends voluntarily.
rate-limit	Limits the packets that are sent to the Route Processor (RP).
fsol_rate *fsol-rate*	Limits the broadband and Ethernet Flow Point (EFP) First Sign of Life (FSOL) packets, in bits per second (b/s). The default is 40000 b/s (or 50 packets per second for a 100-byte packet). • This keyword is specific to the ES+ line card.
punt_rate *punt-packet-rate*	Limits the Layer 4 and Port-Bundle Host Key (PBHK) packets, in bits per second (b/s). The default is 1000000 b/s. • This keyword is specific to the ES+ line card.
srp	Converts a module to Spatial Reuse Protocol (SRP) mode.
subslot *slot-number* **only**	Specifies the secondary slot number to enable a slot to support a single Shared Port Adapter (SPA).
mp-recovery-enable	Enables metropolis stuck recovery. This option is enabled by default. Use the **no** form to disable this option.

ipv6-hbh-rl *rate*	Specifies the policing rate-limit for the IPv6 Hop-by-Hop extension header packets. • For the SIP-400, you can configure a rate of up to 25600 packets per second (PPS). The default police rate is 21.36 kpps. • For the ES+ line cards, you can configure a rate of up to 100000 kbps. The default police rate is 12000 kbps.

Command Default

Ports are not enabled on a module.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)S	This command was introduced.
15.2(4)S	This command was modified. The **mp-recovery-enable** keyword was added.
12.2(33)SRE6	This command was integrated into Cisco IOS Release 12.2(33)SRE6.
12.2(33)SRE7	This command was modified. The **mp-recovery-enable** keyword was added.
15.3(1)S	This command was modified. The **ipv6-hbh-rl** keyword was added.

Usage Guidelines

- The FSOL queue is used by broadband FSOL and EFP FSOL.
- The punt queue is used by Layer 4 and PBHK packets.
- An increase in the number of either FSOL or punt rate limiters enables more packets to reach the RP. This increase exerts more load on the RP CPU. Therefore, changing the default values of either FSOL or punt rate limiters is not recommended.
- On the ES+ line cards, setting the police rate to 0 turns off the policing. On the SIP-400, the policing does not stop but all the packets are dropped.
- For both the ES+ line cards and the SIP-400, when the policer is set from the line card console, the setting remains effective even if the line card is moved to another chassis running the Cisco IOS Release 15.3(1)S or later images.
- For the SIP-400, IPv6 HBH packets continue to go through the QoS policing configured on the line card. For the ES+ line cards, IPv6 HBH packets bypass any QoS policing configured on the line card.

Examples

The following example shows how to set the FSOL rate to 50000 b/s:

```
Device(config)# hw-module slot 2 rate-limit fsol_rate 50000
```

The following example shows how to set the punt rate to 70000 b/s:

```
Device(config)# hw-module slot 2 rate-limit punt_rate 70000
```

The following example shows how to set the rate limit for the IPv6 Hop-by-Hop extension header packets to 777 kbps:

```
Device(config# hw-module slot 2 ipv6-hbh-rl 777
```

Related Commands

Command	Description
show hw-module slot	Displays system information for a SPA interface processor (SIP) or a module.

hw-module slot (ASR 1000 Series)

To start, stop, reload, or enable logging for an Embedded Services Processor (ESP), Route Processor (RP), or Shared Port Adapter (SPA) Interface Processor (SIP) on a Cisco ASR 1000 Series Aggregation Services Router, use the **hw-moduleslot** command in privileged EXEC or global configuration or diagnostic mode.

hw-module slot *slot action*

Syntax Description

slot	Slot on which logging action is to be taken. Options are as follows: • *number* --the number of the SIP slot. • **f0** --The ESP in ESP slot 0. • **f1** --The ESP in ESP slot 1 • **r0** --The RP in RP slot 0. • **r1** --The RP in RP slot 1.
action	The action to take on the hardware in the specified *slot*. Options are as follows: • **logging onboard** [**disable**| **enable**] --Disables or enables onboard logging of the hardware. • **reload** --Reloads the specified hardware. • **start** --Starts the hardware if it has been stopped. • **stop** --Stops the hardware if it is currently active.

Command Default

The router sends and receives traffic by default, so this command is not necessary to enable any hardware on a router. Onboard logging for all of the hardware is enabled by default.

Command Modes

Diagnostic (diag) Privileged EXEC (#) Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.

Usage Guidelines

The **hw-moduleslot** command does not have a **no** form.

To start, stop, or reload a SPA, use the **hw-modulesubslot**command.

The **stop** and **reload** options cannot be used on an active RP.

All traffic to hardware that has been set to stop using the **stop** option will be dropped until the hardware is reenabled by either physically removing and reinserting the hardware, or entering the **start** option. After the hardware is modified as appropriate or the **start** option is entered, the hardware has to reinitialize before it is able to send and receive traffic. Note that in some cases reinitialization can take several minutes, and that the reinitialization time required depends on the hardware and the system configuration.

When a SIP is stopped, all traffic to all SPAs in the SIP is dropped. The SPAs in the SIP can begin receiving traffic after the SIP is restarted using the **start** option and all SPAs and the SIP finish reinitializing.

Since this is a privileged EXEC-level command, this command setting cannot be saved to the startup configuration and therefore the command setting cannot be maintained after a system reload. If you want the hardware to stay in the **stop** state across system reloads, use the **hw-moduleslot***slot***shutdown** global configuration command.

The **reload** option can be used to reload hardware for any reason; for example, to finish a software upgrade that requires reloading of the hardware or to reload the hardware as part of a troubleshooting step.

The contents of onboard logging logs can be displayed using the **showloggingonboardslot** privileged EXEC and diagnostic mode commands.

Enter the **showloggingonboardslot***slot***status** privileged EXEC or diagnostic command to see if onboard logging is enabled or disabled for the hardware in a particular slot.

When the **hw-moduleslot***slot***loggingonboarddisable** command is entered, onboard logging for the specified hardware component is disabled but the existing logs are preserved; if you want to erase the existing logs, enter the **clearloggingonboardslot** command.

When the **hw-moduleslot** command is entered in global configuration mode (for ESP40 and SIP40 cards), you have a link option that allows you to choose among a set of backplane enhanced serializer/deserializer (SerDes) interconnect (ESI) links between ESP and a given SIP slot. The range of possible values for the link depends on the type of ESP and SIP cards. Only a combination of ESP40 and SIP40 cards can have more than two ESI links (link A and link B). All other cards have only link A. For example, a combination of ESP40 and SIP10 or ESP20 and SIP40 cards can have only one link (link A).

Examples

The following example shows how to stop the RP in RP slot 0:

```
Router# hw-module slot r0 stop
```

The following example shows how to disable the onboard logging for the RP in RP slot 0. The output of the **showloggingonboardslotr0status**command is given both before and after onboard logging is disabled to verify that onboard logging was properly disabled.

```
Router# show logging onboard slot r0 status

Status: Enabled
Router# hw-module slot r0 logging onboard disable
Router# show logging onboard slot r0 status

Status: Disabled
```

The following example shows how to display the available link options for ESP40 and SIP40 cards:

```
Router(config)# hw-module slot 0 qos input link ?
A  ESI Link A
B  ESI Link B
```

Related Commands

Command	Description
clear logging onboard slot	Clears the data in an onboard slot log.
hw-module subslot	Starts, stops, or reloads a SPA.

Command	Description
show logging onboard slot	Displays the status of onboard logging, or the contents of an onboard logging log.

hw-module slot image

To specify a high availability Cisco IOS image to run on an active or standby Route Switch Processor (RSP), use the **hw-moduleslotimage** command in global configuration mode. To remove a high availability Cisco IOS image from the running configuration, use the **no** form of this command.

hw-module slot *slot-number* **image** *file-spec*
no hw-module slot *slot-number* **image** *file-spec*

Syntax Description

slot-number	Specifies the number of the RSP slot.
file-spec	Specifies the flash memory card location to load the image into and the name of the image.

Command Default

No high availability Cisco IOS images are specified to run on the active or standby RSPs.

Command Modes

Global configuration

Command History

Release	Modification
12.0(16)ST	This command was introduced.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.

Examples

The following example shows a Cisco 7513 router with the active RSP loaded in slot 6 and the standby RSP loaded in slot 7. The rsp-pv-mz high availability Cisco IOS image is specified to run on both the active and the standby RSP. Both RSPs have slot 0 flash memory cards.

```
Router(config)# hw-module slot 6 image slot0:rsp-pv-mz
Router(config)# hw-module slot 7 image slot0:rsp-pv-mz
```

Related Commands

Command	Description
hw-module sec-cpu reset	Resets and reloads the standby RSP with the specified Cisco IOS image and executes the image.
mode (HSA redundancy)	Configures the redundancy mode.
redundancy	Enters redundancy configuration mode.

hw-module slot subslot only

Note This command is deleted effective with Cisco IOS Release 12.2SXI.

To change the mode of the Cisco 7600 SSC-400 card to allocate full buffers to the specified subslot, use the **hw-moduleslotsubslotonly** command in global configuration mode. If this command is not used, the total amount of buffers available is divided between the two subslots on the Cisco 7600 SSC-400.

Note This command automatically generates a reset on the Cisco 7600 SSC-400. See Usage Guidelines below for details.

hw-module slot *slot* **subslot** *subslot* **only**

Syntax Description

slot	Chassis slot number where the Cisco 7600 SSC-400 is located. Refer to the appropriate hardware manual for slot information. For SIPs and SSCs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on the SSC where the IPSec VPN SPA is installed.

Command Default

No default behavior or values.

Command Modes

Global configuration mode

Command History

Release	Modification
12.2(18)SXF2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2SXI	This command was deleted.

Usage Guidelines

Follow these guidelines and restrictions when configuring a Cisco 7600 SSC-400 and IPSec VPN SPAs using the **hw-moduleslotsubslotonly**command:

- This command is useful when supporting IP multicast over GRE on the IPSec VPN SPA.
- When this command is executed, it automatically takes a reset action on the Cisco 7600 SSC-400 and issues the following prompt to the console:

```
Module n will be reset? Confirm [n]:
```

The prompt will default to "N" (no). You must type "Y" (yes) to activate the reset action.

- When in this mode, if you manually plug in a second SPA, or if you attempt to reset the SPA (by entering a **nohw-modulesubslotshutdown** command, for example), a message is displayed on the router console which refers you to the customer documentation.

Examples

The following example allocates full buffers to the SPA that is installed in subslot 0 of the SIP located in slot 1 of the router and takes a reset action of the Cisco 7600 SSC-400.

```
Router(config)# hw-module slot 4 subslot 1 only
Module 4 will be reset? Confirm [no]: y
```

Note that the prompt will default to "N" (no). You must type "Y" (yes) to activate the reset action.

Related Commands

Command	Description
ip multicast-routing	Enables IP multicast routing.
ip pim	Enables Protocol Independent Multicast (PIM) on an interface.

hw-module standby

To reset the standby Route Processor (RP), use the **hw-modulestandby**command in privileged EXEC mode.

hw-module standby {**reset** | **reload**}

Syntax Description

reset	Resets the redundant RP.
reload	Reloads the redundant RP.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(10)EX2	This command was introduced.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2(18)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to reset or reload the standby RP. Use the **reload** keyword to cause the standby RP to reload with an upgraded image. Use this option when the standby RP is operating normally. Use the **reset**keyword for a hard reset of the standby RP. Use this option if the standby RP is experiencing problems and does not respond to the **reload** option.

Examples

The following example shows how to reset the standby RP (NSE-100):

```
Router# hw-module standby reset
Proceed with reset of standby NSE? [confirm]y
```

The following example shows an attempt to reset a standby RP, which is down or experiencing some other problem such as being hung.

```
Router# hw-module standby reload
Proceed with reload of standby NSE? [confirm]y
%Standby RP is not up
```

If there is a failure to reset a standby RP because it is in some fault condition, try performing a reload of the RP.

The following example shows how to reload the standby RP:

```
Router# hw-module standby reload
Proceed with reload of standby NSE? [confirm]y
```

Related Commands

Command	Description
debug redundancy	Enables RP redundancy debugging.
redundancy force-switchover	Forces the standby RP to assume the role of the active RP.
show c7300	Displays the types of cards (RP and line cards) installed in a Cisco 7304 router.
show redundancy	Displays redundancy information for the active and standby RPs.

hw-module subslot

To restart, stop, or start a shared port adapter (SPA) and its interfaces, use the **hw-modulesubslot**command in privileged EXEC mode.

hw-module subslot *slot/subslot* {**reload** [**force**] | **start** | **stop** [**force**]}

For ASR 900 Series Routers, **hw-module** *slot* / *subslot* [**default** | **ether-mode 1G** | **ether-mode 10G**]

Syntax Description

slot	Physical slot number of the interface
subslot	Subslot of the interface
default	Default of all the interfaces of the interface module
ether-mode 1G	Mode of the ethernet imterface module
ether-mode 10G	Mode of the ethernet imterface module

Command Default

The SPA and its interfaces are not started.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(25)S3	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE on the Cisco 7600 series router and Catalyst 6500 series switch.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE Release 2.4	This commad was modified. The **force** keyword was added. This command was integrated into Cisco IOS XE Release 2.4.
Cisco IOS XE 16.5.1 Everest	The keyword **ether-mode 1G** was introduced.

Usage Guidelines

The **hw-modulesubslot** command stops and starts power to the SPA. This command is useful when you want to restart all interfaces on a SPA. When the **stop** and **reload** keywords are used, you get a prompt to confirm. Enter “y” or use the return key to confirm. Power to the SPA is now stopped or reloaded. If you use the **force** keyword along with the **reload** keyword, you can proceed further without getting any prompt for confirmation. The Excalibur and Ethernet Services cards do not have the **reload** option.

The command is recommended to restart a SPA under the following conditions:

- To restart a SPA after it has been powered off because of a failure.
- To recover from corrupted messaging between the Route Processor (RP) and the SIP.

Examples

The following command power cycles the SPA in subslot 1 of the SIP installed in chassis slot 1:

```
Router# hw-module subslot 1/1 reload
Proceed with reload of module? [confirm]
```

Related Commands

Command	Description
show hw-module subslot oir	Displays the operational status of a SPA.

hw-module subslot (4400)

To restart, stop, or start a module and its interfaces, use the **hw-modulesubslot** command in privileged EXEC mode.

hw-module subslot *slot/subslot* {**reload** | **start** | **stop** }

Syntax Description

reload	Restarts the target subslot.
slot	Specifies the chassis slot number where the module is installed. Refer to the hardware installationg guide for more information on slots. For module and interfaces, refer to the module-specific hardware installation guide.
start	Activates the specified module.
stop	Stops the specified module.
/ *subslot*	Specifies the subslot number of the chassis where the module is installed. Refer to the hardware installation guide for subslot information.

Command Default

The modules and its interfaces are not activated.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced.

Usage Guidelines

The **hw-module subslot** command allows you to stop and start the power supply to a supported cisco services or network interface module (NIM) on a Cisco 4400 Series Integrated Services Router (ISR). This functionality is also referred as the online insertion and removal (OIR) and it is useful when you want to remove a module from one of the subslots while another active module remains installed on your router.

Note If you are not planning to immediately replace a module, ensure that you install a blank filter plate in the subslot.

The **stop** option allows you to gracefully deactivate a module and the module is rebooted when the **start** command is executed. The **reload** option will stop or deactivate a specified module and restart it.

Examples

The following command activates a module in subslot 1:

```
Router# hw-module subslot 1/1 start
```

Related Commands

Command	Description
show hw-module subslot oir	Displays the operational status of a module.

hw-module subslot ethernet vlan unlimited

To remove the restriction of a maximum of 8100 IEEE 802.1Q VLANs per Ethernet shared port adapter (SPA), use the **hw-modulesubslotethernetvlanunlimited** command in global configuration mode. To disable and return to a maximum limit of 8100 VLANs per SPA, use the **no** form of this command.

hw-module subslot *slot/subslot* **ethernet vlan unlimited**
no hw-module subslot *slot/subslot* **ethernet vlan unlimited**

Syntax Description

slot /	Specifies the chassis slot number where the SIP is installed.
subslot	Specifies the slot of the SIP where the SPA is installed.

Command Default

There is no default behavior or values. When this command is not configured, up to 8100 dot1q VLANs per Ethernet SPA are supported.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.5	This command was introduced.

Usage Guidelines

For any Ethernet SPA on the Cisco ASR 1000 Series aggregation services routers, the maximum number of IEEE 802.1Q VLANs that can be configured per port is 4094. The default total maximum number of VLANs per SPA is 8100.

The limit on this total maximum number of VLANs per SPA (which means, the default of 8100 VLANs) can be removed using the **hw-modulesubslotethernetvlanunlimited** command. However, the limit on the maximum number of VLANs per Ethernet port or interface (i.e. 4094) still applies. Therefore, the new maximum number of supported VLANs per SPA varies by the number of ports on the SPA multiplied by 4094. On the 5-Port Gigabit Ethernet SPA, you can configure up to 20,470 dot1q (or unambiguous QinQ) VLANs. On an 8-Port Gigabit Ethernet SPA, you can configure up to 32752 dot1q (or unambiguous QinQ) VLANs.

When the **hw-modulesubslotethernetvlanunlimited** command is configured, VLAN filtering, accounting, and classification are no longer performed by the Ethernet SPA and all 802.1Q frames and QinQ frames are processed by the Quantum Flow Processor (QFP) on the Cisco ASR1000 Series Router. Sending all of the dot1q VLAN frames to the QFP (without filtering) may reduce the QFP packet switching performance.

The default classification of CoS bits 6-7 as high priority is still supported. However, other user-defined CoS values for high and low priority classification using the **plimqosinputmapcosqueue** command are not supported when this command is in use.

Examples

The following example enables support for maximum per-port dot1q VLAN configuration for the SPA located in the first subslot (0) of the SIP located in slot 1 of the Cisco ASR1000 Series Router:

```
Router(config)# hw-module subslot 1/0 ethernet vlan unlimited
```

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on the router.

hw-module subslot (LAN WAN)

To configure the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter to run in either the LAN mode or WAN mode, use the **hw-modulesubslotslot/subslotenable{LAN|WAN}**commandin Global configuration mode.

hw-module subslot *slot/subslot* **enable** {**LAN** | **WAN**}

Syntax Description

slot/subslot	The slot and subslot number in which the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter has been installed.
enable	Enables the specified LAN or WAN operational mode on the SPA.
LAN	Specifies the LAN mode of operation for theCisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter.
WAN	Specifies the WAN mode of operation for the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter.

Command Default

By default, the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter operates in the WAN mode when the SPA boots-up.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

By default, the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter initializes in the WAN mode. The Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter can operate in either the LAN mode or the WAN mode. To change the LAN mode or WAN mode, execute the **hw-modulesubslot***slot/subslot***enable** {**LAN** | **WAN**} command from the Global configuration mode.

Examples

The following example shows how to enable the LAN mode on a Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter:

```
Router# config
Router(config)# hw-module subslot 2/1 enable LAN
```

The following example shows how to enable the WAN mode on a Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter:

```
Router# config
Router(config)# hw-module subslot 2/1 enable WAN
```

Tip

If the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter is working in LAN mode, you can change the mode to WAN by either using the **hw-modulesusblot***slot/subslot***enableWAN** command.

Related Commands

Command	Description
show controllers wanphy	Displays the SPA mode (LAN mode or WAN mode), alarms, and the J1 byte string value.

hw-module subslot service-engine session

To open a console session to access the Cisco WebEx Node SPA console, use the **hw-modulesubslotservice-enginesession**command in privileged EXEC mode.

hw-module subslot *slot/subslot* **service-engine session**

Syntax Description

slot	Specifies the chassis slot number for the Cisco ASR 1000 Series Router SIP.
/ *subslot*	Specifies the secondary subslot number on a Cisco ASR 1000 Series Router SIP where a SPA is installed.

Command Default

No command default.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

To open a console session on a Cisco WebEx Node SPA, the SPA must first be configured with a minimum of the following commands:

- **ip address**
- **service-engine ip address**
- **service-engine default-gateway**

The **service-engineipaddress** command must be configured before the **service-enginedefault-gateway** command.

Examples

The following example shows how to access the console for a WebEx Node SPA located in slot 1/0, and the change to the SPA console prompt (service-spa is the default hostname) when complete:

```
Router# hw-module subslot 1/0 service-engine session
MontaVista(R) Linux(R) Carrier Grade Edition 5.0 (custom)
Linux/mips64 2.6.21_mvlcge500-octeon-mips64_octeon_v2_be
        Vegas Shell  --  CGE 5.0 Version
        Copyright (c) 1985-2008 by Cisco Systems, Inc.
        All rights reserved.
service-spa#
```

Related Commands

Command	Description
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.

Command	Description
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.

hw-module subslot session

To start or close a Cisco Integrated Management Controller (CIMC) session or host server module session, use the **hw-module subslot session** command in privileged EXEC mode.

hw-module subslot *slot/subslot* **session** {**imc** | **server**}

Syntax Description

slot/	Number of the router slot in which the server module is installed. **Note** For the NIM E-Series NCE, the slot number is 0.
subslot	Number of the subslot in which the server module is installed. **Note** For Cisco UCS E-Series Servers and the SM E-Series NCE, the subslot number is 0.
imc	Starts a session with CIMC.
server	Starts a session with the host server module.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).
Cisco IOS XE Release 3.15S	This command was supported on an additional platform: the NIM E-Series Network Compute Engine (NIM E-Series NCE) installed in a Cisco ISR 4000 series.

Usage Guidelines

Only one active session is allowed on the CIMC or server module at any time.

Examples

The following example shows how to start a CIMC session in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# hardware-module subslot 1/0 session imc
```

The following example shows how to start a server module session in an E-Series Server installed in a Cisco ISR 4000 series:

```
Router# hardware-module subslot 1/0 session server
```

hw-module subslot shutdown

To disable a shared port adapter (SPA) with or without power, and save the configuration to the configuration file, use the **hw-modulesubslotshutdown**command in global configuration mode. To re-enable the SPA, use the **no** form of this command.

hw-module subslot *slot/subslot* **shutdown** [{**powered** | **unpowered**}]
no hw-module subslot *slot/subslot* **shutdown** [{**powered** | **unpowered**}]

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
powered	(Optional) Shuts down the SPA and all of its interfaces, and leaves them in an administratively down state with power enabled. This is the default state.
unpowered	(Optional) Shuts down the SPA and all of its interfaces, and leaves them in an administratively down state wihout power.

Command Default

If this command is not used, **nohw-modulesubslotshutdown** is the default behavior. When **nohw-modulesubslot** is configured, the SPA will be powered for normal operation.

If the **hw-modulesubslotshutdown** command is entered but neither **powered** or **unpowered** are specified in the CLI, **powered** is the default behavior.

Command Modes

Global configuration

Command History

Release	Modification
12.2(25)S3	This command was introduced.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When you shut down a SPA using this command, you can choose to put it into one of two states:

- Powered state--(Default) Shuts down the SPA, but the SPA remains powered on. Use this option when you plan to leave the SPA physically installed and cabled in the SPA. You might choose to do this if you want to install a SPA and configure it, but do not want it online or to start communicating with the remote end of the connection.

- Unpowered state--Shuts down the SPA and removes power from the SPA. Use this option when you plan to remove the SPA from the chassis.

This command is useful when a user wants all the interfaces on a SPA disabled but does not or cannot remove the SPA. Unlike the **hw-modulesubslotstop** EXEC command on the Cisco 7304 router, this command is saved in the configuration file and will keep the SPA disabled when other router events (such as a router reload or OIR) attempt to restart the SPA. All other settings and configurations of the SPA will be maintained even if the SPA itself is shutdown using this command.

As a general rule, you do not need to shut down a SPA if you are removing it and replacing it with the same exact model of SPA in an online insertion and removal (OIR) operation. However, you should shut down a SPA whenever you are replacing a SPA with a different model of SPA.

When you shut down a SPA using the **hw-modulesubslotshutdown**command, it remains shutdown even if you reset the SPA or install a new SPA in that subslot. To begin using the card again, you must manually re-enable the card using the **nohw-modulesubslotshutdown**command.

Note This is a global configuration command, not an EXEC command. On the Cisco 7304 router, another **hw-modulesubslot** command is also available in EXEC mode, but that command is used for different purposes. An important distinction between this command and the **hw-modulesubslot** command in EXEC mode on the Cisco 7304 router is that this command is saved in the configuration.

Examples

The following example shows how to disable the SPA in subslot 4/1 while leaving the SPA in the SPA chassis. This command will be saved to the configuration file and no actions, outside of changing this configuration, will re-enable the SPA:

```
Router(config)# hw-module subslot 4/1 shutdown unpowered
```

The following example shows how to configure the SPA to resume normal operation after the unpowered option has been used to disable the SPA:

```
Router(config)# hw-module subslot 4/1 shutdown powered
```

No messages are provided on the console when you shut down or re-enable a SPA.

Related Commands

Command	Description
show hw-module subslot oir	Displays the operational status of a SPA.
hw-module slot [1]	Deactivates or reactivates a carrier card that is installed in a router slot. This command is entered in EXEC mode and is not saved to the configuration file.

1 Refer to the Cisco 7300 Series Platform-Specific Commands publication.

hw-module subslot shutdown (4400)

To disable a module with or without power, and save the configuration to the configuration file, use the **hw-module subslot shutdown** command in global configuration mode. To re-activate the module, use the **no** form of this command.

hw-module subslot *slot /subslot* **shutdown** [{**powered** | **unpowered**}]
no hw-module subslot *slot /subslot* **shutdown** [{ **powered** | **unpowered** }]

Syntax Description

slot	Specifies the chassis slot number where the module installed. Refer to the hardware installation guide for more information on slots. For information on modules and interfaces, refer to the module specific hardware installation guide.
/ *subslot*	Specifies the subslot number of the chassis where the module is installed. Refer to the hardware installation guide for subslot information.
powered	(Optional) Shuts down the module and all of its interfaces, and leaves them in an administratively down state with power enabled. This is the default state.
unpowered	(Optional) Shuts down the module and all of its interfaces, and leaves them in an administratively down state without power.

Command Default

If this command is not used, **no hw-module subslot shutdown** is the default behavior. When **no hw-module subslot** is configured, the module is powered on for normal operation.

If the **hw-module subslot shutdown** command is entered but neither **powered** or **unpowered** are specified in the CLI, **powered** is the default behavior.

Command Modes

Global configuration

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced.

Usage Guidelines

When you shut down a Cisco Services or Network Interface Module (NIM) using this command, you can choose to put it into one of two states:

- Powered state--(Default) Shuts down the module, but the router remains powered on. Use this option when you plan to leave the module physically installed and cabled into the router. You might choose to do this if you want to install a module and configure it, but do not want it online or to start communicating with the remote end of the connection.
- Unpowered state--Shuts down the module and removes power from the module. Use this option when you plan to remove the module from the chassis.

If you choose to deactivate your module and its interfaces by executing the **hw-module subslot shutdown** command in global configuration mode, you are able to change the configuration in such a way that no matter how many times the router is rebooted, the module does not boot. This command is useful when you need to shut down a module located in a remote location and ensure that it does not boot automatically when the router is rebooted. To begin using the interface again, you must manually re-enable the module using the **no hw-module subslot shutdown** command.

Examples

The following example shows how to disable the module in subslot 0/2 without removing the module from the router :

```
Router(config)# hw-module subslot 0/2 shutdown unpowered
```

The following example shows how to configure a module to resume normal operation after the unpowered option has been used to disable the module:

```
Router(config)# hw-module subslot 0/2 shutdown powered
```

Related Commands

Command	Description
show hw-module subslot oir	Displays the operational status of a module.
hw-module subslot	Deactivates or reactivates a module in a router slot. This command is entered in EXEC mode and is not saved to the configuration file.

I through K

id aa-group

To configure the asynchronous acknowledgement group ID, use the **idaa-group**command in satellite initial configuration mode. To remove the ID configuration, use the **no** form of this command.

id aa-group *number*
no id aa-group

Syntax Description

aa-group	Asynchronous acknowledgement group ID.
number	ID number in the range from 256 to 511.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the asynchronous acknowledgement group identification number:

```
Router(sat-init-config)# id aa-group 336
```

id software group

To configure the operational software group identification number, use the **idsoftwaregroup**command in satellite initial configuration mode. To remove the ID configuration, use the **no** form of this command.

id software group *number*
no id software group

Syntax Description

number	ID number in the range from 512 to 767.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the operational software group identification number:

```
Router(sat-init-config)# id software group 598
```

id vsat

To configure the component physical address (CPA), use the **idvsat**command in satellite initial configuration mode. To remove the CPA configuration, use the **no** form of this command.

id vsat *number*
no id vsat *number*

Syntax Description

number	CPA number in the range from 1280 to 32766.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(22)T	The CPA number range was increased to 32766.

Usage Guidelines

The CPA uniquely identifies the VSAT endpoint in the satellite network.

Note This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the CPA number:

```
Router(sat-init-config)# id vsat 1284
```

idle-pattern

To define the idle pattern that a circuit emulation (CEM) channel transmits when the channel experiences an underrun condition or to replace any missing packets, use the **idle-pattern**command in CEM configuration mode. To stop sending idle pattern data, use the **no** form of this command.

idle-pattern {*pattern* | *length* *pattern1* [*pattern2*]}
no idle-pattern

Syntax Description

pattern	An 8-bit hexadecimal number. T1 and E1 channels require only this argument.
length	Length, in bits, of the pattern. Serial cards require that you enter a value for *length* .
pattern1	Specifies (in hex notation) up to 32 bits of the least significant bits of the idle data pattern. Default is 0xFF.
pattern2	(Optional) Specifies (in hex notation) the most significant bits of the idle data pattern. If the *length* argument is 32 bits or less, this argument is not permitted.

Command Default

For T1 or E1 channels, the default idle pattern is 0xFF. For serial channels, the default idle pattern is 0xFF and 8 bits in length.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
XE 3.18SP	This command is integrated in Cisco NCS 4200 Series.

Usage Guidelines

Idle pattern data is always sent in multiples of one entire packet payload. If a single packet is missing from the arriving data stream it is replaced by an idle packet of the same payload size and composed of repetitions of the specified idle pattern. If the CEM channel outbound (egress) buffer experiences an underrun condition, identical idle packets are transmitted until the dejitter buffer is filled to at least half its total depth.

Examples

The following example shows how to configure a 32-bit idle pattern for a serial CEM channel.

```
Router(config-cem)# idle-pattern 32 0x12345678
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM channel statistics.
show cem	Displays CEM channel statistics.

ids-service-module monitoring

To enable Intrusion Detection System (IDS) monitoring on a specified interface, use the **ids-service-modulemonitoring** command in interface configuration mode. To perform IDS monitoring, the routing device must have a Cisco IDS network module installed. To disable IDS monitoring, use the **no** form of this command.

ids-service-module monitoring
no ids-service-module monitoring

Syntax Description

This command has no arguments or keywords.

Command Default

IDS monitoring is not enabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

Use the **ids-service-modulemonitoring** command to enable IDS monitoring on a specified interface or subinterface. Both inbound and outbound packets on the specified interface are forwarded for monitoring.

The Cisco IDS network module is also referred to as the NM-CIDS.

Examples

The following example shows how to configure Fast Ethernet interface 0/0 to copy network traffic to the Cisco IDS network module and enable IDS monitoring:

```
Router(config)# interface FastEthernet0/0
Router(config-if)# ids-service-module monitoring
```

Related Commands

Command	Description
service-module ids-sensor	Reboots, resets, enables console access to, shuts down, and monitors the status of the Cisco IDS network module.

if-mgr delete

To delete the unused interface identification numbers (ifIndex) from the system interface, use the **if-mgrdelete** command in privileged EXEC mode.

if-mgr delete {**ifindex-pool** *initial-ifindex number-of-ifindexes* | **interfaceType** *interface-name*}

Syntax Description

ifindex-pool	Specifies the ifIndex pool to delete.
initial-ifindex	Initial ifIndex value in the ifIndex pool. The range is from 1 to 3200.
number-of-ifindexes	The number of ifIndexes to be deleted. The range is from 1 to 3200.
interfaceType	Specifies the type of interface to which the ifIndex value is assigned.
interface-name	Name of the interface to which the ifIndex is assigned.

Command Default

The ifIndexes assigned for the specified system interface are deleted.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2 SXH	This command was introduced.

Usage Guidelines

The ifIndex is a unique identification value associated with a physical or logical interface.

While specifying the ifIndex to be deleted, also provide the interface description (ifDescr) and the ifindex value assigned to that interface.

Examples

The following example shows how to delete the pool of unused ifIndexes:

```
Router# if-mgr delete ifindex-pool 2 5
```

Related Commands

Command	Description
show snmp mib ifmib ifindex	Displays all SNMP ifIndex identification numbers for all system interfaces.

ignore (interface)

To configure the serial interface to ignore the specified serial signals as the line up/down indicator, use the **ignore**command in interface configuration mode. To restore the default, use the **no** form of this command.

DCE Asynchronous Mode
ignore [{**dtr** | **rts**}]
no ignore [{**dtr** | **rts**}]

DCE Synchronous Mode
ignore [{**dtr** | **local-loopback** | **rts**}]
no ignore [{**dtr** | **local-loopback** | **rts**}]

DTE Asynchronous Mode
ignore [{**cts** | **dsr**}]
no ignore [{**cts** | **dsr**}]

DTE Synchronous Mode
ignore [{**cts** | **dcd** | **dsr**}]
no ignore [{**cts** | **dcd** | **dsr**}]

Syntax Description

dtr	Specifies that the DCE ignores the Data Terminal Ready (DTR) signal.
rts	Specifies that the DCE ignores the Request To Send (RTS) signal.
local-loopback	Specifies that the DCE ignores the local loopback signal.
cts	Specifies that the DTE ignores the Clear To Send (CTS) signal.
dsr	Specifies that the DTE ignores the Data Set Ready (DSR) signal.
dcd	Specifies that the DTE ignores the Data Carrier Detect (DCD) signal.

Command Default

The **no** form of this command is the default. The serial interface monitors the serial signal as the line up/down indicator.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced on the following platforms: Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3631, Cisco 3660, Cisco 3725, and Cisco 3745 routers.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T.

Usage Guidelines

Serial Interfaces in DTE Mode

When the serial interface is operating in DTE mode, it monitors the DCD signal as the line up/down indicator. By default, the attached DCE device sends the DCD signal. When the DTE interface detects the DCD signal, it changes the state of the interface to up.

SDLC Multidrop Environments

In some configurations, such as a Synchronous Data Link Control (SDLC) multidrop environment, the DCE device sends the DSR signal instead of the DCD signal, which prevents the interface from coming up. Use this command to tell the interface to monitor the DSR signal instead of the DCD signal as the line up/down indicator.

Examples

The following example shows how to configure serial interface 0 to ignore the DCD signal as the line up/down indicator:

```
Router(config)# interface serial 0
Router(config-if)# ignore dcd
```

Related Commands

Command	Description
debug serial lead-transition	Activates the leads status transition debug capability for all capable ports.
show interfaces serial	Displays information about a serial interface.

ignore-dcd

To configure the serial interface to monitor the Data Set Ready (DSR) signal instead of the Data Carrier Detect (DCD) signal as the line up/down indicator, use the **ignore-dcd** command in interface configuration mode. To restore the default, use the **no** form of this command.

ignore-dcd
no ignore-dcd

Syntax Description

This command has no arguments or keywords.

Command Default

The serial interface, operating in DTE mode, monitors the DCD signal as the line up/down indicator.

Command Modes

Interface configuration

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to Quad Serial NIM interfaces on the Cisco 4000 series routers and Hitachi-based serial interfaces on the Cisco 2500 and Cisco 3000 series routers.

Serial Interfaces in DTE Mode

When the serial interface is operating in DTE mode, it monitors the DCD signal as the line up/down indicator. By default, the attached DCE device sends the DCD signal. When the DTE interface detects the DCD signal, it changes the state of the interface to up.

SDLC Multidrop Environments

In some configurations, such as an Synchronous Data Link Control (SDLC) multidrop environment, the DCE device sends the DSR signal instead of the DCD signal, which prevents the interface from coming up. Use this command to tell the interface to monitor the DSR signal instead of the DCD signal as the line up/down indicator.

Examples

The following example shows how to configure serial interface 0 to monitor the DSR signal as the line up/down indicator:

```
Router(config)# interface serial 0
Router(config-if)# ignore-dcd
```

ignore-error-duration

To ignore initial train-up errors when the DSL controller is connected to DSLAMs with chipsets other than Globespan, use the**ignore-error-duration** command in controller configuration mode. To set the error duration to the default of 0 seconds, use the **no** form of the command.

ignore-error-duration *seconds*

Syntax Description

seconds	Sets the time in seconds for which errors will be ignored during training of the line. Range is from 15 to 30 seconds.

Command Default

0 seconds

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(4)XG	This command was integrated into the Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was implemented on Cisco 2600 series, Cisco 3631, and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

This command is used to ignore initial train-up errors when connected to DSLAMs with chipsets other than Globespan. Use the time period of 15 to 30 seconds to allow the line to train without being affected by errors that result because of the line training.

Examples

The following example sets the time during which errors will be ignored to 15 seconds:

```
Router(config)# controller dsl
4/0
Router(config-controller)# ignore-error-duration
15
```

Related Commands

Command	Description
controller dsl	Configures the DSL controller.

ignore-hw local-loopback

To disable the monitoring of the (local-loopback) LL pin when in DCE mode, use the **ingnore-hwlocal-loopback** command in interface configuration mode. To enable the monitoring of the LL pin, use the **no** form of this command.

ignore-hw local-loopback
no ignore-hw local-loopback

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Interface configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command if your system is experiencing spurious modem interrupts that momentarily cause the interface to enter loopback mode. The end result of this behavior is the loss of Synchronous Data Link Control (SDLC) Logical Link Control (SDLLC) sessions.

Note This command works only with the low-speed serial interfaces.

Examples

The following example shows how to disable the monitoring of the LL pin when in DCE mode:

```
Router(config)# interface serial 2
Router(config-if)# ignore-hw local-loopback
```

imc access-port

To configure Cisco Integrated Management Controller (CIMC) access through the server module's dedicated, management, or host ports, use the **imc access-port** command in interface configuration mode or UCSE configuration mode.

Cisco UCS E-Series Server Installed in Cisco 2900 and 3900 ISR G2 and the Cisco ISR 4451-X

imc access-port {**dedicated** | **shared-lom** [{**GE1** | **GE2** | **GE3** | **console** | **failover** [*option*]}]}

no imc access-port {**dedicated** | **shared-lom** [{**GE1** | **GE2** | **GE3** | **console** | **failover** [*option*]}]}

Cisco UCS E-Series Server Installed in the Cisco ISR 4451-X—Applicable Only with Cisco IOS XE Release 3.9S

imc access-port {**MGMT** | [{**GE0** | **GE1** | **GE2** | **GE3**[*failover-option*]}]}

no imc access-port {**MGMT** | [{**GE0** | **GE1** | **GE2** | **GE3**[*failover-option*]}]}

Syntax Description

Table 18: Cisco UCS E-Series Server Installed in Cisco 2900 and 3900 ISR G2 and the Cisco ISR 4451-X

dedicated	Configures CIMC access using the IMC dedicated port.
shared-lom	Configures CIMC access using one of the following host ports: • **GE1** • **GE2** • **GE3** • **console** • **failover** **Note** If you enter **failover**, you must also enter one additional parameter: • **GE1 GE1** [**GE2**] | [**GE3**] [**GE2 GE3**] • **GE2 GE2 GE3**

Table 19: Cisco UCS E-Series Server Installed in the Cisco ISR 4451-X—Applicable Only with Cisco IOS XE Release 3.9S

MGMT	Configures CIMC access using the Cisco UCS E-Series Server's management port.

GE0, **GE1**, **GE2**, **GE3**	(Optional) Configures CIMC access using one of the following NIC interfaces:
	• **GE0**—Cisco UCS E-Series Server's internal NIC interface connecting to the router's UCSE *slot*/**0**/**0** interface.
	• **GE1**—Cisco UCS E-Series Server's internal NIC interface connecting to the router's UCSE *slot*/**0**/**1** interface.
	• **GE2**—Cisco UCS E-Series Server's external NIC interface.
	• **GE3**—Cisco UCS E-Series Server's external NIC interface. Applicable to double-wide Cisco UCS E-Series Servers.
	• *failover-option*—To configure failover, enter one additional parameter:
	  • **GE2 backplane**—Applicable to single-wide and double-wide Cisco UCS E-Series Servers.
	  • **GE3 backplane**—Applicable to double-wide Cisco UCS E-Series Servers.
	  • **GE2 GE3**—Applicable to double-wide Cisco UCS E-Series Servers.
	  • **GE3 GE2**—Applicable to double-wide Cisco UCS E-Series Servers.
	  • **GE2 GE3 backplane**—Applicable to double-wide Cisco UCS E-Series Servers.
	  • **GE3 GE2 backplane**—Applicable to double-wide Cisco UCS E-Series Servers.

Command Modes

Interface configuration (config-if) for a Cisco UCS E-Series Server installed in Cisco 2900 and 3900 ISR G2.

UCSE configuration (config-ucse) for a Cisco UCS E-Series Server installed in the Cisco ISR 4451-X.

Command History

Release	Modification
Cisco IOS Release 15.2(4)M	This command was introduced on the Cisco UCS E-Series Servers installed in Cisco 2900 and 3900 Series Integrated Services Routers (ISR G2).
Cisco IOS XE Release 3.9S	This command was implemented on Cisco UCS E-Series Servers installed in the Cisco 4451-X Integrated Services Router (Cisco ISR 4451-X).
Cisco IOS XE Release 3.10S	This command was modified so that all platforms—Cisco 2900 and 3900 ISR G2 and the Cisco ISR 4451-X—use the same command.

Usage Guidelines

If the Cisco UCS E-Series Server is installed in Cisco 2900 and 3900 ISR G2, use the **imc access-port** command in interface configuration mode:

```
Router(config)# interface ucse 2/0
Router(config-if)#
```

If the Cisco UCS E-Series Server is installed in Cisco ISR 4451-X, use the **imc access port** command in UCSE configuration mode:

```
Router(config)# ucse subslot 1/0
Router(config-ucse)#
```

Examples

The following example shows how to configure CIMC access using the dedicated port:

```
Router# configure terminal
Router(config)# interface ucse 2/0
Router(config-if)# imc ip address 10.0.0.2 255.0.0.0 default-gateway 10.0.0.1
Router(config-if)# imc access-port dedicated
Router(config-if)# no shut
Router(config-if)# end
```

Cisco UCS E-Series Server Installed in the Cisco ISR 4451-X—Applicable Only with Cisco IOS XE Release 3.9S

The following example shows how to configure CIMC access using the MGMT port:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# ucse subslot 1/0
Router(config-ucse)# imc access-port mgmt
Router(config-ucse)#
 IMC ACK: Access ports received: MGMT

 IMC ACK: UCSE access port operation successful.
```

imc config file

To store the name of a CIMC configuration file in the running configuration, use the **imc config file** command from interface configuration mode .

imc config file *file_name*
no imc config file *file_name*

Syntax Description

file_name	The name of the CIMC configuration file that you want to store.

Command Modes

Interface configuration mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command from interface configuration mode:

```
Router(config)# interface ucse slot/port
```

Examples

The following example shows how to store a configuration CIMC file to the running configuration. Note that there is no output after you issue the command:

```
Router(config)# interface ucse 2/0
Router(config-if)# imc config file flash0:my-imc-config
```

imc dns

To configure a domain name system (DNS) server for CIMC, use the **imc dns** command from interface configuration mode.

imc dns
no imc dns

Syntax Description

This command has no arguments.

Command Modes

Interface configuration mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command from interface configuration mode:

```
Router(config)# interface ucse slot/port
```

Examples

The following example shows how to configure the DNS server for CIMC:

```
Router(config)# interface ucse 2/0
Router(config-if)# imc dns
```

imc ip address default-gateway

To configure a static IP address for CIMC and the IP address of the default gateway router that CIMC must use, use the **imc ip address default-gateway** command in interface configuration mode. To remove the static IP address, use the **no** form of this command.

imc ip address *ip-address subnet-mask* **default-gateway** *gateway-address*
no imc ip address *ip-address subnet-mask* **default-gateway** *gateway-address*

Syntax Description

ip-address	IP address of CIMC.
subnet-mask	Subnet mask to append to the IP address; must be in the same subnet as the host router.
gateway-address	IP address of the default gateway router.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

If you do not enable DHCP, you must specify a static IP address and subnet mask.

Examples

The following example shows how to configure a static IP address for CIMC:

```
Router(config)# interface ucse 2/0
Router(config-if)# imc ip address 10.0.0.2 255.0.0.0 default-gateway 10.0.0.1
```

imc ip address dhcp

To configure a DHCP IP address for CIMC, use the **imc ip address dhcp** command in interface configuration mode. To remove the DHCP IP address, use the **no** form of the this command.

imc ip address dhcp
no imc ip address dhcp

Syntax Description

This command has no arguments or keywords.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.2(4)M	This command was introduced.

Examples

The following example shows how to configure a DHCP IP address for CIMC:

```
Router(config)# interface ucse 2/0
Router(config-if)# imc ip address dhcp
```

imc ip dhcp

To configure a DHCP IP address for the Cisco Integrated Management Controller (CIMC), use the **imc ip dhcp** command in UCSE configuration mode. To remove the DHCP IP address, use the **no** form of this command.

imc ip dhcp
no imc ip dhcp

Syntax Description

This command has no arguments or keywords.

Command Modes

UCSE configuration (config-ucse)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco UCS E-Series Servers installed in the Cisco 4400 Series Integrated Services Router (ISR).

Examples

The following example shows how to configure a dynamic IP address for CIMC:

```
Router# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# ucse subslot 1/0
Router(config-ucse)# imc ip dhcp
Router(config-ucse)#
 IMC ACK: DHCP enable received for IMC.

 IMC ACK: UCSE setting DHCP enable for IMC successful.
```

imc remote-manager

To configure the IP address of the remote manager, use the **imc remote-manager** command from interface configuration mode .

imc remote-manager *ip_address*
no imc remote-manager

Syntax Description

ip_address	IP address of the remote manager.

Command Modes

Interface configuration mode.

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command from interface configuration mode:

```
Router(config)# interface ucse slot/port
```

Examples

The following example shows how to configure the IP address of the remote manager:

```
Router(config)# interface ucse 2/0
Router(config-if)# imc remote-manager 10.0.0.0
```

imc vlan

To enter VLAN configuration mode for the specified VLAN number, use the **imc vlan** command in interface configuration mode. To remove the VLAN configuration, use the **no** form of this command.

imc vlan *vlan-number*
no imc vlan *vlan-number*

Syntax Description

vlan-number	IP address of the remote manager.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.2(4)M	This command was introduced.

Examples

The following example shows how to enter VLAN configuration mode in CIMC for a specified VLAN:

```
Router(config)# interface ucse 2/0
Router(config-if)# interface vlan 40
```

input

To enable Precision Time Protocol input clocking using a 1.544Mhz, 2.048Mhz, or 10Mhz timing interface or phase using the 1PPS or RS-422 interface, use the **input** command in global configuration mode. To disable PTP input, use the **no** form of this command.

input [**1pps**] *slot/bay*
no input [**1pps**] *slot/bay*

Syntax Description

1pps	Configures the device to receive 1 pulse per second (1PPS) time of day messages using the RS422 port or 1PPS port. You can select 1PPS with or without selecting a timing port.
slot	Slot of the 1PPS interface.
bay	Bay of the 1PPS interface.

Command Default

Precision Time Protocol input clocking is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(31)SB2	This command was introduced.
15.0(1)S	This command was integrated into Cisco IOS Release 15.0(1)S.

Usage Guidelines

If you are using GPS to provide clock source to the device, configure this command in PTP master mode.

This command applies only to platforms that have a 1PPS port.

Examples

The following example shows how to configure PTP input clocking:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# input 1pps 3/1
Device(config-ptp-clk)# clock-port masterport master
```

Related Commands

Command	Description
output	Enables output of time of day messages using the 1PPS interface.

interface

To configure an interface type and to enter interface configuration mode, use the **interface** command in the appropriate configuration mode.

Standard Syntax
interface *type* *number* [*name-tag*]

Module-Specific and Platform-Specific Syntax

Analysis Module Network Module
interface **analysis-module** *slot*/*unit*

Content Engine Network Module
interface **content-engine** *slot*/*unit*

Cisco 830 Series
interface *type* [*number*]

Cisco 2600 Series
interface *type* *slot*/{*port-adapter* | *port* **.** *subinterface-number*}

Cisco 2600 Series on Voice Interfaces
interface *type* *slot*/*voice-module-slot*/*voice-interface-slot*

Cisco 3600 Series
interface *type* *slot*/{*port* | *port* **.** *subinterface-number*}

Cisco 3600 Series on Voice Interfaces
interface *type* *slot*/*voice-module-slot*/*voice-interface-slot*

Cisco 4400 Series Integrated Services Router (ISR)
interface *type* *number*

Cisco 7100 Series
interface *type* *slot*/{*port-adapter* | *port* **.** *subinterface-number*}

Cisco 7200 Series and Cisco 7500 Series with a Packet over SONET Interface Processor
interface *type* *slot*/*port*

Cisco 7200 VXR Router Used as a Router Shelf in a Cisco AS5800 Universal Access Server
interface *type* *router-shelf*/*slot*/*port*

Cisco 7500 Series with Channelized T1 or E1
interface **serial** *slot*/*port* **:** *channel-group*

Cisco 7500 Series with Ports on VIP Cards
interface *type* *slot*/*port-adapter*/*port*

Cisco 7600 Series
interface *type number*

Note: The number format varies depending on the network module or line card type and the router's chassis slot it is installed in. Refer to the appropriate hardware manual for numbering information

Cisco 7600 Series with Ports on Ethernet Service Cards
interface type *slot/bay/port* **access**

Note: The syntax may vary depending on the Ethernet service line card type. Refer to the appropriate hardware manual for numbering information. For example, for the ES20 line card the syntax takes the following format:

Subinterface Syntax Forms in Global Configuration Mode

Cisco 7200 Series
interface *type slot/port* **.** *subinterface-number* [{**multipoint** | **point-to-point**}]

Cisco 7500 Series
interface *type slot/port-adapter* **.** *subinterface-number* [{**multipoint** | **point-to-point**}]

Cisco 7500 Series with Ports on VIP Cards
interface *type slot/port-adapter/port* **.** *subinterface-number* [{**multipoint** | **point-to-point**}]

Cisco ASR 901 Series Aggregation Services Routers
no interface *type number*

Shared Port Adapters
interface *type slot/subslot/port* [**.** *subinterface-number*]

Syntax Description

type	Type of interface to be configured. See the table below.
number	Port, connector, or interface card number. On Cisco 830 series routers, the *number*argumentspecifies the ethernet interface number. On Cisco 4700 series routers, the number argument specifies the network interface module (NIM) or network processor module (NPM) number. The numbers are assigned at the factory at the time of installation or when added to a system; they can be displayed with the **showinterfaces** command. For Cisco ASR 901 Series Aggregation Services Routers, the range is from 1 to 8.
name-tag	(Optional) Specifies the logic name to identify the server configuration so that multiple server configurations can be entered. This optional argument is for use with the Redundant Link Manager (RLM) feature.
slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.

/ *voice-module-slot*	Voice module slot number. The slash(/)is required. Refer to the "Cisco 3700 Series Routers Voice Interface Numbering" section of the "Understanding Interface Numbering and Cisco IOS Basics" chapter in the platform-specific SPA software configuration guide.
/ *voice-interface-slot*	Voice interface slot number. The slash(/)is required. Refer to the "Cisco 3700 Series Routers Voice Interface Numbering" section of the "Understanding Interface Numbering and Cisco IOS Basics" chapter in the platform-specific SPA software configuration guide.
/ *subslot*	Secondary slot number on a SIP where a SPA is installed. The slash (/) is required. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
/ *unit*	Number of the daughter card on the network module. For analysis module and content engine (CE) network modules, always use 0. Theslash(/)is required.
/bay	Card interface bay number in a slot. Theslash(/)is required. Refer to the appropriate hardware manual for bay information.
/ *port*	Port or interface number. Theslash(/)is required. Refer to the appropriate hardware manual for port information. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide.
router-shelf	Router shelf number in a Cisco AS5800 universal access server. Refer to the appropriate hardware manual for router shelf information.
: *channel-group*	Channel group number. Cisco 7500 series routers specify the channel group number in the range of 0 to 4 defined with the **channel-group** controller configuration command.
/ *port-adapter*	Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility. Theslash(/) is required.
. *subinterface-number*	Subinterface number in the range 1 to 4294967293. The number that precedes the period (.) must match the number to which this subinterface belongs.
access	Creates an access interface for an IP subscriber. The access interface is configured as a subinterface of the physical interface that the IP subscriber is connected to.
multipoint | **point-to-point**	(Optional) Specifies a multipoint or point-to-point subinterface. There is no default .

Command Default

No interface types are configured.

Command Modes

Global configuration (config)

RITE configuration (config-rite)

Note To use this command with the RLM feature, the networking device must be in interface configuration mode.

Command History

Release	Modification
10.0	This command was introduced for the Cisco 7000 series routers.
11.0	This command was implemented on the Cisco 4000 series routers.
12.0(3)T	The optional *name-tag*argument was added for the RLM feature.
12.2(13)T	The **content-engine** keyword was added.
12.2(15)T	The **lex** keyword was removed because the LAN Extension feature is no longer available in Cisco IOS software.
12.2(20)S2	This command was implemented for SPAs on the Cisco 7304 router.
12.3(4)T	The **serviceengine** keyword was added. Support was added for the **interface** command to be used in RITE configuration mode to support IP trfaffic export profiles.
12.3(7)T	The **analysis-module** keyword was added.
12.2(22)S	Support for RITE configuration mode and IP traffic export profiles was added.
12.3(14)T	The **satellite** keyword was added to support satellite interface configuration on network modules.
12.2(18)SXE	This command was implemented for SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was implemented for SPAs on the Cisco 12000 series routers.
12.2(18)SXF	The **tengigabitethernet** keyword was added for support of the10 Gigabit Ethernet interface type.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
Cisco IOS XE 2.1	This command was implemented on Cisco ASR 1000 series routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
Cisco IOS XE Release 3.9S	This command was implemented on Cisco 4400 Series ISR.
15.2(02)SA	This command was implemented on Cisco ME 2600X Series Ethernet Access Switches.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

This command does not have a **no** form except for Cisco ASR 901 Series Aggregation Services Routers.

The table below displays the keywords that represent the types of interfaces that can be configured with the **interface** command. Replace the *type* argument with the appropriate keyword from the table.

Table 20: Interface Type Keywords

Keyword	Interface Type
analysis-module	Analysis module interface. The analysis module interface is a Fast Ethernet interface on the router that connects to the internal interface on the Network Analysis Module (NAM). This interface cannot be configured for subinterfaces or for speed, duplex mode, and similar parameters. See the command-line interface (CLI) help for a list of valid parameters.
async	Port line used as an asynchronous interface.
atm	ATM interface.
bri	ISDN BRI. This interface configuration is propagated to each of the B channels. B channels cannot be individually configured. The interface must be configured with dial-on-demand commands in order for calls to be placed on that interface.
content-engine	Content engine (CE) network module interface. The CE network module interface cannot be configured for subinterfaces or for speed, duplex mode, and similar parameters. See the command-line interface (CLI) help for a list of valid parameters. **Note** The **content-engine** keyword was formerly documented as the **interfacecontent-engine** command.
dialer	Dialer interface.
ethernet	Ethernet IEEE 802.3 interface.
fastethernet	100-Mbps Ethernet interface. In RITE configuration mode, specifies the outgoing (monitored) interface for exported IP traffic. **Note** The **fastethernet** keyword was formerly documented as the **interfacefastethernet** command.
fddi	FDDI interface.
gigabitethernet	1000-Mbps Ethernet interface. **Note** The **gigabitethernet** keyword was formerly documented as the **interfacegigabitethernet** command.
group-async	Master asynchronous interface. **Note** The **group-async** keyword was formerly documented as the **interfacegroup-async** command.
hssi	High-Speed Serial Interface (HSSI).

Keyword	Interface Type
loopback	Software-only loopback interface that emulates an interface that is always up. It is a virtual interface supported on all platforms. The *number* argument is the number of the loopback interface that you want to create or configure. There is no limit on the number of loopback interfaces that you can create.
null	Null interface.
port-channel	Port channel interface. **Note** The **port-channel** keyword was formerly documented as the **interfaceport-channel** command.
pos	Packet OC-3 interface on the Packet-over-SONET (POS) interface processor. **Note** The **pos** keyword was formerly documented as the **interfacepos** command.
Satellite	Satellite network module. Enters satellite configuration mode.
sdcc	Section data communications channel interface.
serial	Serial interface.
service-engine	Network module (NM) or an Advanced Integration Module (AIM), this command may be used for NMs and AIMs only. If your system does not have this hardware, you will be unable to enter this command. The no form of this command (no interface service-engine) is not available. The exit command can be used to exit interface configuration mode.
switch	Switch interface.
tengigabitethernet	10-Gigabit Ethernet interface.
tokenring	Token Ring interface.
tunnel	Tunnel interface; a virtual interface. The *number* argument is the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces that you can create.
vg-anylan	100VG-AnyLAN port adapter. **Note** The **vg-anylan** keyword was formerly documented as the **interfacevg-anylan** command.

Creating an IP Traffic Export Profile

Ip traffic export is intended only for software switching platforms; distributed architectures are not supported.

After you configure an IP traffic export profile using the **iptraffic-exportprofile**global configuration command, you must also include the **interface**command after the **iptraffic-exportprofile**command; otherwise, the profile will be unable to export the captured IP packets. If you do not use the **interface** command, you will receive a warning that indicates that the profile is incomplete.

Subinterfaces

Subinterfaces can be configured to support partially meshed Frame Relay networks. Refer to the “Configuring Serial Interfaces” chapter in the *CiscoIOSInterfaceandHardwareComponentConfigurationGuide*.

Using the analysis-module Keyword

The analysis module interface is used to access the NAM console for the initial configuration. After the NAM IP parameters are configured, the analysis module interface is typically used only during NAM software upgrades and while troubleshooting if the NAM Traffic Analyzer is inaccessible.

Visible only to the Cisco IOS software on the router, the analysis module interface is an internal Fast Ethernet interface on the router that connects to the internal NAM interface. The analysis module interface is connected to the router’s Peripheral Component Interconnect (PCI) backplane, and all configuration and management of the analysis module interface must be performed from the Cisco IOS CLI.

Using the group-async Keyword

Using the **group-async** keyword, you create a single asynchronous interface with which other interfaces are associated as members using the **group-range**command. This one-to-many configuration allows you to configure all associated member interfaces by entering one command on the group master interface, rather than entering this command on each individual interface. You can create multiple group masters on a device; however, each member interface can be associated only with one group.

Using the port-channel Keyword

The Fast EtherChannel feature allows multiple Fast Ethernet point-to-point links to be bundled into one logical link to provide bidirectional bandwidth of up to 800 Mbps. You can configure the port-channel interface as you would any Fast Ethernet interface.

After you create a port-channel interface, you assign upto four Fast Ethernet interfaces to it. For information on how to assign a Fast Ethernet interface to a port-channel interface, refer to the **channel-group** command in the interface configuration mode.

Caution The port-channel interface is the routed interface. Do not enable Layer 3 addresses on the physical Fast Ethernet interfaces. Do not assign bridge groups on the physical Fast Ethernet interfaces because doing so creates loops. Also, you must disable spanning tree.

Caution With Release 11.1(20)CC, the Fast EtherChannel supports Cisco Express Forwarding (CEF) and distributed Cisco Express Forwarding (dCEF). We recommend that you clear all explicit**iproute-cachedistributed** commands from the Fast Ethernet interfaces before enabling dCEF on the port-channel interface. Clearing the route cache gives the port-channel interface proper control of its physical Fast Ethernet links. When you enable CEF/dCEF globally, all interfaces that support CEF/dCEF are enabled. When CEF/dCEF is enabled on the port-channel interface, it is automatically enabled on each of the Fast Ethernet interfaces in the channel group. However, if you have previously disabled CEF/dCEF on the Fast Ethernet interface, CEF/dCEF is not automatically enabled. In this case, you must enable CEF/dCEF on the Fast Ethernet interface.

As you work with the **port-channel**keyword, consider the following points:

- Currently, if you want to use the Cisco Discovery Protocol (CDP), you must configure it only on the port-channel interface and not on the physical Fast Ethernet interface.

- If you do not assign a static MAC address on the port-channel interface, the Cisco IOS software automatically assigns a MAC address. If you assign a static MAC address and then later remove it, Cisco IOS software automatically assigns a MAC address.
- The **access** keyword creates an ethernet channel access interface for an IP subscriber and is specific to Cisco 7600 series routers only. For more information on access interface, see IP Subscriber Interfaces.

Using the vg-anylan Keyword

The 100VG-AnyLAN port adapter provides a single interface port that is compatible with and specified by IEEE 802.12. The 100VG-AnyLAN port adapter provides 100 Mbps over Category 3 or Category 5 cable with RJ-45 terminators and supports IEEE 802.3 Ethernet packets.

You configure the 100VG-AnyLAN port adapter as you would any Ethernet or Fast Ethernet interface. The 100VG-AnyLAN port adapter can be monitored with the IEEE 802.12 Interface MIB.

Cisco ASR 901 Series Aggregation Services Routers

The first EtherChannel interface configured becomes the bundled master for all EtherChannel interfaces in the group. That is, the MAC address of the first EtherChannel interface is the MAC address for all EtherChannel interfaces in the group. If the first EtherChannel interface is removed at any time, the second EtherChannel interface becomes the bundled master by default.

Repeat this configuration on every EtherChannel port to be bundled into a Fast Ether Channel (FEC) or Gigabit Ether Channel (GEC) group. This configuration must be present on all EtherChannel interfaces before the EtherChannel group can be configured.

Cisco 4400 Series Integrated Services Router (ISR)

The Gigabit Ethernet interface allows you to perform management tasks on the router and is often referred as the management interface port. You can use the Gigabit Ethernet interface to access the router via Telnet and SSH to perform management tasks on the router. The interface is most useful before a router has begun routing, or in troubleshooting scenarios when other forwarding interfaces are inactive. You can configure a Gigabit Ethernet interface on your router using the **interface GigabitEthernet0** command in Global configuration mode.

Analysis Module Interface with NAM Router: Example

The following example configures an analysis module interface when the NAM router is in router slot 1:

```
Router(config)# interface analysis-module 1/0
```

Asynchronous Group Master Interface: Example

The following example shows how to define asynchronous group master interface 0:

```
Router(config)# interface group-async 0
```

Content Engine Network Module Interface: Example

The following example configures an interface for a content engine network module in slot 1:

```
Router(config)# interface content-engine 1/0
```

Ethernet Interface on Cisco 830 Router: Example

The following example configures a new **ethernet2**interface on the LAN or on the WAN side of the Cisco 830 series router.

```
c837# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.
c837(config)# interface ethernet 2
```

Ethernet Port on Ethernet Interface Processor on Cisco 7500 Series Router: Example

The following example shows how to configure Ethernet port 4 on the Ethernet Interface Processor (EIP) in slot 2 on the Cisco 7500 series router:

```
Router(config)# interface ethernet 2/4
```

Exporting IP Traffic (RITE): Example

The following example shows how to configure the profile “corp1,” which will send captured IP traffic to host “00a.8aab.90a0” at the interface “FastEthernet 0/1.” This profile is also configured to export one in every 50 packets and to allow incoming traffic only from the access control list “ham_ACL.”

```
Router(config)# ip traffic-export profile corp1
Router(config-rite)# interface FastEthernet 0/1
Router(config-rite)# bidirectional
Router(config-rite)# mac-address 00a.8aab.90a0
Router(config-rite)# outgoing sample one-in-every 50
Router(config-rite)# incoming access-list ham_acl
Router(config-rite)# exit
Router(config)# interface FastEthernet 0/0
Router(config-if)# ip traffic-export apply corp1
```

Fast Ethernet Interface on Cisco 2600 Router: Example

The following example shows how to configure Fast Ethernet interface 0 on a Cisco 2600 series router:

```
Router(config)# interface fastethernet0/0
```

or

```
Router(config)# interface fastethernet0/0.1
```

Fast Ethernet Interface on Cisco 3600 Router: Example

The following example shows how to configure Fast Ethernet interface 0 on a Cisco 3600 series router:

```
Router(config)# interface fastethernet0/0
```

or

```
Router(config)# interface fastethernet0/0.1
```

Fast Ethernet Interface with ARPA Encapsulation on Cisco 4700 Router: Example

The following example shows how to configure Fast Ethernet interface 0 for standard ARPA encapsulation (the default setting) on a Cisco 4700 series router:

```
Router(config)# interface fastethernet 0
```

Fast Ethernet Interface on Cisco 7100 Router: Example

The following example shows how to configure Fast Ethernet interface 0 on a Cisco 7100 series router:

```
Router(config)# interface fastethernet0/0
```

or

```
Router(config)# interface fastethernet0/0.1
```

Fast Ethernet Interface on Cisco 12000 Router: Example

The following example shows how to configure Fast Ethernet interface 6 on a Cisco 12000 series router:

```
Router(config)# interface fastethernet6/0
```

or

```
Router(config)# interface fastethernet6/0.1
```

Gigabit Ethernet Interface: Example

The following example shows how to configure the Gigabit Ethernet interface for slot 0, port 0:

```
Router(config)# interface gigabitethernet 0/0
```

Gigabit Ethernet Interface on Cisco 4400 Series ISR: Example

The following example shows how to configure the Gigabit Ethernet Interface. The Gigabit Ethernet Interface or the management port is always GigabitEthernet0.

```
Router# config t
Enter configuration commands, one per line.  End with CNTL/Z.
Router(config)# interface gigabitethernet0
Router(config-if)#
```

Gigabit Ethernet Interface on Cisco uBR10012 Router: Example

The following example shows how to specify the second interface (1) on a Gigabit Ethernet SPA installed in the first subslot of a SIP (0) installed in chassis slot 3:

```
Router(config)# interface gigabitethernet 3/0/1
```

Loopback Interface: Example

The following example shows how to enable loopback mode and assign an IP network address and network mask to the interface. The loopback interface established here will always appear to be up.

```
Router(config)# interface loopback 0
Router(config-if)# ip address 10.108.1.1 255.255.255.0
```

Packet over SONET Interface: Example

The following example shows how to specify the single Packet OC-3 interface on port 0 of the POS OC-3 port adapter in slot 2:

```
Router(config)# interface pos 2/0
```

Partially Meshed Frame Relay Network: Example

The following example shows how to configure a partially meshed Frame Relay network. In this example, subinterface serial 0.1 is configured as a multipoint subinterface with two associated Frame Relay permanent virtual connections (PVCs), and subinterface serial 0.2 is configured as a point-to-point subinterface.

```
Router(config)# interface serial 0
Router(config-if)# encapsulation frame-relay
Router(config-if)# exit
Router(config)# interface serial 0/0.1 multipoint
Router(config-if)# ip address 10.108.10.1 255.255.255.0
Router(config-if)# frame-relay interface-dlci 42 broadcast
Router(config-if)# frame-relay interface-dlci 53 broadcast
Router(config-if)# exit
Router(config)# interface serial 0/0.2 point-to-point
```

```
Router(config-if)# ip address 10.108.11.1 255.255.255.0
Router(config-if)# frame-relay interface-dlci 59 broadcast
```

Port Channel Interface: Example

The following example shows how to create a port-channel interface with a channel group number of 1 and add two Fast Ethernet interfaces to port-channel 1:

```
Router(config)# interface port-channel 1
Router(config-if)# ip address 10.1.1.10 255.255.255.0
Router(config-if)# exit
Router(config)# interface fastethernet 1/0/0
Router(config-if)# channel-group 1
Router(config-if)# exit
Router(config)# interface fastethernet 4/0/0
Router(config-if)# channel-group 1
```

SDCC Interface on a POS Shared Port Adapter: Example

The following example configures the first interface (port 0) as a section data communications channel (SDCC) interface on a POS SPA, where the SPA is installed in the top subslot (0) of the MSC, and the MSC is installed in slot 4 of the Cisco 7304 router:

```
Router(config)# interface sdcc 4/3/0
Router(config-if)# ip address 10.1.9.2 255.255.255.0
Router(config-if)# logging event link-status
Router(config-if)# load-interval 30
Router(config-if)# no keepalive
Router(config-if)# no fair-queue
Router(config-if)# no cdp enable
```

Serial Interface with PPP Encapsulation: Example

The following example shows how to configure serial interface 0 with PPP encapsulation:

```
Router(config)# interface serial 0
Router(config-if)# encapsulation ppp
```

Shared Port Adapter Interface: Example

The following example configures the second interface (port 1) on a 4-Port 10/100 Fast Ethernet SPA for standard ARPA encapsulation (the default setting), where the SPA is installed in the bottom subslot (1) of the MSC, and the MSC is installed in slot 2 of the Cisco 7304 router:

```
Router(config)# interface fastethernet 2/1/1
```

T1 Serial Interface: Example

The following example shows how to configure circuit 0 of a T1 link for PPP encapsulation:

```
Router(config)# controller t1 4/1
Router(config-controller)# circuit 0 1
Router(config-controller)# exit
Router(config)# interface serial 4/1:0
Router(config-if)# ip address 10.108.13.1 255.255.255.0
Router(config-if)# encapsulation ppp
```

Token Ring Interface Processor: Example

The following example shows how to configure the Token Ring interface processor in slot 1 on port 0 of a Cisco 7500 series router:

```
Router(config)# interface tokenring 1/0
```

100VG-AnyLAN Interface: Example

The following example shows how to specify the 100VG-AnyLAN port adapter in the first port adapter in slot 1:

```
Router(config)# interface vg-anylan 1/0/0
```

Related Commands

Command	Description
channel-group	Defines the time slots that belong to each T1 or E1 circuit.
channel-group (Fast EtherChannel)	Assigns a Fast Ethernet interface to a Fast EtherChannel group.
clear interface	Resets the hardware logic on an interface.
controller	Configures an E1, J1, T1, or T3 controller and enters controller configuration mode.
group-range	Creates a list of asynchronous interfaces that are associated with a group interface on the same device.
ip traffic-export profile	Create or edit an IP traffic export profile.
mac-address	Sets the MAC layer address.
ppp	Starts an asynchronous connection using PPP.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces	Displays information about interfaces.
show interfaces	Displays information about interfaces.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.
shutdown (RLM)	Shuts down all of the links under the RLM group.

Command	Description
slip	Starts a serial connection to a remote host using SLIP.

interface analysis-module

To configure the Analysis-Module interface on the router that connects to an installed Network Analysis Module (NM-NAM), use the **interfaceanalysis-module** command in global configuration mode. This command does not have a not form.

interface analysis-module *slot/unit*

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For NM-NAM, always use 0. The slash (/) between the slot and unit arguments is required.

Command Default

The interface is not configured.

Command Modes

Global configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and the Cisco 2851 series.
12.3(11)T	This command was made available on the Cisco 3800 series.

Usage Guidelines

The Analysis-Module interface is a Fast Ethernet interface on the router that connects to the internal interface on the Network Analysis Module (NM-NAM).

This type of interface cannot be configured for subinterfaces or for speed, duplex mode, and similar parameters. See the command-line interface (CLI) help for a list of valid parameters.

The **interfaceanalysis-module**command enters Analysis-Module interface configuration mode.

Examples

The following example shows how to configure the Analysis-Module interface when the NM-NAM is in router slot 1:

```
Router(config)# interface analysis-module 1/0
```

Related Commands

Command	Description
ip unnumbered	Enables IP processing on an interface without assigning an explicit IP address to the interface.
show interfaces analysis-module	Displays status, traffic data, and configuration information about the Analysis-Module interface.

interface content-engine

The **interfacecontent-engine**command is now documented as the **content-engine**keyword of the **interface** command. For more information, see the **interface**command.

interface fastethernet

The **interfacefastethernet**command is now documented as the **fastethernet**keyword of the **interface** command. For more information, see the **interface** command.

interface gigabitethernet

The **interfacegigabitethernet**command is now documented as the **gigabitethernet**keyword of the **interface** command. For more information, see the interface command.

interface group-async

The **interfacegroup-async**command is now documented as the **group-async**keyword of the **interface** command. For more information, see the **interface** command.

interface integrated-service-engine

To configure the Cisco wireless LAN controller network module (WLCM) interface with dot1q encapsulation on the router, use the **interfaceintegrated-service-engine** command.

interface integrated-service-engine slot/unit

Syntax Description

slot/unit	Specifies the router slot and unit numbers for the WLCM.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.4(15)T	This command was introduced.

Examples

The following example shows how to create dot1Q virtual LAN (VLAN) subinterfaces under the **interfaceintegrated-service-engine** command:

```
Router(config)# interface integrated-service-engine
 1/0
Router(config-if)# exit
Router(config)# interface integrated-service-engine
 1/0.10
Router(config-subif)# encapsulation dot1q
 10

If the interface doesn't support baby giant frames
maximum mtu of the interface has to be reduced by 4
bytes on both sides of the connection to properly
transmit or receive large packets. Please refer to
documentation on configuring IEEE 802.1Q vLANs.

Router(config-subif)# end
```

Related Commands

show interfaces integrated-service-engine

interface ism

To configure an interface on the router that connects to an internal service module (ISM), use the **interfaceism** command in global configuration mode. This command does not have a no form.

interface ism *slot/port*

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Range: 0 or 1. The slash mark (/) is required.

Command Default

The interface is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command enters interface configuration mode to configure the interface between the router and the ISM or between the ISM and Multi-Gigabit Fabric (MGF).

Examples

The following example shows how to enter interface configuration mode for the ISM:

```
Router(config)# interface ism 0/0
```

Related Commands

Command	Description
ip unnumbered	Enables IP processing on an interface without assigning an explicit IP address to the interface.
service-module ip address	Specifies the IP address of the module side of the interface.
show interfaces ism	Displays status, traffic data, and configuration information about the ISM interface.

interface port-channel

The **interfaceport-channel** command is now documented as the **port-channel**keyword of the **interface** command. For more information, see the **interface** command.

interface pos

The **interfacepos** command is now documented as the **pos**keyword of the **interface** command. For more information, see the **interface**command.

interface range

To execute commands on multiple subinterfaces at the same time, use the **interfacerange** command in global configuration mode.

interface range {*type number* [[-**interface** *number*]] [,]... *type number* | **macro** *word*}
no interface range *type number*

Syntax Description

type number	Interface type and interface or subinterface number. For more information about the numbering syntax for your networking device, use the question mark (?) online help function. • You can enter any number of interface type and numbers.
- *interface-number*	(Optional) Ending interface number.
,	Allows you to configure more interface types.
macro	Specifies a macro keyword.
word	Previously defined keyword, up to 32 characters long.

Command Default

No interface range is set.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.0(7)XE	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(2)DD	This command was expanded to support subinterface ranges.
12.2(4)B	This command was integrated into Cisco IOS Release 12.2(4)B.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(18)SX	This command was integrated into Cisco IOS Release 12.2(18)SX.
12.2(33)SXH	The **create** keyword was added to enable the creation of VLANs that operate within a specified range of physical interfaces.

Usage Guidelines

Configuration Changes

All configuration changes made to a range of subinterfaces are saved to NVRAM, but the range itself does not get saved to NVRAM. Use the **defineinterfacerange** command to create and save a range.

You can enter the range in two ways:

- Specifying up to five interface ranges

- Specifying a previously defined macro

You can specify either the interfaces or the name of a range macro. A range must consist of the same interface type, and the interfaces within a range cannot span slots.

You cannot specify both the **interfacerange**and **macro** keywords in the same command. After creating a macro, the command does not allow you to enter additional ranges. Likewise, if you have already specified an interface range, the command does not allow you to enter a macro.

The spaces around the hyphen in the **interfacerange** command syntax are required. For example, using a Catalyst 6500 router, the command **interfacerangefastethernet1-6**is valid; the command **interfacerangefastethernet1-6**is not valid.

VLANs

When you define a Catalyst VLAN, valid values are from 1 to 4094. The last VLAN number cannot exceed 4094.

You cannot use the **interfacerange** command to create switch virtual interfaces (SVIs) in that particular range. You can use the **interfacerange** command only to configure existing VLAN SVIs within the range. To display VLAN SVIs, enter the **showrunning-config** command. VLANs not displayed cannot be used in the **interfacerange** command.

The commands entered under the**interfacerange** command are applied to all existing VLAN SVIs within the range.

You can enter the command **interfacerangecreatevlan***x-y* to create all VLANs in the specified range that do not already exist. If you are using discontiguous VLANs, you can use the **interfacerangevlan** command to configure multiple SVIs without creating unneeded SVIs and wasting interface descriptor blocks (IDBs).

After specifying a VLAN range, you can continue using the **interfacerange** command to specify another interface (**ATM**, **FastEthernet**, **GigabitEthernet**, **loopback**, **port-channel**, or **tunnel**).

Examples

interface range Fast Ethernet Examples

The following example shows how to use the **interfacerange** command to configure a Fast Ethernet range:

```
Router(config)# interface range fastethernet 5/1 - 4
```

The following example configures the Fast Ethernet subinterfaces within the range 5/1.1 to 5/1.4 and applies the following VLAN IDs to those subinterfaces:

```
Fast Ethernet5/1.1 = VLAN ID 301 (vlan-id)
Fast Ethernet5/1.2 = VLAN ID 302 (vlan-id = 301 + 2 - 1 = 302)
Fast Ethernet5/1.3 = VLAN ID 303 (vlan-id = 301 + 3 - 1 = 303)
Fast Ethernet5/1.4 = VLAN ID 304 (vlan-id = 301 + 4 - 1 = 304)
Router(config)# interface range fastethernet 5/1 - 4

Router(config-if-range)# encapsulation dot1q 301
Router(config-if-range)# no shutdown

Router(config-if)#
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1.1, changed state to up
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1.2, changed state to up
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1.3, changed state to up
```

```
*Oct  6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1.4, changed state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/1.1, changed
 state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/1.2, changed
 state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/1.3, changed
 state to up
*Oct  6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/1.4, changed
 state to up
```

interface range Gigabit Ethernet Example

The following example shows how to set a Gigabit Ethernet range:

```
Router(config)# interface range gigabitethernet 1/1 - 6
```

interface range Loopback Example

The following example shows how to use the loopback interface:

```
Router(config)# interface range loopback 34567
```

interface range Tunnel Example

The following example shows how to use the tunnel interface:

```
Router(config)# interface range tunnel 55555
```

interface range Port Channel Example

The following example shows how to use the port-channel interface:

```
Router(config)# interface range port-channel 100
```

interface range VLAN Examples

The following example shows how to set a VLAN:

```
Router(config)# interface range vlan 123
```

The following example shows how to create a range of VLANs:

```
Router(config)# interface range create vlan 4
```

interface range macro Example

The following example shows how to execute a range macro:

```
Router(config)# interface range macro macro1
```

Related Commands

Command	Description
define interface range	Defines an interface range macro.
encapsulation dot1q	Applies a unique VLAN ID to each subinterface within the range.
interface vlan	Configures a VLAN interface.

interface satellite

To enter satellite interface configuration mode, use the **interfacesatellite** command in global configuration mode.

interface satellite *slot*/*unit*

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.

Command Default

No default behavior or values

Command Modes

Global configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Examples

The following example shows how to enter satellite interface configuration mode:

```
Router(config)# interface satellite 1/0
Router(config-if)#
```

Related Commands

Command	Description
service-module satellite status	Displays status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters.
show controllers satellite	Displays controller information about the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
show interface satellite	Displays general interface settings and traffic rates for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

interface service-engine

To enter the interface configuration mode for a network module (NM) or an advanced Integration Module (AIM), use the **interfaceservice-engine** command in global configuration mode.

interface service-engine *slot/port*

Syntax Description

slot	Interface slot number.
port	Interface port number.

Command Default

No default behavior or values.

Command Modes

Global configuration

Command History

Release	Modification
12.2(15)ZJ	This command was introduced for NMs.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(7)T	Support was added for AIMs.

Usage Guidelines

This command may only be used for NMs and AIMs. If your system does not have this hardware, then you will be unable to enter this command.

The **no** form of this command (**nointerfaceservice-engine**) is not available. The **exit** command can be used to exit the interface configuration mode.

Examples

The following example shows the command for entering configuration mode for either a NM or AIM located in slot 1, unit 1:

```
Router (config)# interface service-engine 1/1
Router (config-if)# exit
```

interface sm

To configure an interface on the router that connects to an SM-SRE service module, use the **interfacesm** command in global configuration mode. This command does not have a no form.

interface sm *slot/port*

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Range: 0 or 1. The slash mark (/) is required.

Command Default

The interface is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command enters interface configuration mode to configure the interface between the router and the service module or between the service module and Multi-Gigabit Fabric (MGF).

Examples

The following example shows how to enter interface configuration mode for the service module:

```
Router(config)# interface sm 1/0
```

Related Commands

Command	Description
ip unnumbered	Enables IP processing on an interface without assigning an explicit IP address to the interface.
service-module ip address	Specifies the IP address of the module side of the interface.
show interfaces sm	Displays status, traffic data, and configuration information about the service module interface.

interface vg-anylan

The **interfacevg-anylan** command is now documented as the **vg-anylan** keyword of the **interface** command. For more information, see the **interface**command.

interface vmi

To create a virtual multipoint interface (VMI) that can be configured and applied dynamically, use the**interfacevmi** command in global configuration mode. To remove a VMI interface, use the **no** form of this command.

interface vmi *interface-number*
no interface vmi *interface-number*

Syntax Description

interface-number	Number assigned to the VMI. The value range for VMI interface numbers is from 1 to 2147483647

Command Default

No VMI is defined.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.4(15)XF	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

VMI Interface Aggregation Point

The VMI interface acts as an aggregation point for multiple PPPoE connections from one or more radios over one or more physical interfaces.

OSPFv3 and EIGRP Route Advertisements

All OSPFv3, EIGRPv4, and EIGRPv6 route advertisements that are received over the PPPoE connections are reported to the routing protocol as coming from a single interface, thus simplifying the routing protocol topology table and providing scalability benefits of each of the routing protocols.

Examples

The following example shows how to create a VMI interface:

```
interface vmi 1
 ip address 10.2.1.1 255.255.255.0
 no ip redirects
 no ip split-horizon eigrp 1
 load-interval 30
 ipv6 address 2001:0DB8:1:1:FFFF:FFFF:FFFF:FFFE/64
 ipv6 enable
 no ipv6 redirects
 ipv6 eigrp 1
 no ipv6 split-horizon eigrp 1
 physical-interface GigabitEthernet 0/0
 end
```

Related Commands

Command	Description
debug vmi	Displays debugging output for virtual multipoint interfaces (VMIs).

Command	Description
eigrp interface	Sets a threshold value to minimize hysteresis in a router-to-radio configuration.
mode bypass	Enables virtual multipoint interfaces (VMIs) to support multicast traffic.
physical interface	Creates a physical subinterface to be associated with the virtual multipoint interfaces (VMIs) on a router.

interface wlan-controller

To configure the Cisco Wireless Local Area Network (WLAN) controller network module interface with dot1q encapsulation on the router, use the **interfacewlan-controller** command in global configuration mode.

interface wlan-controller slot/unit

Syntax Description

slot/unit	Specifies the router slot and unit numbers for the WLAN controller network module.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
12.4(2)XA1	This command was introduced on the router software.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.

Examples

The following example shows how to create dot1Q virtual LAN (VLAN) subinterfaces under interface wlan-controller:

```
Router(config)# interface wlan-controller 1/0
Router(config-if)# exit
Router(config)# interface wlan-controller 1/0.10
Router(config-subif)# encapsulation dot1q 10

If the interface doesn't support baby giant frames
maximum mtu of the interface has to be reduced by 4
bytes on both sides of the connection to properly
transmit or receive large packets. Please refer to
documentation on configuring IEEE 802.1Q vLANs.

Router(config-subif)# end
```

international bit

To set the E3 international bit in the G.751 frame used by the PA-E3 port adapter, use the **internationalbit**command in interface configuration mode. To return to the default international bit, use the **no** form of this command.

international bit commandinternational bit {**0** | **1**} {**0** | **1**}
no international bit

Syntax Description

0	Sets either of the two required E3 international bits in the G.751 frame to 0. This is the default.
1	Sets either of the two required E3 international bits in the G.751 frame to 1.

Command Default

The default value for each bit is 0.

Command Modes

Interface configuration

Command History

Release	Modification
11.1 CA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **internationalbit** command sets bits 6 and 8, respectively, of set II in the E3 frame.

To verify the international bit configured on the interface, use the **showcontrollersserial** EXEC command.

Examples

The following example sets the international bit to 1 1 on the PA-E3 port adapter in slot 1, port adapter slot 0, interface 0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# international bit 1 1
```

Related Commands

Command	Description
national bit (interface)	Sets the E3 national bit in the G.751 frame used by the PA-E3 port adapter.
show controllers serial	Displays information that is specific to the interface hardware.

inter-packet gap 6502-mode

To set the Inter-Packet Gap (IPG) value, use the **inter-packetgap6502-mode**command in interface configuration mode. To return to the default setting, use the **no** form of this command.

inter-packet gap 6502-mode
no inter-packet gap 6502-mode

Syntax Description

This command has no keywords or arguments.

Command Default

All fragments from flows that are received from an ACE with Layer 4 ports and permit action are permitted. All other fragments are dropped in the hardware. This action also applies to flows that are handled in the software regardless of this command setting.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXF5	This command was introduced on the Supervisor Engine 720.

Usage Guidelines

This command is supported only when a WS-X6704-10GE is connected to a WS-X6502-10GE. You enter this command to change the IPG value of the WS-X6704-10GE to match the IPG value of the WS-X6502-10GE.

The default 6704 mode sets the IPG value to average 12. Based on packet size, the IPG between successive packets ranges from 9 to 15.

The 6502 mode sets the IPG value to average 16. Based on packet size, the IPG between successive packets ranges from 13 to 19.

Examples

This example shows how to set the IPG to 6502 mode:

```
inter-packet gap 6502-mode
```

This example shows how to set the IPG to the default mode:

```
no inter-packet gap 6502-mode
```

invert data

To invert the data stream, use the **invertdata** command in interface configuration mode. This command applies only to the Cisco 7000 series routers with the RSP7000 and RSP7000CI, Cisco 7200 series routers, and Cisco 7500 series routers. To disable inverting the data stream, use the **no** form of this command.

invert data commandinvert data
no invert data

Syntax Description

This command has no arguments or keywords.

Command Default

Data is not inverted.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CA	This command was introduced.
11.2P	This command was integrated into Cisco IOS Release 11.2 P.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

T1 Line Without B8ZS Encoding

If the interface on the PA-8T and PA-4T+ synchronous serial port adapters and the PA-T3 and PA-2T3 synchronous serial port adapters is used to drive a dedicated T1 line that does not have B8ZS encoding (a method to avoid 15 zeros), the data stream must be inverted (both transmitting and receiving data) either in the connecting CSU/DSU or in the interface.

Inverting is a method of avoiding excessive zeroes that is superseded by the use of B8ZS encryption. This option could be needed for use with legacy equipment that supports this option. By inverting the High-Level Data Link Control (HDLC) data stream, the HDLC zero insertion algorithm becomes a ones insertion algorithm that satisfies the T1 requirements. Be careful not to invert data both on the interface and on the CSU/DSU because two data inversions will cancel each other out.

AMI Line Coding

If the interface on the CT3IP uses alternate mark inversion (AMI) line coding, you must also invert the data on the T1 channel. For more information, see the **t1linecode**controller configuration command.

Examples

The following example inverts data on serial interface 3/1/0:

```
Router(config)# interface serial 3/1/0
Router(config-if)# invert data
```

Related Commands

Command	Description
t1 linecode	Specifies the type of linecoding used by the T1 channels on the CT3IP in Cisco 7500 series routers.

invert rxclock

To invert the phase of the receive (RX) clock signal on the universal I/O (UIO) serial interface that does not use the T1/E1 interface, use the **invertrxclock** command in interface configuration mode. To disable the phase inversion, use the **no** form of this command.

invert rxclock commandinvert rxclock
no invert rxclock

Syntax Description

This command has no arguments or keywords.

Command Default

The receive clock signal is not inverted.

Command Modes

Interface configuration

Command History

Release	Modification
11.3 MA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When a delay occurs between a signal being sent and the signal being received it can indicate that the receive clock signal is not appropriate for the interface rate. This command allows the receive clock signal to be inverted to attempt to correct the delay.

Examples

The following example inverts the receive clock signal on serial interface 1:

```
Router(config)# interface serial 1
Router(config-if)# invert rxclock
```

invert txclock

To invert the transmit (TX) clock signal, use the **inverttxclock** command in interface configuration mode. To return the TX clock signal to its initial state, use the **no** form of this command.

invert txclock
no invert txclock

Syntax Description

This command has no arguments or keywords.

Command Default

The transmit clock signal is not inverted.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
11.3	The **invert-transmit-clock** command was replaced by the **inverttxclock** command.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Delays between the serial clock transmit external (SCTE) clock and data transmission indicate that the TX clock signal might not be appropriate for the interface rate and length of cable being used. Different ends of the wire can have variances that differ slightly. The **inverttxclock** command compensates for these variances. This command replaces the **invert-transmit-clock** command.

Systems that use long cables or cables that are not transmitting the TxC signal (transmit echoed clock line, also known as TXCE or SCTE clock) can experience high error rates when operating at the higher transmission speeds. For example, if a PA-8T synchronous serial port adapter is reporting a high number of error packets, a phase shift might be the problem. Inverting the clock might correct this shift.

When a PA-8T or PA-4T+ port adapter interface is DTE, the **inverttxclock**command inverts the TxC signal it received from the remote DCE. When the PA-8T or PA-4T+ port adapter interface is DCE, this command changes the signal back to its original phase.

Examples

The following example inverts the TX clock signal on serial interface 3/0:

```
Router(config)# interface serial 3/0
Router(config-if)# invert txclock
```

ip dscp

To enable the use of IP differentiated services code point (DSCP) for packets that originate from a circuit emulation (CEM) channel, use the **ipdscp** command in CEM configuration mode. To disable the use of IP DSCP, use the **no** form of this command.

ip dscp [*dscp-value*]
no ip dscp

Syntax Description

dscp-value	(Optional) Value placed in the DSCP field of IP packets that originate from a CEM channel. Range is from 0 to 63. Default is 46.

Command Default

IP DSCP is enabled for packets that originate from a CEM channel.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

DSCP is mutually exclusive from both IP type of service (ToS) and IP precedence. Thus, if DSCP is configured, the **iptos** command and the **ipprecedence** command are both unavailable at the command-line interface (CLI).

Examples

The following example shows how to set the IP DSCP field value to 36.

```
Router(config-cem)# ip dscp 36
```

Related Commands

Command	Description
ip precedence	Configures the IP precedence bits for the CEM channel.
ip tos	Configures the IP ToS bits for the CEM channel.

ip pxf

To manually enable the PXF processors, use the **ippxf** command in global configuration mode. To manually disable the PXF processors, use the **no** form of this command.

ip pxf
no ip pxf

Syntax Description

This command has no arguments or keywords.

Command Default

The PXF processors are enabled by default.

Command Modes

Global configuration

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2(18)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The PXF processors are enabled by default. If they are ever disabled, you must enable them to take advantage of IP packet switching and feature acceleration. The PXF processors should never be disabled except for very short durations for debugging purposes.

Note You must also have IP Cisco Express Forwarding switching turned on for accelerated IP packet switching.

Examples

The following example enables the PXF processors:

```
ip pxf
```

Related Commands

Command	Description
show c7300 pxf accounting	Displays the number of packets entering or exiting the PXF processors.
show pxf accounting	Displays the PXF accounting.
show c7300 pxf interfaces	Displays the status of various interfaces known to the PXF processors.
show pxf interfaces	Displays a list of PXF interfaces.

ip rbscp ack-split

To configure the TCP ACK splitting feature of the Rate-Based Satellite Control Protocol (RBSCP) on an outgoing interface for packets that are permitted by a specified access list, use the **iprbscpack-split**command in interface configuration mode. To disable the feature on the interface, use the **no** form of this command.

ip rbscp ack-split *size* {*access-list-nameaccess-list-number*} **out**
no ip rbscp ack-split

Syntax Description

size	The number of TCP ACKs to send for every TCP ACK received. A *size*of 0 or 1 indicates that this feature is disabled (that is, no TCP ACK splitting will occur). The range is 0 through 32.
access-list-name | *access-list-number*	Standard or extended IP access list name or number that controls which packets are subject to TCP ACK splitting. That is, the feature is applied to packets that a **permit** statement allows; the feature is not applied to packets that a **deny** statement filters.
out	Specifies that this feature is applied to an outgoing interface.

Command Default

Disabled (TCP ACK splitting is not required on an outgoing interface for packets that are permitted by a specified acccess list).

Command Modes

Interface configuration

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

This command enables TCP ACK splitting for outgoing packets that are permitted by the access list. TCP ACK splitting is a software technique to improve performance for clear-text TCP traffic using acknowledgment (ACK) splitting, in which a number of additional TCP ACKs are generated for each TCP ACK received.

TCP ACK splitting causes TCP to open the congestion window more quickly than usual, thus decreasing the effect of long latencies. TCP will generally open the congestion window by one maximum transmission unit (MTU) for each TCP ACK received. Opening the congestion window results in increased bandwidth becoming available. Configure this feature only when the satellite link is not using all the available bandwidth. Encrypted traffic cannot use TCP ACK splitting.

Caution Plan your network carefully so that no more than one Cisco IOS router in a given routing path has this feature enabled. You do not want to recursively ACK-split traffic.

An interface can use only one instance of this feature at a time. Each instance of this feature can be used on multiple interfaces.

If you configure this feature but it refers to a nonexistent access list, this is interpreted as having an access list that denies all traffic from being processed by the Access-List-Based RBSCP feature, so the feature is essentially disabled and the traffic goes through the normal switching path.

Examples

In the following example, the access list performs TCP ACK splitting on packets going out Ethernet interface 0 from a source at 172.22.18.5 to a destination at 172.23.27.4:

```
ip access-list extended satellite
 permit tcp 172.22.18.5 172.23.27.4
 exit
interface ethernet 0
 ip rbscp ack-split 6 satellite out
```

Related Commands

Command	Description
debug ip rbscp	Displays general error messages about access-list-based RBSCP.
debug ip rbscp ack-split	Displays information about TCP ACK splitting done in conjunction with RBSCP.

ip verify unicast source reachable-via

To enable Unicast Reverse Path Forwarding (Unicast RPF), use the **ip verify unicast source reachable-via** command in interface configuration mode. To disable Unicast RPF, use the **no** form of this command.

ip verify unicast source reachable-via {**any** | **rx** [**l2-src**]} [**allow-default**] [**allow-self-ping**] [*access-list*]
no ip verify unicast source reachable-via

Syntax Description

any	Examines incoming packets to determine whether the source address is in the Forwarding Information Base (FIB) and permits the packet if the source is reachable through any interface (sometimes referred to as loose mode).
rx	Examines incoming packets to determine whether the source address is in the FIB and permits the packet only if the source is reachable through the interface on which the packet was received (sometimes referred to as strict mode).
l2-src	(Optional) Enables source IPv4 and source MAC address binding.
allow-default	(Optional) Allows the use of the default route for RPF verification.
allow-self-ping	(Optional) Allows a router to ping its own interface or interfaces. **Caution** Use caution when enabling the **allow-self-ping** keyword. This keyword opens a denial-of-service (DoS) hole.
access-list	(Optional) Specifies a numbered access control list (ACL) in the following ranges: • 1 to 99 (IP standard access list) • 100 to 199 (IP extended access list) • 1300 to 1999 (IP standard access list, expanded range) • 2000 to 2699 (IP extended access list, expanded range)

Command Default

Unicast RPF is disabled.

Source IPv4 and source MAC address binding is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.1(CC), 12.0	This command was introduced. This command was not included in Cisco IOS Release 11.2 or 11.3.
12.1(2)T	Added access control list (ACL) support using the *access-list* argument. Added per-interface statistics on dropped or suppressed packets.

Release	Modification
12.0(15)S	This command replaced the **ip verify unicast reverse-path** command, and the following keywords were added: **allow-default**, **allow-self-ping**, **rx**, and **any**.
12.1(8a)E	This command was integrated into Cisco IOS Release 12.1(8a)E.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command was introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRC	This command was modified. The **l2-src** keyword was added to support the source IPv4 and source MAC address binding feature on platforms that support the Cisco Express Forwarding software switching path.
15.0(1)M	This command was integrated into Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use the **ip verify unicast source reachable-via** interface command to mitigate problems caused by malformed or forged (spoofed) IP source addresses that pass through a router. Malformed or forged source addresses can indicate DoS attacks based on source IP address spoofing.

To use Unicast RPF, enable Cisco Express Forwarding or distributed Cisco Express Forwarding in the router. There is no need to configure the input interface for Cisco Express Forwarding. As long as Cisco Express Forwarding is running on the router, individual interfaces can be configured with other switching modes.

Note It is important for Cisco Express Forwarding to be configured globally on the router. Unicast RPF does not work without Cisco Express Forwarding.

Note Unicast RPF is an input function and is applied on the interface of a router only in the ingress direction.

When Unicast RPF is enabled on an interface, the router examines all packets that are received on that interface. The router checks to make sure that the source address appears in the FIB. If the **rx** keyword is selected, the source address must match the interface on which the packet was received. If the **any** keyword is selected, the source address must be present only in the FIB. This ability to "look backwards" is available only when Cisco Express Forwarding is enabled on the router because the lookup relies on the presence of the FIB. Cisco Express Forwarding generates the FIB as part of its operation.

Note If the source address of an incoming packet is resolved to a null adjacency, the packet will be dropped. The null interface is treated as an invalid interface by the new form of the Unicast RPF command. The older form of the command syntax did not exhibit this behavior.

Unicast RPF checks to determine whether any packet that is received at a router interface arrives on one of the best return paths to the source of the packet. If a reverse path for the packet is not found, Unicast RPF can drop or forward the packet, depending on whether an ACL is specified in the Unicast RPF command. If an ACL is specified in the command, when (and only when) a packet fails the Unicast RPF check, the ACL is checked to determine whether the packet should be dropped (using a deny statement in the ACL) or forwarded (using a permit statement in the ACL). Whether a packet is dropped or forwarded, the packet is counted in the global IP traffic statistics for Unicast RPF drops and in the interface statistics for Unicast RPF.

If no ACL is specified in the **ip verify unicast source reachable-via** command, the router drops the forged or malformed packet immediately, and no ACL logging occurs. The router and interface Unicast RPF counters are updated.

Unicast RPF events can be logged by specifying the logging option for the ACL entries that are used by the **ip verify unicast source reachable-via** command. Log information can be used to gather information about the attack, such as source address, time, and so on.

Strict Mode RPF

If the source address is in the FIB and reachable only through the interface on which the packet was received, the packet is passed. The syntax for this method is **ip verify unicast source reachable-via rx**.

Exists-Only (or Loose Mode) RPF

If the source address is in the FIB and reachable through any interface on the router, the packet is passed. The syntax for this method is **ip verify unicast source reachable-via any**.

Because this Unicast RPF option passes packets regardless of which interface the packet enters, it is often used on Internet service provider (ISP) routers that are "peered" with other ISP routers (where asymmetrical routing typically occurs). Packets using source addresses that have not been allocated on the Internet, which are often used for spoofed source addresses, are dropped by this Unicast RPF option. All other packets that have an entry in the FIB are passed.

allow-default

Normally, sources found in the FIB but only by way of the default route will be dropped. Specifying the **allow-default** keyword option will override this behavior. You must specify the **allow-default** keyword in the command to permit Unicast RPF to successfully match on prefixes that are known through the default route to pass these packets.

allow-self-ping

This keyword allows the router to ping its own interface or interfaces. By default, when Unicast RPF is enabled, packets that are generated by the router and destined to the router are dropped, thereby, making certain troubleshooting and management tasks difficult to accomplish. Issue the **allow-self-ping** keyword to enable self-pinging.

Caution Caution should be used when enabling the **allow-self-ping** keyword because this option opens a potential DoS hole.

Using RPF in Your Network

Use Unicast RPF strict mode on interfaces where only one path allows packets from valid source networks (networks contained in the FIB). Also, use Unicast RPF strict mode when a router has multiple paths to a given network, as long as the valid networks are switched through the incoming interfaces. Packets for invalid networks will be dropped. For example, routers at the edge of the network of an ISP are likely to have symmetrical reverse paths. Unicast RPF strict mode is applicable in certain multihomed situations, provided that optional Border Gateway Protocol (BGP) attributes, such as weight and local preference, are used to achieve symmetric routing.

Note With Unicast RPF, all equal-cost "best" return paths are considered valid. This means that Unicast RPF works in cases where multiple return paths exist, provided that each path is equal to the others in terms of the routing cost (number of hops, weights, and so on) and as long as the route is in the FIB. Unicast RPF also functions where Enhanced Internet Gateway Routing Protocol (EIGRP) variants are being used and unequal candidate paths back to the source IP address exist.

Use Unicast RPF loose mode on interfaces where asymmetric paths allow packets from valid source networks (networks contained in the FIB). Routers that are in the core of the ISP network have no guarantee that the best forwarding path out of the router will be the path selected for packets returning to the router.

IP and MAC Address Spoof Prevention

In Release 15.0(1)M and later, you can use the **l2-src**keyword to enable source IPv4 and source MAC address binding. To disable source IPv4 and source MAC address binding, use the **no** form of the **ip verify unicast source reachable-via**command.

If an inbound packet fails this security check, it will be dropped and the Unicast RPF dropped-packet counter will be incremented. The only exception occurs if a numbered access control list has been specified as part of the Unicast RPF command in strict mode, and the ACL permits the packet. In this case the packet will be forwarded and the Unicast RPF suppressed-drops counter will be incremented.

Note The **l2-src** keyword cannot be used with the loose uRPF command, **ip verify unicast source reachable-via any**command.

Not all platforms support the **l2-src** keyword. Therefore, not all the possible keyword combinations for strict Unicast RPF in the following list will apply to your platform:

Possible keyword combinations for strict Unicast RPF include the following:

```
allow-default
allow-self-ping
l2-src
<ACL-number>
allow-default allow-self-ping
allow-default l2-src
allow-default <ACL-number>
allow-self-ping l2-src
allow-self-ping <ACL-number>
l2-src <ACL-number>
allow-default allow-self-ping l2-src
allow-default allow-self-ping <ACL-number>
allow-default l2-src <ACL-number>
allow-self-ping l2-src <ACL-number>
allow-default allow-self-ping l2-src <ACL-number>
```

Examples

Single-Homed ISP Connection with Unicast RPF

The following example uses a very simple single-homed ISP connection to demonstrate the concept of Unicast RPF. In this example, an ISP peering router is connected through a single serial interface to one upstream ISP. Hence, traffic flows into and out of the ISP will be symmetric. Because traffic flows will be symmetric, a Unicast RPF strict-mode deployment can be configured.

```
ip cef
! or "ip cef distributed" for Route Switch Processor+Versatile Interface Processor-
(RSP+VIP-) based routers.
!
interface Serial5/0/0
 description - link to upstream ISP (single-homed)
 ip address 192.168.200.225 255.255.255.252
 no ip redirects
 no ip directed-broadcasts
 no ip proxy-arp
 ip verify unicast source reachable-via
```

ACLs and Logging with Unicast RPF

The following example demonstrates the use of ACLs and logging with Unicast RPF. In this example, extended ACL 197 provides entries that deny or permit network traffic for specific address ranges. Unicast RPF is configured on interface Ethernet 0/1/1 to check packets arriving at that interface.

For example, packets with a source address of 192.168.201.10 arriving at interface Ethernet 0/1/1 are dropped because of the deny statement in ACL 197. In this case, the ACL information is logged (the logging option is turned on for the ACL entry) and dropped packets are counted per-interface and globally. Packets with a source address of 192.168.201.100 arriving at interface Ethernet 0/1/2 are forwarded because of the permit statement in ACL 197. ACL information about dropped or suppressed packets is logged (the logging option is turned on for the ACL entry) to the log server.

```
ip cef distributed
!
int eth0/1/1
 ip address 192.168.200.1 255.255.255.0
 ip verify unicast source reachable-via rx 197
!
int eth0/1/2
 ip address 192.168.201.1 255.255.255.0
!
access-list 197 deny   ip 192.168.201.0 0.0.0.63 any log-input
access-list 197 permit ip 192.168.201.64 0.0.0.63 any log-input
access-list 197 deny   ip 192.168.201.128 0.0.0.63 any log-input
access-list 197 permit ip 192.168.201.192 0.0.0.63 any log-input
access-list 197 deny ip host 0.0.0.0 any log-input
access-list 197 deny ip 172.16.0.0 0.255.255.255 any log-input
access-list 197 deny ip 10.0.0.0 0.255.255.255 any log-input
access-list 197 deny ip 172.16.0.0 0.15.255.255 any log-input
access-list 197 deny ip 192.168.0.0 0.0.255.255 any log-input
```

MAC Address Binding on Software Switching Platforms Like the Cisco 7200 Series Routers

The following example shows how to enable source IPv4 and source MAC address binding on Ethernet 0/0:

```
Router# configure terminal
Router(config)# interface Ethernet0/0
Router(config-if)# ip address 10.0.0.1 255.255.255.0
Router(config-if)# ip verify unicast source reachable-via rx l2-src
```

Related Commands

Command	Description
ip cef	Enables Cisco Express Forwarding on the route processor card.
ip cef distributed	Enables Cisco Express Forwarding on the line card.

ipc buffers

To resize the interprocessor communication (IPC) buffer pool, use the **ipcbuffers** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ipc buffers {**max-free** | **min-free** | **permanent**} *buffers*
no ipc buffers {**max-free** | **min-free** | **permanent**}

Syntax Description

max-free *buffers*	Specifies the maximum number of buffers that must be free. The range is from 8 to 10000.
min-free *buffers*	Specifies the minimum number of buffers that must be free. The range is from 1 to 17.
permanent *buffers*	Specifies the number of buffers that must be permanantly allocated for IPC apart from the buffers that are dynamically allocated and freed. The range is from 2 to 5000.

Command Default

The default buffer value is set by the platform during initialization.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

You can use the **ipcbuffers** command when you would want to resize the buffer pool.

Examples

The following example shows how to set the maximum number of free buffers to 10:

```
Router(config)# ipc buffers max-free 10
```

Related Commands

Command	Description
ipc holdq threshold	Configures IPC holdq threshold values.
show ipc	Displays IPC statistics.

ipc header-cache

To resize the interprocess communication (IPC) permanent cache, use the **ipcheader-cache** command in global configuration mode. To disable the configuration, use the **no** form of this command.

ipc header-cache permanent *high-cache low-cache*
no ipc header-cache permanent

Syntax Description

permanent	Specifies the permanent IPC cache.
high-cache	Maximum permanent cache size. The range is from 1000 to 10000.
low-cache	Lower cache watermark. The range is from 100 to 2000.

Command Default

The default values are set by the platform during initialization.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Examples

The following example shows how to set the maximum permanent cache value to 1000 and lower cache value to 200 of an IPC server:

```
Router(config)# ipc header-cache permanent 1000 200
```

Related Commands

Command	Description
ipc holdq threshold	Configures IPC holdq threshold values.
show ipc	Displays IPC statistics.

ipc holdq threshold

To configure interprocessor communication (IPC) holdq threshold values, use the **ipcholdqthreshold**command in global configuration mode. To disable the configuration, use the **no** form of this command.

ipc holdq threshold {**lower** *start-threshold* | **upper** *stop-threshold*}
no ipc holdq threshold {**lower** | **upper**}

Syntax Description

lower	Specifies the lower threshold for IPC holdq.
start-threshold	Threshold to start sending IPC messages. The range is from 10 to 2000.
upper	Specifies the upper threshold for IPC holdq.
stop-threshold	Threshold to stop sending IPC messages. The range is from 40 to 4000.

Command Default

The default values threshold is set by the platform during initialization.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.
12.2(33)SXI	This command was integrated into a release earlier than Cisco IOS Release 12.2(33)SXI.
Cisco IOS XE Release 2.1	This command was implemented on the Cisco ASR 1000 Series Aggregation Services Routers.

Usage Guidelines

The holdq OFF and ON thresholds are used to throttle the message sent based on the traffic at the driver. If the number of messages to be processed by the driver has increased than the OFF threshold, then the messages are not passed from the transport layer to the driver. The messages will be sent again once the count decreases below the ON threshold.

You can use the**ipcholdq**command when the driver message processing speed has decreased or increased to a greater extent than the specifications.

Examples

The following example shows how to configure a lower threshold value of 100 for IPC holdq:

```
Router(config)# ipc holdq threshold lower 100
```

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Examples

The following example shows how to configure 192.0.2.1 as the IP address of the master server:

```
Router(config)# ipc master 192.0.2.1
```

Related Commands

Command	Description
ipc buffers	Resizes the IPC buffer pool.
show ipc	Displays IPC statistics.

ipc zone default

To enter interprocess communication (IPC) zone configuration mode, use the **ipczonedefault**command in global configuration mode. To remove a previously configured association, use the **no** form of this command.

ipc zone default
no ipc zone default

Syntax Description

This command has no arguments or keywords.

Command Default

The user is not in IPC zone configuration mode.

Command Modes

Global configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

The **ipczonedefault** command places the router into IPC zone configuration mode. In this mode, the user can configure the default IPC zone.

The **no** form of the **ipczonedefault** command removes any previously configured association.

Examples

The following example places the router into IPC zone configuration mode:

```
Router(config)# ipc zone default
Router(config-ipczone)#
```

Related Commands

Command	Description
show ipc	Displays IPC statistics.

iphc-profile

To create an IP Header Compression (IPHC) profile and to enter IPHC-profile configuration mode, use the **iphc-profile** command in global configuration mode. To attach an existing IPHC profile to an interface or subinterface, use the **iphc-profile** command in interface configuration mode. To delete the IPHC profile, use the **no** form of this command.

iphc-profile *profile-name* {**ietf** | **van-jacobson**}
no iphc-profile *profile-name*

Syntax Description

profile-name	Name of the IPHC profile to be created or attached. The IPHC profile name can be a maximum of 32 characters. The name may not include quotation marks, white space, or special characters.
ietf	Specifies that the IPHC profile is for Internet Engineering Task Force (IETF) header compression.
van-jacobson	Specifies that the IPHC profile is for Van Jacobson header compression.

Command Default

No IPHC profile is created or attached.

Command Modes

Global configuration (to create an IPHC profile) Interface configuration (to attach an existing IPHC profile to an interface or subinterface)

Command History

Release	Modification
12.4(9)T	This command was introduced.

Usage Guidelines

The **iphc-profile** command creates an IPHC profile used for enabling header compression and enters IPHC-profile configuration mode (config-iphcp). An IPHC profile is a template within which you can configure the type of header compression that you want to use, enable any optional features and settings for header compression, and then apply the profile to an interface, a subinterface, or a Frame Relay permanent virtual circuit (PVC).

Specifying the IPHC Profile Type

When you create an IPHC profile, you must specify the IPHC profile type by using either the **ietf** keyword or the **van-jacobson** keyword. The IETF profile type conforms to and supports the standards established with RFC 2507, RFC 2508, RFC 3544, and RFC 3545 and is typically associated with non-TCP header compression (for example, RTP header compression). The Van Jacobson profile type conforms to and supports the standards established with RFC 1144 and is typically associated with TCP header compression.

Note: If you are using Frame Relay encapsulation, you must specify the **ietf**keyword (not the **van-jacobson** keyword).

Considerations When Specifying the IPHC Profile Type

When specifying the IPHC profile type, consider whether you are compressing TCP traffic or non-TCP traffic (that is, RTP traffic). Also consider the header compression format capabilities of the remote network link that will receive traffic. The IPHC profile type that you specify directly affects the header compression format used on the remote network links to which the IPHC profile is applied. *Only* TCP traffic is compressed on remote network links using a Van Jacobson IPHC profile, whereas TCP *and/or* non-TCP traffic (for example, RTP traffic) is compressed on remote network links using an IETF IPHC profile.

Note The header compression format in use on the router that you are configuring and the header compression format in use on the remote network link must match.

Configurable Header Compression Features and Settings

The specific set of header compression features and settings that you can configure (that is, enable or modify) is determined by the IPHC profile type that you specify (either IETF or Van Jacobson) when you create the IPHC profile. Both sets are listed below.

If you specify Van Jacobson as the IPHC profile type, you can enable TCP header compression and set the number of TCP contexts. The table below lists each available Van Jacobson IPHC profile type header compression feature and setting and the command used to enable it.

Table 21: Van Jacobson IPHC Profile Type Header Compression Features and Settings

Command	Feature or Setting
tcp	Enables TCP header compression.
tcp contexts	Sets the number of contexts available for TCP header compression.

If you specify IETF as the IPHC profile type, you can enable non-TCP header compression (that is, RTP header compression), along with a number of additional features and settings. The table below lists each available IETF IPHC profile type header compression feature and setting and the command or commands used to enable it.

Table 22: IETF IPHC Profile Type Header Compression Features and Settings

Command	Feature or Setting
feedback	Enables the context-status feedback messages from the interface or link.
maximum header	Sets the maximum size of the compressed IP header.
non-tcp	Enables non-TCP header compression.
non-tcp contexts	Sets the number of contexts available for non-TCP header compression.
rtp	Enables RTP header compression.
recoverable-loss	Enables Enhanced Compressed Real-Time Transport Protocol (ECRTP) on an interface.
refresh max-period refresh max-time refresh rtp	Sets the context refresh (full-header refresh) options, such as the amount of time to wait before a full header is refreshed.

Command	Feature or Setting
tcp	Enables TCP header compression.
tcp contexts	Sets the number of contexts available for TCP header compression.

For More Information About IPHC Profiles

For more information about using IPHC profiles to configure header compression, see the "Header Compression" module and the "Configuring Header Compression Using IPHC Profiles" module of the Cisco IOS Quality of Service Solutions Configuration Guide, Release 12.4T.

Examples

In the following example, an IPHC profile called profile1 is created, and the Van Jacobson IPHC profile type is specified.

```
Router> enable
Router# configure terminal
Router(config)# iphc-profile profile1 van-jacobson
Router(config-iphcp)# end
```

In the following example, a second IPHC profile called profile2 is created. For this IPHC profile, the IETF IPHC profile type is specified.

```
Router> enable
Router# configure terminal
Router(config)# iphc-profile profile2 ietf
Router(config-iphcp)# end
```

In the following example, an existing IPHC profile called profile2 is attached to serial interface 3/0. For this IPHC profile, the IPHC profile type (in this case, IETF) of profile2 is specified.

```
Router> enable
Router# configure terminal
Router(config)# interface serial 3/0
Router(config-if)# iphc-profile profile2 ietf
Router(config-iphcp)# end
```

Related Commands

Command	Description
feedback	Enables the context-status feedback messages from the interface or link.
maximum header	Specifies the maximum size of the compressed IP header.
non-tcp	Enables non-TCP header compression within an IPHC profile.
non-tcp contexts	Sets the number of contexts available for non-TCP header compression.
recoverable-loss	Enables ECRTP on an interface.
refresh max-period	Sets the number of packets sent between full-header refresh occurrences.
refresh max-time	Sets the amount of time to wait before a full-header refresh occurrence.
refresh rtp	Enables a context refresh occurrence for RTP header compression.

Command	Description
rtp	Enables RTP header compression within an IPHC profile.
show iphc-profile	Displays configuration information for one or more IPHC profiles.
tcp	Enables TCP header compression within an IPHC profile.
tcp contexts	Set the number of contexts available for TCP header compression.

keepalive

To enable keepalive packets and to specify the number of times that the Cisco IOS software tries to send keepalive packets without a response before bringing down the interface or before bringing down the tunnel protocol for a specific interface, use the **keepalive** command in interface configuration mode. When the keepalive function is enabled, a keepalive packet is sent at the specified time interval to keep the interface active. To turn off keepalive packets entirely, use the **no** form of this command.

keepalive [*period*[{**retries**}]]
no keepalive [*period*[{**proto-up**}]]

Syntax Description

period	(Optional) Integer value that represents the time interval, in seconds, between messages sent by the Cisco IOS software to ensure that a network interface is alive. • The valid range is from 0 to 32767 and the default value is 10.
retries	(Optional) Number of times that the device will continue to send keepalive packets without a response before bringing the interface down. • The valid range is 2 to 244. If omitted, the value that was previously set is used; if no value was specified, the default of 5 is used. • If this command is used with a tunnel interface, this argument value specifies the number of times that the device will continue to send keepalive packets without a response before bringing down the tunnel interface protocol.
proto-up	(Optional) Modifies the interface and protocol status to up even if the router is not connected to a wire or the interface of the peer router is down.

Command Default

The time interval between messages is10 seconds, and the number of retries is 3.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
10.0	This command was introduced.
12.2(8)T	This command was modified. The *retries* argument was added and made available on tunnel interfaces.
12.2(13)T	This command was modified. The default value for the *retries* argument was increased to 5.
12.2SX	This command was added in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(4)M8	This command was modified. The **proto-up** keyword was added.
15.2(2)SNI	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.
15.3(1)S	This command was integrated into Cisco IOS Release15.3(1)S.

Usage Guidelines

The **service interval**command must be enabled to run the **no keepalive**command.

Defaults for the keepalive Command

If you enter only the keepalive command with no arguments, default values for both arguments are used. If you enter the keepalive command and the timeout parameter, the default number of retries (5) is used. If you enter the **nokeepalive**command, keepalive packets are disabled on the interface. When the interface goes down, the session continues without shutting down because the keepalive packets are disabled.

Keepalive Time Interval

You can configure the keepalive time interval, which is the frequency at which the Cisco IOS software sends messages to itself (Ethernet and Token Ring) or to the other end (serial and tunnel), to ensure that a network interface is alive. The interval is adjustable in 1-second increments down to 1 second. An interface is declared down after five update intervals have passed without receiving a keepalive packet unless the retry value is set higher. If you are running a Cisco IOS image prior to Cisco IOS Release 12.2(13)T, the default retry value is 3.

Note Ethernet interface drivers on some access platforms use the keepalive time as the interval to test for network connectivity. By default, Ethernet link failure detection occurs between 1 and 9 seconds. Keepalive packets are still transmitted on the interface during this time.

Setting the keepalive timer to a low value is very useful for rapidly detecting Ethernet interface failures (transceiver cable disconnecting, cable not terminated, and so on).

Line Failure

A typical serial line failure involves losing the Carrier Detect (CD) signal. Because this sort of failure is typically noticed within a few milliseconds, adjusting the keepalive timer for quicker routing recovery is generally not useful.

Keepalive Packets with Tunnel Interfaces

Generic routing encapsulation (GRE) keepalive packets may be sent from both sides of a tunnel or from just one side. If they are sent from both sides, the period and retry parameters can be different at each side of the link. If you configure keepalives on only one side of the tunnel, the tunnel interface on the sending side might perceive the tunnel interface on the receiving side to be down because the sending interface is not receiving keepalives. From the receiving side of the tunnel, the link appears normal because no keepalives were enabled on the second side of the link.

Dropped Packets

Keepalive packets are treated as ordinary packets, so it is possible that they will be dropped. To reduce the chance that dropped keepalive packets will cause the tunnel interface to be taken down, increase the number of retries.

Note When adjusting the keepalive timer for a very low bandwidth serial interface, large datagrams can delay the smaller keepalive packets long enough to cause the line protocol to go down. You may need to experiment to determine the best values to use for the timeout and the number of retry attempts.

GRE Tunnels with IPsec

When GRE is used with IPsec, the keepalives are encrypted like any other traffic. As with user data packets, if the IKE and IPsec security associations are not already active on the GRE tunnel, the first GRE keepalive packet will trigger IKE/IPsec initialization.

Note GRE tunnel with IPSEC tunnel protection does not encrypt replies to incoming GRE keepalive packets. For more information, see the GRE Tunnel Keepalive Troubleshooting Technical Notes.

Examples

The following example shows how to enable keepalive packets and set the keepalive interval to 3 seconds:

```
Router(config)# interface ethernet 0
Router(config-if)# keepalive 3
```

The following example shows how to enable keepalive packets, set the keepalive interval to 3 seconds, and the retry value to 7 in a tunnel interface:

```
Router(config)# interface tunnel 1
Router(config-if)# keepalive 3 7
```

The following example shows how to bring up the interface of a router even if the peer router is down.

```
Router(config)# interface tunnel 1
Router(config)# service internal
Router(config-if)# no keepalive proto-up
```

Related Commands

Command	Description
service internal	Sets a primary or secondary IP address for an interface.

l2 vfi manual through loopback PA-MC-8TE1 + port adapter

l2 vfi manual

To create a Layer 2 virtual forwarding instance (VFI) and enter Layer 2 VFI manual configuration mode, use the **l2vfimanual** command in global configuration mode. To remove the Layer 2 VFI, use the **no** form of this command.

l2 vfi *name* **manual**
no l2 vfi *name* **manual**

Syntax Description

name	Name of a new or existing Layer 2 VFI .

Command Default

The Layer 2 VFI is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(18)SXF	This command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.0(1)M	This command was integrated into a release earlier than Cisco IOS Release 15.0(1)M.
Cisco IOS XE Release 3.7S	This command was integrated into Cisco IOS XE Release 3.7S.

Usage Guidelines

A VFI is a collection of data structures used by the data plane, software-based or hardware-based, to forward packets to one or more virtual circuits (VC). It is populated and updated by both the control plane and the data plane and also serves as the data structure interface between the control plane and the data plane.

Within the Layer 2 VFI manual configuration mode, you can configure the following parameters:

- VPN ID of a Virtual private LAN service (VPLS) domain
- Addresses of other PE routers in this domain
- Type of tunnel signaling and encapsulation mechanism for each peer

Within the Layer 2 VFI manual configuration mode, the following commands are available:

- **vpn id** *vpn-id*
- [**no**] **neighbor***remote-router-id* {**encapsulation** {**l2tpv3** | **mpls**} | **pw-class***pw-name*| **no-split-horizon**}

Examples

This example shows how to create a Layer 2 VFI, enter Layer 2 VFI manual configuration mode, and configure a VPN ID:

```
Router(config)# l2 vfi vfitest1 manual
Router(config-vfi)# vpn id 303
```

Related Commands

Command	Description
l2 vfi point-to-point	Establishes a point-to-point Layer 2 VFI between two separate networks.
vpn id	Configures a VPN ID in RFC 2685 format. You can change the value of the VPN ID only after its configuration, and you cannot remove it.
neighbor	Specifies the type of tunnel signaling and encapsulation mechanism for each peer.

l2protocol-tunnel

To enable the protocol tunneling on an interface and specify the type of protocol to be tunneled, use the **l2protocol-tunnel** command in global or interface configuration mode. To disable protocol tunneling, use the **no** form of this command.

Global Configuration
l2protocol-tunnel [{**cos** **cos-value** | **global** | **mac-address**}]
no l2protocol-tunnel

Interface Configuration
l2protocol-tunnel [{**cdp** | **lldp** | **stp** | **vtp**}]
no l2protocol-tunnel

Syntax Description

cos cos-value	(Optional) Specifies a class of service (CoS) value globally on all ingress Layer 2 protocol tunneling ports.
global	(Optional) Displays global settings.
mac-address	(Optional) Displays L2PT MAC address.
cdp	(Optional) Enables Cisco Discovery Protocol (CDP) tunneling.
lldp	(Optional) Enables Link Layer Discovery Protocol (LLDP) tunneling.
stp	(Optional) Enables Spanning Tree Protocol (STP) tunneling.
vtp	(Optional) Enables VLAN Trunking Protocol (VTP) tunneling.

Command Default

Disabled

Command Modes

Global configuration (config)

Interface configuration (config-if)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.2(2)T	This command was modified. The **lldp**, cos, global, and mac-address keywords were added.

Usage Guidelines

On all the service provider edge switches, you must enable PortFast BPDU filtering on the 802.1Q tunnel ports by entering these commands:

```
Router(config-if)# spanning-tree bpdufilter enable
Router(config-if)# spanning-tree portfast
```

Note PortFast BPDU filtering is enabled automatically on tunnel ports.

If you do not specify a protocol, all protocols are tunneled.

You can configure protocol tunneling on VLAN and trunk interfaces.

You must enter the **switchport** command once without any keywords to configure the LAN port as a Layer 2 interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

Examples

This example shows how to enable a tunneling protocol on an interface:

```
Router> enable
Router# configure terminal
Router#(config)interface FastEthernet 0/0
Router(config-if)# l2protocol-tunnel cdp
```

This example shows how to disable a tunneling protocol on an interface:

```
Router> enable
Router# configure terminal
Router#(config)interface fastEthernet 4/0
Router(config-if)# no l2protocol-tunnel
Protocol tunneling disabled on interface fastEthernet 4/1
```

Related Commands

Command	Description
show l2protocol-tunnel	Displays the protocols that are tunneled on an interface or on all interfaces.
switchport	Modifies the switching characteristics of the Layer 2-switched interface.

l2protocol-tunnel cos

To specify a class of service (CoS) value globally on all ingress Layer-2 protocol tunneling ports, use the **l2protocol-tunnelcos**command in global configuration mode. To return to the default , use the **no** form of this command.

l2protocol-tunnel cos *cos-value*
no l2protocol-tunnel cos

Syntax Description

cos-value	CoS value; valid values are from 0 to 7.

Command Default

The *cos-value* is **5**

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The *cos-value* is the CoS value that you assign to the PDUs on a Layer 2-protocol tunnel port before tunneling the PDUs through the service-provider network.

You can specify a CoS value globally on all ingress Layer 2-protocol tunneling ports. Because the CoS value applies to all ingress tunneling ports, all encapsulated PDUs that are sent out by the Cisco 7600 series router have the same CoS value.

On all the service-provider edge switches, you must enable PortFast BPDU filtering on the 802.1Q tunnel ports by entering these commands:

```
Router(config-if)# spanning-tree bpdufilter enable
Router(config-if)# spanning-tree portfast
```

Note PortFast BPDU filtering is enabled automatically on tunnel ports.

Examples

This example shows how to specify a CoS value on all ingress Layer 2-protocol tunneling ports:

```
Router(config)# l2protocol-tunnel cos 6
Router(config)#
```

Related Commands

Command	Description
show l2protocol-tunnel	Displays the protocols that are tunneled on an interface or on all interfaces.

l2protocol-tunnel drop-threshold

To specify the maximum number of packets that can be processed for the specified protocol on that interface before being dropped, use the **l2protocol-tunneldrop-threshold** command in interface configuration mode. To reset all the threshold values to 0 and disable the drop threshold, use the **no** form of this command.

l2protocol-tunnel drop-threshold [{**cdp** | **stp** | **vtp**}] *packets*
no l2protocol-tunnel drop-threshold [{**cdp** | **stp** | **vtp**}]

Syntax Description

cdp	(Optional) Specifies CDP packets.
stp	(Optional) Specifies STP packets.
vtp	(Optional) Specifies VTP packets.
packets	Maximum number of packets; valid values are from 1 to 4096 packets.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

On all the service-provider edge switches, you must enable PortFast BPDU filtering on the 802.1Q tunnel ports by entering these commands:

```
Router(config-if)# spanning-tree bpdufilter enable
Router(config-if)# spanning-tree portfast
```

Note PortFast BPDU filtering is enabled automatically on tunnel ports.

If you do not specify a protocol, the threshold applies to all protocols.

You can configure protocol tunneling on switch ports only. You must enter the **switchport** command once without any keywords to configure the LAN port as a Layer 2 interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

Refer to the “Configuring IEEE 802.1Q Tunneling and Layer 2 Protocol Tunneling” chapter of the Cisco 7600 Series Router Cisco IOS Software Configuration Guide for additional information on setting the drop threshold value.

Examples

This example shows how to set the drop threshold:

```
Router(config-if)# switchport
Router(config-if)# l2protocol-tunnel drop-threshold 3000
Router(config-if)#
```

Related Commands

Command	Description
l2protocol-tunnel	Enables the protocol tunneling on an interface and specifies the type of protocol to be tunneled.
l2protocol-tunnel cos	Specifies a CoS value globally on all ingress Layer-2 protocol tunneling ports.
l2protocol-tunnel global drop-threshold	Enables rate limiting at the software level.
l2protocol-tunnel shutdown-threshold	Specifies the maximum number of packets that can be processed for the specified protocol on that interface in 1 second.
show l2protocol-tunnel	Displays the protocols that are tunneled on an interface or on all interfaces.
switchport	Modifies the switching characteristics of the Layer 2-switched interface.

l2protocol-tunnel global drop-threshold

To enable rate limiting at the software level, use the **l2protocol-tunnelglobaldrop-threshold** command in global configuration mode. To disable the software rate limiter on the Cisco 7600 series routers, use the **no** form of this command.

l2protocol-tunnel global drop-threshold *threshold*
no l2protocol-tunnel global drop-threshold

Syntax Description

threshold	Maximum rate of incoming PDUs before excessive PDUs are dropped; valid values are from 100 to 20000 PDUs.

Command Default

Global thresholds are not configured.

Command Modes

Global configuration

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

All three PDUs (normal BPDU, CDP, and VTP packets) that arrive on Layer 2-protocol tunnel-enabled ports are rate limited. Rate limiting occurs in the ingress direction in Layer 2-protocol tunneling. If the rate of the incoming PDUs exceeds the configured threshold , the excessive PDUs are dropped.

Examples

This example shows how to enable rate limiting globally:

```
Router(config)# l2protocol-tunnel global drop-threshold 3000
Router(config)#
```

Related Commands

Command	Description
l2protocol-tunnel	Enables the protocol tunneling on an interface and specifies the type of protocol to be tunneled.
l2protocol-tunnel cos	Specifies a CoS value globally on all ingress Layer-2 protocol tunneling ports.
l2protocol-tunnel drop-threshold	Specifies the maximum number of packets that can be processed for the specified protocol on that interface before being dropped.
l2protocol-tunnel shutdown-threshold	Specifies the maximum number of packets that can be processed for the specified protocol on that interface in 1 second.
show l2protocol-tunnel	Displays the protocols that are tunneled on an interface or on all interfaces.

l2protocol-tunnel point-to-point

To enable point-to-point protocol tunneling, use the l2protocol-tunnel point-to-point command in interface configuration mode. To disable, use the **no** form of this command.

l2protocol-tunnel point-to-point [{**pagp** | **lacp** | **udld**}]
no l2protocol-tunnel point-to-point [{**pagp** | **lacp** | **udld**}]

Syntax Description

pagp	(Optional) Enables port aggregation on a point-to-point protocol tunneling.
lacp	(Optional) Enables link aggregation on a point-to-point protocol tunneling.
udld	(Optional) Enables a unidirectional link dectection on a point-to-point protocol tunneling.

Command Default

If no keyword is selected, tunneling is enabled for all three protocols.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.2(2)T	This command was introduced.

Usage Guidelines

To avoid a network failure, make sure that the network is a point-to-point topology before you enable tunneling for PAgP, LACP, or UDLD packets.

Examples

The following example shows how to enable link aggregation on a point-to-point protocol tunneling:

```
Router(config-if
)# l2protocol-tunnel point-to-point lacp
```

Related Commands

Command	Description
show l2protocol-tunnel	Displays the enabled protocols and their values.

l2protocol-tunnel shutdown-threshold

To specify the maximum number of packets that can be processed for the specified protocol on that interface in 1 second, use the **l2protocol-tunnelshutdown-threshold**command in interface configuration mode. To reset all the threshold values to 0 and disable the shutdown threshold, use the **no** form ofthis command.

l2protocol-tunnel shutdown-threshold [{**cdp** | **stp** | **vtp**}] *packets*
no l2protocol-tunnel shutdown-threshold [{**cdp** | **stp** | **vtp**}] *packets*

Syntax Description

cdp	(Optional) Specifies CDP tunneling.
stp	(Optional) Specifies STP tunneling.
vtp	(Optional) Specifies VTP tunneling.
packets	Shutdown threshold; valid values are from 1 to 4096.

Command Default

This command has no default settings.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When the number of *packets* is exceeded, the port is put in error-disabled state.

On all the service-provider edge switches, you must enable PortFast BPDU filtering on the 802.1Q tunnel ports by entering these commands:

```
Router(config-if)# spanning-tree bpdufilter enable
Router(config-if)# spanning-tree portfast
```

Note PortFast BPDU filtering is enabled automatically on tunnel ports.

If you do not specify a protocol, the *packets* value applies to all protocols.

You can configure protocol tunneling on switch ports only. You must enter the **switchport** command once without any keywords to configure the LAN port as a Layer 2 interface before you can enter additional **switchport** commands with keywords. This action is required only if you have not entered the **switchport** command for the interface.

Refer to the “Configuring IEEE 802.1Q Tunneling and Layer 2 Protocol Tunneling” chapter of the Cisco 7600 Series Router Cisco IOS Software Configuration Guide for additional information on setting the drop threshold value.

Examples

This example shows how to specify the maximum number of CDP packets that can be processed on that interface in 1 second:

```
Router(config-if)# switchport
Router(config-if)# l2protocol-tunnel shutdown-threshold cdp 200
Router(config-if)#
```

Related Commands

Command	Description
l2protocol-tunnel	Enables the protocol tunneling on an interface and specifies the type of protocol to be tunneled.
show l2protocol-tunnel	Displays the protocols that are tunneled on an interface or on all interfaces.
switchport	Modifies the switching characteristics of the Layer 2-switched interface.

l3vpn encapsulation ip

To configure an L3VPN encapsulation profile, use the **l3vpnencapsulationip** command in global configuration mode. To remove the encapsulation profile, use the **no** form of this command.

l3vpn encapsulation ip *profile name*
no l3vpn encapsulation ip *profile name*

Syntax Description

profile name	Name of the Layer 3 encapsulation profile.

Command Default

The L3VPN encapsulation profile is not configured.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SRE	This command was introduced.

Usage Guidelines

When you use the **l3vpnencapsulationip** command you enter into L3VPN encapsulation configuration mode. You can then specify the transport source mode and interface using the**transportipv4** command, set the GRE key using the **protocolgre** command, and configure the L3VPN encapsulation profile.

Examples

The following example shows how to configure an L3VPN encapsulation profile:

```
Router(config)# l3vpn encapsulation ip tunnelencap
```

Related Commands

Command	Description
show l3vpn encapsulation ip	Displays the profile health and the underlying tunnel interface.
transport ipv4	Specifies IPv4 transport source mode and the transport source interface.
protocol gre	Specifies GRE as the tunnel mode and sets the GRE key.

lacp active-port distribution automatic

To have an effective auto interleaved port priority distribution of active and bundled ports across different slots that are part of the same port channel distributed EtherChannel (DEC) and multichassis EtherChannel (MEC), use the **lacp active-port distribution automatic**command in port channel configuration mode.

lacp active-port distribution automatic
no lacp active-port distribution automatic

Syntax Description

This command has no keywords or arguments.

Command Default

Auto interleaved port priority is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI4	This command was introduced.

Usage Guidelines

The auto interleaved port-priority feature automatically distributes active and bundled ports based on the position of a port link when it comes up and is effective only if you configure it on the system that has the higher LACP system priority.

The port priority per port that you configured continues to take precedence over a dynamic port number. You need to perform a shutdown and no shutdown on the interface port channel to enable the auto interleaved port priority feature on all ports.

Examples

This example shows how to configure interleaved port priority:

```
Router(config)# interface port23
Router(config-if)# lacp active-port distribution automatic
Please shut/no shut the port-channel for configuration to take effect immediately.
Router(config-if)# shutdown
Router(config-if)# no shutdown
Router(config-if)# end
```

This example shows how to verify that interleaved port priority is configured:

```
Router# show running interface port23
Building configuration...
Current configuration : 81 bytes
!
interface Port-channel23
no switchport
no ip address
lacp max-bundle 4
lacp active-port distribution automatic
end
Router# show etherchannel 23 summary
Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
```

```
U - in use N - not in use, no aggregation
f - failed to allocate aggregator
M - not in use, no aggregation due to minimum links not met
m - not in use, port not aggregated due to minimum links not met
u - unsuitable for bundling
d - default port
w - waiting to be aggregated
Number of channel-groups in use: 9
Number of aggregators: 9
Group     Port-channel Protocol      Ports
------+-------------+-----------+-----------------------------------------------
23      Po23(RU)       LACP       Gi1/1/21(P) Gi1/1/22(P) Gi1/1/23(P)
                                  Gi1/1/24(P) Gi2/1/17(H) Gi2/1/18(H)
                                  Gi2/1/19(H) Gi2/1/20(H)
Last applied Hash Distribution Algorithm: Fixed
```

Note The four active and bundled ports are from the same chassis and slot.

Related Commands

Command	Description
show etherchannel	Displays EtherChannel information for a port channel.

lacp fast-switchover

To enable Link Aggregation Control Protocol (LACP) 1:1 link redundancy, use the **lacp fast-switchover** command in interface configuration mode. To dis able LACP 1:1 link redundancy, use the **no** form of this command.

lacp fast-switchover
no lacp fast-switchover

Syntax Description

This command has no arguments or keywords.

Command Default

LACP 1:1 link redundancy is disabled by default.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
12.2(33)SB	Support for this command was implemented on the Cisco 10000 series router and integrated into Cisco IOS Release 12.2(33)SB. The time allowed for a link switchover was modified from the default of 2 seconds to 250 milliseconds.
Cisco IOS XE Release 2.5	This command was integrated into Cisco IOS XE Release 2.5

Usage Guidelines

Prior to entering the **lacp fast-switchover** command, you must ensure the following:

- The port channel protocol type is LACP.
- The **lacp max-bundle 1**command has been entered on the port channel. The **lacp fast-switchover** command will not affect the **lacp max-bundle** command.

When you enable LACP 1:1 link redundancy, based on the system priority and port priority, the port with the higher system priority chooses the link as the active link and the other link as the standby link. When the active link fails, the standby link is selected as the new active link without taking down the port channel. When the original active link recovers, it reverts to its active link status. During this change-over, the port channel is also up.

Note We recommend that you configure two ports only (one active and one hot-standby) in the bundle for optimum performance.

You can enter this command on any port channels with different EtherChannel protocol types of LACP, Port Aggregation Protocol (PAgP), or Fast EtherChannel (FEC).

Examples

This example shows how to enable LACP 1:1 link redundancy:

```
Router(config-if)# lacp fast-switchover
```

This example shows how to disable LACP 1:1 link redundancy:

```
Router(config-if)# no lacp fast-switchover
```

Related Commands

Command	Description
lacp max-bundle	Assigns and configures an EtherChannel interface to an EtherChannel group.
show etherchannel	Displays the EtherChannel information for a channel.

lacp max-bundle

To define the maximum number of active bundled Link Aggregation Control Protocol (LACP) ports allowed in a port channel, use the **lacp max-bundle** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

lacp max-bundle *max-bundles*
no lacp max-bundle

Syntax Description

max-bundles	Maximum number of active bundled ports allowed in the port channel. Valid values are from 1 to 8. On the Cisco ASR 1000 series router, valid values are 1 to 4. The default settings are as follows: • Maximum of 8 bundled ports per port channel. • Maximum of 8 bundled ports and 8 hot-standby ports per port channel if the port channels on both sides of the LACP bundle are configured in the same way. • On the Cisco 10000 series router, maximum of 8 bundled ports per port channel.

Command Default

A maximum number of active bundled ports is not configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(18)SXD	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	Support for this command was implemented on the Cisco 10000 series router and integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	Support for this command on the Cisco 7600 router was integrated into Cisco IOS Release 12.2(33)SRB.
12.2(33)SB	On the Cisco 10000 series router, the maximum number of bundled ports per port channel was increased from 4 to 8.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.
12.2(33)SRE	This command was integrated into Cisco IOS Release 12.2(33)SRE.

Usage Guidelines

The value specified in the *max-bundles* argument determines the number of active links that are bundled in the port channel. The remaining links are in hot-standby mode.

On the Cisco 10000 series router, this command requires a Performance Routing Engine 2 (PRE2) or PRE3.

Examples

This example shows how to set 3 ports to bundle in port channel 2:

```
Router(config)# interface port-channel 2
Router(config-if)# lacp max-bundle 3
Router(config-if)#
```

Related Commands

Command	Description
interface port-channel	Creates a port-channel virtual interface and puts the CLI in interface configuration mode.
ip address	Sets a primary or secondary IP address on an interface.
show etherchannel	Displays the EtherChannel information for a channel.
show interfaces port-channel	Displays traffic that is seen by a specific port channel.

lacp port-priority

To set the priority for a physical interface, use the **lacp port-priority** command in interface configuration mode. To return to the default setting, use the **no** form of this command.

lacp port-priority *priority*

no lacp port-priority

Syntax Description

priority	Integer from 1 to 65535 that indicates the priority for the physical interface. The default is 32768. • On the Cisco ASR 1000 series router, the range is 0 to 65535.

Command Default

The default port priority is set.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.1(13)EW	This command was introduced on the Cisco Catalyst 4500 series switches.
12.2(14)SX	Support for this command on the Supervisor Engine 720 was integrated into Cisco IOS Release12.2(14)SX.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was integrated into Cisco IOS Release12.2(17d) SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	Support for this command on the Cisco 7600 router was integrated into Cisco IOS Release 12.2(33)SRB.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

You may assign a port priority to each port on a device running Link Aggregation Control Protocol (LACP). You can specify the port priority by using the **lacp port-priority** command at the command-line interface (CLI) or use the default port priority (32768) that is carried as part of the LACP protocol data unit (PDU) exchanged with the partner. Port priority is used to decide which ports should be put in standby mode when a hardware limitation or the **lacp max-bundle** command configuration prevents all compatible ports from aggregating. Priority is supported only on port channels with LACP-enabled physical interfaces.

Note A high priority number means a low priority.

Port priority together with port number form a port identifier.

To verify the configured port priority, issue the **show lacp** command.

Examples

This example shows how to set a priority of 23700 for an interface:

```
Device> enable
Device#  configure terminal
Device(config)#  interface ethernet0/0
Device(config-if)# lacp port-priority 23700
Device(config-if)#
```

Related Commands

Command	Description
channel-group	Assigns and configures an EtherChannel interface to an EtherChannel group.
debug lacp	Enables debugging of LACP activities.
lacp max-bundle	Defines the maximum number of active bundled LACP ports allowed in a port channel.
lacp system-priority	Sets the priority of the system.
show lacp	Displays information about LACP activity on the device.

lacp rate

To set the rate at which Link Aggregation Control Protocol (LACP) control packets are ingressed to an LACP-supported interface, use the **lacp rate** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

lacp rate {**normal** | **fast**}
no lacp rate

Syntax Description

normal	Specifies that LACP control packets are ingressed at the normal rate, every 30 seconds after the link is bundled.
fast	Specifies that LACP control packets are ingressed at the fast rate, once every 1 second.

Command Default

The default ingressed rate for control packets is 30 seconds after the link is bundled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(18)SXF2	This command was introduced on the Catalyst 6500 series switch.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
Cisco IOS XE Release 3.6S	This command was implemented on Cisco ASR 1000 Series Aggregation Services Routers in Cisco IOS XE Release 3.6S.

Usage Guidelines

Use this command to modify the duration of a LACP timeout. The LACP timeout value is set on Cisco switches to a value of 90 seconds. Using the **lacp rate** command, you can select the LACP timeout value for a switch to be either 30 seconds or 1 second.

This command is supported only on LACP-enabled interfaces.

Examples

This example shows how to specify the fast (1-second) ingress rate on interface Ethernet 0/1:

```
Router(config)# interface ethernet 0/1
Router(config-if)# lacp rate fast
```

Related Commands

Command	Description
show lacp	Displays LACP information.

lacp system-priority

To set the priority for a system, use the **lacp system-priority** command in global configuration mode. To return to the default setting, use the **no** form of this command.

lacp system-priority *priority*

no lacp system-priority

Syntax Description

priority	Integer from 1 to 65535 that indicates the priority for the system. The default is 32768. • On the Cisco ASR 1000 series router, the range is 0 to 65535.

Command Default

The default system priority is set.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(13)EW	This command was introduced on the Cisco Catalyst 4500 series switches.
12.2(14)SX	Support for this command on the Supervisor Engine 720 was integrated into Cisco IOS Release12.2(14)SX.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was integrated into Cisco IOS Release12.2(17d) SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(31)SB2	This command was integrated into Cisco IOS Release 12.2(31)SB2.
12.2(33)SRB	Support for this command on the Cisco 7600 router was integrated into Cisco IOS Release 12.2(33)SRB.
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

You can assign a system priority to each device running Link Aggregation Control Protocol (LACP). You can specify the system priority by using the **lacp system-priority** command at the command-line interface (CLI) or use the default system priority (32768) that is carried as part of the LACP protocol data unit (PDU) exchanged with the partner. System priority is used with the MAC address of the device to form the system ID and also is used during negotiation with other systems. Priority is supported only on port channels with LACP-enabled physical interfaces.

Note A high priority number means a low priority.

To verify the configured system priority, issue the **show lacp** command.

Examples

The following example shows how to set a system priority of 25500 for a device:

```
Router> enable
Router# configure terminal
Router(config)# lacp system-priority 25500
```

Related Commands

Command	Description
channel-group	Assigns and configures an EtherChannel interface to an EtherChannel group.
debug lacp	Enables debugging of LACP activities.
lacp port-priority	Sets the priority of a port.
show lacp	Displays information about LACP activity on the device.

lbo

To set a cable length longer than 655 feet for a DS-1 link, use the**lbo**command in interface configuration mode on the interface for a T1 link. To delete the **lbo**value, use the **no** form of this command.

lbo {**long** {**gain26** | **gain36**} {**-15db** | **-22 . 5db** | **-7 . 5db** | **0db**} | **short** {**133** | **266** | **399** | **533** | **655**}}
no lbo

Syntax Description

long	Specifies the long-haul mode where the gain and line build out must be configured.
gain26	Specifies the decibel pulse gain at 26 decibels. This is the default pulse gain.
gain36	Specifies the decibel pulse gain at 36 decibels.
-15db	Specifies the decibel pulse rate at -15 decibels.
-22.5db	Specifies the decibel pulse rate at -22.5 decibels.
-7.5db	Specifies the decibel pulse rate at -7.5 decibels.
0db	Specifies the decibel pulse rate at 0 decibels. This is the default.
short	Specifies the short-haul mode where the cable length, in feet, must be configured.
133	Specifies a cable length from 0 to 133 feet.
266	Specifies a cable length from 134 to 266 feet.
399	Specifies a cable length from 267 to 399 feet.
533	Specifies a cable length from 400 to 533 feet.
655	Specifies a cable length from 534 to 655 feet.

Command Default

gain26 and**0db**

Command Modes

Interface configuration

Command History

Release	Modification
11.3MA	This command was introduced as a Cisco MC3810 controller configuration command.
12.0(5)XE	The command was introduced as an ATM interface command.
12.0(7)XE1	This command was implemented on Cisco 7100 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is supported on T1 links only.

Each T1 port can operate in long-haul or short-haul mode. In long haul mode, the user must specify the gain and the line build out. In short-haul mode, the user must specify the cable length in feet.

The transmit attenuation value is best obtained by experimentation. If the signal received by the far-end equipment is too strong, reduce the transmit level by entering additional attenuation.

Examples

On Cisco 7100 or Cisco 7200 series routers, the following example specifies a pulse gain of 36 decibels and a decibel pulse rate of -7.5 decibels:

```
Router(config)# interface atm 1/2
Router(config-if)# lbo long gain36 -7.5db
```

lex burned-in-address

To set the burned-in MAC address for a LAN Extender interface, use the **lexburned-in-address** command in interface configuration mode. To clear the burned-in MAC address, use the **no** form of this command.

lex burned-in-address *ieee-address*
no lex burned-in-addresslex burned-in-address command

Syntax Description

ieee-address	48-bit IEEE MAC address written as a dotted triplet of 4-digit hexadecimal numbers.

Command Default

No burned-in MAC address is set.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

Use this command only on a LAN Extender interface that is not currently active (not bound to a serial interface).

Examples

The following example sets the burned-in MAC address on LAN Extender interface 0:

```
Router(config)# interface serial 4
Router(config-if)# encapsulation ppp
Router(config)# interface lex 0
Router(config-if)# lex burned-in-address 0000.0c00.0001
Router(config-if)  ip address 10.108.172.21 255.255.255.0
```

lex input-address-list

To assign an access list that filters on MAC addresses, use the **lexinput-address-list** command in interface configuration mode. To remove an access list from the interface, use the **no** form of this command.

lex input-address-list *access-list-number*
no lex input-address-listlex input-address-list command

Syntax Description

access-list-number	Number of the access list assigned with the **access-list** global configuration command. It can be a number from 700 to 799.

Command Default

No access lists are preassigned to a LAN Extender interface.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

Use the **lexinput-address-list** command to filter the packets that are allowed to pass from the LAN Extender to the core router. The access list filters packets on the basis of the source MAC address.

The LAN Extender interface does not process MAC-address masks. Therefore, you should omit the mask from the **access-list** commands.

For LAN Extender interfaces, an implicit permit everything entry is automatically defined at the end of an access list. Note that this default differs from other access lists, which have an implicit deny everything entry at the end of each access list.

Examples

The following example applies access list 710 to LAN Extender interface 0. This access list denies all packets from MAC address 0800.0214.2776 and permits all other packets.

```
Router(config-if)# access-list 710 deny 0800.0214.2776
Router(config)# interface lex 0
Router(config-if)# lex input-address-list 710
```

Related Commands

Command	Description
access-list	Configures the access list mechanism for filtering frames by protocol type or vendor code.

lex input-type-list

To assign an access list that filters Ethernet packets by type code, use the **lexinput-type-list** command in interface configuration mode. To remove an access list from an interface, use the **no** form of this command.

lex input-type-list *access-list-number*
no lex input-type-list lex input-type-list command

Syntax Description

access-list-number	Number of the access list that you assigned with the **access-list** command. It can be a number in the range 200 to 299.

Command Default

No access lists are preassigned to a LAN Extender interface.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

Filtering is done on the LAN Extender chassis.

The LAN Extender interface does not process masks. Therefore, you should omit the mask from the **access-list** commands.

For LAN Extender interfaces, an implicit permit everything entry is automatically defined at the end of an access list. Note that this default differs from other access lists, which have an implicit deny everything entry at the end of each access list.

Examples

The following example applies access list 220 to LAN Extender interface 0. This access list denies all AppleTalk packets (packets with a type field of 0x809B) and permits all other packets.

```
Router(config-if)# access-list 220 deny 0x809B 0x0000
Router(config)# interface lex 0
Router(config-if)# lex input-type-list 220
```

Related Commands

Command	Description
access-list	Configures the access list mechanism for filtering frames by protocol type or vendor code.

lex priority-group

To activate priority output queueing on the LAN Extender, use the **lexpriority-group** command in interface configuration mode. To disable priority output queueing, use the **no** form of this command.

lex priority-group *group*
no lex priority-group

Syntax Description

group	Number of the priority group. It can be a number in the range 1 to 10.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

To define queueing priorities, use the **priority-listprotocol** global configuration command. Note that you can use only the following forms of this command:

```
priority-list

list
 protocol

protocol

{
high
 |
medium
 |
normal
 |
low
priority-list

list
 protocol
 bridge

{
high
 |
medium
 |
normal
 |
low
}
```

list

list-number

If you specify a protocol that does not have an assigned Ethernet type code, such as **x25**, **stun**, or **pad**, it is ignored and will not participate in priority output queueing.

Examples

The following example activates priority output queueing on LAN Extender interface 0:

```
Router(config-if)# priority-list 5 protocol bridge medium list 701
Router(config-if)# lex interface 0
Router(config-if)# lex priority-group 5
```

Related Commands

Command	Description
priority-list protocol	Establishes queueing priorities based on the protocol type.

lex retry-count

To define the number of times to resend commands to the LAN Extender chassis, use the **lexretry-count** command in interface configuration mode. To return to the default value, use the **no** form of this command.

lex retry-count *number*
no lex retry-count *number* **lex retry-count command**

Syntax Description

number	Number of times to retry sending commands to the LAN Extender. It can be a number in the range 0 to 100. The default is 10.

Command Default

10 retries

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

After the router has sent a command the specified number of times without receiving an acknowledgment from the LAN Extender, it stops sending the command altogether.

Examples

The following example resends commands 20 times to the LAN Extender:

```
Router(config-if)# lex interface 0
Router(config-if)# lex retry-count 20
```

Related Commands

Command	Description
lex timeout	Defines the amount of time to wait for a response from the LAN Extender.

lex timeout

To define the amount of time to wait for a response from the LAN Extender, use the **lextimeout** command in interface configuration mode. To return to the default time, use the **no** form of this command.

lex timeout *milliseconds*
no lex timeout [*milliseconds*] **lex timeout command**

Syntax Description

milliseconds	Time, in milliseconds, to wait for a response from the LAN Extender before resending the command. It can be a number in the range 500 to 60,000. The default is 2000 ms.

Command Default

2000 ms (2 seconds)

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco_IOS Mainline or Technology-based (T) releases. It may continue to appear in Cisco_IOS 12.2S-family releases.

Usage Guidelines

The **lextimeout** command defines the amount of time that the router waits to receive an acknowledgment after having sent a command to the LAN Extender.

Examples

The following example causes unacknowledged packets to be resent at 4-second intervals:

```
Router(config-if)# lex interface 0
Router(config-if)# lex timeout 4000
```

Related Commands

Command	Description
lex retry-count	Defines the number of times to resend commands to the LAN Extender chassis.

license feature gnss

To configure the license for the global navigation satellite system (GNSS) module on the Cisco ASR 920 routers, use the **license feature gnss** command in the global configuration mode. To remove the license, use the **no** form of this command.

license feature gnss
no license feature gnss

Command Default

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
IOS-XE 3.17	This command was introduced on the Cisco ASR 920 routers.

Usage Guidelines

Only when the GNSS license is in use, the **shutdown** and **no shutdown** operations for the GNSS module can be performed.

Examples

The following example shows how to configure the GNSS license:

```
Router# configure terminal
Router(config)# license feature gnss
```

Related Commands

Command	Description
gnss	Configures the GNSS on the router.

linecard-group y-cable

To create a line card group for one-to-one line card redundancy, use the linecard-group y-cable command in redundancy mode. To remove the line card redundancy group, use the no form of this command.

linecard-group *linecard-groupId* **y-cable**
no linecard-group *linecard-groupId* **y-cable**

Syntax Description

linecard-groupId	An unsigned integer in the range 0 to the (maximum number of chassis line card subslots/2) -1.
y-cable	The link protection type for the line card group.

Command Default

No default behavior or values .

Command Modes

Redundancy

Command History

Release	Modification
12.2(28)SB	This command was introduced on the Cisco 10000 series router.

Usage Guidelines

The no linecard-group y-cable command removes the line card redundancy group and frees the *linecard-groupId*for reuse. The no linecard-group y-cable command succeeds only if there are no subslot members in the line card redundancy group.

Examples

The following example creates line card group number 1 for one-to-one line card redundancy:

```
Router(config)# redundancy
Router(config-red)# linecard-group 1 y-cable
```

Related Commands

Command	Description
member subslot	Configures the redundancy role of a line card in the line card group.
redundancy	Enters redundancy mode.
show redundancy linecard	Displays information about a redundant line card or line card group.

linecode

To select the line-code type for T1 or E1 lines, use the **linecode** command in controller configuration mode.

linecode {**ami** | **b8zs** | **hdb3**}

Syntax Description

ami	Specifies alternate mark inversion (AMI) as the line-code type. Valid for T1 or E1 controllers. This is the default for T1 lines.
b8zs	Specifies B8ZS as the line-code type. Valid for T1 controller only.
hdb3	Specifies high-density bipolar 3 (hdb3) as the line-code type. Valid for E1 controller only. This is the default for E1 lines.

Command Default

AMI is the default for T1 lines. High-density bipolar 3 is the default for E1 lines.

Command Modes

Controller configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

Use this command in configurations in which the router or access server must communicate with T1 fractional data lines. The T1 service provider determines which line-code type, either **ami** or **b8zs**, is required for your T1 circuit. Likewise, the E1 service provider determines which line-code type, either **ami** or **hdb3**, is required for your E1 circuit.

This command does not have a **no** form.

Examples

The following example specifies B8ZS as the line-code type:

```
Router(config-controller)# linecode b8zs
```

line-mode

To configure the mode of the controller for the Symmetrical High-Speed Digital Subscriber Line (SHDSL) port, use the **line-mode** command in controller configuration mode. To return to the default two-wire mode, use the **no** form of this command.

line-mode [{**2-wire** | **4-wire** [{**enhanced** | **standard**}] | **auto**}]
no line-mode

Syntax Description

2-wire	(Optional) Configures the controller to operate in two-wire mode.
4-wire	(Optional) Configures the controller to operate in four-wire mode.
enhanced	(Optional) Configures 4-wire mode to exchange handshake status on both wire pairs. This is the default if the handshake mode is not specified.
standard	(Optional) Configures 4-wire mode to exchange handshake status on the master wire pair only.
auto	(Optional) Configures the controller to automatically operate in the mode to match the other line termination. This mode is compatible with a remote host that is in one of the following modes: • line-mode 2-wire line 0 • line-mode 2-wire line 1 • line-mode 4-wire enhanced

Command Default

The default is two-wire mode if this command is omitted or if the **4-wire** keyword is omitted.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.
12.4(2)XA	The **enhanced** and **standard** keywords were added to four-wire mode.
12.4(5)A	Modified **auto** keyword to to disallow use of **line-rate** command
12.4(4)T	Modified **auto** keyword to to disallow use of **line-rate** command

Usage Guidelines

This command is used to configure the controller for two-wire or four-wire mode.

Note To operate in four-wire mode for SHDSL, the **line-mode4-wire**command must be set.

Note When the **line-mode** command is set to **auto**, the **line-rate** command is not available.

Examples

4-Wire Line Mode Example

The following example shows how to configure the controller mode of DSL on the controller in slot 4 and port 0 to operate in four-wire mode:

```
Router(config)# controller dsl 4/0
Router(config-controller)# line-mode
 4-wire
```

CPE Line Mode Example

The following example configures the controller in slot 1 and port 0. The router is set to terminate as CPE with the line mode automatically selecting between two-wire mode and four-wire mode.

```
Router(config)# controller dsl 1/0
Router(config-controller)# line-mode auto
Router(config-controller)# line-term cpe
```

Related Commands

Command	Description
line-rate	Specifies a line rate for the DSL controller.
line-term	Specifies a termination for a line.

line-mode bonding

To enable bonding mode on a CPE, use the **line-mode bonding** command in controller configuration mode. To disable the bonding mode, use the **no** form of this command.

line-mode bonding
no line-mode bonding

Syntax Description

This command has no keywords or arguments.

Command Default

Bonding is not the default mode.

Command Modes

Controller configuration (config-controller)#

Command History

Release	Modification
15.4(4)T	This command was introduced.

Usage Guidelines

Use this command when a CPE is expected to operate in bonding mode.

Examples

The following example shows how to enable bonding mode:

```
Router(config-controller)# line-mode bonding
```

The following example shows how to disable bonding mode:

```
Router(config-controller)# no line-mode bonding
```

Related Commands

Command	Description
line-mode single-wire line	Enables single-wire (nonbonding) mode on a selected line.

line-mode single-wire line

To enable single-wire (nonbonding) mode on a selected line, use the **line-mode single-wire line** command in controller configuration mode. To disable the mode, use the **no** form of this command.

line-mode single-wire line *line-number*
`or`
line-mode single-wire line *line-number* **[profile 30a]**
no line-mode single-wire line *line-number*

Syntax Description

line-number	Line number. Valid values are either 1 or 0.
profile 30a	Enables 30a profile on line 1. If profile 30a is not specified, profiles 8a to 17a are enabled on that line.

Command Default

By default, single-wire mode is enabled on line 0 with profiles from 8a to17a enabled.

Command Modes

Controller configuration (config-controller)#

Command History

Release	Modification
15.4(4)T	This command was introduced.

Usage Guidelines

Use this command to configure either line 0 or line 1 in single-wire (non-bonding) mode.

Examples

The following example shows how to enable 30a profile on line 1:

```
Router(config-controller)# line-mode single-wire line 1 profile 30a
```

Related Commands

Command	Description
line-mode bonding	Changes the mode of a CPE to bonding.

line-rate

To specify a line rate for the DSL controller, use the **line-rate** command in controller configuration mode.

line-rate {**auto***rate*}

Syntax Description

auto	Allows the controller to select the rate. This option is available only in two-wire mode.
rate	DSL line rate, in kbps. The line will train at the selected rate plus 8 kbps of DSL framing overhead. The supported line rates are as follows: • For two-wire mode: • 192, 256, 320, 384, 448, 512, 576, 640, 704, 768, 832, 896, 960, 1024, 1088, 1152, 1216, 1280, 1344, 1408, 1472, 1536, 1600, 1664, 1728, 1792, 1856, 1920, 1984, 2048, 2112, 2176, 2240, and 2304 • For four-wire mode: • 384, 512, 640, 768, 896, 1024, 1152, 1280, 1408, 1536, 1664, 1792, 1920, 2048, 2176, 2304, 2432, 2560, 2688, 2816, 2944, 3072, 3200, 3328, 3456, 3584, 3712, 3840, 3968, 4096, 4224, 4352, 4480, and 4608

Command Default

No default behavior or values.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(4)XG	This command was implemented on Cisco 1700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.
12.4(5)A	Modified **line-rate** command to be disallowed when **line-mode**command is set to **auto**.
12.4(4)T	Modified **line-rate** command to be disallowed when **line-mode**command is set to **auto**.

Usage Guidelines

This command does not have a **no** form.

This command specifies the DSL line rate for the Symmetrical High-Speed Digital Subscriber Line (SHDSL) port. Use this command to configure the line rate in two-wire or four-wire mode. The SHDSL rate is in kbps, but the line trains at the selected rate plus two times the 8 kbps of DSL framing overhead.

Note Automatic rate mode (auto) is used only in two-wire mode. It is not available in four-wire mode.

Note If different DSL line rates are configured at opposite ends of the DSL uplink, the actual DSL line rate is always the lower rate.

Note The maximum peak cell rate is 8 kbps less than the line rate.

Note When the **line-mode** command is set to **auto**, the **line-rate** command is not available.

Examples

The following example displays the **line-mode** command selecting four-wire mode, which is different from the previous line mode of the router as indicated by the router output, and then the line rate is selected. The rate of 4608 is selected, and the output of the router is shown.

```
Router(config)# controller dsl 1/0
Router(config-controller)# line-mode
 4-wire
Router(config-controller)#
*Jun 15 18:00:48.159: %CONTROLLER-5-UPDOWN: Controller DSL 1/0, changed state tn
*Jun 15 18:00:50.159: %LINK-3-UPDOWN: Interface ATM1/0, changed state to down
*Jun 15 18:00:51.159: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM1/0, cn
Router(config-controller)# line-rate
 4608
Router(config-controller)#
*Jun 15 18:01:36.627: %CONTROLLER-5-UPDOWN: Controller DSL 1/0, changed state tn
*Jun 15 18:01:36.967: %CONTROLLER-5-UPDOWN: Controller DSL 1/0, changed state tn
Router(config-controller)# exit
```

Related Commands

Command	Description
line-mode	Configures the mode of the controller.
line-term	Specifies a termination for a line.

line-term

To specify a termination for a line, use the **line-term** command in controller configuration mode.

line-term {**co** | **cpe**}

Syntax Description

co	Central office.
cpe	Customer premises equipment. This is the default.

Command Default

The default value is **cpe**.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

This command does not have a no form.

This command is used to configure the line termination for use as either the central office (CO) or the customer premises equipment (CPE).

Examples

The following example shows how to configure the controller in slot 1 and port 0. The router is set to terminate as CPE with the line mode automatically selecting between two-wire mode and four-wire mode.

```
Router(config)# controller dsl 1/0
Router(config-controller)# line-term
 cpe
Router(config-controller)# line-mode
auto

No change in line mode
```

Related Commands

Command	Description
line-mode	Configures the mode of the controller.
line-rate	Specifies a line rate for the DSL controller.

line-termination

To set the line termination on an E1 controller, use the **line-termination**command in controller configuration mode. To return to the default line termination, use the **no** form of this command.

line-termination {**75-ohm** | **120-ohm**}
no line-termination

Syntax Description

75-ohm	Specifies 75-ohm unbalanced termination.
120-ohm	Specifies 120-ohm balanced termination. This is the default.

Command Default

120-ohms

Command Modes

Controller configuration

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies only to E1 controllers. To determine the line termination setting for the controller, use the **showcontrollerse1**command.

Examples

In the following example, the line termination is set to 75 ohms for the E1 port located in shelf 6, slot 0, port 0:

```
Router# configure terminal
Router(config)# controller e1 6/0/0
Router(config-controller)# line-termination 75-ohm
Router(config-controller)# end
```

Related Commands

Command	Description
show controllers e1	Displays information about the E1 links supported by the NPM (Cisco 4000) or MIP (Cisco 7500 series).

link debounce

To enable the debounce timer on an interface, use the **linkdebounce** command in interface configuration mode. To disable the timer, use the **no** form of this command.

link debounce [**time** *time*]
no link debounce

Syntax Description

time *time*	(Optional) Specifies the extended debounce timer; va lid values are from 100 to 5000 milliseconds.

Command Default

The table below lists the debounce timer defaults.

Table 23: Port Debounce Timer Delay Time

Port Type	Debounce Timer Disabled	Debounce Timer Enabled
10BASE-FL ports	300 milliseconds	3100 milliseconds
10/100BASE-TX ports	300 milliseconds	3100 milliseconds
100BASE-FX ports	300 milliseconds	3100 milliseconds
10/100/1000BASE-TX ports	300 milliseconds	3100 milliseconds
1000BASE-TX ports	300 milliseconds	3100 milliseconds
Fiber Gigabit ports	10 milliseconds	100 milliseconds
10-Gigabit ports except WS-X6501-10GEX4 and WS-X6502-10GE	10 milliseconds	100 milliseconds
WS-X6501-10GEX4 and WS-X6502-10GE 10-Gigabit ports	1000 milliseconds	3100 milliseconds

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17a)SX	This command was changed to remove support for the following modules: • WS-X6501-10GEX4 • WS-X6502-10GE
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **time***time* keyword and argument are supported on Gigabit Ethernet and 10-Gigabit Ethernet interfaces only.

The **linkdebounce** command is not supported on the following modules in releases prior to Release 2.2(17a)SX:

- WS-X6501-10GEX4
- WS-X6502-10GE

The debounce timer sets the amount of time that the firmware waits before it notifies the software that the link is down. The debounce timer does not apply to linkup because the linkup is immediately notified by the firmware.

The default debounce time applies when you enter the **linkdebounce** command with no arguments. For example, when you enter the **linkdebouncetime100** command, it is equivalent to entering the **linkdebounce** command with no arguments and you will see the following link debounce entry in the configuration:

```
interface GigabitEthernet1/1
 no ip address
 link debounce
```

Enter the **showinterfacesdebounce** command to display the debounce configuration of an interface.

Examples

This example shows how to configure the debounce timer on a Gigabit Ethernet fiber interface:

```
Router(config-if)# link debounce time 100
Router(config-if)#
```

Related Commands

Command	Description
show interfaces debounce	Displays the status and configuration for the debounce timer.

link state group

To configure the link state group, use the **linkstategroup** command in interface configuration mode.

link state group [*number*] {**upstream** | **downstream**}

Syntax Description

number	Specifies a link-state group. The acceptable range of group number is between 1 to 10 and the default value is 1.
upstream	Configures the interface as an upstream interface in the group.
downstream	Configures the interface as a downstream interface in the group.

Command Default

The default **linkstategroup**number is 1.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

Link State Ttracking (LST), also known as trunk failover, is a feature that binds the link state of multiple interfaces. When you configure LST for the first time, add upstream interfaces to the link state group before adding the downstream interface, otherwise the downstream interfaces would move into error-disable mode. The maximum number of link state groups configurable is 10. These are the limitations:

- An interface can only be an upstream or downstream interface.
- An interface cannot be part of more than one link state tracking group.

Examples

The following example shows how to configure the link state group number.

```
Router# configure terminal
Router(config)# link state track 1
Router(config)# interface gigabitethernet3/1
Router(config-if)# link state group 1 upstream
Router(config-if)# interface gigabitethernet3/3
Router(config-if)# link state group 1 upstream
Router(config-if)# interface gigabitethernet3/5
Router(config-if)# link state group 1 downstream
Router(config-if)# interface gigabitethernet3/7
Router(config-if)# link state group 1 downstream
```

Related Commands

Command	Description
link state track	Configures the link-state track number.
show link state group	Displays the link-state group information.

link state track

To configure a link state tracking number, use the **linkstatetrack** command in global configuration mode. To restore the default **linkstatetrack**number, use the no form of this command.

link state track *number*
no link state track *number*

Syntax Description

number	Specifies the link state tracking number. The acceptable range is between 1 and 10 and the default value is 1.

Command Default

The default link state track number is 1.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.1(1)S	This command was introduced.

Usage Guidelines

Link State Ttracking (LST), also known as trunk failover, is a feature that binds the link state of multiple interfaces. When you configure LST for the first time, add upstream interfaces to the link state group before adding the downstream interface, otherwise the downstream interfaces would move into error-disable mode.

Examples

The following example shows how to configure the link state tracking number.

```
Router# configure terminal
Router(config)# link state track 1
```

Related Commands

Command	Description
link state group	Configures the link state group and the interface as either an upstream or downstream interface in the group.
show link state group	Displays the link state group information.

li-slot rp rate

To apply the user specified Packets Per Second (PPS) value when an Lawful Intercept (LI) is provisioned in RP mode, use the **li-slot rp rate** command in global configuration mode. To disable the user specified value, use the no form of this command .

li-slot rp rate *pps*

Syntax Description

pps	Packets per second (pps). The range is from 10 to 8500 for SUP720, 10 to 6000 for SUP32, and 10 to 12000 for RSP720.

Command Default

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)S5	This command was introduced on the Cisco 7600 series routers.

Examples

This example shows how to apply PPS value when an LI is provisioned in RP mode:

```
router# configure terminal
router(config)# li-slot rp rate 5000
```

Related Commands

Command	Description
show mls rate-limit	Displays information about the configured rate limiters.

link-test

To reenable the link-test function on a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router, use the **link-test** command in hub configuration mode. To disable this function, use the **no** form of this command.

link-test commandlink-test
no link-test

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Hub configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies to a port on an Ethernet hub only. Disable this feature if a 10Base-T twisted-pair device at the other end of the hub does not implement the link test function.

Examples

The following example disables the link test function on hub 0, ports 1 through 3:

```
Router(config)#
 hub ethernet 0 1 3
Router(config-hub)#
 no link-test
```

Related Commands

Command	Description
hub	Enables and configures a port on an Ethernet hub of a Cisco 2505 or Cisco 2507 router.

load-balancing

To apply a load-balancing method to a Gigabit EtherChannel (GEC) interface, use the **load-balancing** command in interface configuration mode. To reset to the default, use the **no** form of this command.

load-balancing {**flow** | **vlan**}
no load-balancing

Syntax Description

flow	Flow-based load balancing is used.
vlan	VLAN-manual load balancing is used.

Command Default

The port channel uses the global load-balancing configuration.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
Cisco IOS XE Release 2.5	This command was introduced.

Usage Guidelines

The **load-balancing** command sets the load-balancing method on a specific port channel. The load-balancing method configured with this command takes precedence over the global configuration defined with the **port-channelload-balancingvlan-manual** command.

If you do not explicitly configure load balancing either globally or on the port channel, the load-balancing method on the port channel is set to flow-based.

Load balancing uses the concept of buckets to map traffic flows to the member links of the port channel. The different traffic flows are mapped to the buckets and each bucket has one active member link associated with it. All flows that are mapped to a bucket use the member link associated with that bucket.

There are two methods of load balancing on a GEC interface:

- VLAN-manual--All packets forwarded over the same VLAN subinterface are considered part of the same flow and are mapped to the member link specified in the configuration.
- Flow-based--Traffic flows are mapped to different member links based on the packet header.

Examples

This example shows how to set the load-balancing method to VLAN-manual:

```
Router(config)# interface port-channel 1
Router(config-if)# load-balancing vlan
```

Related Commands

Command	Description
interface port-channel	Creates a port-channel virtual interface.
port-channel load-balancing vlan-manual	Applies the VLAN-manual load-balancing method globally to all GEC interfaces.

Command	Description
show interfaces port-channel etherchannel	Displays the load-balancing bucket distribution currently in use for a GEC interface.
show etherchannel load-balancing	Displays the load-balancing method applied to GEC interfaces.

load-interval

To change the length of time for which data is used to compute load statistics, use the **load-interval** command in interface configuration, Frame Relay DLCI configuration, or template configuration modes. To revert to the default setting, use the **no**form of this command.

load-interval *seconds*
no **load-interval** *seconds*

Syntax Description

seconds	Length of time for which data is used to compute load statistics. Value is a multiple of 30, from 30 to 600 (30, 60, 90, 120, and so on). The default is 300 seconds.

Command Default

Enabled

Command Modes

Interface configuration

Frame Relay DLCI configuration

Template configuration (config-template)

Command History

Release	Modification
10.3	This command was introduced.
12.2(4)T	This command was made available in Frame Relay DLCI configuration mode.
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.
15.2(2)E	This command was integrated into Cisco IOS Release 15.2(2)E. This command is supported in template configuration mode.
Cisco IOS XE Release 3.6E	This command was integrated into Cisco IOS XE Release 3.6E. This command is supported in template configuration mode.

Usage Guidelines

To make computations more reactive to short bursts of traffic, you can shorten the length of time over which load averages are computed.

If the load interval is set to 30 seconds, new data is used for load calculations over a 30-second period. This data is used to compute load statistics, including the input rate in bits and packets per second, the output rate in bits and packets per second, the load, and reliability.

Load data is gathered every five seconds. This data is used for a weighted-average calculation in which recent load data has more weight in the computation than older load data. If the load interval is set to 30 seconds, the average is computed for the last 30 seconds of load data.

If you change the calculation interval from the default of five minutes to a shorter period of time, the input and output statistics that are displayed by the **show interface** command or the **show frame-relay pvc** command will be more current and will be based on more nearly instantaneous data, rather than reflecting the average load over a longer period of time.

This command is often used for dial backup purposes to increase or decrease the likelihood of implementation of a backup interface, but it can be used on any interface.

Examples

Interface Example

In the following example, the default average of five minutes is changed to a 30-second average. A burst in traffic that would not trigger a dial backup for an interface configured with the default five-minute interval might trigger a dial backup for this interface, which is set for the shorter 30-second interval.

```
Router(config)# interface serial 0
Router(config-if)# load-interval 30
```

Frame Relay PVC Example

In the following example, the load interval is set to 60 seconds for a Frame Relay PVC with the DLCI 100:

```
Router(config)# interface serial 1/1
Router(config-if)# frame-relay interface-dlci 100
Router(config-fr-dlci)# load-interval 60
```

Interface Template Example

In the following example, the load interval is set to 60 seconds in an interface template:

```
Device# configure terminal
Device(config)# template user-template1
Device(config-template)# load-interval 60
Device(config-template)# end
```

Related Commands

Command	Description
show interfaces	Displays statistics for all interfaces configured on the router or access server.

local ip address

To define an IP address to identify a local circuit emulation (CEM) channel, use the **localipaddress**command in CEM xconnect configuration mode.

local ip address *ip-address*

Syntax Description

ip-address	IP address of a regular or loopback interface in the local router. Default is 0.0.0.0

Command Default

The default local IP address is 0.0.0.0 for a CEM channel.

Command Modes

CEM xconnect configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command does not have a **no** form. To remove a local IP address, either configure a new local IP address or enter the **noxconnect** command to disable the connection and all its parameters.

The local IP address used to identify the local end of a CEM connection must be the same as the IP address defined by the *remote-ip-address*argument used in the **xconnect** command to identify the CEM channel at the other end of the CEM connection.

Note If there are multiple CEM connections that originate from the same router, they may share the same local IP address provided that each local IP address defines a unique UDP port number using the**localudpport** command.

Examples

The following example demonstrates how to configure the IP address of the local endpoint of the CEM over IP (CEoIP) connection.

```
Router(config-cem-xconnect)# local ip address 10.0.5.1
```

Related Commands

Command	Description
clear cem	Clears CEM statistics.
local udp port	Defines the UDP port at the local end of a CEM connection.
show cem	Displays CEM statistics.
xconnect (CEM)	Builds one end of a CEM connection and enters CEM xconnect configuration mode.

local-priority

To set the PTP clock's local priority.

Note This command is used only for the G.8275.1 telecom profile.

local-priority *local-priority*

Syntax Description

local-priority	Local priority value of the clock. The valid values are from 1 to 255.

Command Default

The default local priority is 1.

Command Modes

PTP Clock Configuration

Command History

Release	Modification
IOS-XE 3.18	This command was introduced.

Usage Guidelines

The configured local priority is ignored on ports without the G.8275.1 or G.8275.2 profile.

Examples

The following example demonstrates how to configure the local priority of the master-only ordinary clock.

```
Router# configure terminal
Router(config)# ptp clock ordinary domain 24
Router(config-ptp-clk)# local-priority 1
```

Related Commands

Command	Description
ptp clock	Creates a Precision Time Protocol clock and specifies the clock mode .
priority1	Sets priority1.
priority2	Sets priority2.
show ptp clock dataset default	Verifies the local priority of the PTP clock.

local udp port

To define the User Datagram Protocol (UDP) port of the local endpoint of a circuit emulation (CEM) connection, use the **localudpport**command in CEM xconnect configuration mode.

local udp port *port*

Syntax Description

port	Number of the CEM local UDP port. Possible values are 0, 2141, and 15872 through 16383. The default is 0.

Command Default

The default local UDP port number is 0 for the local endpoint of a CEM connection.

Command Modes

CEM xconnect configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

This command does not have a **no** form. To remove a local UPD port number, either configure a new UPD port number or enter the **noxconnect** command to disable the connection and all its parameters.

Examples

The following example demonstrates how to configure the UDP port of the local endpoint of the CEM over IP (CEoIP) connection.

```
Router(config-cem-xconnect)# local udp port 2141
```

Related Commands

Command	Description
remote udp port	Defines the UDP port of the remote endpoint of a CEM connection.
show cem	Displays CEM channel statistics.
xconnect (CEM)	Builds one end of a CEM connection and enters CEM xconnect configuration mode.

local-lnm

To enable Lanoptics Hub Networking Management of a PCbus Token Ring interface, use the **local-lnm** command in interface configuration mode. To disable Lanoptics Hub Networking Management, use the **no** form of this command.

local-lnm commandlocal-lnm
no local-lnm

Syntax Description

This command has no arguments or keywords.

Command Default

Management is not enabled.

Command Modes

Interface configuration

Command History

Release	Modification
10.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The Token Ring interface on the AccessPro PC card can be managed by a remote LAN manager over the PCbus interface. At present, the Lanoptics Hub Networking Management software running on an IBM compatible PC is supported.

Examples

The following example enables Lanoptics Hub Networking Management:

```
Router(config-if)# local-lnm
```

logging event

To enable notification of interface, subinterface, and Frame Relay data link connection identifier (DLCI) data link status changes, use the **loggingevent** command in interface configuration mode. To disable notification, use the **no** form of this command.

logging event {**dlci-status-change** | **link-status** | **subif-link-status** [**ignore-bulk**]}
no logging event {**dlci-status-change** | **link-status** | **subif-link-status** [**ignore-bulk**]}

Syntax Description

dlci-status-change	Enables notification of Frame Relay DLCI status changes. **Note** This option is supported only when the encapsulation on the interface is Frame Relay.
link-status	Enables notification of interface data link status changes.
subif-link-status	Enables notification of subinterface data link status changes.
ignore-bulk	Suppresses link status messages for subinterfaces when they are caused by a state change of the main interface.

Command Default

For system images, notification of interface, subinterface, and Frame Relay DLCI data link status changes is enabled by default.

For boot images, notification of Frame Relay subinterface and DLCI data link status changes is disabled by default. Notification of interface data link status changes is enabled by default.

Command Modes

Interface configuration

Command History

Release	Modification
12.0	This command was introduced.
12.2(32)S	The **ignore-bulk** keyword was integrated into the Cisco IOS Release 12.2(32)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.3(7)T	The **ignore-bulk** keyword was integrated into Cisco IOS Release 12.3(7)T.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example shows how to enable notification of subinterface link status changes:

```
Router(config-if)# logging event subif-link-status
```

The following are examples of Frame Relay DLCI and subinterface status change notification messages filtered by the **loggingevent** command:

```
00:16:22: %FR-5-DLCICHANGE: Inteface Serial3/0/0:1 - DLCI 105 state changed to INACTIVE
```

```
00:16:22: %LINEPROTO-5-UPDOWN: Line protocol on Interface Serial3/0/0:1.5, changed state
to down
```

logging source-interface

To specify the source IPv4 or IPv6 address of system logging packets, use the **loggingsource-interface** command in global configuration mode . To remove the source designation, use the **no** form of this command.

logging source-interface *type number*
no logging source-interface

Syntax Description

type number	Interface type and number.

Command Default

The wildcard interface address is used.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.2	This command was introduced.
12.4(4)T	This command was modified. IPv6 support was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command can be configured on the Virtual Routing and Forwarding (VRF) and non-VRF interfaces. Normally, a syslog message contains the IPv4 or IPv6 address of the interface used to leave the router. The **loggingsource-interface** command configures the syslog packets contain the IP or IPv6 address of a particular interface, regardless of which interface the packet uses to exit the router.

When no specific interface is configured, a wildcard interface address of 0.0.0.0 (for IPv4) or :: (for IPv6) is used, and the IP socket selects the best outbound interface.

Examples

In the following example, the user specifies that the IP address of Ethernet interface 0 is the source IP address for all syslog messages:

```
Router(config)# logging source-interface ethernet 0
```

The following example specifies that the IP address for Ethernet interface 2/1 is the source IP address for all syslog messages:

```
Router(config)# logging source-interface ethernet 2/1
```

The following sample output displays that the **loggingsource-interface** command is configured on a VRF source interface:

```
Router# show running interface loopback49
             Building configuration...
             Current configuration : 84 bytes
```

```
             !
             interface Loopback49
              ip vrf forwarding black
              ip address 49.0.0.1 255.0.0.0
             end
Router# show running | includes logging
      logging source-interface Loopback49 vrf black
      logging host 130.0.0.1 vrf black
```

Related Commands

Command	Description
logging	Logs messages to a syslog server host.

logging event link-status (global configuration)

To change the default or set the link-status event messaging during system initialization, use the **logging event link-status** command in global configuration mode. To disable the link-status event messaging, use the **no** form of this command.

logging event link-status {**default** | **boot**}
no logging event link-status {**default** | **boot**}

Syntax Description

default	Enables system logging of interface state-change events on all interfaces in the system.
boot	Enables system logging of interface state-change events on all interfaces in the system during system initialization.

Command Default

Interface state-change messages are not sent.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You do not have to enter the **logging event link-status boot** command to enable link-status messaging during system initialization. The **logging event link-status default** command logs system messages even during system initialization.

If you enter both the **logging event link-status default** and the **no logging event link-status boot**commands, the interface state-change events are logged after all modules in the Cisco 7600 series router come online after system initialization. The **logging event link-status default** and the **no logging event link-status boot** commands are saved and retained in the running configuration of the system.

When both the **logging event link-status default** and the **no logging event link-status boot**commands are present in the running configuration and you want to display the interface state-change messages during system initialization, enter the **logging event link-status boot** command.

Examples

This example shows how to enable the system logging of the interface state-change events on all interfaces in the system:

```
Router(config)# logging event link-status default
Router(config)#
```

This example shows how to enable the system logging of interface state-change events on all interfaces during system initialization:

```
Router(config)# logging event link-status boot
Router(config)#
```

This example shows how to disable the system logging of interface state-change events on all interfaces:

```
Router(config)# no logging event link-status default
Router(config)#
```

This example shows how to disable the system logging of interface state-change events during system initialization:

```
Router(config)# no logging event link-status boot
Router(config)#
```

Related Commands

Command	Description
show running-config	Displays the status and configuration of the module or Layer 2 VLAN.

logging event link-status (interface configuration)

To enable link-status event messaging on an interface, use the **logging event link-status** command in interface configuration mode. To disable link-status event messaging, use the **no** form of this command.

logging event link-status [{**bchan** | **dchan** | **nfas**}]
no logging event link-status [{**bchan** | **dchan** | **nfas**}]

Syntax Description

bchan	(Optional) Logs B-channel status messages. This keyword is available only for integrated services digital network (ISDN) serial interfaces.
dchan	(Optional) Logs D-channel status messages. This keyword is available only for ISDN serial interfaces.
nfas	(Optional) Logs non-facility associated signaling (NFAS) D-channel status messages. This keyword is available only for ISDN serial interfaces.

Command Default

Interface state-change messages are not sent.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was modified to support the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

To enable system logging of interface state-change events on a specific interface, enter the **logging event link-status** command.

Examples

The following example shows how to enable link-status event messaging on an interface:

```
Router(config-if)# logging event link-status
```

This example shows how to disable link-status event messaging on an interface:

```
Router(config-if)# no logging event link-status
```

logging event subif-link-status

To enable the link-status event messaging on a subinterface, use the **logging event subif-link-status** command in interface configuration mode. To disable the link-status event messaging on a subinterface, use the **no** form of this command.

logging event subif-link-status
no logging event subif-link-status

Syntax Description

This command has no arguments or keywords.

Command Default

Subinterface state-change messages are not sent.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 720.

To enable system logging of interface state-change events on a specific subinterface, enter the **logging event subif-link-status** command.

To enable system logging of interface state-change events on a specific interface, enter the **logging event link-status** command.

To enable system logging of interface state-change events on all interfaces in the system, enter the **logging event link-status** command.

Examples

This example shows how to enable the system logging of the interface state-change events on a subinterface:

```
Router(config-if)# logging event subif-link-status
Router(config-if)#
```

This example shows how to disable the system logging of the interface state-change events on a subinterface:

```
Router(config-if)# no logging event subif-link-status
Router(config-if)#
```

Related Commands

Command	Description
show running-config	Displays the status and configuration of the module or Layer 2 VLAN.

logging-events

to print typical T3 controller Up and Down messages on a Channelized T3 Port Adapter**,**use the **logging-eventscommand**in T3 controller configuration mode**.Usethenoformofthiscommandtodisableprintingof theT3controllerUpandDownmessages.**

logging-events [**detail**]
[**no**] **logging-events**

Syntax Description

detail	(Optional) Enables printing the reason code when a T3 controller changes from the Up to Down state.

Command Default

The **logging-eventscommandisthedefault.**

Command Modes

T3 controller configuration

Command History

Release	Modification
12.2(19c)	This command was introduced.

Usage Guidelines

When the no logging-events command disables printing of the T3 controller Up and Down messages, these messages will neither appear on the console nor in the logs.

Examples

The following example uses the **logging-events** [**detail**] command to show the Out-of-Frame (OOF) reason code when the T3 controller changes from an Up state to a Down state:

```
Router(config-controller)# logging-events detail
*Jun 19 17:47:50: %CONTROLLER-5-DOWNDETAIL: Controller T3 4/1, changed state to down due
to OOF
```

Related Commands

Command	Description

logging-events (T1-E1 controller)

To show the controller state change and alarms on a controller, use the **logging-events**command in controller configuration mode. To turn off controller state change reporting, use the **no** form of the command.

logging-events *detail*
no logging-events

Syntax Description

detail	Alarm along with the controller state change.

Command Default

Logging-events is the default.

Command Modes

Controller configuration

Command History

Release	Modification
12.2(18)SXE	This command was introduced to support SPAs on the Cisco 7600 series router and Catalyst 6500 series switch.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **logging-events**command to show the state change and alarms on a controller on an 8-Port Channelized T1/E1 Serial SPA.

Examples

The following shows enabling the logging-events command.

```
Router(config)#contr e1 2/1/0
Router(config-controller)# logging-events
```

Related Commands

Command	Description
controller	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller	Displays controller configuration.

loopback (CEM)

To set the loopback method for testing a T1, E1, serial CEM interface, and VCoP Smart SFP, use the **loopback** command in controller configuration or CEM configuration mode. To remove any existing loopback, use the **no** form of this command.

Cisco NM-CEM-4SER
loopback {**local** | **network**}
no loopback

Cisco NM-CEM-4TE1
loopback {**local** {**payload** | **line**} | **network**}
no loopback

Cisco IOS XE Release 3.18SP
loopback {**diag** | **local** | {**payload** | **line**}}
no loopback

Cisco IOS XE Release 3.18.1SP
loopback {**local** | **network** {**payload** | **line**}}
no loopback

Syntax Description

diag	Loops the outgoing transmit signal back to the receive signal. This is done using the diagnostic loopback feature in the interface module's framer.
local	Places the interface into local loopback mode and creates a loopback wherein information received from the locally-attached customer premises equipment (CPE) is transmitted back to the locally-attached CPE. • **payload** --(Used only if a local loopback is specified for a T1/E1 channel) Creates a loopback of only the data in individual time slots. In this mode, framing bits are terminated and then regenerated instead of being looped back. This mode is not available if the port is configured for **framingunframed**. • **line** --(Used only if a local loopback is specified for a T1/E1 channel) Creates a full physical layer loopback of all bits, including data and framing bits.
network	Creates a loopback wherein data received over the network from the remote CPE is transmitted back to the remote CPE.

Command Default

No loopback is configured for a CEM interface.

Command Modes

CEM configuration

Controller configuration

Controller configuration

Controller configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
XE 3.18SP	This command was integrated in Cisco NCS 4200 Series.
XE 3.18.1SP	This command was integrated in Cisco 900 Series Router.
Cisco IOS XE Everest 16.5.1	This command was integrated in Cisco ASR 903 Series Router and Cisco NCS 4200 Series.

Usage Guidelines

Use this command to create a loopback for a CEM interface. You can use a loopback to test for equipment malfunction caused by the interface.

The NM-CEM-4TE1 does not respond to loopback requests initiated by the CPE, locally attached or remote, using the extended super frame (ESF) Facility Data Link (FDL) mechanism or by any other mechanism.

The NM-CEM-4SER does not respond to any form of loopback request initiated by the locally attached or remote CPE on the Local Loop (LL) or Remote Loop (RL) control leads. Nor does the NM-CEM-4SER respond to any form of loopback request initiated by the locally attached or remote CPE using in-band loopback codes.

Examples

The following example shows how to create a loopback on a CEM T1/E1 interface so that data received from a remote CPE is transmitted back to the remote CPE on the network.

```
Router(config-controller)# loopback network
```

The following example shows how to create a loopback of data in individual time slots on a CEM T1/E1 interface. Data received from a locally attached CPE will be sent back to the locally attached CPE.

```
Router(config-controller)# loopback local payload
```

The following example shows how to create a loopback on a serial CEM channel so that data received from a remote CPE is transmitted back to the remote CPE on the network.

```
Router(config-cem)# loopback network
```

The following example shows how to set a loopback on the T1 interfaces for loopback diag.

```
Router(config-controller)# loopback diag
```

The following example shows how to set a loopback on the C37.94 interface for loopback local.

```
Router(config-controller)# loopback local line
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
controller	Enters controller configuration mode.

loopback (DSL controller)

To test the controller and configure the core loopback, use the **loopback(DSLController)**command in controller configuration mode. To remove the loopback interface, use the **no** form of this command.

loopback {**analog** | **digital**}
no loopback

Syntax Description

analog	Loops the circuit at the analog hybrid to verify the analog loopback hardware to the analog hybrid.
digital	Loops the circuit at the framer to verify the hardware to the framer.

Command Default

No default behavior or values.

Command Modes

Controller configuration

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(4)XG	This command was integrated into Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was integrated in Cisco IOS Release 12.3(7)T on Cisco 2600 series, Cisco 3631, and Cisco 3700 series routers.
12.3(11)T	This command was integrated into Cisco IOS Release 12.3(11)T on Cisco 2800 series and Cisco 3800 series routers.
12.3(14)T	This command was integrated into Cisco IOS Release 12.3(14)T on Cisco 1800 series routers.

Usage Guidelines

Analog and digital loopbacks are local loopbacks. Digital loopbacks loop the circuit at the framer to verify the hardware to the framer, and analog loopbacks loop the circuit at the analog hybrid to verify the analog loopback hardware to the analog hybrid. The controller must be shut down before loopback can be configured.

Examples

If the controller is still up, the router will prompt you to turn the controller off as shown in this example:

```
Router(config-controller)# loopback
 analog

 Please shut down the xDSL controller
Router(config-controller)# loopback
 digital

 Please shut down the xDSL controller
```

The following example shows the configuration of a loopback digital interface:

```
Router(config-controller)# loopback digital
 Please shut down the xDSL controller
Router(config-controller)# shutdown
```

```
Router(config-controller)#

Command History

Release	Modification
11.3	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for E3: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

Use this command for troubleshooting purposes. To verify that a loopback is configured on the interface, use the **showcontrollerse3**EXEC command. Note that line loopback is available only in C-bit parity mode.

Examples

The following example shows how to configure the controller located in slot 1, port 0 for a local loopback:

```
Router(config)# controller e3 1/0
Router(config-controller)# loopback local
```

Related Commands

Command	Description
show controllers e3	Displays information about the E3 controllers.

loopback (interface)

To diagnose equipment malfunctions between the interface and device, use the **loopback**command in interface configuration mode. To disable the test, use the **no** form of this command.

loopback
no loopback

Syntax Description

This command has no arguments or keywords.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Loopback on HSSI Cards

On High-Speed Serial Interface (HSSI) cards, the loopback function configures a two-way internal and external loop on the HSA applique of the specific interface.

Loopback on MCI and SCI Serial Interface Cards

On MCI and SCI serial interface cards, the loopback functions when a CSU/DSU or equivalent device is attached to the router or access server. The**loopback** command loops the packets through the CSU/DSU to configure a CSU loop, when the device supports this feature.

Loopback on MCI and MEC Ethernet Cards

On the MCI and MEC Ethernet cards, the interface receives back every packet it sends when the **loopback** command is enabled. Loopback operation has the additional effect of disconnecting network server functionality from the network.

Loopback on CSC-FCI FDDI Cards

On the CSC-FCI FDDI card, the interface receives back every packet it sends when the **loopback** command is enabled. Loopback operation has the additional effect of disconnecting network server functionality from the network.

Loopback on Token Ring Interface Cards

On all Token Ring interface cards (except the 4-megabit CSC-R card), the interface receives back every packet it sends when the **loopback** command is enabled. Loopback operation has the additional effect of disconnecting network server functionality from the network.

Active Loopback Interfaces

To show interfaces currently in loopback operation, use the **showinterfacesloopback** EXEC command.

Note Loopback does not work on an X.21 DTE because the X.21 interface definition does not include a loopback definition.

Examples

The following example configures the loopback test on Ethernet interface 4:

```
Router(config)# interface ethernet 4
Router(config-if)# loopback
```

Related Commands

Command	Description
down-when-looped	Configures an interface to inform the system it is down when loopback is detected.
show interfaces loopback	Displays information about the loopback interface.

loopback (J1 controller)

To set the loopback method for testing the J1 interface, use the **loopback** command in controller configuration mode. To turn off loopback, use the **no** form of this command. This command should be used for testing purposes only.

loopback {**local** | **line** | **isolation**}
no loopback {**local** | **line** | **isolation**}

Syntax Description

local	Places the interface into local loopback mode.
line	Places the interface into external loopback mode at the line level.
isolation	Places the interface into both local and line loopback mode.

Command Default

No loopback is configured.

Command Modes

Controller configuration

Command History

Release	Modification
11.3 MA	This command was implemented on the Cisco MC3810.
12.0(5)T and 12.0(7)XR	The command was implemented on the Cisco 2600 and Cisco 3600 series.
12.0(5)XE	The command was implemented on the Cisco 7200 and Cisco 7500 series.
12.1(1)T	The command was implemented on the Cisco 2600 series.
12.2(8)T	The command was implemented on the Cisco 2600 and Cisco 3600 series.

Examples

The following example establishes a loopback of the incoming J1 signal on controller J1 3/0:

```
Router(config)# controller j1 3/0
Router(config-controller)# loopback line
```

loopback (PA-MC-8TE1+ port adapter)

To enable loopback testing of data for the PA-MC-8TE1+ port adapter, use the **loopback** command in interface configuration mode. To disable loopback testing, use the **no** form of this command.

loopback [{**internal** | **line**}]
no loopback [{**internal** | **line**}]

Syntax Description

internal	(Optional) Loops any data received at the PA-MC-8TE1+ port adapter's network interface back into the PA-MC-8TE1+ port adapter.
line	(Optional) Loops any data received at the PA-MC-8TE1+ port adapter's network interface back into the network.

Command Default

Loopback mode is not enabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(13)T	This command was introduced.

Examples

In the following example, a loopback is set for the PA-MC-8TE1+ port adapter in slot 2:

```
Router(config)# interface 2/0
Router(config-if)# loopback line
```

loopback T1 interface through nrzi-encoding

loopback (T1 interface)

To loop individual T1 channels on the CT3IP in Cisco 7000 series routers that have the RSP7000 and RSP7000CI and in Cisco 7500 series routers, use the **loopback**command in interface configuration mode. To remove the loopback, use the **no** form of this command.

loopback [{**local** | **network** {**line** | **payload**} | **remote** {**line** {**fdl** {**ansi** | **bellcore**} | **inband**} | **payload** [**fdl**] [**ansi**]}}]
no loopback

Syntax Description

local	(Optional) Loops the router output data back toward the router at the T1 framer and sends an alarm indication signal (AIS) signal out toward the network.
network line | **payload**	(Optional) Loops the data back toward the network before the T1 framer and automatically sets a local loopback at the High-Level Data Link Control (HDLC) controllers (line), or loops the payload data back toward the network at the T1 framer and automatically sets a local loopback at the HDLC controllers (payload).
remote l**inefdl** {**ansi**|**bellcore**	(Optional) Sends a repeating, 16-bit Extended Superframe (ESF) data link code word (00001110 11111111 for FDL ANSI and 00010010 11111111 for FDL Bellcore) to the remote end requesting that it enter into a network line loopback. Specify the **ansi** keyword to enable the remote line Facility Data Link (FDL) ANSI bit loopback on the T1 channel, per the ANSI T1.403 specification. Specify the **bellcore** keyword to enable the remote SmartJack loopback on the T1 channel, per the TR-TSY-000312 specification.
remote line inband	(Optional) Sends a repeating, 5-bit inband pattern (00001) to the remote end requesting that it enter into a network line loopback.
remote payload [**fdl**] [**ansi**]	(Optional) Sends a repeating, 16-bit ESF data link code word (00010100 11111111) to the remote end requesting that it enter into a network payload loopback. Enables the remote payload FDL ANSI bit loopback on the T1 channel. You can optionally specify **fdl** and **ansi**, but it is not necessary.

Command Default

No loopback is configured.

Command Modes

Interface configuration

Command History

Release	Modification
11.1 CA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command for troubleshooting purposes.

To better diagnose T1 provisioning problems, you can place the remote CSU or remote SmartJack into loopback. The **loopbackremotelinefdl** interface configuration command allows you to place either the CSU or the SmartJack into loopback:

- **ansi** --Places the CSU into loopback, per the ANSI T1.403 Specification.
- **bellcore** --Places the SmartJack into loopback, per the TR-TSY-000312 Specification.

When both are configured, transmission of loss of frame (LOF) indication (yellow alarm) takes priority over transmission of some facilities data link (FDL) messages.

If the remote loopback appears not to be working, use the show controllers t3 command to determine if the given T1 is currently attempting to transmit a LOF indication (yellow alarm):

```
Router#
show controllers t3 0/0/0:2
T3 0/0/0 is up.
   CT3 H/W Version: 5, CT3 ROM Version: 1.2, CT3 F/W Version: 2.5.9
   Mx H/W version: 2, Mx ucode ver: 1.34

   T1 2 is down, speed: 1536 kbs, non-inverted data
   timeslots: 1-24
   FDL per AT&T 54016 spec.
   Transmitter is sending LOF Indication.
   Receiver is getting AIS.
```

If the transmitter is sending a LOF indication, as in the previous example, stop the transmission of the LOF indication (yellow alarm) with the no t1 yellow generation configuration command as shown in the following example:

```
Router(config)# controllers t3 0/0/0
Router(config-controller)# no t1 2 yellow generation
Router(config-controller)# Ctrl-D
```

To verify that the transmission of the LOF indication (yellow alarm) has stopped, use the show controllers t3 command:

```
Router# show controllers t3 0/0/0:2
T3 0/0/0 is up.
   CT3 H/W Version: 5, CT3 ROM Version: 1.2, CT3 F/W Version: 2.5.9
   Mx H/W version: 2, Mx ucode ver: 1.34
   T1 2 is down, speed: 1536 kbs, non-inverted data
   timeslots: 1-24
   FDL per AT&T 54016 spec.
   Receiver is getting AIS.
   Framing is ESF, Line Code is B8ZS, Clock Source is Internal.
   Yellow Alarm Generation is disabled
```

Then retry the remote loopback command. When diagnosis is complete, remember to reenable the LOF indication (yellow alarm).

You can also loopback all the T1 channels by using the**loopback**(CT3IP) interface configuration command.

Examples

The following example configures T1 channel 5 for a local loopback:

```
Router(config)# interface serial 3/0/0:5
Router(config-if)# loopback local
```

Related Commands

Command	Description
loopback (T3 controller)	Loops the entire T3 (all 28 T1 channels) on the CT3IP in Cisco 7500 series routers.
t1 yellow generation	Enables detection and generation of yellow alarms for a T1 channel on the CT3IP in Cisco 7500 series routers.

loopback (T3/E3 controller)

To loop the entire T3 (all 28 T1 channels) line on the T3 controller or E3 (all 16 E1 channels) in Cisco NCS 4200 Series or on the CT3IP in Cisco 7500 series routers, use the **loopback** command in controller configuration mode. To remove the loop, use the **no** form of this command.

loopback {**local** | **network** {**line** | **payload**} | **remote**}
no loopback

Syntax Description

local	Loops the data back toward the router and sends an alarm indication signal (AIS) out toward the network.
network line payload	Sets the loopback toward the network either before going through the framer (line) or after going through the framer (payload).
remote	Sends a far-end alarm control (FEAC) request to the remote end requesting that it enter into a network line loopback. FEAC requests (and therefore remote loopbacks) are possible only when the T3 is configured for C-bit framing. The M23 format does not support remote loopbacks.

Command Default

No loops are configured on the T3/E3 line.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for T3: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

Use this command for troubleshooting purposes. To verify that a loopback is configured on the interface, use the **showcontrollersT3/E3**EXEC command. Note that remote loopback is available only in C-bit parity mode.

You can also loopback each T1/E1 channel by using the**loopback** interface configuration command for T1/E1.

For more information, refer to the "Troubleshooting the T3 and T1 Channels" section in the "Configuring Serial Interfaces" chapter of the *CiscoIOSInterfaceandHardwareComponentConfigurationGuide*.

Examples

The following example configures the T3/E3 or CT3IP for a local loopback:

```
Router(config)# controller t3/e3 3/0/0
Router(config-controller)# loopback local
```

Related Commands

Command	Description
framing	Selects the frame type for the T1 or E1 data line.
loopback (interface)	Places the specified module in loopback mode.
loopback remote (interface)	Loops packets through a CSU/DSU, over a DS3 link or a channelized T1 link, to the remote CSU/DSU and back.
show controllers t3/e3	Displays information about the T3/E3 controllers.

loopback (T3-E3 interface)

To loopback at various points in the transmit and receive path, use the **loopback**command in interface configuration mode. To stop the loopback, use the no form of this command.

PA-T3 Port Adapter
loopback {**dte** | **local** | **network** {**line** | **payload**} | **remote**}
no loopback

PA-E3 Port Adapter
loopback {**dte** | **local** | **network** {**line** | **payload**}}
no loopback

T3/E3 Shared Port Adapters
loopback {**dte** | **local** | **dual** | **network** {**line** | **payload**} | **remote**}
no loopback {**dte** | **local** | **dual** | **network** {**line** | **payload**} | **remote**}

Syntax Description

dte	Loopback after the line interface unit (LIU) towards the terminal.
local	Loopback after going through the framer toward the terminal.
dual	Sets both local loopback and network line loopback. The dual keyword is not supported on Cisco 7304 routers with the 2-Port and 4-Port Channelized T3 SPA.
network line | **payload**	Sets the loopback toward the network before going through the framer (**line**) or after going through the framer (**payload**).
remote	Sends FEAC to set remote in loopback.

Command Default

No loopback by default.

Command Modes

Interface configuration

Command History

Release	Modification
11.1	This command was introduced.
11.3	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms for E3: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 routers.

Release	Modification
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches. The **dual** keyword was added.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the loopback command to diagnose problems on the local port, between the framer and the line interface unit (LIU) level.

To verify that a loopback is configured on the interface, use the **showinterfacesserial** or **showinterfacesloopback** command.

The dual keyword is not supported on Cisco 7304 routers with the 2-Port and 4-Port Channelized T3 SPA.

Examples

The following example configures the serial interface located in slot 3/0/0 for a local loopback:

```
Router(config)# interface serial 3/0/0
Router(config-if)# loopback local
```

The following example creates a loopback on slot 5, bay 0 after the LIU towards the terminal.

```
Router# configure terminal
Router(config)# interface serial 5/0/0
Router(config-if)# loopback dte
```

Related Commands

Command	Description
show controllers serial	Displays information that is specific to the interface hardware.
show interfaces loopback	Displays information about the loopback interface.
show interfaces serial	Displays information about a serial interface.

loopback applique

To configure an internal loop on the High-Speed Serial Interface (HSSI) applique, use the **loopbackapplique** command in interface configuration mode. To remove the loop, use the **no** form of this command.

loopback applique commandloopback applique
no loopback applique

Syntax Description

This command has no arguments or keywords.

Command Default

No loops are configured on the HSSI applique.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.

Usage Guidelines

This command loops the packets within the applique to provide a way to test communication within the router or access server. It is useful for sending pings to yourself to check functionality of the applique.

To show a specific interface that is currently in loopback operation, use the **showinterfacesloopback** EXEC command.

Examples

The following example configures the loopback test on the HSSI applique:

```
Router(config)# interface serial 1
Router(config-if)# loopback applique
```

Related Commands

Command	Description
show interfaces loopback	Displays information about the loopback interface.

loopback dte

To loop packets back to the DTE from the CSU/DSU, when the device supports this function, use the **loopbackdte**command in interface configuration mode. To remove the loop, use the **no** form of this command.

loopback dte commandloopback dte
no loopback dte

Syntax Description

This command has no arguments or keywords.

Command Default

No loops are configured.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is useful for testing the DTE-to-DCE cable.

This command is used to test the performance of the integrated CSU/DSU. Packets are looped from within the CSU/DSU back to the serial interface of the router. Send a test ping to see if the packets successfully looped back. To cancel the loopback test, use the **noloopbackdte** command.

When using the 4-wire 56/64-kbps CSU/DSU module, an out-of-service signal is transmitted to the remote CSU/DSU.

To show a specific interface that is currently in loopback operation, use the**showinterfacesloopback** EXEC command.

Examples

The following example configures the loopback test on the DTE interface:

```
Router(config)# interface serial 0
Router(config-if)# loopback dte
```

Related Commands

Command	Description
show interfaces loopback	Displays information about the loopback interface.

loopback line

To loop packets completely through the CSU/DSU to configure the CSU loop, use the **loopbackline** command in interface configuration mode. To remove the loop, use the **no** form of this command.

loopback line [**payload**]
no loopback line [**payload**]

Syntax Description

payload	(Optional) Configures a loopback point at the DSU and loops data back to the network on an integrated CSU/DSU.

Command Default

No loops are configured.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is useful for testing the DCE device (CSU/DSU) itself. When the **loopbackline** command is configured on the 2-wire 56-kbps CSU/DSU module or the 4-wire 56/64-kbps CSU/DSU modules, the network data loops back at the CSU and the router data loops back at the DSU. If the CSU/DSU is configured for switched mode, you must have an established connection to perform a payload-line loopback. To loop the received data through the minimum amount of CSU/DSU circuitry, issue the **loopbackline** command.

When you issue the **loopbacklinepayload** command on an integrated CSU/DSU module, the router cannot transmit data through the serial interface for the duration of the loopback. Choosing the DSU as a loopback point loops the received-network data through the maximum amount of CSU/DSU circuitry. Data is not looped back to the serial interface. An active connection is required when operating in switched mode for payload loopbacks.

If you enable the **loopbackline** command on the fractional T1/T1 module, the CSU/DSU performs a full-bandwidth loopback through the CSU portion of the module and data transmission through the serial interface is interrupted for the duration of the loopback. No reframing or corrections of bipolar violation errors or cyclic redundancy check (CRC) errors are performed. When you configure the **loopbacklinepayload**command on the FT1/T1 module, the CSU/DSU performs a loopback through the DSU portion of the module. The **loopbacklinepayload**command reframes the data link, regenerates the signal, and corrects bipolar violations and Extended Super Frame CRC errors.

When performing a T1-line loopback with Extended Super Frame, communication over the facilities data link is interrupted, but performance statistics are still updated. To show interfaces currently in loopback operation, use the **showservice-module**EXEC command.

To show interfaces that are currently in loopback operation on other routers, use the **showinterfacesloopback** EXEC command.

Examples

The following example configures the loopback test on the DCE device:

```
Router(config)# interface serial 1
Router(config-if)# loopback line
```

The following example shows how to configure a payload loopback on a Cisco 2524 or Cisco 2525 router:

```
Router1(config-if)# loopback line payload
Loopback in progress
Router1(config-if)# no loopback line
```

The following example shows the output on a Cisco 2524 or Cisco 2525 router when you loop a packet in switched mode without an active connection:

```
Router1(config-if)# service-module 56k network-type switched
Router1(config-if)# loopback line payload
Need active connection for this type of loopback
% Service module configuration command failed: WRONG FORMAT.
```

Related Commands

Command	Description
show interfaces loopback	Displays information about the loopback interface.
show service-module	Displays the performance report for an integrated CSU/DSU.

loopback remote (interface)

To loop packets through a CSU/DSU, over a DS3 link or a channelized T1 link, to the remote CSU/DSU and back, use the **loopbackremote**command in interface configuration mode. To remove the loopback, use the **no** form of this command.

FT1/T1 CSU/DSU Modules

loopback remote {**full** | **payload** | **smart-jack**} [{**0in1** | **1in1** | **1in2** | **1in5** | **1in8** | **3in24** | **qrw** | **user-pattern** *24-bit-binary-value*}]

no loopback remote {**full** | **payload** | **smart-jack**}

2- and 4-Wire, 56/64-kbps CSU/DSU Modules

loopback remote [{**2047** | **511** | **stress-pattern** *pattern-number*}]

no loopback remote

Syntax Description

full	Transmits a full-bandwidth line loopback request to a remote device, which is used for testing.
payload	Transmits a payload line loopback request to a remote device, which is used for testing the line and remote DSU.
smart-jack	Transmits a loopback request to the remote smart jack, which some service providers attach on the line before the customer premises equipment (CPE). You cannot put the local smart jack into loopback.
0in1	(Optional) Transmits an all-zeros test pattern used for verifying B8ZS line encoding. The remote end might report a loss of signal when using alternate mark inversion (AMI) line coding.
1in1	(Optional) Transmits an all-ones test pattern used for signal power measurements.
1in2	(Optional) Transmits an alternating ones-and-zeroes test pattern used for testing bridge taps.
1in5	(Optional) Transmits the industry-standard test-pattern loopback request.
1in8	(Optional) Transmits a test pattern used for stressing timing recovery of repeaters.
3in24	(Optional) Transmits a test pattern used for testing the ones density tolerance on AMI lines.
qrw	(Optional) Transmits a quasi-random word test pattern, which is a random signal that simulates user data.
user-pattern *24-bit-binary-value*	(Optional) Transmits a test pattern that you define. Enter a binary string up to 24 bits long. For the fixed patterns such **0in1** and **1in1**, the T1 framing bits are jammed on top of the test pattern; for the **user-pattern**, the pattern is simply repeated in the time slots.
2047	(Optional) Transmits a pseudorandom test pattern that repeats after 2047 bits.
511	(Optional) Transmits a pseudo random test pattern that repeats after 511 bits.

stress-pattern *pattern-number*	(Optional) Transmits a DDS stress pattern available only on the 4-wire 56/64-kbps CSU/DSU module. You may enter a stress pattern from 1 to 4. A 1 pattern sends 100 bytes of all 1s and then 100 bytes of all 0s to test the stress clocking of the network. A 2 pattern sends 100 bytes of a 0x7e pattern and then 100 bytes of all 0s. A 3 pattern sends continuous bytes of a 0x46 pattern. A 4 pattern sends continuous bytes of a 0x02 pattern.

Command Default

No remote loopback interface is configured.

Command Modes

Interface configuration

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used for testing the data communication channels along with or without remote CSU/DSU circuitry. The loopback is usually performed at the line port, rather than the DTE port, of the remote CSU/DSU.

For a multiport interface processor connected to a network via a channelized T1 link, the **loopbackremote** interface configuration command applies if the remote interface is served by a DDS line (56 kbps or 64 kbps) and if the device at the remote end is a CSU/DSU. In addition, the CSU/DSU at the remote end *must* react to latched DDS CSU loopback codes. Destinations that are served by other types of lines or that have CSU/DSUs that do not react to latched DDS CSU codes cannot participate in an interface remote loopback. Latched DDS CSU loopback code requirements are described in AT&T specification TR-TSY-000476, "OTGR Network Maintenance Access and Testing."

For the integrated FT1/T1 CSU/DSU module, the **loopbackremotefull** command sends the loopup code to the remote CSU/DSU. The remote CSU/DSU performs a full-bandwidth loopback through the CSU portion of the module. The**loopbackremotepayload** command sends the loopup code on the configured time slots, while maintaining the D4-extended super frame. The remote CSU/DSU performs the equivalent of a loopback line payload request. The remote CSU/DSU loops back only those time slots that are configured on the remote end. This loopback reframes the data link, regenerates the signal, and corrects bipolar violations and extended super frame CRC errors. The **loopbackremotesmart-jack**command sends a loopup code to the remote smart jack. You cannot put the local smart jack into loopback.

Failure to loopup or initiate a remote loopback request could be caused by enabling the **noservice-modulet1remote-loopback** command or having an alternate remote-loopback code configured on the remote end. When the loopback is terminated, the result of the pattern test is displayed.

For the 2- and 4-wire, 56/64-kbps CSU/DSU module, an active connection is required before a loopup can be initiated while in switched mode. When transmitting V.54 loopbacks, the loopback mode is initiated on the remote device using V.54 messages. Failure to loopup or initiate a remote loopback request could be caused by enabling the **noservice-module56kremote-loopback** command.

To display interfaces that are currently in loopback operation, use the **showinterfacesloopback** EXEC command.

Examples

Example for Remote Loopback Test

The following example configures a remote loopback test:

```
Router(config)# interface serial 0

Router(config-if)# loopback remote
```

Example of Full-Bandwidth Line Loopback

The following example configures the remote device into full-bandwidth line loopback while specifying the **qrw** test pattern over the T1 CSU/DSU module on a Cisco 2524 or Cisco 2525 router:

```
Router(config)# interface serial 0
Router(config-if)# loopback remote full qrw
Router(config-if)#
%LINEPROTO-5-UPDOWN: Line protocol on Interface Serial0, changed state to down
%LINK-3-UPDOWN: Interface Serial0, changed state to down
%SERVICE_MODULE-5-LOOPUPREMOTE: Unit 0 - Remote unit placed in loopback
```

Example of Loopback Stress Pattern

The following example transmits a remote loopback stress pattern over the 4-wire, 56/64-kbps CSU/DSU module, which tests the stress clocking of the network:

```
Router(config-if)# loopback remote stress-pattern 1
Router(config-if)#
%LINEPROTO-5-UPDOWN: Line protocol on Interface Serial1, changed state to down
%LINK-3-UPDOWN: Interface Serial1, changed state to down
%SERVICE_MODULE-5-LOOPUPREMOTE: Unit 1 - Remote unit placed in loopback
```

Related Commands

Command	Description
clear service-module serial	Resets an integrated CSU/DSU.
loopback dte	Loops packets back to the DTE device from the CSU/DSU.
loopback line	Loops packets completely through the CSU/DSU to configure the CSU loop.
service-module 56k remote-loopback	Enables the acceptance of a remote loopback request on a serial interface on a 2- or 4-wire, 56/64-kbps CSU/DSU module.
service-module t1 remote-loopback	Specifies whether the fractional T1/T1 CSU/DSU module enters loopback mode when it receives a loopback code on the line.
show interfaces loopback	Displays information about the loopback interface.
show service-module serial	Displays the performance report for an integrated CSU/DSU.

loopback remote (T1/T3/SDH/SONET Controller)

To put the far-end T1 or T3 interfaces into a loopback use the **loopback remote** command in the global configuration mode.The remote loopback setting loops back the far-end at line or payload, using inband bit-orientated CDE (IBOC) or the extended super frame (ESF) loopback codes to communicate the request to the far-end.

T1 Controller
loopback remote {esf | {line {csu} | payload} iboc {fac1 | fac2 | csu}}

T3 Controller
loopback remote {line | payload}

Syntax Description

esf line csu	Remote line CSU loopback through FDL. This is the default option.
esf payload	Remote payload loopback through FDL.
iboc fac1	Remote inband line facility1 loopback.
iboc fac2	Remote inband line facility2 loopback.
iboc csu	Remote inband line CSU loopback.

Command Default

Loopback remote is disabled.

Command Modes

Global configuration mode

Command History

Release	Modification
IOS XE Fuji Release 16.8.1	This command was introduced.

Usage Guidelines

Loopback testing is one of the troubleshooting methods which is an effective way to isolate the failing links. When the loopback is configured, all the data sent is received back. If the same data is not received then it is declared as link failure. In the similar way, remote loopback is configured to troubleshoot the link failure between two nodes.

Examples

The following example shows how to set T1 loopback remote iboc fac1 for DS1:

```
Router(config)# controller t1 0/0/1
Router(config-controller)#loopback remote iboc fac1
exit
```

The following example shows how to set T3 loopback remote line for DS3:

```
Router(config)# controller t3 0/0/1
Router(config-controller)#loopback remote line
exit
```

The following example shows how to set T3 loopback remote payload for OCX in sonet:

```
Router(config)# controller sonet 0/0/1
Router(config-controller)#sts 1
Router(config-ctrlr-sts1)#mode t3
Router(config-ctrlr-sts1)#t3 loopback remote payload
```

The following example shows how to set T1 loopback remote esf line csu for OCX in SDH:

```
Router(config)#controller sdh 0/4/7
Router(config-controller)#au-4 1
Router(config-ctrlr-tug3)#tug-3 3
Router(config-ctrlr-tug3)#mode vc1x
Router(config-ctrlr-tug3)#tug-2 1 payload vc11
Router(config-ctrlr-tug2-vcx)#t1 1 loopback remote esf line csu
```

loopback (SONET)

To set the loopback method for testing an interface, use the **loopback** command in the controller configuration mode. To reset to the default, use the **no** form of this command.

loopback [*local* | *network* {*line* | *payload*}]

Syntax Description

local	The name of a CEM interface parameters class.
network {*line* | *payload*	Sets the loopback toward the network before going through the framer (*line*) or after going through the framer (*payload*).

Command Default

No loopback is configured.

Command Modes

Controller configuration

Command History

Release	Modification
3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

You can use a loopback test on lines to detect and distinguish equipment malfunctions caused by the line. If correct data transmission is not possible when an interface is in loopback mode, the interface is the source of the problem.

Examples

The following example shows the configuration of VT 1.5-T1 loopback :

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
loopback local
sts-1 1
mode ct3
vtg 1 t1 1 loopback line
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

mac-address-table learning

To enable MAC-address learning, use the **mac-address-tablelearning**command in global configuration mode. To disable learning, use the **no** form of this command.

`mac-address-table learning`{`vlan`*vlan-id* | `interface`*interface slot/port*} {`module`[*module num*]}

`no mac-address-table learning`{`vlan`*vlan-id* | `interface`*interface slot/port*} {`module`[*module num*]}

Syntax Description

default	(Optional) Returns to the default settings.
vlan *vlan-id*	Specifies the VLAN to apply the per-VLAN learning of all MAC addresses; valid values are from 1 to 4094.
interface	Specifies per-interface based learning of all MAC addresses.
interface slot / port	Interface type, the slot number, and the port number.
module *num*	(Optional) Specifies the module number.

Command Default

If you configure a VLAN on a port in a module, all the supervisor engines and Distributed Forwarding Cards (DFCs) in the Cisco 7600 series router are enabled to learn all the MAC addresses on the specified VLAN.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

You can use the **module***num* keyword and argument to specify supervisor engines or DFCs only.

You can use the **vlan***vlan-id* keyword and argument on switch-port VLANs only. You cannot use the **vlan***vlan-id* keyword and argument to configure learning on routed interfaces.

You can use the **interface***interfaceslot/port* keyword and arguments on routed interfaces, supervisor engines, and DFCs only. You cannot use the **interface***interfaceslot/port* keyword and arguments to configure learning on switch-port interfaces or non-DFC modules.

Examples

This example shows how to enable MAC-address learning on a switch-port interface on all modules:

```
Router(config)# mac-address-table learning vlan 100
Router(config)#
```

This example shows how to enable MAC-address learning on a switch-port interface on a specified module:

```
Router(config)# mac-address-table learning vlan 100 module 4
Router(config)#
```

This example shows how to disable MAC-address learning on a specified switch-port interface for all modules:

```
Router(config)# no mac-address-table learning vlan 100
Router(config)#
```

This example shows how to enable MAC-address learning on a routed interface on all modules:

```
Router(config)# mac-address-table learning vlan 100
Router(config)#
```

This example shows how to enable MAC-address learning on a routed interface for a specific module:

```
Router(config)# mac-address-table learning interface FastEthernet 3/48 module 4
Router(config)#
```

This example shows how to disable MAC-address learning for all modules on a specific routed interface:

```
Router(config)# no mac-address-table learning interface FastEthernet 3/48
Router(config)#
```

Related Commands

Command	Description
show mac-address-table learning	Displays the MAC-address learning state.

mac-address (virtual switch)

To specify a Media Access Control (MAC) address to use as the common router MAC address for interfaces on the active and standby chassis, use the **mac-address** virtual switch configuration submode command. To return to the default setting, use the **no** form of this command.

mac-address {*mac-address* | **use-virtual**}

Syntax Description

mac-address	MAC address in hexadecimal format.
use-virtual	Specifies the MAC address range reserved for the virtual switch system (VSS).

Command Default

The router MAC address is derived from the backplane of the active chassis.

Command Modes

Virtual switch configuration submode (config-vs-domain)

Command History

Release	Modification
12.2(33)SXH2	Support for this command was introduced.

Usage Guidelines

When a virtual switch comes up, the router MAC address is derived from the backplane of the active chassis and is used as the common router MAC address for interfaces on both the active and the standby chassis. Between switchovers, this MAC address is maintained on the new active switch. You can enter the **mac-address***mac-address*command to specify a MAC address to use or the **mac-address**use-virtual to use the MAC address range reserved for the VSS.

The MAC address range reserved for the VSS is derived from a reserved pool of addresses with the domain ID encoded in the leading 6 bits of the last octet and trailing 2 bits of the previous octet of the mac-address. The last two bits of the first octet is allocated for protocol mac-address which is derived by adding the protocol ID (0 to 3) to the router MAC address.

Note You must reload the virtual switch for the new router MAC address to take effect. If the MAC address you configured is different from the current MAC address, the following message is displayed: Configured Router mac address is different from operational value. Change will take effect after config is saved and switch is reloaded.

Examples

The following example shows how to specify the MAC address to use in hexadecimal format:

```
Router(config)# switch virtual domain test-mac-address
Router(config-vs-domain)# mac-address 0000.0000.0000
Router(config-vs-domain)#
```

The following example shows how to specify the MAC address range reserved for the VSS:

```
Router(config)# switch virtual domain test-mac-address
Router(config-vs-domain)# mac-address use-virtual
Router(config-vs-domain)#
```

Related Commands

Command	Description
switch virtual domain	Assigns a switch number and enters virtual switch domain configuration submode.

mac-address-table secure

To add secure addresses to the MAC address table, use the **mac-address-tablesecure** command in global configuration mode. To remove secure entries from the MAC address table, use the **no** form of this command.

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

no mac-address-table secure *hw-address* **vlan** *vlan-id*

Catalyst Switches

mac-address-table secure *hw-address* [**atm** *slot/port***vlan** *vlan-id*]
no mac-address-table secure *hw-address* [**vlan** *vlan-id*]

Cisco 860 Series Integrated Services Routers (ISRs) and Cisco 880 Series ISRs

mac-address-table secure [{**H . H . H** | **maximum** *maximum addresses*}]
no mac-address-table secure [{**H . H . H** | **maximum** *maximum addresses*}]

Syntax Description

hw -address	MAC address that is added to the table.
interface	Port to which packets destined for *hw-address* are forwarded.
fa	Specifies FastEthernet.
gi	Specifies Gigabit Ethernet.
H.H.H	(Optional) Specifies 48-bit hardware address.
slot	(Optional) The slot (slot 1 or slot 2) to which to add dynamic addresses.
port	(Optional) Port interface number. The ranges are based on type of Ethernet switch network module used: • 0 to 15 for NM-16ESW • 0 to 35 for NM-36ESW • 0 to 1 for GigabitEthernet
atm *slot* / *port*	(Optional) Add secure addresses to the ATM module in slot 1 or 2. The port is always 0 for an ATM interface.
maximum *maximum addresses*	(Optional) Applies only to Cisco 860 series and Cisco 880 series ISRs. Range is 1-200.

vlan *vlan -id*	Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers The *interface* and **vlan** parameters together specify a destination to which packets destined for *hw-address* are forwarded. The **vlan** keyword is optional if the port is a static-access VLAN port. In this case, the VLAN assigned to the port is assumed to be that of the port associated with the MAC address. This keyword is required for multi-VLAN and trunk ports. The value of *vlan-id* is the ID of the VLAN to which secure entries are added. Valid IDs are 1 to 1005; do not enter leading zeroes. Catalyst Switches (Optional) The *interface* and **vlan** parameters together specify a destination to which packets destined for *hw-address* are forwarded. The **vlan** keyword is optional if the port is a static-access VLAN port. In this case, the VLAN assigned to the port is assumed to be that of the port associated with the MAC address. This keyword is required for multi-VLAN and trunk ports. The value of *vlan-id* is the ID of the VLAN to which secure entries are added. Valid IDs are 1 to 1005; do not enter leading zeroes.

Command Default

Secure addresses are not added to the MAC address table.

Command Modes

Global configuration (config)

Command History

Release	Modification
11.2(8)SA	This command was introduced.
11.2(8)SA3	The **vlan** keyword was added.
11.2(8)SA5	The **atm** keyword was added.
12.2(2)XT	This command was implemented on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T, on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(20)T	This command with the **H.H.H** and **maximum** keyword was added for Cisco Series 860 ISRs and Cisco Series 880 ISRs.

Usage Guidelines

Cisco 860 Series ISRs, Cisco 880 Series ISRs, Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

Secure addresses can be assigned to only one port at a time. Therefore, if a secure address table entry for the specified MAC address and VLAN already exists on another port, it is removed from that port and assigned to the specified one.

If the maximum number is more than the MAC addresses statically specified by using the **H.H.H** keyword, the switch learns the MAC address automatically up to the specified maximum. If the maximum number is less than the number of MAC addresses already specified statically, then an error message displays.

Usage Guidelines

Catalyst Switches

Secure addresses can be assigned to only one port at a time. Therefore, if a secure address table entry for the specified MAC address and VLAN already exists on another port, it is removed from that port and assigned to the specified one.

Dynamic-access ports cannot be configured with secure addresses.

Cisco 860 Series ISRs, Cisco 880 Series ISRs

The following example shows how to allow ten devices on Fast Ethernet port 2:

```
Router(config)#
 mac-address-table secure maximum 10 ?
FastEthernet  FastEthernet IEEE 802.3
Router(config)#
 mac-address-table secure maximum 10 f ?
<0-4>  FastEthernet interface number
Router(config)#
mac-address-table secure maximum 10 f 2
```

Cisco 2600 Series, Cisco 3600 Series, and Cisco 3700 Series Routers

The following example shows how to add a secure MAC address to VLAN 6 of port fa1/1:

Router(config)# mac-address-table secure 00c0.00a0.03fa fa1/1 vlan 6

Catalyst Switches

The following example shows how to add a secure MAC address to VLAN 6 of port fa1/1:

```
Switch(config)# mac-address-table secure 00c0.00a0.03fa fa1/1 vlan 6
```

The following example shows how to add a secure MAC address to ATM port 2/1:

```
Switch(config)# mac-address-table secure 00c0.00a0.03fa atm 2/1
```

Related Commands

Command	Description
clear mac -address-table	Deletes entries from the MAC address table.
mac -address-tableaging-time	Sets the length of time that a dynamic entry remains in the MAC address table after the entry is used or updated.
mac -address-tabledynamic	Adds dynamic addresses to the MAC address table.

Command	Description
mac -address-tablestatic	Adds static addresses to the MAC address table.
show mac -address-table	Displays the MAC address table.

main-fiber port

To specify the port number to use for the optical link connection on the SDH/STM-1 trunk card on a Cisco AS5850, use the **main-fiberport** command in controller configuration mode.

main-fiber port {**0** | **1**}

Syntax Description

0	Specifies use of port 0 as the optical link connection. This is the default.
1	Specifies use of port 1 as the optical link connection.

Command Default

Port 0

Command Modes

Controller configuration

Command History

Release	Modification
12.2(15)T	This command was introduced.

Usage Guidelines

Use the**main-fiber** controller configuration command if you need to use optical port 1 during installation of the SDH/STM-1 trunk card on a Cisco AS5850 or if you suspect some problem with optical port 0.

This command does not have a **no** form. To restore the default value, use the **main-fiberport0**command.

Examples

The following example selects port 1 as the port with the optical connection:

```
Router(config)# controller sonet 1/0
Router(config-controller)# main-fiber port 1
```

max-reserved-bandwidth

To change the percent of interface bandwidth allocated for Resource Reservation Protocol (RSVP), class-based weighted fair queueing (CBWFQ), low latency queueing (LLQ), IP RTP Priority, Frame Relay IP RTP Priority, and Frame Relay PVC Interface Priority Queueing (PIPQ), use the **max-reservedbandwidth** command in interface configuration mode. To restore the default value, use the **no** form of this command.

max-reserved-bandwidth *percent*
no max-reserved-bandwidth

Syntax Description

percent	Percent of interface bandwidth allocated for RSVP, CBWFQ, LLQ, IP RTP Priority, Frame Relay IP RTP Priority, and Frame Relay PIPQ.

Command Default

75 percent on all supported platforms except the Cisco 7500 series routers, which do not have this restriction.

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The sum of all bandwidth allocation on an interface should not exceed 75 percent of the available bandwidth on an interface. The remaining 25 percent of bandwidth is used for overhead, including Layer 2 overhead, control traffic, and best-effort traffic.

If you need to allocate more than 75 percent for RSVP, CBWFQ, LLQ, IP RTP Priority, Frame Relay IP RTP Priority, and Frame Relay PIPQ, you can use the **max-reserved-bandwidth** command. The *percent* argument specifies the maximum percentage of the total interface bandwidth that can be used.

If you do use the **max-reserved-bandwidth** command, make sure that not too much bandwidth is taken away from best-effort and control traffic.

Examples

In the following example, the policy map called policy1 is configured for three classes with a total of 8 Mbps configured bandwidth, as shown in the output from the **showpolicy-map** command:

```
Router# show policy-map policy1
 Policy Map policy1
  Weighted Fair Queueing
    Class class1
      Bandwidth 2500 (kbps) Max Threshold 64 (packets)
    Class class2
      Bandwidth 2500 (kbps) Max Threshold 64 (packets)
    Class class3
      Bandwidth 3000 (kbps) Max Threshold 64 (packets)
```

When you enter the **service-policy**command in an attempt to attach the policy map on a 10-Mbps Ethernet interface, an error message such as the following is produced:

```
I/f Ethernet1/1 class class3 requested bandwidth 3000 (kbps) Available only 2500 (kbps)
```

The error message is produced because the default maximum configurable bandwidth is 75 percent of the available interface bandwidth, which in this example is 7.5 Mbps. To change the maximum configurable bandwidth to 80 percent, use the **max-reserved-bandwidth** command in interface configuration mode, as follows:

```
max-reserved-bandwidth 80
service output policy1
end
```

To verify that the policy map was attached, enter the **showpolicy-mapinterface** command:

```
Router# show policy-map interface e1/1
 Ethernet1/1  output :policy1
  Weighted Fair Queueing
    Class class1
      Output Queue:Conversation 265
        Bandwidth 2500 (kbps) Packets Matched 0 Max Threshold 64 (packets)
        (discards/tail drops) 0/0
    Class class2
      Output Queue:Conversation 266
        Bandwidth 2500 (kbps) Packets Matched 0 Max Threshold 64 (packets)
        (discards/tail drops) 0/0
    Class class3
      Output Queue:Conversation 267
        Bandwidth 3000 (kbps) Packets Matched 0 Max Threshold 64 (packets)
        (discards/tail drops) 0/0
```

Virtual Template Configuration Example

The following example configures a strict priority queue in a virtual template configuration with CBWFQ. The **max-reserved-bandwidth** command changes the maximum bandwidth allocated between CBWFQ and IP RTP Priority from the default (75 percent) to 80 percent.

```
multilink virtual-template 1
interface virtual-template 1
 ip address 172.16.1.1 255.255.255.0
 no ip directed-broadcast
 ip rtp priority 16384 16383 25
 service-policy output policy1
 ppp multilink
 ppp multilink fragment-delay 20
 ppp multilink interleave
 max-reserved-bandwidth 80
 end
interface Serial0/1
 bandwidth 64
 ip address 10.1.1.2 255.255.255.0
 no ip directed-broadcast
 encapsulation ppp
 ppp multilink
 end
```

Note To make the virtual access interface function properly, do not configure the **bandwidth** command on the virtual template. Configure it on the actual interface, as shown in the example.

Related Commands

Command	Description
bandwidth (policy-map class)	Specifies or modifies the bandwidth allocated for a class belonging to a policy map.
ip rtp priority	Reserves a strict priority queue for a set of RTP packet flows belonging to a range of UDP destination ports.
service-policy	Attaches a policy map to an input interface or VC, or an output interface or VC, to be used as the service policy for that interface or VC.
show policy-map	Displays the configuration of all classes comprising the specified service policy map or all classes for all existing policy maps.
show policy-map interface	Displays the configuration of all classes configured for all service policies on the specified interface or displays the classes for the service policy for a specific PVC on the interface.

mdix auto

To enable automatic media-dependent interface with crossover detection, use the **mdixauto** command in interface configuration mode. To turn automatic detection off, use the **no** form of this command.

mdix auto
no mdix auto

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on all 10/100 and 10/100/1000 modules except for the following modules:

- WS-X6248-RJ45
- WS-X6248-TELCO
- WS-X6348-RJ-45
- WS-X6348-RJ-21
- WS-X6148-RJ-45
- WS-X6148-RJ-21

Examples

This example shows how to enable automatic media-dependent interface with crossover detection:

```
Router(config-if)# mdix auto
Router(config-if)
```

This example shows how to disable automatic media-dependent interface with crossover detection:

```
Router(config-if) no mdix auto
Router(config-if)
```

Related Commands

Command	Description
show interfaces	Displays the status and traffic statistics for the interfaces in the chassis.

mdl

To configure the Maintenance Data Link (MDL) message defined in the ANSI T1.107a-1990 specification, use the **mdl** command in controller configuration mode. To remove the message, use the **no** form of this command.

mdl {**transmit** {**path** | **idle-signal** | **test-signal**} | **string** {**eic** | **lic** | **fic** | **unit** | **pfi** | **port** | **generator**} *string*}
no mdl {**transmit** {**path** | **idle-signal** | **test-signal**} | **string** {**eic** | **lic** | **fic** | **unit** | **pfi** | **port** | **generator**} *string*}

Syntax Description

transmit path	Enables transmission of the MDL Path message.
transmit idle-signal	Enables transmission of the MDL Idle Signal message.
transmit test-signal	Enables transmission of the MDL Test Signal message.
string eic *string*	Specifies the Equipment Identification Code; can be up to 10 characters.
string lic *string*	Specifies the Location Identification Code; can be up to 11 characters.
string fic *string*	Specifies the Frame Identification Code; can be up to 10 characters.
string unit *string*	Specifies the Unit Identification Code; can be up to 6 characters.
string pfi *string*	Specifies the Path Facility Identification Code sent in the MDL Path message; can be up to 38 characters.
string port *string*	Specifies the Port number string sent in the MDL Idle Signal message; can be up to 38 characters.
string generator *string*	Specifies the Generator number string sent in the MDL Test Signal message; can be up to 38 characters.

Command Default

No MDL message is configured.

Command Modes

Controller configuration

Command History

Release	Modification
11.3	This command was introduced.
12.1(13)EX	This command was introduced on the Cisco 7304 router.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2(18)S.

Release	Modification
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPA on the Cisco 7304 routers.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the mdl command to send messages in maintenance data link in T3 c-bit framing mode.

Note MDL is supported only when the DS3 framing is C-bit parity.

Examples

The following example shows the **mdl** commands on a T3 controller in slot 1, port 0:

```
Router(config)# controller t3 1/0
Router(config-controller)# clock source line
Router(config-controller)# mdl string eic ID
Router(config-controller)# mdl string fic Building B
Router(config-controller)# mdl string unit ABC
Router(config-controller)# mdl string pfi Facility Z
Router(config-controller)# mdl string port Port 7
Router(config-controller)# mdl transmit path
Router(config-controller)# mdl transmit idle-signal
```

Related Commands

Command	Description
controller	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controllers serial	Displays serial line statistics.
show controllers t3	Displays information about T3 controllers.

media-type

To specify the physical connection on an interface, use the **media-type** command in interface configuration mode. To restore the default value, use the **no** form of this command.

media-type {**aui** | **10baset** | **100baset** | **mii** | **rj45** | **gbic**}
no media-type {**aui** | **10baset** | **100baset** | **mii**}

Syntax Description

aui	Selects an AUI 15-pin physical connection. This is the default on Cisco 4000 series routers.
10baset	Selects an R-J45 10BASE-T physical connection.
100baset	Specifies an RJ-45 100BASE-T physical connection. This is the default on Cisco 7000 series and Cisco 7200 series routers.
mii	Specifies a media-independent interface.
rj45	Specifies an RJ-45 physical connection. This is the default on Cisco 7304 series routers.
gbic	Specifies a Gigabit Interface Converter (GBIC) or small-form factor pluggable (SFP) physical connection for fiber media.

Command Default

An AUI 15-pin physical connection is the default setting on Cisco 4000 series routers. A 100BASE-T physical connection is the default setting on Cisco 7000 series and Cisco 7200 series routers. An RJ-45 physical connection is the default setting on Cisco 7304 series routers

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.1E	Support for Gigabit Ethernet was added with the **gbic** keyword.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(20)S2	This command was implemented on the 2-Port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

To specify the physical connection on an interface, use the following interface configuration:

- Ethernet network interface module configuration on Cisco 4000 series routers
- Fast Ethernet Interface Processor (FEIP) on Cisco 7000 series, 7200 series, and 7500 series routers
- Full-duplex or half-duplex mode on a serial interface

Use the **media-type**interface configuration command to modify the default physical media connection type from **rj45** to **gbic** to configure a Gigabit Ethernet interface to support fiber media using a GBIC or SFP optical transceiver.

RJ-45 is the only media type supported by the 4-Port 10/100 Fast Ethernet SPA on the Cisco 7304 router, so the **media-type**command does not apply.

Examples

RJ-45 10BASE-T Example

The following example selects an RJ-45 10BASE-T physical connection on Ethernet interface 1:

```
Router(config)# interface ethernet 1
Router(config-if)# media-type 10baset
```

Fast Ethernet on a Cisco 7000 or Cisco 7200 Series Example

The following example specifies a media-independent interface physical connection to Fast Ethernet slot 0, port 1 on the Cisco 7000 or Cisco 7200 series:

```
Router(config)# interface fastethernet 0/1
Router(config-if)# media-type mii
```

Cisco 7500 Series Example

The following example specifies a media-independent interface physical connection to Fast Ethernet slot 0, port adapter 1, port 1 on the Cisco 7500 series:

```
Router(config)# interface fastethernet 0/1/1
Router(config-if)# media-type mii
```

Gigabit Ethernet with SPA on a Cisco 7304 Router Example

The following example configures the second interface (port 1) on a 2-Port 10/100/1000 Gigabit Ethernet SPA for a fiber SFP, where the SPA is installed in the bottom subslot (1) of the MSC, and the MSC is installed in slot 2 of the Cisco 7304 router:

Related Commands

Command	Description
show interfaces gigabitethernet	Displays information about the Gigabit Ethernet interfaces.

media-type auto-failover

To assign primary and secondary failover media on the GE-SFP port enter the **media-typeauto-failover** command in interface configuration mode. To automatically detect which media is connected, use the **no** form of this command.

media-type {**sfp** | **rj45**} **auto-failover**
no media-type

Syntax Description

sfp	Designates the SFP port as the primary media.
rj45	Designates the RJ45 port as the primary media
auto-failover	Configures the port with the primary media for automatic failover from SFP to RJ45 or vice-versa when the system goes down, reloads, and is unable to bring up primary media.

Command Default

No media-type. The primary media is not configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.0 (1) M	This command was introduced.

Examples

The following example shows how to configure the primary media as RJ45 and the secondary failover media as SFP:

```
Router(config-if)# media-type rj45 auto-failover
```

The following example shows how to configure the primary media as SFP and the secondary failover media as RJ45:

```
Router(config-if)# media-type sfp auto-failover
```

The following example shows how to configure the router to automatically detect which media is connected:

```
Router(config-if)# no media-type
```

Related Commands

Command	Description
media-type sfp	Specifies an SFP physical connection.
media-type rj45	Specifies an RJ-45 physical connection.

member subslot

To configure the redundancy role of a line card, use the member subslot command in line card redundancy group mode.

member subslot *slot/subslot* {**primary** | **secondary**}
no member subslot *slot/subslot* {**primary** | **secondary**}

Cisco uBR10012 Universal Broadband Routers

member subslot *slot/subslot* {
protect [**config** *slot/subslot* | **rf-power** [**rf-connector** *rfconnector-value*] {**hccp-delta** *diff-pwr* | **hccp-override** *override-pwr*}] | **working** [**rfsw-slot** *slot-value*] | **revertive** | **reverttime** *value*}

no member subslot *slot/subslot* {
protect [**config** *slot/subslot* | **rf-power** [**rf-connector** *rfconnector-value*] {**hccp-delta** *diff-pwr* | **hccp-override** *override-pwr*}] | **working** [**rfsw-slot** *slot-value*] | **revertive** | **reverttime** *value*}

Syntax Description

slot	Chassis line card slot number.
subslot	Chassis line card subslot number.
primary | **secondary**	Configures the redundancy role of the line card. • **primary** --Active line card. • **secondary** --Standby line card.
protect	Specifies the protect slot in the line card group.
config *slot/subslot*	(Optional) Specifies the appropriate working interface configuration that is used for the protect interface when a switchover occurs.
rf-power	(Optional) Specifies the RF power output level on an integrated upconverter.
rf-connector *rfconnector-value*	(Optional) Specifies the RF connector in the protect line card. The default value is all.
hccp-delta *diff-pwr*	When using N+1 Hotstandby Connection-to-Connection Protocol (HCCP) redundancy, the protect interface adds the diff-pwr value to the current power value of the working interface when a switchover occurs. This allows the router to accommodate relative differences between the RF power levels in working and protect interfaces. The valid value for diff-pwr ranges from –12 to +12 dBmV.

hccp-override *override-pwr*	When using N+1 HCCP redundancy, the protect interface uses the override power value instead of the power value of the working interface when a switchover occurs. This allows the router to accommodate absolute differences between the RF power levels in working and protect interfaces. The valid value for override-pwr ranges from 45 to 63 dBmV. **Note** The official range for acceptable power levels in the DOCSIS specification is 50 to 61 dBmV. Cisco cable interfaces exceed the DOCSIS standard, but power levels outside the DOCSIS standards should be used only in lab and test environments.
working	Specifies the working slot in the line card group.
rfsw-slot *slot-value*	(Optional) Specifies the RF switch slot for the working line card.
revertive	Specifies the revert operation on the protect card.
reverttime *value*	Specifies the time interval for the revert operation in minutes. If you specify the time interval as 30 minutes, the protect card switches back to the protect mode after 30 minutes.

Command Default

None

Command Modes

Line card redundancy group

Command History

Release	Modification
12.2(28)SB	This command was introduced on the Cisco 10000 series routers.
12.2(28)BC	This command was integrated into Cisco IOS Release 12.3(23)BC.
12.2(28)SCA	Support for the following keywords was removed in Cisco IOS Release 12.2(33)SCA and later releases: • **revertive** • **reverttime** **Note** Use the revertive command in line card redundancy group mode to enable the revert operation on a protect card in Cisco IOS Release 12.2(33)SCA and later releases.
12.2(28)SCC4	Support for the following keywords was added in Cisco IOS Release 12.2(33)SCC4 for Cisco uBR10012 routers: • **rf-power** • **rf-connector** • **hccp-delta** • **hccp-override**
12.2(28)SCE	The **config** option of the command was made the default. When more than one working line cards are configured, the config option is automatically applied to the first working card.

Usage Guidelines

The primary line card must be the first line card configured and must occupy subslot 1. The secondary line card must be the second line card configured and must occupy subslot 0. Only one primary line card and one secondary line card can be configured.

Note Configuration changes to the working line card cause the upstream links on the protect line card to flap. This is applicable only to Cisco uBR10012 routers.

Examples

The following example creates line card group number 1 for one-to-one line card redundancy. It also specifies the line card in subslot 1 as the primary (active) line card, and the line card in subslot 0 as the secondary (standby) line card:

```
Router(config)# redundancy
Router(config-red)# linecard-group 1 y-cable
Router(config-red-lc)# member subslot 2/1 primary
Router(config-red-lc)# member subslot 2/0 secondary
```

Note The rest of the examples listed here are only applicable to Cisco uBR10012 routers.

The following example shows how to configure a protect interface to add 3 dBmV to the current working RF power level when a switchover occurs:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# linecard-group 1 cable
Router(config-red-lc)# member subslot 5/1 protect rf-power hccp-delta 3
```

The following example shows how to configure a protect interface to use an RF power level of 48 dBmV instead of the current working RF power level when a switchover occurs:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# linecard-group 1 cable
Router(config-red-lc)# member subslot 5/1 protect rf-power hccp-override 48
```

The following example shows how to configure a rf-connector 3 on a protect interface to add 5 dBmV to the current working RF power level when a switchover occurs:

```
Router# configure terminal
Router(config)# redundancy
Router(config-red)# linecard-group 1 cable
Router(config-red-lc)# member subslot 5/1 protect rf-power rf-connector 3 hccp-delta 5
```

Related Commands

Command	Description
linecard-group	Creates a line card group for one-to-one line card redundancy.

Command	Description
redundancy	Enters redundancy mode.
show redundancy linecard	Displays information about a redundant line card or line card group.

microcode reload controller

To reload the firmware and field programmable gate array (FPGA) without reloading the Cisco IOS image, use the **microcode reload controller** command in privileged EXEC mode.

microcode reload controller {**t1** | **e1** | **j1**} *x/y*

Syntax Description

t1	T1
e1	E1
j1	J1 controller.
x / *y*	Controller slot and unit numbers. The slash must be typed.

Command Default

No microcode reload activity is initiated.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(2)XH	This command was introduced on the Cisco 2600 series and Cisco 3600 series.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.
12.2(8)T	The **j1** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Loopbacks in the running configuration are restored after this command is entered. If the controller is in a looped state before this command is issued, the looped condition is dropped. You have to reinitiate the loopbacks from the remote end by entering the **no loop**command from the controller configuration.

Examples

The following example shows how to start the microcode reload activity:

```
Router# microcode reload controller j1 3/0
TDM-connections and network traffic will be briefly disrupted.
Proceed with reload microcode?[confirm]
Router#
*Mar  3 209.165.200.225: clk_src_link_up_down: Status of this CLK does not matter
*Mar  3 209.165.200.226: clk_src_link_up_down: Status of this CLK does not matter
*Mar  3 209.165.200.227: %CONTROLLER-5-UPDOWN: Controller J1 3/0, changed state to)
*Mar  3 209.165.200.227: clk_src_link_up_down: Status of this CLK does not matter
*Mar  3 209.165.200.228: clk_src_link_up_down: Status of this CLK does not matter
*Mar  3 209.165.200.229: %CONTROLLER-5-UPDOWN: Controller J1 3/0, changed state top
*Mar  3 209.165.200.229: clk_src_link_up_down: Status of this CLK does not matter
*Mar  3 209.165.200.229: clk_src_link_up_down: Status of this CLK does not matter
```

mls exclude protocol

To specify the interface protocol to exclude from shortcutting, use the **mlsexcludeprotocol**command in global configuration mode. To remove a prior entry, use the **no** form of this command.

mls exclude protocol {**both** | **tcp** | **udp**} **port** *port-number*
no mls exclude

Syntax Description

both	Specifies both UDP and TCP.
tcp	Excludes TCP interfaces from shortcutting.
udp	Specifies UDP interfaces from shortcutting.
port *port-number*	Specifies the port number; valid values are from 1 to 65535.

Command Default

This command has no default settings.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to configure MLS to exclude UDP on port 69:

```
Router(config)#
mls exclude protocol udp port 69
Router(config)#
```

Related Commands

Command	Description
show mls ip multicast	Displays the MLS IP information.
show mls ipx	Displays MLS IPX information.

mls ip delete-threshold

To delete the configured access control list (ACL) thresholds, use the **mlsipdelete-threshold** comman d in global configuration mode.

mls ip delete-threshold *acl-num*

Syntax Description

acl-num	Reflective ACL number; valid values are from 1 to 10000.

Command Default

This command has no default settings.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

The **mlsipdelete-threshold** command is active only when you enable the **mlsipreflexivendr-entrytcam** command.

Examples

This example shows how to delete an ACL threshold:

```
Router(config)# mls ip delete-threshold 223
Router(config)#
```

Related Commands

Command	Description
mls ip install-threshold	Installs the configured ACL thresholds.
mls ip reflexive ndr-entry tcam	Enables the shortcuts in TCAM for the reflexive TCP/UDP entries when installed by the NDR.

mls ip directed-broadcast

To enable the hardware switching of the IP-directed broadcasts, use the **mlsipdirected-broadcast** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

mls ip directed-broadcast {**exclude-router** | **include-router**}
no mls ip directed-broadcast

Syntax Description

exclude-router	Forwards the IP-directed broadcast packet in the hardware to all hosts in the VLAN except the router.
include-router	Forwards the IP-directed broadcast packet in the hardware to all hosts in the VLAN including the router.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **exclude-router** and **include-router** keywords both support hardware switching, but **exclude-router** does not send a copy of the hardware-switched packets to the router. If you enter the **include-router** keyword, the router does not forward the IP-directed broadcast packet again.

In the default mode, IP-directed broadcast packets are not hardware forwarded; they are handled at the process level by the MSFC. The MSFC decision to forward or not forward the packet is dependent on the **ipdirected-broadcast** command configuration.

There is no interaction between the **ipdirected-broadcast** command and the **mlsipdirected-broadcast** command. The **ipdirected-broadcast** command involves software forwarding, and the **mlsipdirected-broadcast** command involves hardware forwarding.

MLS IP-directed broadcast supports a secondary interface address.

Any packets that hit the CPU are not forwarded unless you add the **ipdirected-broadcast** command to the same interface.

You can configure the MLS IP-directed broadcasts on a port-channel interface but not on the physical interfaces on the port-channel interface. If you want to add a physical interface to a port-channel group, the physical interface cannot have the MLS IP-directed broadcast configuration. You have to first remove the configuration manually and then add the physical interface to the channel group. If a physical interface is already part of a channel group, the CLI will not accept the **mlsipdirected-broadcast** configuration command on that physical interface.

Examples

This example shows how to forward the IP-directed broadcast packet in the hardware to all hosts in the VLAN with the exception of the router:

```
Router(config-if)#
mls ip directed-broadcast exclude-router
Router(config-if)#
```

This example shows how to forward the IP-directed broadcast packet in the hardware to all hosts in the VLAN:

```
Router(config-if)#
mls ip directed-broadcast include-router
Router(config-if)#
```

Related Commands

Command	Description
show mls cef adjacency	Displays information about the MLS-hardware Layer 3-switching adjacency node.

mls ipx

To enable Multilayer Switching (MLS) Internetwork Packet Exchange (IPX) on the interface, use the **mlsipx**command in interface configuration mode. To disable IPX on the interface, use the **no** form of this command.

mls ipx
no mls ipx

Syntax Description

This command has no arguments or keywords.

Command Default

Multicast is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 720.

Examples

This example shows how to enable MLS IPX on an interface:

```
Router(config-if)#
mls ipx
Router(config-if)#
```

Related Commands

Command	Description
mls rp ipx (interface configuration mode)	Allows the external systems to enable MLS IPX on the interface.
show mls ipx	Displays MLS IPX information.

mls verify

To enable Layer 3 error checking in the hardware, use the **mlsverify** command in global configuration mode. To disable Layer 3 error checking in the hardware, use the **no** form of this command.

mls verify {**ip** | **ipx**} {**checksum** | **length** {**consistent** | **minimum**}}
no mls verify {**ip** | **ipx**} {**checksum** | **length** {**consistent** | **minimum**}}

Syntax Description

ip	Specifies the IP-checksum errors.
ipx	Specifies the IPX checksum errors.
checksum	Enables the checksum-error check.
length consistent	Enables the length-consistency check in Layer 2.
length minimum	Enables the minimum-length packet check in Layer 2.
consistent	Specifies the length-consistency check in Layer 2.
minimum	Enables the minimum-length packet check in Layer 2.

Command Default

checksum

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was changed to include the **minimum** keyword on the Supervisor Engine 720. Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The minimum-length packets are the packets with an IP header length or IP total length field that is smaller than 20 bytes.

When entering the minimum keyword, follow these guidelines:

- When enabling the IP "too short" check using the mls verify ip length minimum command, valid IP packets with with an IP protocol field of ICMP(1), IGMP(2), IP(4), TCP(6), UDP(17), IPv6(41), GRE(47), or SIPP-ESP(50) will be hardware switched. All other IP protocol fields are software switched.

Caution Using optimized access-list logging (OAL) and the mls verify ip length minimum command together can cause routing protocol neighbor flapping as they are incompatible

- When entering the **nomlsverifyiplengthminimum** command, minimum-length packets are hardware switched. The packets that have IP protocol = 6 (TCP) are sent to the software.

Examples

This example shows how to enable Layer 3 error checking in the hardware:

```
Router(config
)# mls verify ip checksum
Router(config)#
```

This example shows how to disable Layer 3 error checking in the hardware:

```
Router(config
)# no mls verify ip checksum
Router(config)#
```

mobility

To configure the wireless mGRE tunnels, use the **mobility** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

mobility {**network-id** *id* | **tcp** **adjust-mss**}
mobility [{**trust** | **broadcast**}]

Syntax Description

network-id *id*	Specifies the wireless network ID for the mGRE tunnel; valid values are from 1 to 4095.
tcp adjust-mss	Adjusts the MSS value in TCP SYN and TCP ACK on the access points automatically.
trust	(Optional) Specifies the trusted network.
broadcast	(Optional) Specifies that the mGRE tunnel convert the NBMA to the BMA.

Command Default

Untrusted network

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXD	Support for this command was introduced on the Supervisor Engine 720.
12.2(18)SXD3	This command was changed to include the **tcpadjust-mss** keywords.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on Cisco 7600 series routers that are configured with a WLSM only.

The **tcpadjust-mss** keywords are supported on mGRE tunnel interfaces only.

You can enter the **iptcpadjust-mss***value* command to change the TCP MSS to a lower value.

A trusted network can use DHCP or a static IP address. An untrusted network supports only DHCP clients.

Examples

This example shows how to specify the network identification number for the mGRE tunnel:

```
Router(config-if)# mobility network-id 200
Router(config-if)#
```

This example shows how to specify the trusted network:

```
Router(config-if)# mobility trust
Router(config-if)#
```

This example shows how to specify that the mGRE tunnel convert the NBMA to the BMA:

```
Router(config-if)# mobility broadcast
Router(config-if)#
```

This example shows how to adjust the MSS value in TCP SYN and TCP ACK on the access points automatically:

```
Router(config-if)# mobility tcp adjust-mss
Router(config-if)#
```

Related Commands

Command	Description
ip tcp adjust-mss	Adjusts the MSS value of TCP SYN packets going through a router.
show mobility	Displays information about the Layer 3 mobility and the wireless network.

mode

To set the redundancy mode, use the **mode** command in redundancy configuration mode.

Syntax for 12.2S Release
mode {**rpr** | **rpr-plus** | **sso**}

Syntax for Cisco IOS XE Release 2.5 and Later Releases
mode {**rpr** | **sso**}

Syntax for 12.2XNE Release
mode **sso**

Syntax Description

rpr	Specifies Route Processor Redundancy (RPR) mode.
rpr-plus	Specifies Route Processor Redundancy Plus (RPR+) mode.
sso	Specifies stateful switchover (SSO) mode.

Command Default

- The default is SSO mode if the system is not configured for redundancy and the active and standby supervisor engines have the same image.
- The default is RPR mode if different versions are installed.
- If redundancy is enabled, the default is the mode that you have configured.

- The default is RPR+ mode if the system is not configured for redundancy and the active and standby supervisor engines have the same image.
- The default is RPR mode if different versions are installed.
- If redundancy is enabled, the default is the mode that you have configured.

- The default is SSO mode if the system is not configured for redundancy and the active and standby supervisor engines have the same image.
- The default is RPR mode if different versions are installed.

- The default is SSO mode if the system is not configured for redundancy and the active and standby supervisor engines have the same image.
- The default is RPR mode if different versions are installed.

Command Modes

Redundancy configuration (config-red)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17b)SXA	This command was modified. Support was added for SSO mode and the default mode change.

Release	Modification
12.2(17d)SXB	This command was modified. Support was added for multicast and unicast traffic.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)XNE	This command was modified. This command was implemented on the Cisco 10000 router.
Cisco IOS XE Release 2.5	This command was modified. This command was implemented on the Cisco ASR 1000 Series Routers.

Usage Guidelines

Cisco IOS Release 12.2S and 7600 Series Routers

SSO is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

On releases prior to Release 12.2(17d)SXB, single router mode (SRM) with SSO redundancy does not support stateful switchover for multicast traffic. When a switchover occurs, all multicast hardware switching entries are removed and are then re-created and reinstalled in the hardware by the newly active multilayer switch feature card (MSFC).

SRM/SSO is supported in the following releases only:

- Release 12.2(17b)SXA and subsequent rebuilds.
- Release 12.2(17d)SXB and subsequent rebuilds.

Nonstop forwarding (NSF) with SSO redundancy mode supports IPv4. NSF with SSO redundancy mode does not support IPv6, Internetwork Packet Exchange (IPX), and Multiprotocol Label Switching (MPLS).

If you have configured MPLS on the Cisco 7600 series routers with redundant supervisor engines, you must configure the Cisco 7600 series router in RPR mode. The switch should not be running in the default mode of SSO.

Enter the **redundancy** command in global configuration mode to enter redundancy configuration mode. You can enter the **mode** command within redundancy configuration mode.

Follow these guidelines when configuring your system for RPR+ mode:

- You must install compatible images on the active and standby supervisor engines to support RPR+ mode and SSO mode.
- Both supervisor engines must run the same Cisco IOS software version.
- Any modules that are not online at the time of a switchover are reset and reloaded on a switchover.
- The Forwarding Information Base (FIB) tables are cleared on a switchover. As a result, routed traffic is interrupted until route tables reconverge.

The standby supervisor engine reloads on any change of mode and begins to work in the current mode. When you use this command to force the standby supervisor engine to run as a Distributed Forwarding Card (DFC) card, the uplink ports in the standby engine continue to be in use and are not disabled.

Cisco IOS Release XE Release 2.5 and ASR 1000 Series Routers

For Cisco ASR 1002 and 1004 routers, RRP and stateful switchover can be used to switch between Cisco IOS processes. RPR and SSO need to be configured by the user, however, because a second Cisco IOS process is not available by default on Cisco ASR 1002 and 1004 routers. Enter the **redundancy** command in global configuration mode to enter redundancy configuration mode. You can enter the **mode** command within redundancy configuration mode.

The Cisco ASR 1006 Router supports a second Route Processor. The second Cisco IOS process can run only on the standby Route Processor. This means that hardware redundancy is available and RPR and SSO do not need to be configured by the user because a second Cisco IOS process is available by default on the Cisco ASR 1006 router.

RPR+ mode is not supported on the Cisco ASR 1000 Series Routers.

Cisco IOS Release 12.2XNE and 1000 Series Routers

Enter the **redundancy** command in global configuration mode to enter redundancy configuration mode. You can enter the **mode** command within redundancy configuration mode.

RPR mode is not supported on the Cisco 10000 router.

Examples

This example shows how to set the redundancy mode to RPR+:

```
Router(config)# redundancy
Router(config-red)# mode rpr-plus
```

This example shows how to set the redundancy mode to SSO:

```
Router(config)# redundancy
Router(config-red)# mode sso
```

Related Commands

Command	Description
redundancy	Enters redundancy configuration mode.
redundancy force-switchover	Forces a switchover from the active to the standby supervisor engine.
route-converge-interval	Configures the time interval after which the old FIB entries are purged.
show redundancy	Displays RF information.
show running-config	Displays the status and configuration of the module or Layer 2 VLAN.

mode (ATM T1 E1 controller)

To set the DSL controller into ATM mode and create an ATM interface or to set the T1 or E1 controller into T1 or E1 mode and create a logical T1/E1 controller, use the **mode** command in controller configuration mode. To disable the current mode and prepare to change modes, use the **no** form of this command.

Cisco 1800, Cisco 2800, Cisco 3700, Cisco 3800 Series
mode atm
no mode atm

Cisco 1700 Series, Cisco 2600XM
mode {**atm** | **t1** | **e1**}
no mode {**atm** | **t1** | **e1**}

Cisco IAD2430
mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}
no mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

Syntax Description

atm	Sets the controller into ATM mode and creates an ATM interface (ATM 0). When ATM mode is enabled, no channel groups, DS0 groups, PRI groups, or time-division multiplexing (TDM) groups are allowed, because ATM occupies all the DS0s on the T1/E1 trunk. When you set the controller to ATM mode, the controller framing is automatically set to extended super frame (ESF) for T1 or cyclic redundancy check type 4 (CRC4) for E1. The line code is automatically set to binary 8-zero substitution (B8ZS) for T1 or high-density bipolar C (HDBC) for E1. When you remove ATM mode by entering the **nomodeatm** command, ATM interface 0 is deleted. **Note** The **modeatm** command without the **aim** keyword uses software to perform ATM segmentation and reassembly (SAR). This is supported on Cisco 2600 series WIC slots only; it is not supported on network module slots.
aim	(Optional) The configuration on this controller uses the Advanced Integration Module (AIM) in the specified slot for ATM SAR. The **aim** keyword does not apply to the Cisco IAD2430 series IAD.
aim-slot	(Optional) AIM slot number on the router chassis: • Cisco 2600 series--0. • Cisco 3660--0 or 1.
cas	(Cisco 2600 series WIC slots only) Channel-associated signaling (CAS) mode. The T1 or E1 in this WIC slot is mapped to support T1 or E1 voice (that is, it is configured in a DS0 group or a PRI group). CAS mode is supported on both controller 0 and controller 1. On the Cisco IAD2430 series IAD, CAS mode is not supported.

t1	Sets the controller into T1 mode and creates a T1 interface. When you set the controller to T1 mode, the controller framing is automatically set to ESF for T1. The line code is automatically set to B8ZS for T1.
e1	Sets the controller into E1 mode and creates an E1 interface. When you set the controller to E1 mode, the controller framing is automatically set to CRC4 for E1. The line code is automatically set to HDB3 for E1.

Command Default

The controller mode is disabled.

Command Modes

Controller configuration

Command History

Release	Modification
11.3 MA	This command was introduced on the Cisco MC3810.
12.1(5)XM	Support for this command was extended to the merged SGCP/MGCP software.
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T for the Cisco IAD2420.
12.2(2)XB	Support was extended to the Cisco 2600 series and Cisco 3660. The keyword **aim** and the argument *aim-slot* were added. The parenthetical modifier for the command was changed from “Voice over ATM” to “T1/E1 controller.”
12.2(15)T	This command was implemented on the Cisco 2691 and the Cisco 3700 series.
12.3(4)XD	This command was integrated into Cisco IOS Release 12.3(4)XD on Cisco 2600 series and Cisco 3700 series routers to configure DSL Frame mode and to add T1/E1 Framed support.
12.3(4)XG	This command was integrated into Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

When a DSL controller is configured in ATM mode, the mode must be configured identically on both the CO and CPE sides. Both sides must be set to ATM mode.

Note If using the **nomodeatm** command to leave ATM mode, the router must be rebooted immediately to clear the mode.

When configuring a DSL controller in T1 or E1 mode, the mode must be configured identically on the CPE and CO sides.

Examples

ATM Mode Example

The following example configures ATM mode on the DSL controller.

```
Router(config)# controller
 dsl
 3/0
Router(config-controller)# mode atm
```

T1 Mode Example

The following example configures T1 mode on the DSL controller.

```
Router(config)# controller
 dsl
 3/0
Router(config-controller)# mode t1
```

Related Commands

Command	Description
channel-group	Configures a list of time slots for voice channels on controller T1 0 or E1 0.
tdm-group	Configures a list of time slots for creating clear channel groups (pass-through) for time-division multiplexing (TDM) cross-connect.

mode (HSA redundancy)

To configure the redundancy mode, use the **mode**command in redundancy configuration mode. To configure the default redundancy mode, use the **no**form of this command.

mode {**hsa** | **rpr** | **rpr-plus**}
no **mode** {**hsa** | **rpr** | **rpr-plus**}

Syntax Description

hsa	Selects High System Availability (HSA) redundancy mode. This is the default.
rpr	Selects Route Processor Redundancy (RPR) mode.
rpr-plus	Selects Route Processor Redundancy Plus (RPR+) redundancy mode.

Command Default

HSA redundancy mode

Command Modes

Redundancy configuration

Command History

Release	Modification
12.0(16)ST	This command was introduced.
12.0(19)ST1	The **rpr-plus**keyword was added.
12.0(22)S	This command was integrated into Cisco IOS Release 12.0(22)S.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

The mode selected by the **mode** command in redundancy configuration mode must be fully supported by the image that has been installed in both the active and standby Route Switch Processors (RSPs). A high availability image must be installed in the RSPs before RPR+ can be configured. Use the**hw-moduleslotimage**command to specify a high availability image to run on the standby RSP.

If the mode cannot be set on both RSPs, HSA is the default mode. A Cisco 7507 or Cisco 7513 router that has only one RSP installed operates in single Route Processor mode.

Examples

The following example enters redundancy configuration mode and sets RPR+ as the redundancy mode for a Cisco 7500 series router.

```
Router(config)# redundancy
Router(config-r)# mode rpr-plus
Router(config-r)# end
```

Related Commands

Command	Description
hw-module sec-cpu reset	Resets and reloads the standby RSP with the specified Cisco IOS image and executes the image.

Command	Description
hw-module slot image	Specifies a high availability Cisco IOS image to run on an active or standby RSP.
redundancy	Enters redundancy configuration mode.
redundancy force-switchover	Switches control of a router from the active RSP to the standby RSP.
show redundancy	Displays the current redundancy mode.

mode (RSC redundancy)

To choose between classic-split mode (maximum throughput with no load sharing) and handover-split mode (maximum availability with load sharing), use the **mode** command in redundancy configuration mode. To reset to the default mode, use the **no** form of this command.

mode {**classic-split** | **handover-split**}
no mode

Syntax Description

classic-split	Nonredundant mode in which slots are split in a fixed 6/6 pattern between the two route-switch-controller (RSC) cards, and no handover occurs. This is the default.
handover-split	Redundant mode in which, if one RSC fails, the peer RSC takes over control of the failed RSC's resources (slots and cards).

Command Default

Classic-split mode

Command Modes

Redundancy configuration

Command History

Release	Modification
12.2(2)XB1	This command was introduced.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

You must be connected to an RSC card on your Cisco AS5850 to use this command.

Examples

The following example selects handover-split mode:

```
Router(config)# redundancy
Router(config-r)#

mode handover-split
```

Related Commands

Command	Description
show chassis	Displays, for a router with two RSCs, information about mode (handover-split or classic-split), RSC configuration, and slot ownership.
show chassis clocks	Displays all configured clock sources, even those from non-owned cards. This is because only one RSC can provide the master clock, and it may need to have backup clock sources configured from all cards present, regardless of ownership.
show context	Displays information about specified slots.
show redundancy debug-log	Displays up to 256 redundancy-related debug entries.

mode (T1 E1 controller)

To set the T1 or E1 controller into asynchronous transfer mode (ATM) and create an ATM interface, to set the T1 or E1 controller into T1 or E1 mode and create a logical T1 or E1 controller, or to set the T1 or E1 controller into channel-associated signaling (CAS) mode, use the **mode** command in controller configuration mode. To disable the current mode and prepare to change modes, use the **no**form of this command.

mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}
no mode {**atm** [**aim** *aim-slot*] | **cas** | **t1** | **e1**}

Syntax Description

atm	Sets the controller into ATM mode and creates an ATM interface (ATM 0). When ATM mode is enabled, no channel groups, DS0 groups, PRI groups, or time-division multiplexing (TDM) groups are allowed, because ATM occupies all the DS0s on the T1/E1 trunk. When you set the controller to ATM mode, the controller framing is automatically set to extended super frame (ESF) for T1 or cyclic redundancy check type 4 (CRC4) for E1. The line code is automatically set to binary 8-zero substitution (B8ZS) for T1 or high-density bipolar C (HDB3) for E1. When you remove ATM mode by entering the **no mode atm** command, ATM interface 0 is deleted. On the Cisco MC3810, ATM mode is supported only on controller 0 (T1 or E1 0). **Note** The **mode atm** command without the **aim** keyword uses software to perform ATM segmentation and reassembly (SAR). This is supported on Cisco 2600 series WIC slots only and is not supported on network module slots.
aim	(Optional) The configuration on this controller uses the Advanced Integration Module (AIM) in the specified slot for ATM SAR. The **aim** keyword does not apply to the Cisco MC3810 and the Cisco IAD2420 series IAD.
aim-slot	(Optional) AIM slot number on the router chassis. For the Cisco 2600 series, the AIM slot number is 0; for the Cisco 3660, the AIM slot number is 0 or 1.
cas	(CAS mode on Cisco 2600 series WIC slots only) The T1 or E1 in this WIC slot is mapped to support T1 or E1 voice (it is configured in a DS0 group or a PRI group). CAS mode is supported on both controller 0 and controller 1.
t1	(Cisco 2600XM series using the G.SHDSL WIC only) Sets the controller into T1 mode and creates a T1 interface. When you set the controller to T1 mode, the controller framing is automatically set to ESF for T1. The line code is automatically set to B8ZS for T1.
e1	(Cisco 2600XM series using the G.SHDSL WIC only) Sets the controller into E1 mode and creates an E1 interface. When you set the controller to E1 mode, the controller framing is automatically set to CRC4 for E1. The line code is automatically set to HDB3 for E1.

Command Default

No controller mode is configured.

Command Modes

Controller configuration

Command History

Release	Modification
11.3 MA	This command was introduced on the Cisco MC3810.
12.1(5)XM	Support for this command was extended to Simple Gateway Control Protocol (SGCP) and Media Gateway Control Protocol (MGCP).
12.2(2)T	This command was integrated into Cisco IOS Release 12.2(2)T and implemented on the Cisco 7200 series.
12.2(2)XB	Support was extended to the Cisco 2600 series and Cisco 3660. The **aim**keyword and the *aim-slot* argument were added. The parenthetical modifier for the command was changed from "Voice over ATM" to "T1/E1 controller."
12.2(8)T	This command was implemented on the Cisco IAD2420 series.
12.2(11)T	This command was implemented on the Cisco AS5300 and Cisco AS5850.
12.2(15)T	This command was implemented on the Cisco 2691 and the Cisco 3700 series.
12.3(4)XD	Support was extended on Cisco 2600 series and Cisco 3700 series routers to configure DSL Frame mode and to add T1/E1 Framed support.
12.3(7)T	The support that was added in Cisco IOS Release 12.3(4)XD was integrated into Cisco IOS Release 12.3(7)T.

Usage Guidelines

This command has the following platform-specific usage guidelines:

- Cisco 2600 series, Cisco 3660 routers, or Cisco 3700 series that use an AIM for ATM processing must use the **mode atm aim***aim-slot* command.
- Cisco 2600 series routers that use an AIM for DSP processing and specify DS0 groups must use the **mode cas** command if they are using WIC slots for voice. This command does not apply if network modules are being used.
- Cisco 3660 routers or Cisco 3700 series that use an AIM only for DSP resources should not use this command.
- On Cisco 2600 series routers that use WIC slots for voice, the **mode atm** command without the **aim** keyword specifies software ATM segmentation and reassembly. When the **aim** keyword is used with the **mode atm** command, the AIM performs ATM segmentation and reassembly.
- Cisco MC3810 routers cannot use the **aim** keyword.
- Cisco MC3810 routers with digital voice modules (DVMs) use some DS0s exclusively for different signaling modes. The DS0 channels have the following limitations when mixing different applications (such as voice and data) on the same network trunk:
  - On E1 controllers, DS0 16 is used exclusively for either CAS or common channel signaling (CCS), depending on which mode is configured.
  - On T1 controllers, DS0 24 is used exclusively for CCS.

- Cisco MC3810--When no mode is selected, channel groups and clear channels (data mode) can be created using the **channel group** and **tdm-group** commands, respectively.
- Cisco MC3810 is not supported in the AIM-ATM, AIM-VOICE-30, and AIM-ATM-VOICE-30 on the Cisco 2600 Series, Cisco 3660, and Cisco 3700 Series feature.
- On Cisco 2600 series and Cisco 3700 series routers when configuring a DSL controller in ATM mode, the mode must be set to the same mode on both the CO and CPE sides. Both sides must be set to ATM mode.
    - If the **no mode atm** command is used to leave ATM mode, the router must be rebooted immediately to clear the mode.
- On Cisco 2600 series and Cisco 3700 series routers when configuring a DSL controller in T1 or E1 mode, the mode must be configured identically on the CO and CPE sides.

Examples

The following example configures ATM mode on controller T1 0. This step is required for Voice over ATM.

```
Router(config)# controller
 T1 0
Router(config-controller)# mode atm
```

The following example configures ATM mode on controller T1 1/ 0 on a Cisco 2600 series router using an AIM in slot 0 for ATM segmentation and reassembly:

```
Router(config)# controller
 t1 1/0
Router(config-controller)# mode atm aim 0
```

The following example configures CAS mode on controller T1 1 on a Cisco 2600 series router:

```
Router(config)# controller
 T1 1
Router(config-controller)# mode cas
```

The following example configures ATM mode on the DSL controller.

```
Router(config)# controller
 dsl 3/0
Router(config-controller)# mode atm
```

The following example configures T1 mode on the DSL controller.

```
Router(config)# controller
 dsl
 3/0
Router(config-controller)# mode t1
```

Related Commands

Command	Description
channel-group	Defines the time slots for voice channels on controller T1 0 or E1 0.
tdm-group	Configures a list of time slots for creating clear channel groups (pass-through) for TDM cross-connect.

mode bypass

To enable Virtual Multipoint Interfaces (VMI) to support multicast traffic, use the **modebypass** command in interface configuration mode. To return the interface to the default mode of aggregate, use the **no** form of this command.

mode [{**aggregate** | **bypass**}]
no mode bypass

Syntax Description

aggregate	Sets the mode to aggregate. All virtual-access interfaces created by PPPoE sessions are logically aggregated under the VMI.
bypass	Sets the mode to bypass.

Command Default

No mode

Command Modes

Interface configuration

Command History

Release	Modification
12.4(15)XF	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T to support multicast traffic on Virtual Multipoint Interfaces (VMIs).

Usage Guidelines

Use the mode bypass command when you need to support multicast traffic in router-to-radio configurations.

Aggregate Mode

The default mode for operation of the VMI is **aggregate** mode. In aggregate mode, all of the virtual-access interfaces created by PPPoE sessions are logically aggregated under the VMI. As such, applications above Layer 2, such as, EIGRP and OSPFv3, should be defined on the VMI interface only. Packets sent to the VMI will be correctly forwarded to the correct virtual-access interface.

Bypass Mode

Using **bypass** mode is recommended for multicast applications.

In **bypass** mode, the virtual-access interfaces are directly exposed to applications running above Layer2. In bypass mode, definition of a VMI is still required because the VMI will continue to manage presentation of cross-layer signals, such as, neighbor up, neighbor down, and metrics. However, applications will still be aware on the actual underlying virtual-access interfaces and send packets to them directly.

Using **bypass** mode can cause databases in the applications to be larger because knowledge of more interfaces are required for normal operation.

After you enter the **modebypass** command, Cisco recommends that you copy the running configuration to NVRAM. because the default mode of operation for VMI is to logically aggregate the virtual-access interfaces.

Examples

The following example sets the interface mode to bypass:

```
Router# enable
Router# configure terminal
Router(config)# interface vmi1
Router(config-if)# mode bypass
```

Related Commands

Command	Description
interface vmi	Creates a VMI interface.

mode c-12

To configure the mode of an E1 line that has been mapped to a TUG-3, use the mode c-12 command in configuration controller tug3 mode.To configure the mode of an E1 line that has been mapped to a AU-3, use the mode c-12 command in configuration controller au3 mode. To disable the mode configuration, use the **no** form of this command.

mode c-12
no mode c-12m

Syntax Description

This command has no arguments or keywords

Command Default

Disabled

Command Modes

Configuration controller tug3 (for an E1 line mapped to a TUG-3) Configuration controller au3 (for an E1 line mapped to an AU-3)

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(7)E	This command was integrated into Cisco IOS Release 12.1(7)E, and support was added for Cisco 7200 VXR routers and Catalyst 6000 family switches.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can configure each of the TUG-3s or AU-3s of a PA-MC-STM-1 to carry a set of TU-12s (E1s mapped into TU-12s). The **modec-12**command configures the mode of operation of a TUG-3 or AU-3 and specifies that the TUG-3 or AU-3 is divided into 21 TU-12s, each carrying an E1.

Examples

The following example configures the AUG-mapping of the SONET controller to AU-3 and specifies the mode of AU-3 1 to c-12 on a Cisco 7500 series router:

```
Router(config)# controller sonet 1/0/0
Router(config-controller)# aug mapping au-3
Router(config-controller)# au3 1
Router(config-ctrlr-au3)# mode c-12
```

The following example configures the AUG-mapping of the SONET controller to AU-4 and specifies the mode of TUG-3 1 of AU-4 1 to c-12 on a Cisco 7200 VXR router or a Catalyst 6000 family switch:

```
Router(config)# controller sonet 1/0
```

```
Router(config-controller)# aug mapping au-4
Router(config-controller)# au-4 1 tug-3 1
Router(config-ctrlr-tug3)# mode c-12
```

mode ct3

Use this command to configure channelized T3 mode.

mode ct3

Syntax Description

Syntax Description:

show controller t3	Displays T3 controller configuration.

mode download

To enable operational code download mode for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **modedownload**command in satellite initial configuration mode. To disable operational code download mode, use the **no** form of this command.

mode download
no mode download

Syntax Description

This command has no arguments or keywords.

Command Default

Operational code download mode is enabled.

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to disable operational code download mode:

```
Router(sat-init-config)# no mode download
```

mode e3

Use this command to configure E3 mode.

mode e3

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

You can change the mode of a controller only when there are no subinterfaces defined for the controller.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm4
au-4 1
mode tug-3
tug-3 1
mode e3
cem-group 100 unframed
end
```

Related Commands

Command	Description
show running configuration	Verifies mode E3 configuration.

mode sonet

Use this command to configure SONET controller configuration mode.

mode sonet

Syntax Description

Syntax Description:

This command has no arguments or keywords.

Command Default

This command is disabled by default; no AIS is sent.

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

This command is used to configure the SONET controller mode.

Examples

The following example shows how to configure SONET mode:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
end
```

Related Commands

Command	Description
controller mediatype	Configures the mediatype controller.
controller sonet	Displays information about Synchronous Optical Network (SONET) controllers.
show controller sonet	Displays SONET controller configuration.

mode sts-nc

To configure the concatenated signals in the SONET network, use the **mode** *sts-nc* command. The concatenated signals are obtained by "gluing" together the payloads of the constituent signals, and they come in fixed sizes. In *SONET*, these are called STS-*N*c Synchronous Payload Envelopes (SPEs), where *N* = 3*X* and *X* is restricted to the values 1, 4, 16, 64, or 256..

mode *sts-nc*

Syntax Description

Syntax Description

This command has no keywords or arguments.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

The command is used to concatenate continuous STS into a bundle. supported modes are STS-3c, STS-12c, STS-48c, STS-192c.

Examples

The following example shows the configuration of STS-Nc - contiguous concatenation:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
rate oc12
sts-1 1-3 mode sts-3c
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

mode t3/e3

To set the T3/E3 controller in T3/E3 mode and create a logical T3/E3 controller, use the mode command in controller configuration mode.

mode t3.e3

Syntax Description

t3/e3	To set the T3/E3controller into T3/E3 mode and create a logical T3/E3 controller, use the mode command in controller configuration mode.

Command Default

The controller mode is disabled.

Command Modes

Controller configuration

Command History

Command History

Release	Modification
XE 3.18SP	This command was introduced.

Usage Guidelines

Use this command to enable the port in T3 mode. When the port is enabled for T3, it can be used for clear channel mode or channelized T3 mode based on configuration.

Examples

The following example shows how to create the local loopback on the controller :

```
Router(config-controller)# mode t3/e3
```

Related Commands

Command	Description
controller media-type	Enters controller configuration mode.

mode two-way

To enable two-way operational mode for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **modetwo-way**command in satellite initial configuration mode. To revert to one-way operational mode, use the **no** form of this command.

mode two-way
no mode two-way

Syntax Description

This command has no arguments or keywords.

Command Default

Two-way mode is enabled.

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to specify two-way operational mode:

```
Router(sat-init-config)# mode two-way
```

The following example shows how to specify one-way operational mode:

```
Router(sat-init-config)# no mode two-way
```

mode vc-1x

Use this command to configure mode VC-1x mode.

mode vc-1x

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

When you configure mode VC-1x, seven TUG-2 payloads are created. TUG-2 payloads can be of two types, VC-11 and VC-12. Default for TUG-2 payload mode is VC-11. TUG-2 payload VC-11 can be configured as VC or T1 and the range is 1 to 4. TUG-2 payload VC-12 can be configured as VC or E1 and the range is 1 to 3.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm1
no ais-shut
alarm-report all
clock source internal
overhead s1s0 0
aug mapping au-4
au-4 1
clock source internal
mode tug-3
tug-3 1
mode VC1x
tug-2 1 payload VC11
tug-2 2 payload VC11
tug-2 3 payload VC11
tug-2 4 payload VC11
tug-2 5 payload VC11
tug-2 6 payload VC11
tug-2 7 payload VC11
end
```

Related Commands

Command	Description
show running configuration	Verifies mode vc-1z configuration.

mode vc-4

Use this command to configure mode VC4 CEP.

mode vc-4

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

CEP mode is used to encapsulate SDH payload envelopes (SPEs) like VC11, VC12, VC4, or VC4-Nc over PSN. In this mode, the bytes from the corresponding SPE are sent out as they arrive on the TDM line. The interface is considered as a continuous framed bit stream. The packetization of the stream is done according to IETF RFC 4842. The supported ports are STM1, STM4, STM16, and STM64.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm 4
aug mapping au-4
au-4 1
mode vc4
cem-group 100 cep
end
```

Related Commands

Command	Description
show running configuration	Verifies mode VC-4 configuration.

mode vc4-Nc

Use this command to configure mode VC-4 Nc under AU-4.

mode vc4-Nc

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

CEP mode is used to encapsulate SDH payload envelopes (SPEs) like VC11, VC12, VC4, or VC4-Nc over PSN. In this mode, the bytes from the corresponding SPE are sent out as they arrive on the TDM line. The interface is considered as a continuous framed bit stream. The packetization of the stream is done according to IETF RFC 4842. The supported ports are STM1, STM4, STM16, and STM64.

Examples

```
enable
configure terminal
controller sdh 0/5/0
au-4 1-4 mode vc4-4c
cem-group 100 cep
end
```

Related Commands

Command	Description
show running configuration	Verifies configuration.

mode vt-15

To configure the path operation mode, use the **mode vt-15** command in controller configuration STS mode.

mode vt-15

Syntax Description

vt-15	Specifies the mode of operation.

Command Default

None

Command Modes

Controller configuration STS

Command History

Release	Modification
15.1(01)S	This command was introduced on the Cisco 7600 routers.

Examples

This example shows how to configure the **mode vt-15**:

```
Router(config)# controller sonet-acr 1
Router(config-controller)#
sts-1 2
Router(config-ctrlr-sts1)# mode vt-15
```

Related Commands

Command	Description
sts-1	Configures the Synchronous Transport Signal (STS) (level)-1 in the SONET hierarchy.
vtg	Configures the (CESoPSN) CEM group.
controller sonet-acr	Configures the SONET Access Circuit Redundancy (ACR) virtual controller.

mode t3

Use this command to configure T3 mode.

mode t3

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

You can change the mode of a controller only when there are no subinterfaces defined for the controller.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm4
au-4 1
mode tug-3
tug-3 1
mode t3
cem-group 100 unframed
end
```

Related Commands

Command	Description
show running configuration	Verifies configuration.

mode tug-3

Use this command to configure mode Tributary Unit group type 3 (TUG-3) number that has been mapped to an AU-4.

mode tug-3

Syntax Description

Syntax Description

None

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Usage Guidelines

An AUG of an STM-1 can be derived from either AU-3s or an AU-4. Use the **aug mapping au-4** configuration controller command to map the AUG to a TUG-3. Configuring the **au-4** command enables you to enter configuration controller tug3 command mode and creates a serial interface.

Mode TUG-3 creates three TUG-3 paths. TUG-3 range is 1 to 3.

Examples

```
enable
configure terminal
controller sdh 0/5/0
rate stm4
au-4 1
mode tug-3
end
```

Related Commands

Command	Description
show running configuration	Verifies TUG-3 configuration.

modem dtr-delay

To control the time that a data terminal ready (DTR) signal is held down when a line clears, use the **modemdtr-delay** command in line configuration mode. To restore the default hold down time, use the **no** form of this command.

modem dtr-delay *seconds*
no modem dtr-delay *seconds*

Syntax Description

seconds	Number of seconds. The default is 5.

Command Default

The default DTR signal hold down time is 5 seconds.

Command Modes

Line configuration

Command History

Release	Modification
12.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to reduce the time that a DTR signal is held down after an asynchronous line clears and before the DTR signal is raised again to accept new calls. Incoming calls may be rejected in heavily loaded systems even when modems are unused because the default DTR hold down interval may be too long. The**modemdtr-delay** command is designed for lines used for an unframed asynchronous session such as Telnet. Lines used for a framed asynchronous session such as PPP should use the **pulse-time** interface command.

Examples

The following example shows how to specify a DTR hold down interval of 2 seconds:

```
Router(config)# line 7
Router(config-line)# modem dtr-delay 2
```

Related Commands

Command	Description
pulse-time	Enables pulsing DTR signal intervals on serial interfaces.

monitoring

To enable monitoring of all optical transceivers and to specify the time period for monitoring the transceivers, use the **monitoring**command in transceiver type configuration mode. To disable the monitoring, use the **no** form of this command.

monitoring [**interval** *seconds*]
no monitoring [**interval**]

Syntax Description

interval *seconds*	(Optional) Specifies the time interval for monitoring optical transceivers; valid range is 300 to 3600, in seconds, and the default interval time is 600.

Command Default

The interval time is 600 seconds.

Command Modes

Transceiver type configuration (config-xcvr-type)

Command History

Release	Modification
12.2(18)SXE	This command was introduced.
12.2(33)SXH	This command was modified. The**interval** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
15.2(2)SNI	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

You need digital optical monitoring (DOM) feature and transceiver module compatibility information to configure the **monitoring** command. Refer to the compatibility matrix to get the lists of Cisco platforms and minimum required software versions to support Gigabit Ethernet transceiver modules.

Gigabit Ethernet Transceivers transmit and receive Ethernet frames at a rate of a gigabit per second, as defined by the IEEE 802.3-2008 standard. Cisco's Gigabit Ethernet Transceiver modules support Ethernet applications across all Cisco switching and routing platforms. These pluggable transceivers offer a convenient and cost effective solution for the adoption in data center, campus, metropolitan area access and ring networks, and storage area networks.

The **monitoring** command helps you to enable DOM feature and to evaluate threshold violations for all transceiver types. The **interval**keyword enables you to change the default polling interval.For example, if you set the interval as 1500 seconds, this setting causes a delay (of 1500 seconds) for the trap to be sent out by the Simple Network Management Protocol (SNMP) manager running on Cisco IOS software.

Examples

This example shows how to enable monitoring of optical transceivers and set the interval time for monitoring to 1500 seconds:

```
Router# configure terminal
Router(config)# transceiver type all
Router(config-xcvr-type)# monitoring interval 1500
```

This example shows how to disable monitoring for all transceiver types:

```
Router(config-xcvr-type)# no monitoring
```

Related Commands

Command	Description
transceiver type all	Enables monitoring on all transceivers.

mop enabled

To enable an interface to support the Maintenance Operation Protocol (MOP), use the **mopenabled** command in interface configuration mode. To disable MOP on an interface, use the **no** form of this command.

mop enabled
no mop enabled

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled on Ethernet interfaces and disabled on all other interfaces.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example enables MOP for serial interface 0:

```
Router(config)# interface serial 0
Router(config-if)# mop enabled
```

Related Commands

Command	Description
mop retransmit-timer	Configures the length of time that the Cisco IOS software waits before sending boot requests again to a MOP server.
mop retries	Configures the number of times the Cisco IOS software will send boot requests again to a MOP server.
mop sysid	Enables an interface to send out periodic MOP system identification messages.

mop sysid

To enable an interface to send out periodic Maintenance Operation Protocol (MOP) system identification messages, use the **mopsysid** command in interface configuration mode. To disable MOP message support on an interface, use the **no** form of this command.

mop sysid
no mop sysid

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

You can still run MOP without having the background system ID messages sent. This command lets you use the MOP remote console, but does not generate messages used by the configurator.

Examples

The following example enables serial interface 0 to send MOP system identification messages:

```
Router(config)# interface serial 0
Router(config-if)# mop sysid
```

Related Commands

Command	Description
mop device-code	Identifies the type of device sending MOP sysid messages and request program messages.
mop enabled	Enables an interface to support the MOP.

mtu

To adjust the maximum packet size or maximum transmission unit (MTU) size, use the **mtu** command in interface configuration mode, connect configuration mode, or xconnect subinterface configuration mode. To restore the MTU value to its original default value, use the **no** form of this command.

mtu *bytes* **mtu command**
no mtu

Syntax Description

bytes	MTU size, in bytes.

Command Default

The table below lists default MTU values according to media type.

Table 24: Default Media MTU Values

Media Type	Default MTU (Bytes)
Ethernet	1500
Serial	1500
Token Ring	4464
ATM	4470
FDDI	4470
HSSI (HSA)	4470

Command Modes

Interface configuration (config-if) Connect configuration (xconnect-conn-config) xconnect subinterface configuration (config-if-xconn)

Command History

Release	Modification
10.0	This command was introduced.
12.0(26)S	This command was modified. This command was updated to support the connect configuration mode for Frame Relay Layer 2 interworking.
12.2(14)SX	This command was integrated into Cisco IOS Release 12.2(14)SX. Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was modified. Support for this command was introduced on the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.4(11)T	This command was integrated into Cisco IOS Release 12.4(11)T.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Release	Modification
Cisco IOS XE Release 2.4	This command was integrated into Cisco IOS XE Release 2.4. This command supports the xconnect subinterface configuration mode.

Usage Guidelines

Each interface has a default maximum packet size or MTU size. This number generally defaults to the largest size possible for that interface type. On serial interfaces, the MTU size varies but cannot be set to a value less than 64 bytes.

Note The connect configuration mode is used only for Frame Relay Layer 2 interworking.

Changing the MTU Size

Changing the MTU size is not supported on a loopback interface.

Changing the MTU size on a Cisco 7500 series router results in the recarving of buffers and resetting of all interfaces. The following message is displayed: RSP-3-Restart:cbus complex .

You can configure native Gigabit Ethernet ports on the Cisco 7200 series router to a maximum MTU size of 9216 bytes. The MTU values range from 1500 to 9216 bytes. The MTU values can be configured to any range that is supported by the corresponding main interface.

Protocol-Specific Versions of the mtu Command

Changing the MTU value with the **mtu** interface configuration command can affect values for the protocol-specific versions of the command (the **ipmtu** command, for example). If the value specified with the **ipmtu** interface configuration command is the same as the value specified with the **mtu** interface configuration command, and you change the value for the **mtu** interface configuration command, the **ipmtu** value automatically matches the new **mtu** interface configuration command value. However, changing the values for the **ipmtu** configuration commands has no effect on the value for the **mtu** interface configuration command.

ATM and LANE Interfaces

ATM interfaces are not bound by what is configured on the major interface. By default, the MTU on a subinterface is equal to the default MTU (4490 bytes). A client is configured with the range supported by the corresponding main interface. The MTU can be changed on subinterfaces, but it may result in recarving of buffers to accommodate the new maximum MTU on the interface.

VRF-Aware Service Infrastructure Interfaces

The mtu command does not support the VRF-Aware Service Infrastructure (VASI) type interface.

Cisco 7600 Valid MTU Values

On the Cisco 7600 platform, the following valid values are applicable:

- For the SVI ports: from 64 to 9216 bytes
- For the GE-WAN+ ports: from 1500 to 9170 bytes
- For all other ports: from 1500 to 9216 bytes

You can receive jumbo frames on access subinterfaces also. The MTU values can be configured to any range that is supported by the corresponding main interface. If you enable the jumbo frames, the default is 64 bytes for the SVI ports and 9216 bytes for all other ports. The jumbo frames are disabled by default.

Cisco uBR10012 Universal Broadband Router

While configuring the interface MTU size on a Gigabit Ethernet SPA on a Cisco uBR10012 router, consider the following guidelines:

- The default interface MTU size accommodates a 1500-byte packet, plus 22 additional bytes to cover the following overhead:
  - Layer 2 header--14 bytes
  - Dot1Q header--4 bytes
  - CRC--4 bytes
- If you are using MPLS, be sure that the **mplsmtu** command is configured with a value less than or equal to the interface MTU.
- If you are using MPLS labels, you should increase the default interface MTU size to accommodate the number of MPLS labels. Each MPLS label adds 4 bytes of overhead to a packet.

Note For the Gigabit Ethernet SPAs on the Cisco uBR10012 router, the default MTU size is 1500 bytes. When the interface is being used as a Layer 2 port, the maximum configurable MTU is 9000 bytes.

Examples

The following example shows how to specify an MTU of 1000 bytes:

```
Router(config)# interface serial 1
Router(config-if)# mtu 1000
```

Cisco uBR10012 Universal Broadband Router

The following example shows how to specify an MTU size on a Gigabit Ethernet SPA on the Cisco uBR10012 router:

```
Router(config)# interface GigabitEthernet3/0/0
Router(config-if)# mtu 1800
```

Related Commands

Command	Description
encapsulation smds	Enables SMDS service on the desired interface.
ip mtu	Sets the MTU size of IP packets sent on an interface.

national bit (controller)

To set the E3 national bit in the G.751 frame used by the E3 controller, use the national bit command in controller configuration mode. To return to the default E3 controller national bit, use the no form of this command.

national bit {**0** | **1**}
no national bit

Syntax Description

0	Sets the E3 national bit in the G.751 frame to 0.
1	Sets the E3 national bit in the G.751 frame to 1. This is the default.

Command Default

The default value is 1.

Command Modes

Controller configuration

Command History

Release	Modification
11.1 CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.

Usage Guidelines

When G.751 framing is used, bit 11 of the G.751 frame is reserved for national use and is set to 1 by default.

Configure national bit 1 only when required for interoperability with your telephone company.

To verify the national bit configured on the interface, use the **showcontrollersserial** EXEC command.

Examples

The following example sets the national bit to 1 on an E3 controller in slot 1, port 0:

```
Router(config)# controller e3 1/0
Router(config-controller)# national bit 1
```

Related Commands

show controllers serial	Displays information that is specific to the interface hardware.

national bit (interface)

To set the E3 national bit in the G.751 frame used by the PA-E3 port adapter, use the **nationalbit**command in interface configuration mode. To return to the default E3 interface national bit, use the **no** form of this command.

national bit {**0** | **1**}
no national bit

Syntax Description

0	Sets the E3 national bit in the G.751 frame to 0. This is the default.
1	Sets the E3 national bit in the G.751 frame to 1.

Command Default

The default value is 0.

Command Modes

Interface configuration

Command History

Release	Modification
11.1 CA	This command was introduced.

Usage Guidelines

The **nationalbit** command sets bit 12 in the E3 frame.

To verify the national bit configured on the interface, use the **showcontrollersserial** EXEC command.

Examples

The following example sets the national bit to 1 on the PA-E3 port adapter in slot 1, port adapter slot 0, interface 0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# national bit 1
```

Related Commands

Command	Description
international bit	Sets the E3 international bit in the G.751 frame used by the PA-E3 port adapter.
show controllers serial	Displays information that is specific to the interface hardware.

national reserve

To set the E1 national bit, use the**nationalreserve**command in interface configuration mode. To return to the default E1 national bit, use the**no** form of this command.

national reserve {**0** | **1**} {**0** | **1**} {**0** | **1**} {**0** | **1**} {**0** | **1**} {**0** | **1**}
no national reserve

Syntax Description

0	Sets any of the six required E1 national bits in the G.751 frame to 0.
1	Sets any of the six required E1 national bits in the G.751 frame to 1. This is the default.

Command Default

111111

Command Modes

Interface configuration

Command History

Release	Modification
12.0(5)XE	This command was introduced.
12.0(7)XE1	This command was implemented on the Cisco 7100 series routers.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies only for E1. This command not only sets the national reserve bits but also sets the international bit as well. The far left digit represents the international bit. All six digits must be present for the pattern to be valid.

Examples

On Cisco 7100 series routers, the following example sets the E1 national bit on interface 1 on the port adapter in slot 0 to no scrambling:

```
Router(config)# interface atm 1/0
Router(config-if)# national reserve 011011
```

negotiation

To enable advertisement of speed, duplex mode, and flow control on a Gigabit Ethernet interface, use the**negotiation**command in interface configuration mode. To disable automatic negotiation, use the **nonegotiationauto** command.

negotiation {**forced** | **auto**}
no negotiation auto

Syntax Description

forced	Disables flow control and configures the Gigabit Ethernet interface in 1000/full-duplex mode. This keyword is not supported on the 2-port 10/100/1000 Gigabit Ethernet shared port adapter (SPA) on the Cisco 7304 router.
auto	Enables the autonegotiation protocol to configure the speed, duplex, and automatic flow control of the Gigabit Ethernet interface. This is the default.

Command Default

Autonegotiation is enabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.1CC	This command was introduced.
12.0(7)S	This command was modified. The forced keyword was added.
12.0(6)T	This command was modified. The forced keyword was added.
12.1(3a)E	This command was integrated into Cisco IOS Release 12.1E and implemented on the Cisco 7200-I/O-GE+E controller.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(20)S2	This command was implemented on the 2-port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router. The **forced** keyword is not supported.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SCB	This command was integrated into Cisco IOS Release 12.2(33)SCB.

Usage Guidelines

The **negotiation**command is applicable to the Gigabit Ethernet interface of the Cisco 7200-I/O-GE+E and interfaces on the 2-port 10/100/1000 Gigabit Ethernet SPA that are using fiber media. The **negotiationauto**command is used instead of the **duplex** and **speed** commands (which are used on Ethernet and Fast Ethernet interfaces, and interfaces on the 2-port 10/100/1000 Gigabit Ethernet SPA that are using RJ-45 media) to automatically configure the duplex and speed settings of the interfaces.

The **negotiationforced** command is used to configure the Gigabit Ethernet interface of the Cisco 7200-I/O-GE+E to be 1000/full-duplex only and to disable flow control. The **negotiationforced** command is not supported by the 2-port 10/100/1000 Gigabit Ethernet SPA.

The Gigabit Ethernet interface of the Cisco 7200-I/O-GE+E and the interfaces on the 2-port 10/100/1000 Gigabit Ethernet SPA that are using fiber media are restricted to 1000 Mbps/full-duplex only. Autonegotiation advertises and negotiates only to these values.

The **nonegotiationauto** command is used to disable the autonegotiation in the Cisco 3800 series routers. If the speed is set to 1000 Mbps and full-duplex is set for the Gigabit Ethernet interface in small form-factor pluggable (SFP) mode, then the autonegotiation is disabled (forced mode) using the **nonegotiationauto** command.

However, for RJ-45 media the autonegotiation is always enabled for fixed speed and duplex setting. For SFP mode of operation, the autonegotiation can be disabled by using the **nonegotiationauto** command.

Cisco uBR10012 Universal Broadband Router

Autonegotiation is enabled by default and can be disabled on the 5-port Gigabit Ethernet SPA. During autonegotiation, advertisement for flow control, speed, and duplex occurs. If autonegotiation is disabled on one end of a link, it must be disabled on the other end of the link. If one end of a link has autonegotiation disabled and the other end of the link does not, the link does not come up properly on both ends. Flow control is always negotiated when autonegotiation is enabled.

Note Autonegotiation is not supported on the 1-port 10-Gigabit Ethernet SPA in Cisco IOS Release 12.2(33)SCB.

Examples

The following example shows how to enable the second interface (port 1) on a 2-port 10/100/1000 Gigabit Ethernet SPA for autonegotiation, where the SPA is installed in the bottom subslot (1) of the modular services card (MSC), and the MSC is installed in slot 2 of the Cisco 7304 router:

```
Router(config)# interface gigabitethernet 2/1/1
Router(config-if)# media-type gbic
Router(config-if)# negotiation auto
```

The following example shows how to disable the second interface (port 1) on a 2-port 10/100/1000 Gigabit Ethernet SPA for autonegotiation, where the SPA is installed in the bottom subslot (1) of the MSC, and the MSC is installed in slot 2 of the Cisco 7304 router:

```
Router(config)# interface gigabitethernet 2/1/1
Router(config-if)# no negotiation auto
```

Related Commands

Command	Description
show interfaces gigabitethernet	Displays information about the Gigabit Ethernet interfaces.

neighbor (VPLS)

To specify the type of tunnel signaling and encapsulation mechanism for each Virtual Private LAN Service (VPLS) peer, use the **neighbor** command in L2 VFI manual configuration mode. To disable a split horizon, use the **no** form of this command.

neighbor *remote-router-id* *vc-id* {**encapsulation** *encapsulation-type* | **pw-class** *pw-name*} [**no-split-horizon**]
no **neighbor** *remote-router-id* [*vc-id*]

Syntax Description

remote-router-id	Remote peer router identifier. The remote router ID can be any IP address, as long as it is reachable.
vc-id	32-bit identifier of the virtual circuit between the routers.
encapsulation	Specifies tunnel encapsulation.
encapsulation-type	Specifies the tunnel encapsulation type; valid values are **l2tpv3** and **mpls**.
pw-class	Specifies the pseudowire class configuration from which the data encapsulation type is taken.
pw-name	Name of the pseudowire class.
no-split-horizon	(Optional) Disables the Layer 2 split horizon forwarding in the data path.

Command Default

Split horizon is enabled.

Command Modes

L2 VFI manual configuration (config-vfi)

Command History

Release	Modification
12.2(18)SXF	This command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SRB	This command was modified. This command was updated so that the remote router ID need not be the LDP router ID of the peer.
Cisco IOS XE Release XE 3.7S	This command was integrated into Cisco IOS XE Release XE 3.7S.

Usage Guidelines

In a full-mesh VPLS network, keep split horizon enabled to avoid looping.

With the introduction of VPLS Autodiscovery, the remote router ID no longer needs to be the LDP router ID. The address that you specify can be any IP address on the peer, as long as it is reachable. When VPLS Autodiscovery discovers peer routers for the VPLS, the peer router addresses might be any routable address.

Examples

This example shows how to specify the tunnel encapsulation type:

```
Device(config-vfi)# l2 vfi vfi-1 manual
Device(config-vfi)# vpn 1
Device(config-vfi)# neighbor 172.16.10.2 4 encapsulation mpls
```

This example shows how to disable the Layer 2 split horizon in the data path:

```
Device(config-vfi)# l2 vfi vfi-1 manual
Device(config-vfi)# vpn 1
Device(config-vfi)# neighbor 172.16.10.2 4 encapsulation mpls no-split-horizon
```

Related Commands

Command	Description
l2 vfi manual	Creates a Layer 2 VFI.

network-clock (BITS)

To configure BITS port signaling types, use the **network-clock**command in global configuration mode. To disable the BITS port signaling types, use the **no** form of this command.

network-clock slot *slot* **bits** *number* {**2m** | **e1** [**crc4**] | **j1** [**esf**] | **t1** [{**d4** | **esf** [{**133ft** | **266ft** | **399ft** | **533ft** | **655ft**}]}]}
no network-clock slot *slot* **bits** *number* {**2m** | **e1** [**crc4**] | **j1** [**esf**] | **t1** [{**d4** | **esf** [{**133ft** | **266ft** | **399ft** | **533ft** | **655ft**}]}]}

Syntax Description

slot	Selects the slot.
slot	Specifies backplane slot number.
bits	Specifies BITS port signaling types.
number	Specifies the BITS port number starting from 0.
2m	Specifies 2.048 MHz square wave signal type.
e1	Specifies E1 signal type.
j1	Specifies Japan J1 signal type.
t1	Specifies T1 signal type.
crc4	E1 CRC4 framing mode.
esf	T1 ESF framing mode.
d4	T1 D4 framing mode.
133ft	Line Build-Out Select 0 to 133 feet.
266ft	Line Build-Out Select 0 to 266 feet.
399ft	Line Build-Out Select 0 to 399 feet.
533ft	Line Build-Out Select 0 to 533 feet.
655ft	Line Build-Out Select 0 to 655 feet.

Command Default

T1, ESF, 133ft

Command Modes

Global configuration

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco series 7600 router for the 76-ES+XT-2TG3CXL and 76-ES+XT-4TG3CXL.

Usage Guidelines

For 76-ES+XT-2TG3CXL and 76-ES+XT-4TG3CXL line cards, the BITS port number is always 0 because there is only one BITS port.

Examples

The following example shows how to configure the BITS port and 10GE interface as clock sources:

```
Router(config)# network-clock select 2 slot 1 ?
  bits    Network clock source is bits interface
  global  Configure the source as global
  local   Configure the source as local
  <cr>

Router(config)# network-clock select 2 slot 1 bits 0 ?
  global  Configure the source as global
  local   Configure the source as local
  <cr>

Router(config)# network-clock select 3 ?
  controller  Select the controller that should source the clock
  interface   Select the interface that should source the clock
  slot        Select the slot that should source the clock
  system      Select the system clock as source

Router(config)# network-clock select 3 interface TenGigabitEthernet 1/1
```

The following example shows how to configure the BITS port signal type and framing mode:

```
Router(config)# network-clock slot 1 bits 0 ?
  2m  2.048MHz square wave signal type
  e1  E1 signal type
  j1  Japan J1 signal type
  t1  T1 signal type

Router(config)# network-clock slot 1 bits 0 t1 ?
  d4   T1 D4 framing mode
  esf  T1 ESF framing mode

Router(config)# network-clock slot 1 bits 0 t1 d4 ?
  133ft  Line Build-Out Select 0 to 133 feet
  266ft  Line Build-Out Select 133 to 266 feet
  399ft  Line Build-Out Select 266 to 399 feet
  533ft  Line Build-Out Select 399 to 533 feet
  655ft  Line Build-Out Select 533 to 655 feet

Router(config)# network-clock slot 1 bits 0 j1 ?
  esf  J1 ESF framing mode

Router(config)# network-clock slot 1 bits 0 e1 ?
  crc4  E1 CRC4 framing mode

Router(config)# network-clock slot 1 bits 0 2m ?
  <cr>
```

Related Commands

Command	Description
show network-clocks	Displays the current configured and active network clock sources.

Command	Description
show platform hardware network-clocks	Displays network clocks for an ES+ line card.

network-clock clear lockout

To clear the lock-out on a clock source, use the network-clock clear lockout command in the privileged EXEC mode.

Cisco 7600 Series Routers
network-clock clear lockout interface *slot/card/port* | **external** *slot/card/port* **2048K** | **e1** {**cas** | **crc4** | **fas**}

Cisco ASR 1000 Series Routers
network-clock clear lockout external {*slot/card/port* | **R0** | **R1**} **T1** {**d4** | **esf** | **sf**}

Syntax Description

external	Specifies external interface (BITS/SSU/GPS).
slot/card/port	Slot number/Card number/Port number.
R0	Specifies the network synchronization mcprp RP0 bits for source slot.
R1	Specifies the network synchronization mcprp RP1 bits for source slot.
T1	Specifies the T1 signal mode input.
d4	Specifies the D4 super frame signal mode.
esf	Specifies the extended super frame signal mode.
sf	Specifies the super frame signal mode.
2048k	Specifies the option 1 2048KHz on the BITS/SSU port.
e1	Specifies the E1 signal mode.
cas	Specifies the E1 Channel Associated Signal (CAS) mode.
crc4	Specifies the E1 with crc4 signal mode.
fas	Specifies the E1 Frame Alignment Signal mode.

Command Default

No default values are available.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.

Examples

The following example shows how to clear the lock out on a clock source:

```
C7600(config)# network-clock clear lockout external 0/0/0 e1 2048k
ASR1000(config)# network-clock clear lockout external 0/0/0 t1 esf
```

network-clock hold-off global

To configure the hold-off time, use the network-clock hold-off global command in the global configuration mode.

network-clock hold-off *timer* **global**

Syntax Description

timer	Hold-off time, in milliseconds. The range is from 50 to 10000. The default is 300. If you do not want the hold off time, set the timer value to 0.
global	Configures the hold-off timer globally.

Command Default

The default value is 300 milliseconds on Cisco ASR 901 Series Aggregation Services Routers.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

The hold-off timer can also be configured in the interface configuration mode. It displays a warning message for values below 300 milliseconds and above 1800 milliseconds.

Examples

The following example shows how to configure the hold-off timer in the global configuration mode:

```
Router(config)# network-clock hold-off 50 global
```

network-clock input-source

To assign a controller to be the primary or secondary clock source use the **network-clock input-source***priority* command. To set the controller to be a primary clock source, set the value of priority for the input source to be low value, such as 2, (a low value indicates a high priority). To remove the clock source, use the **no** form of this command

network-clock input-source *priority* **controller t1/e1***slot/bay/port*

no network-clock input-source *priority* **controller t1/e1** *slot/bay/port*

Syntax Description

network-clock input-source *priority*	The network-clock input-source priority command selects the configured controller clock as the backplane clock source.
controller t1/e1	Sets the controller into T1 or E1 signal mode.
priority	Sets the controller to be a primary clock source.
slot/bay/port	Specifies slot, bay and port number

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series.
XE Everest 16.5.1	This command was introduced on the Cisco ASR 900 Series Routers and Cisco NCS 4200 Series.

Usage Guidelines

This command is used to assign controller to be the primary or secondary clock source.

Examples

```
enable
configure terminal
network-clock input-source 1controller E1/T10/5/0
```

network-clock set lockout

To lock out a clock source, use the network-clock set lockout command in the privileged EXEC mode. On the Cisco ASR 901 Series Aggregation Services Routers, use the **network-clock clear lockout** command to remove the lockout in global configuration mode.

Cisco 7600 Series Routers

{**network-clock set lockout internal** *slot/card/port* | **external** *slot/card/port* **2048K** | **e1** {**cas** | **crc4** | **fas**}}

Cisco ASR 1000 Series Routers

network-clock set lockout external {*slot/card/port* | **R0** | **R1**} **T1** {**d4** | **esf** | **sf**}

Cisco ASR 901 Cisco ASR 901 Series Aggregation Services Routers

network-clock set lockout {**interface** *interface-name slot/port* | **external** *slot/card/port*}

network-clock clear lockout

Syntax Description

external	Specifies external interface (BITS/SSU/GPS).
slot/card/port	Slot number/card number/port number.
R0	Specifies the network synchronization mcprp RP0 bits for the source slot.
R1	Specifies the network synchronization mcprp RP1 bits for the source slot.
T1	Specifies the T1 signal mode input.
d4	Specifies the D4 super frame signal mode.
esf	Specifies the extended super frame signal mode.
sf	Specifies the super frame signal mode.
2048k	Specifies the option 1 2048KHz on the BITS/SSU port.
e1	Specifies the E1 signal mode.
cas	Specifies the E1 Channel Associated Signal (CAS) mode.
crc4	Specifies the E1 with crc4 signal mode.
fas	Specifies the E1 Frame Alignment Signal mode.
interface	Specifies the interface.
interface-name	Specifies the interface name.

Command Default

No default values are available.

Command Modes

- Global configuration (config)
- Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers. The *interface-name* argument was added.

Usage Guidelines

The **network-clock set lockout** command locks out a clock source. A locked out clock source is not selected for SyncE.

To clear the lock-out on a source, use the **network-clock clear lockout** command.

Note Lock-out takes precedence over force switch, and force switch overrides the manual switch.

Examples

The following example shows how to lock out a clock source:

```
C7600(config)# network-clock set lockout external 2/0/0 e1 cas
ASR1000(config)# network-clock set lockout external R0 t1 esf
```

This example shows how to lockout the clock source on a Cisco ASR 901 Series Aggregation Services Router.

```
Router(config)# network-clock set lockout interface GigabitEthernet 0/1
```

network-clock synchronization ssm option

To configure the equipment to work in a synchronization network, use the **network-clock synchronization ssm option** command in the global configuration mode. To unconfigure the network-clock synchronization option, use the no form of this command.

network-clock synchronization ssm option option_id {**1** | **2** {**GEN1** | **GEN2**}}
no network-clock synchronization ssm option option_id {**1** | **2** {**GEN1** | **GEN2**}}

Syntax Description

option_id	The option_id can have the following values: • 1 - Refers to the synchronization networks design for Europe. This is the default value. (E1 framings are compatible with this option). • 2 - Refers to the synchronization networks design for the U.S. (T1 framings are compatible with this option).
GEN1	If option 2 is configured, then it specifies the generation ID as 1.
GEN2	If option 2 is configured, then it specifies the generation ID as 2.

Command Default

No default values are available.

Cisco ASR 901 Series Aggregation Services Routers

Option 1.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

Network-clock configurations that are not common between options need to be configured again.

On Cisco ASR 901 Series Aggregation Services Routers, the default value for the option_id keyword is 1. If you set the value to 2, you must specify the generation ID.

Examples

The following example shows how the **network-clocksynchronizationssmoption** command is used to configure the equipment to work in a synchronization network:

```
Router> enable
Router# configure terminal
Router(config)# network-clock synchronization automatic
Router(config)# network-clock synchronization ssm option 2 GEN1
```

Related Commands

Command	Description
network-clock eec	Configures the clocking system hardware with the desired parameters.

network-clock synchronization automatic

To enable the network clock synchronization selection process, use the network-clock synchronization automatic command in the global configuration mode. To disable the network clock synchronization selection process, use the no form of this command.

network-clock synchronization automatic
no network-clock synchronization automatic

Syntax Description

This command has no arguments or keywords.

Command Default

No default values are available.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.

Usage Guidelines

This command disables the Cisco-specific network-clock process, and turns on G.781-based automatic clock synchronization selection process.

Examples

The following example shows how the network-clock synchronization automatic command is used to enable the network clock synchronization selection process:

```
Router(config)# network-clock synchronization automatic
```

network-clock synchronization mode QL-enabled

To configure the automatic selection process for the QL-enabled mode, use the network-clock synchronization mode QL-enabled command in the global configuration mode.

network-clock synchronization mode QL-enabled

Syntax Description

This command has no arguments or keywords.

Command Default

No default values are available.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.
15.1(2)SNH	This command was introduced in Cisco ASR 901 Aggregation Services Routers.

Usage Guidelines

The automatic selection process for the QL-enabled mode is successful only if the Synchronous Ethernet interfaces are capable of sending Synchronization Status Messages (SSM).

Examples

The following example shows how to configure network clock synchronization (QL-enabled mode) in the global configuration mode:

```
Router(config)# network-clock synchronization mode QL-enabled
```

network-clock quality-level

To configure the Quality Level (QL) value for the Synchronization Status Messages (SSM) on a BITS port, use the network-clock quality-level command in the global configuration mode.

Cisco 7600 Series Routers
{**network-clock quality-level** {**rx** | **tx**} {**QL-PRC** | **QL-SSU-A** | **QL-SSU-B** | **QL-SEC** | **QL-DNU**} **external** *slot/card/port* **2048K** | **e1** {**cas** | **crc4** | **fas**}}

Cisco ASR 1000 Series Routers
network-clock quality-level {**rx** | **tx**} {**QL-PRS** | **QL-STU** | **QL-ST2** | **QL-TNC** | **QL-ST3** | **QL-ST3E** | **QL-SMC** | **QL-ST4** | **QL-DUS**} **external** {*slot/card/port* | **R0** | **R1**} **T1** {**d4** | **esf** | **sf**}

Syntax Description

rx	Specifies the received QL. The following values are available on Cisco ASR 1000 Series routers for the QL receive: • QL-PRS • QL-STU • QL-ST2 • QL-ST3 • QL-SMC • QL-ST4 • QL-DUS The following values are available on Cisco 7600 Series routers for the QL receive: • QL-PRC • QL-SSU-A • QL-SSU-B • QL-SEC • QL-DNU

tx	Specifies the trasmitted QL. The following values are available on Cisco ASR 1000 Series routers for the QL transmit: • QL-PRS • QL-STU • QL-ST2 • QL-ST3 • QL-SMC • QL-ST4 • QL-DUS The following values are available on Cisco 7600 Series routers for the QL transmit: • QL-PRC • QL-SSU-A • QL-SSU-B • QL-SEC • QL-DNU
external	Specifies the external interface (BITS/SSU/GPS).
slot /*card*/*port*	Slot number/Card number/Port number.
R0	Specifies the network synchronization RP0 bits for source slot.
R1	Specifies the network synchronization RP1 bits for source slot.
T1	Specifies the T1 signal mode output.
d4	Specifies the D4 super frame signal mode.
esf	Specifies the extended super frame signal mode.
sf	Specifies the super frame signal mode.
2048k	Specifies the option 1 2048KHz on the BITS/SSU port.
e1	Specifies the E1 signal mode.
cas	Specifies the E1 Channel Associated Signal (CAS) mode.
crc4	Specifies the E1 with crc4 signal mode.
fas	Specifies the E1 Frame Alignment Signal mode.

Command Default

No default values are available.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2.0S	This command was integrated into Cisco ASR 1000 Series routers.
Cisco IOS Release 12.2(33)SRE	This command was introduced on the Cisco 7600 Series routers.

Examples

The following example shows how to configure network-clock quality-level command in the global configuration mode:

```
C7600(config)# network-clock quality-level rx ql-prc external 0/0/0 e1 cas
ASR1000(config)# network-clock quality-level tx QL-ST2 external R0 t1 sf
```

no channelized

To configure the T3 controller for unchannelized mode, use the**nochannelized**configuration controller command. To configure channelized mode, use the **channelized**form of this command.

channelized
no channelized

Syntax Description

This command has no arguments or keywords.

Command Default

MTU size is set to 4470.

Command Modes

Configuration controller

Command History

Release	Modification
12.0(14)S	This command was introduced.
12.1(5a)E	This command was integrated into Cisco IOS Release 12.1(5a)E.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the no channelized configuration controller command to configure the T3 controller for unchannelized mode. When you configure the PA-MC-2T3+ on a Cisco 7500 series router with the no channelized command, the MTU size is set to 4470. In channelized mode, the default MTU size is 1500. The change in MTU sizes will cause a memory recarve and CBus complex to occur, disrupting all traffic on the router for several minutes.

The following message will be displayed when switching between channelized and unchannelized modes on a Cisco 7500 series router:

```
Change to subrate mode will cause cbus complex reset. Proceed? [yes/no]:
Y
```

Type Y for "yes" at the end of the warning. At the prompt, type ^Z to exit. You will exit configuration mode and enter unchannelized mode.

Examples

The following example configures unchannelized mode on a PA-MC-2T3+ in port adapter slot 1 of a VIP2 or VIP4 in a Cisco 7500 series router:

```
configure terminal
  controller T3 1/1/0
  no channelized
```

```
Change to subrate mode will cause cbus complex reset. Proceed? [yes/no]: Y
  ^Z
```

nrzi-encoding

To enable nonreturn-to-zero inverted (NRZI) line-coding format, use the **nrzi-encoding**command in interface configuration mode. To disable this capability, use the **no** form of this command.

nrzi-encoding [**mark**]
no nrzi-encoding

Syntax Description

mark	(Optional) Specifies that NRZI mark encoding is required on the PA-8T and PA-4T+ synchronous serial port adapters on Cisco 7200 and Cisco 7500 series routers . If the **mark** keyword is not specified, NRZI space encoding is used.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
11.3	The **mark** keyword was added for the Cisco 7200 series routers and Cisco 7500 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

All FSIP, PA-8T, and PA-4T+ interface types support nonreturn-to-zero (NRZ) and NRZI format. This is a line-coding format that is required for serial connections in some environments. NRZ encoding is most common. NRZI encoding is used primarily with EIA/TIA-232 connections in IBM environments.

Examples

The following example configures serial interface 1 for NRZI encoding:

```
Router(config)# interface serial 1
Router(config-if)# nrzi-encoding
```

The following example configures serial interface 3/1/0 for NRZI mark encoding:

```
Router(config)# interface serial 3/1/0
Router(config-if)# nrzi-encoding mark
```

O through R

outbound data-pid

Note Effective with Cisco IOS Release 12.4(2)T, this command is superseded by the **outboundpidmanagement** command. The **outbounddata-pid** command is still available, but use of the **outboundpidmanagement** command is recommended.

To specify the outbound data packet identification (PID) number, use the **outbounddata-pid** command in satellite initial configuration mode. To remove the PID number configuration, use the **no** form of this command.

outbound data-pid *number*
no outbound data-pid

Syntax Description

number	Packet identification (PID) number in the range from 1 to 8190.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(2)T	This command was superseded by the**outboundpidmanagement** command.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to specify the outbound data PID number:

```
Router(sat-init-config)# outbound data-pid 3000
```

outbound data-rate

To specify the VSAT data rate, use the **outbounddata-rate** command in satellite initial configuration mode. To remove the data rate configuration, use the **no** form of this command.

outbound data-rate *rate*
no outbound data-rate

Syntax Description

rate	VSAT data rate in the range from 250000 to 73000000 bits per second.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to specify the VSAT data rate:

```
Router(sat-init-config)# outbound data-rate 450000
```

outbound frequency

To specify the VSAT outbound frequency, use the **outboundfrequency** command in satellite initial configuration mode. To remove the outbound frequency configuration, use the **no** form of this command.

outbound frequency *frequency*
no outbound frequency

Syntax Description

frequency	VSAT outbound frequency in the range from 950000 to 2150000 kilohertz.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the VSAT outbound frequency:

```
Router(sat-init-config)# outbound frequency 950000
```

outbound id

To specify the VSAT outbound ID, use the **outboundid**command in satellite initial configuration mode. To remove the outbound ID configuration, use the **no** form of this command.

outbound id *number*
no outbound id

Syntax Description

number	ID number in the range from 0 to 255.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the VSAT outbound ID:

```
Router(sat-init-config)# outbound id 95
```

outbound modulation-type

To specify the VSAT modulation type, use the **outboundmodulation-type** command in satellite initial configuration mode. To remove the VSAT modulation type configuration, use the **no** form of this command.

outbound modulation-type {**DVB** | **TURBO_QPSK** | **8PSK**}
no outbound modulation-type

Syntax Description

DVB	Digital Video Broadcasting for satellite.
TURBO_QPSK	Turbo-coded quadrature Phase Shift Keying.
8PSK	Phase Shift Keying.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the VSAT modulation type:

```
Router(sat-init-config)# outbound modulation-type DVB
```

outbound sync ip address

To specify the outbound synchronization IP address, use the **outboundsyncipaddress** command in satellite initial configuration mode. To remove the outbound synchronization IP address configuration, use the **no** form of this command.

outbound sync ip address *address*
no outbound sync ip address

Syntax Description

address	Outbound synchronization IP address.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the outbound synchronization IP address:

```
Router(sat-init-config)# outbound sync ip address 10.2.2.2
```

outbound viterbi-rate

To specify the VSAT Viterbi code rate, use the **outboundviterbi-rate** command in satellite initial configuration mode. To return to the default rate, use the **no** form of this command.

outbound viterbi-rate *rate*
no outbound viterbi-rate

Syntax Description

rate	Viterbi code rate. It can be one of the following values: • **1/2** • **1/4** • **2/3** • **3/4** • **3/4(2.05)** • **3/4(2.1)** • **3/4(2.6)** • **5/6** • **6/7** • **7/8** • **8/9**

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to configure the VSAT Viterbi code rate:

```
Router(sat-init-config)# outbound viterbi-rate 3/4(2.6)
```

output

To enable out put of time of day messages using a 1PPS interface, use the **output** command in global configuration mode. To disable PTP output, use the **no** form of this command.

output 1pps *slot/bay* [**offset** *offset-value* [**negative**]] [**pulse-width** *pulse-amount* {**ns** | **us** | **ms**}]
no output 1pps *slot/bay* [**offset** *offset-value* [**negative**]] [**pulse-width** *pulse-amount* {**ns** | **us** | **ms**}]

Syntax Description

1pps	Configures the device to send 1 packet per second (1PPS) time of day messages using the RS422 port or 1PPS port. You can select 1PPS output with or without selecting a timing port.
slot	Slot of the 1PPS interface.
bay	Bay of the 1PPS interface.
offset	(Optional) Specifies an offset to compensate for a known phase error such as network asymmetry.
offset-value	Amount of offset in nanoseconds. The range is from 0 to 500,000,000.
negative	Specifies a negative offset 1PPS output value.
pulse-width	(Optional) Specifies a pulse width value.
pulse-amount	Amount of the pulse width. The range is from 1 to 4096. For 1PPS output using the RS422 port, you must specify a value of at least 2 ms.
ns	Specifies a pulse width value in nanoseconds.
us	Specifies a pulse width value in microseconds.
ms	Specifies a pulse width value in milliseconds.

Command Default

Time of day message output is not enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(31)SB2	This command was introduced.
15.0(1)S	This command was integrated into Cisco IOS Release 15.0(1)S.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

If you want to provide output frequency clock, configure this command in PTP mode. This command only applies to platforms that have 1PPS ports.

Examples

The following example shows how to configure output clocking:

```
Device> enable
Device# configure terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# output 1pps 3/0 offset 10 pulse-width 1000 ms
Device(config-ptp-clk)# end
```

The following example shows the time of day (ToD) configuration on the 1588V2 subordinate and corresponding output:

```
Device> enable
Device# config terminal
Device(config)# ptp clock ordinary domain 0
Device(config-ptp-clk)# tod 3/3 cisco
Device(config-ptp-clk)# output 1pps 0 250 ns
Device(config-ptp-clk)# clock-port SLAVE slave
```

Related Commands

Command	Description
input	Enables PTP input clocking using the 1.544 Mhz, 2.048 Mhz, or 10 Mhz timing interface or phase using the 1PPS or RS-422 interface.

overhead c2

To set the SONET path overhead bytes in the frame header to a specific standards requirement or to ensure interoperability with equipment from another vendor, use the **overhead** command in SONET path configuration mode. To remove the setting of the SONET path overhead bytes from the configuration file and restore the system to its default condition, use the **no** form of this command.

overhead c2 *value*

no overhead c2 *value*

Syntax Description

Syntax Description

c2 *value*	Configures the C2 byte in the Path OverHead (POH) to indicate the contents of the payload inside the frame. C2 byte is to communicate the payload type that the SONET Framing OverHead (FOH) encapsulates.

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series.
XE Everest 16.5.1	This command was introduced on the Cisco ASR 920 Routers and Cisco NCS 4200 Series.

Usage Guidelines

This command is used to configure C2 flag as the path overhead.

Examples

The following example shows the configuration of C2 flag:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
sts-1 1
overhead c2 10
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

overhead j0

To specify the Regenerator Section (RS) Trace identifier (J0), use the **overheadj0** command in controller configuration mode. To restore the default value, use the **no** form of this command.

overhead j0 {**transmit** | **receive**} *string*
no overhead j0 {**transmit** | **receive**} *string*

Syntax Description

For NCS 4200 Series:

overhead j0 {*expected* | *tx*} [**length** *number* | **tracebuffer** *string*]

transmit	Specifies that the *string* argument is sent on the transmit line.
receive	Specifies that the configured *string* argument is matched with the string received from a peer.
string	Value in the range from 0 to 255 that is converted into character format and embedded in a 16-byte frame. The default is 1.
expected	Configures the expected trace identifier of the controller.
tx	Configures the packets transmitted.
length *number*	Specifies the length of the expected trace identifier.
tracebuffer *string*	Configures the SONET path trace buffer. Enters the ACSII text for the controller.

Command Default

The default value is 1, and no peer authentication is performed.

Command Modes

Controller configuration

Command History

Release	Modification
12.0(17)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T, and the **transmit** and **receive** keywords were added.
XE 3.18SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

RS trace is a maintenance feature of SONET. One byte (J0) of the Section overhead associated with each SONET frame is used to carry information identifying the transmitting equipment.

Use this command for peer authentication and continuity testing between two STM-1 optical peers. If the authentication string sent by the originating peer does not match the configured string on the receiving peer, the SONET controller will not come up on the receiving peer. Alarm logs on the originating peer will show that it has RS-Trace Identifier Mismatch (RS-TIM).

For NCS 4200 Series, use this command to configure line and section overhead of SONET line.

Examples

The following example shows how to configure J0 overhead in both the transmit and receive directions on a STM-1 trunk card:

```
Router(config)# controller sonet 2/0
Router(config-controller)# overhead j0 transmit 22
Router(config-controller)# overhead j0 receive 34
```

The following example shows how to set the RS Trace identifier to 82:

```
Router(config-controller)# overhead j0 transmit 82
```

Examples

For NCS 4200 Series, the following example shows how to configure line and section overhead:

```
enable
configure terminal
controller Mediatype 0/5/0
controller sonet 0/5/0
overhead j0 tx length 1-byte
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

overhead j1

To configure the message length and the message text of the High Order Path Trace identifier (J1), use the **overheadj1** command in controller configuration or path configuration mode. To restore the default value, use the **no** form of this command.

overhead j1 length {**16** | **64**} {**transmit-message** | **receive-message**} *string*
no overhead j1 length {**16** | **64**} {**transmit-message** | **receive-message**} *string*

Syntax Description

For NCS 4200 Series, use the following command:

overhead j1 [**expected** | **tx**] [**length** | **message**]

length	Specifies the length of the authentication *string* argument.
16	Specifies that the length of the authentication *string*is 16 characters. The STM-1 trunk card supports a string length of 16.
64	Specifies that the length of the authentication *string*is 64 characters.
transmit-message	Specifies that the *string* argument is sent on the transmit line.
receive-message	Specifies that the configured *string* argument is matched with the string received from a peer.
string	Combination of characters and numbers for the specified **length** value.
tx	Configures the packets transmitted.
expected	Configures the expected trace identifier of the controller.

Command Default

The default message length is 16 for SDH framing and 64 for SONET framing. No peer authentication is performed.

Command Modes

Controller configuration

Path configuration

Command History

Release	Modification
12.0(17)S	This command was introduced.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T, and the **transmit-message** and **receive-message** keywords were added.

Usage Guidelines

Path trace is a maintenance feature of SONET/SDH. One byte (J1) of the Path overhead associated with each path in the SONET/SDH frame is used to carry information identifying the originating Path Terminating Equipment (PTE).

Where you configure the Path Trace identifier depends on the framing (SDH or SONET) and the AUG mapping. In SDH with AU-4 mapping, the Path Trace identifier is configured at the SONET controller level. In SDH with AU-3 mapping or in SONET framing, the Path Trace identifier is configured at the path level.

In accordance with SONET and SDH standard requirements, the Path Trace message you enter is manipulated as follows:

- If you select a message length of 16, the actual message length can be up to 15 characters. An additional byte, prepended to the message, contains the result of a CRC7 calculated on the message. If the actual message text is fewer than 15 characters, the message text is padded to its full length with NULL characters.
- If you select a message length of 64 and the actual message text is fewer than 62 characters, the message text is padded with NULL characters. The last two byte positions, 63 and 64, are always CR/LF (0x0D/0x0A).

Use this command for peer authentication and continuity testing between two STM-1 optical peers. If the authentication string sent by the originating peer does not match the configured string on the receiving peer, the Path (and all E1 controllers within the path) will not come up on the receiving peer. Alarm logs on the originating peer will show that it has High Order Path-Trace Identifier Mismatch (HP-TIM).

Examples

The following example shows J1 configuration in SDH framing with AU-4 AUG mapping. The **overheadj1**command sets the message length to 16, and specifies the message text as metro_SF:

```
Router(config-controller)# au-4 1
Router(config-ctrlr-au4)# overhead j1 length 16 transmit-message metro_SF
```

The following example shows J1 configuration in SDH framing with AU-3 AUG mapping. The **overheadj1** command sets the message length to 16, and specifies the message text as metro_LA:

```
Router(config)# controller sonet 4/0Router(config-controller)# au-3 3
Router(config-ctrlr-au3)# overhead j1 length 16 receive-message metro_L
```

The following example shows J1 configuration in SONET framing in STS-1 mode. The **overheadj1** command sets the message length to 64, and specifies the message text:

```
Router(config)# controller sonet 4/0
Router(config-controller)# sts-1 3
Router(config-ctrlr-sts1)# overhead j1 length 64 transmit-message metro_washington
gsr_0057/4/3
```

The following example shows how to configure j1 overhead in both the transmit and receive directions:

```
Router(config)# controller sonet 2/0
Router(config-controller)# overhead j1 length 2 transmit-message 22
Router(config-controller)# overhead j1 length 2 receive-message 34
```

Examples

For NCS 4200 Series, the following example shows the configuration of J1 flag:

```
enable
configure terminal
controller sonet 0/5/0
sts-1 1
overhead j1 message word
end
```

overhead tunnel

To configure a transparent overhead tunnel on SDH or SONET controller, use the **overhead tunnel** command in the controller mode. To remove the tunnel from SDH or SONET controller, use the **no** form of this command.

For SONET

overhead tunnel {**all** | **sdcc** | **ldcc** | **k1k2** | **loh** | **soh** } **cem-group** *cem-id* **unframed**

For SDH

overhead tunnel {**all** | **ms-dcc** | **rs-dcc** | **k1k2** | **loh** | **soh** } **cem-group** *cem-id* **unframed**

Syntax Description

Syntax Description

all	Specify to include all section and line headers.
sdcc	Specify to include D1, D2, and D3 section header bytes for SONET.
ms-dcc	Specify to include D1, D2, and D3 section header bytes for SDH.
ldcc	Specify to include D4 to D12 line header bytes for SONET.
rs-dcc	Specify to include D4 to D12 line header bytes for SDH.
k1k2	Specify to include K1 and K2 line header bytes.
loh	Specify to include K1, K2, and D4 to D12, E2 line header bytes.
soh	Specify to include E1, F1, D1, D2, and D3 line header bytes.
cem-id	Specify CEM ID configured for the CEM group.

Command Default

None

Command Modes

Configuration mode

Command History

Release	Modification
Cisco IOS XE 16.9.x	Support for this command was introduced on ASR 900 Series.

Usage Guidelines

Before creating transparent overhead tunnel, ensure that you perform the following steps:

- Set mode under STS path before enabling overhead tunnel.
- Mode and TOH type should be same on both PEs in an end-to-end setup.

For more information on prerequisites for transparent overhead tunnel, see 1-Port OC-192 or 8-Port Low Rate CEM Interface Module Configuration Guide, Cisco IOS XE Everest 16.8.x (Cisco ASR 900 Series).

Examples

The following example shows how to configure transparent overhead tunnel on the SONET controller:

```
router(config)#controller sonet 0/7/7
```

```
router(config-controller)#overhead tunnel SDCC cem-group100 unframed
router(config-controller)#end
```

To configure transparent overhead tunnel pseudowire, use the following commands:

```
router(config)#interface cem 0/7/7
router(config-if)#cem  100
router(config-if)#xconnect  203.0.113.1  130  encapsulation MPLS
router(config-controller)#end
```

Related Commands

Command	Description
show cem circuit interface cem *interface-name*	Displays CEM interface configured for transparent overhead tunnel.

overhead s1s0

To set the SONET path overhead bytes in the frame header to a specific standards requirement or to ensure interoperability with equipment from another vendor, use the **overhead** command in SONET path configuration mode. To remove the setting of the SONET path overhead bytes from the configuration file and restore the system to its default condition, use the **no** form of this command.

overhead s1s0 *value*

no overhead s1s0 *value*

Syntax Description

Syntax Description

s1s0 *value*	Sets the SS bits value of the H1 byte in the SONET line overhead. For SONET mode, use 0 (this is the default).

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series.

Usage Guidelines

Use the **overhead** command to set the SONET overhead bytes in the frame header to a specific standards requirement. This command is used to configure line and section overhead.

Examples

The following example shows the configuration of overhead s1s0:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
overhead s1s0 2
overhead j0 tx-length 1-byte
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

password (satellite initial configuration)

To define or to change the password of the NM-1VSAT-GILAT network module required to enter satellite initial configuration mode, use the **password** command in the satellite initial configuration mode.

password *password*

Syntax Description

password	A string of up to 32 alphanumeric characters.

Command Default

The factory-supplied default password is active.

Command Modes

Satellite initial configuration.

Command History

Release	Modification
12.4(11)XJ2	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T.

Usage Guidelines

The NM-1VSAT-GILAT network module has a factory-supplied unique default password to enter satellite initial configuration mode for initial configuration. During this configuration, the **password** command is used to set a user-defined password for subsequent entries to satellite initial configuration mode. The user-defined password consists of up to 32 alphanumeric characters.

Examples

The following example shows how to enter a user-defined password:

```
Router(sat-init-config)# password vsatuser
```

payload-compression

To enable payload compression, use the **payload-compression**command in CEM configuration mode. To disable payload compression, use the **no** form of this command.

payload-compression
no payload-compression

Syntax Description

This command has no arguments or keywords.

Command Default

Payload compression is disabled by default.

Command Modes

CEM configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.

Usage Guidelines

Payload compression can be enabled only for a maximum of 3 Mbps per network module.

Examples

The following example demonstrates how to enable payload compression.

```
Router(config-cem)# payload-compression
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
payload-size	Configures payload size.
show cem	Displays CEM statistics.

payload-size dejitter-buffer

To configure the size of payload and dejitter-buffer of a circuit emulation (CEM) over MPLS, use the **payload-size dejitter-buffer** command in CEM configuration mode. To restore the default the size, use the **no** form of this command.

payload-size *size* **dejitter-buffer** *size*

no payload-size *size* **dejitter-buffer** *size*

size	The payload-size is the integer that defines the number of bytes per packet. Range of payload-size is from 64 to 1312. Range for dejitter-buffer size from 1 to 256 milliseconds. For T1, the valid values of payload size are 32 to 512. The default payload-size is 192 bytes and dejitter-buffer size is 5 milliseconds. For T3 clear channel, the default payload-size is 1024 bytes and dejitter-buffer size is 5 milliseconds. For T3 channelized, the default payload-size is 192 bytes and dejitter-buffer size is 5 milliseconds. For E1, the valid values of payload size are 64 to 1312. The default payload-size is 256 bytes and dejitter-buffer size is 5 milliseconds.

Command Default

The dejitter-buffer defaults to 5 milliseconds.

Command Modes

CEM configuration

Command History

Command History

Release	Modification
XE 3.18SP	This command was introduced.
XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series Routers and Cisco NCS 4200 Series.

Usage Guidelines

Use this command to configure the size of each CEoIP packet. Smaller sizes reduce delay but diminish efficiency.

Note The payload size must be a multiple of the number of time slots and 16. The payload size you enter will automatically change to match the above requirement, and a console message will inform you the change. When you select a value of payload-size, the acceptable range of dejitter-buffer is displayed.

Examples

The following example shows how to set the payload size as 1024 and dejitter buffer to 10 milliseconds.

```
Router(config-controller)# payload-size 1024 dejitter-buffer 10
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.

payload-size

To configure the payload size of a circuit emulation (CEM) over IP (CEoIP) packet, use the **payload-size**command in CEM configuration mode. To restore the default payload size, use the **no** form of this command.

payload-size *size*
no payload-size

Syntax Description

size	Integer that defines the number of bytes per CEoIP packet. Range is from 1 to 1312. The maximum configurable payload size is as follows: • 1312 bytes if data protection is not enabled • 656 bytes if data protection is enabled The minimum configurable payload size for an unframed T1 or E1 channel is 256 bytes. The minimum configurable payload size for a framed T1 or E1 channel is as follows: • 56 bytes if the data rate is less than or equal to 256,000 kbps • 128 bytes if the data rate is greater than 256,000 kbps and less than or equal to 512,000 kbps • 256 bytes if the data rate is greater than 512,000 kbps The minimum configurable payload size for a serial channel is as follows: • 1 byte if the data rate is less than or equal to 2400 kbps • 4 bytes if the data rate is greater than 2400 kbps but less than or equal to 9600 kbps • 16 bytes if the data rate is greater than 9600 kbps but less than or equal to 32,000 kbps • 32 bytes if the data rate is greater than 32,000 kbps but less than or equal to 64,000 kbps • 64 bytes if the data rate is greater than 64,000 kbps but less than or equal to 256,000 kbps • 128 bytes if the data rate is greater than 256,000 kbps but less than or equal to 512,000 kbps • 256 bytes if the data rate is greater than 512,000 kbps **Note** For T1 and E1, the integer must be a multiple of the number of time slots and 16. For Cisco ASR 901 Series Aggregation Services Routers, the value specifies the size of the payload for packets on a structured CEM channel. Valid values are 32 to 512. The default payload size for a T1 channel is 192 bytes and for an E1 channel is 256 bytes. The default payload size is calculated by multiplying 8 by the number of timeslots and then multiplying the result by 1 ms packetization delay.

Command Default

The default payload size for a serial channel is 32 bytes. Defaults for T1 and E1 channels are shown in the tables below.

*Table 25: Default Payload Size for N*64-kbps T1/E1 Channels*

Number of Time Slots	Channel Data Rate (kbps)	Default Payload Size (bytes)
1	64	64
2	128	64
3	192	96
4	256	64
5	320	160
6	384	144
7	448	224

Cisco ASR 901 Series Aggregation Services Routers

The default payload size for a structured CEM channel depends on the number of timeslots that constitute the channel.

Command Modes

- CEM configuration (config-if-cem)
- CEM circuit configuration (config-if-cem)

Command History

Release	Modification
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

Use this command to configure the size of each CEoIP packet. Smaller sizes reduce delay but diminish efficiency.

Note The payload size must be a multiple of the number of time slots and 16. The payload size entered by the user will be automatically changed to match the above requirement, and a console message will inform the user of this change.

The Cisco ASR 901 series router only supports a payload size of 486 (625 packets per second) or 243 (1250 packets per second).

Examples

The following example shows how to configure a payload size of 224.

```
Router(config-cem)# payload-size 224
```

Related Commands

Command	Description
cem	Enters circuit emulation configuration mode.
payload-compression	Enables payload compression.
payload-compression	Enables payload compression.

Command	Description
payload-compression	Enables payload compression.
show cem	Displays CEM channel statistics.

physical-interface

To create a physical subinterface and to associate it with the Virtual Multipoint Interface (VMI) on a router, use the **physical-interface** command in interface configuration mode. To return to the default mode, use the **no** form of this command.

physical-interface *interface-type / slot*
no physical-interface *interface-type / slot*

Syntax Description

interface-type	Type of interface or subinterface.
/ *slot*	Slot in which the interface is present.

Command Default

No physical interface exists.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.4(15)XF	This command was introduced.
12.4(15)T	This command was integrated into Cisco IOS Release 12.4(15)T to support VMIs in Mobile Adhoc Router-to-Radio Networks.
12.4(24)T	This command was modified. This command supports the subinterfaces and VLANS associated with an interface.

Usage Guidelines

The **physical-interface** command supports the subinterfaces and VLANs associated with an interface. This command also allows VMI interface to operate over encapsulated interfaces, if required. Only one physical interface can be assigned to a VMI interface. Because there is very high number of VMI interfaces that can be used, assign a new VMI for each physical interface.

Examples

The following example shows how to create a physical subinterface:

```
Router(config)# interface vmi1
Router(config-if)# physical-interface FastEthernet0/1
```

Related Commands

Command	Description
debug vmi	Displays debugging output for VMIs.
eigrp interface	Sets a threshold value to minimize hysteresis in a router-to-radio configuration.
interface vmi	Creates a VMI interface.
mode bypass	Enables VMIs to support multicast traffic

physical-layer

To specify the mode of a slow-speed serial interface on a router as either synchronous or asynchronous, use the **physical-layer** command in interface configuration mode. To return the interface to the default mode of synchronous, use the **no** form of this command.

physical-layer {**sync** | **async**}
no physical-layer

Syntax Description

sync	Places the interface in synchronous mode. This is the default.
async	Places the interface in asynchronous mode.

Command Default

Synchronous mode

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command applies only to low-speed serial interfaces available on Cisco 2520 through Cisco 2523 series routers.

In synchronous mode, low-speed serial interfaces support all interface configuration commands available for high-speed serial interfaces, except the following two commands:

- **half-duplex timer cts-delay**
- **half-duplex timer rts-timeout**

When placed in asynchronous mode, low-speed serial interfaces support all commands available for standard asynchronous interfaces.

When you enter this command, it does not appear in the output of **moresystem:running-config** and **morenvram:startup-config** commands because the command is a physical-layer command.

Examples

The following example shows how to change a low-speed serial interface from synchronous to asynchronous mode:

```
Router(config)# interface serial 2
Router(config-if)# physical-layer async
```

Related Commands

Command	Description
more	Displays a specified file.

platform console

To select the console that is used to access the virtual router interface, use the **platform console** command in global configuration mode.

platform console {**serial** | **virtual**}

Syntax Description

serial	Specifies that the virtual router is accessed using the virtual serial port on the ESXi host.
virtual	Specifies that the virtual router is accessed using the VMware VM console.

Command Default

No default.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE 3.8S (Controlled Availability)	This command was introduced on the Cisco CSR 1000V Cloud Services Router.

Usage Guidelines

During the first-time installation and bootup of the virtual router, you choose whether to access the virtual router using the VM console or the virtual serial port on the ESXi host. The default setting is to use the VM console.

This command is used for changing the console access to the virtual router after first-time installation and bootup. After you enter the command, you must reload or power-cycle the router in order for the new setting to take effect.

Examples

The following example configures the virtual router to be accessed through the VM console:

```
Router> enable
Router# configure terminal
Router(config)# platform console virtual
Router(config)# end
Router# copy system:running-config nvram:startup-config
Router# reload
```

The following example configures the virtual router to be accessed through the virtual serial port:

```
Router> enable
Router# configure terminal
Router(config)# platform console serial
Router(config)# end
Router# copy system:running-config nvram:startup-config
Router# reload
```

platform cwan acl software-switched

To allow ACLs to be applied to packets that are software-switched between WAN cards and the route processor, use the **platformcwanaclsoftware-switched**command in global configuration mode. To have ACLs applied only to packets that are hardware-switched between WAN cards and the route processor, use the **no** form of this command.

platform cwan acl software-switched {**egress** | **ingress**}
no platform cwan acl software-switched {**egress** | **ingress**}

Syntax Description

egress	Allows ACLs to be applied to software-switched egress WAN packets.
ingress	Allows ACLs to be applied to software-switched ingress WAN packets.

Command Default

ACLs are not applied to packets that are software-switched between WAN cards and the route processor. ACLs are applied only to packets that are hardware-switched between WAN cards and the route processor.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(50)SY	This command was introduced.
12.2(33)SXI2	This command was integrated into Cisco IOS Release 12.2(33)SXI2.

Usage Guidelines

By default, software-switched WAN packets are not subjected to ACL lookup in the ACL TCAM and are therefore not affected by hardware-only features. As a result, VACL capture will fail for software-switched WAN packets. The **platformcwanaclsoftware-switched**command allows ACLs to be applied to ingress or egress software-switched WAN packets.

When you use the **platformcwanaclsoftware-switched**command to allow VACL capture, these limitations apply:

Note The **platformcwanaclsoftware-switched**command is ignored by the SIP-600. Ingress software-switched packets on the SIP-600 are not subjected to ACL lookups, and VACL features are not supported.

Examples

This example shows how to enable ACLs for software-switched ingress WAN packets:

```
Router(config)#
platform cwan acl software-switched ingress
```

Related Commands

Command	Description
show platform acl software-switched	Displays whether ACLs are enabled for software-switched WAN packets.

platform enable controller mediaType

Use this command to to enable a particular license type on the controller port. Providing a particular license type is mandatory to enable the license on the IM.

platform enable controller Mediatype <*slot/bay/port*> <*port rate*>

Syntax Description

Syntax Description:

slot	Physical slot number of the interface
bay	Bay of the interface
port	Mediatype port number
port rate	Rate configured on the port

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
XE Everest 16.7.1	This command was integarted into the Cisco NCS 4200 Series, Cisco ASR 900 Series, and Cisco ASR 920 Routers.

Usage Guidelines

License enabling is allowed when the license with the same rate is configured on the port. The configuration fails if the license with a different rate is configured on the port.

Examples

The following example shows how to enable the license:

```
enable
configure terminal
platform enable controller MediaType 0/4/16 oc3
controller MediaType 0/4/16
mode sonet
exit
controller sonet 0/4/16
rate oc3
exit
```

Related Commands

Command	Description
show license detail	Verifies the license configuration.

platform hardware throughput crypto

To configure a throughput value on a physical router, use the **platform hardware throughput crypto** command in global configuration mode. To revert to the default value, use the **no** form of this command.

platform hardware throughput crypto { *throughput-value* }

no platform hardware throughput crypto

Syntax Description

throughput-value	Enter a throughput value. Use the question mark (?) online help function to display the available values. The available options vary depending on the device.

Command Default

The device-specific default throughput level is effective.

PID	Default Throughput
C8300-1N1S-4T2X	10 Mbps
C8300-2N2S-6T	10 Mbps
C8300-1N1S-6T	10 Mbps
C8300-2N2S-4T2X	10 Mbps
C8200-1N-4T	10 Mbps
C8200-1N-4T-L	10 Mbps
C8500-12X4QC	2.5 Gbps
C8500-12X	2.5 Gbps
C8500L-8S4X	2.5 Gbps
C8500-20X6C	T4

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Amsterdam 17.3.2	This command was introduced on Cisco Catalyst 8300, and 8500 Series Edge Platforms.
Cisco IOS XE Bengaluru 17.4.1	This command was introduced on the Cisco Catalyst 8200 Series Edge Platforms.

Usage Guidelines

Before you configure a throughput level, take note of these aspects:

- Ensure that you have configured a boot-level license. Otherwise **platform hardware throughput crypto** is not recognized as a valid command, on the command line interface. For information about configuring a boot-level license, see Configuring a Boot Level License.

- The throughput you are entitled to. This is a value that is represented in the License product ID (PID) when you order a Cisco DNA license. It can be a numeric throughput value, such as DNA-C-**10M**-E-3Y, or a tier-based throughput value, such as DNA-C-**T0**-E-3Y.

  Support for tier-based throughput configuration was introduced in Cisco IOS XE Cupertino 17.7.1a. Use the question mark (?) online help function to display the available tier-based *and* numeric throughput values. Refer to Tier and Numeric Throughput Mapping for Physical Platforms, Cisco IOS XE Cupertino 17.8.1a and Later Releases to know the numeric equivalent of a tier.

- If you are configuring throughput greater than 250 Mbps, ensure that you have installed a Smart Licensing Authorization Code (SLAC). Options greater than 250 Mbps are displayed only if SLAC is installed. For information about installing SLAC, see Manually Requesting and Auto-Installing a SLAC.

Support for aggregate throughput throttling was introduced in Cisco IOS XE Cupertino 17.8.1a. With this, when you configure throughput levels greater than 250 Mbps or Tier 2 and higher tiers on physical devices, aggregate throughput throttling is effective. *Aggregate throughput is double the bidirectional throughput*.

When aggregate throughput throttling is effective, throttling is not applied to transmitted (Tx) and received (Rx) traffic separately, rather, any ratio within the aggregate throughput limit applies. For example, If you configure a throughput of 500 Mbps on a device, a maximum of 1 Gbps transmitted (Tx) traffic and 0 Mbps received (Rx) traffic, or, 100 Mbps Tx and 900 Mbps Rx, or any other ratio within the aggregate 1 Gbps throughput limit, is supported. For more information and examples, see Throughput as a Numeric Value and Throughput as a Tier.

To display throughput information, enter the **show platform hardware throughput crypto** command in privileged EXEC mode.

The following example shows you how to configure a tier-based throughput value.

Displaying current configuration:

```
Device# show platform hardware throughput crypto
show platform hardware throughput crypto
Current configured crypto throughput level: 250M
     Level is saved, reboot is not required
Current enforced crypto throughput level: 250M
Crypto Throughput is throttled at 250M
Default Crypto throughput level: 10M
Current boot level is network-premier
```

Verifying SLAC is installed before configuring a throughput level greater than 250 Mbps or Tier 2 and higher tiers:

```
Device# show license authorization
Overall status:
  Active: PID:C8300-2N2S-4T2X,SN:FDO2250A0J5
      Status: SMART AUTHORIZATION INSTALLED on Mar 02 05:05:19 2022 UTC
      Last Confirmation code: 418b11b3

Authorizations:
  Router US Export Lic. for DNA (DNA_HSEC):
    Description: U.S. Export Restriction Compliance license for
    DNA based Routers
    Total available count: 1
    Enforcement type: EXPORT RESTRICTED
    Term information:
      Active: PID:C8300-1N1S-4T2X,SN:FDO2250A0J5
        Authorization type: SMART AUTHORIZATION INSTALLED
        License type: PERPETUAL
          Term Count: 1
```

```
Purchased Licenses:
  No Purchase Information Available
```

Configuring a tier-based throughput value from the list of available values for this device:

```
Device# configure terminal
Device(config)# platform hardware throughput crypto ?
  100M  100 mbps bidirectional thput
  10M   10 mbps bidirectional thput
  15M   15 mbps bidirectional thput
  1G    2 gbps aggregate thput
  2.5G  5 gbps aggregate thput
  250M  250 mbps bidirectional thput
  25M   25 mbps bidirectional thput
  500M  1gbps aggregate thput
  50M   50 mbps bidirectional thput
  T0    T0(up to 15 mbps) bidirectional thput
  T1    T1(up to 100 mbps) bidirectional thput
  T2    T2(up to 2 gbps) aggregate thput
  T3    T3(up to 5 gbps) aggregate thput

Device(config)# platform hardware throughput crypto T2
% These values don't take effect until the next reboot.
Please save the configuration.
*Mar 02 05:06:19.042: %CRYPTO_SL_TP_LEVELS-6-SAVE_CONFIG_AND_RELOAD:
New throughput level not applied until reload; please save config
```

Saving configuration to ensure changes persist across reloads and reloading the device:

```
Device# exit
Device# copy running-config startup-config
Destination filename [startup-config]?
Building configuration...
[OK]
Device# reload
Proceed with reload? [confirm]
*Mar 02 05:07:00.979: %SYS-5-RELOAD: Reload requested by console.
Reload Reason: Reload Command.
```

Displaying configuration again:

```
Device# show platform hardware throughput crypto
Current configured crypto throughput level: T2
     Level is saved, reboot is not required
Current enforced crypto throughput level: 1G
Crypto Throughput is throttled at 2G(Aggregate)
Default Crypto throughput level: 10M
Current boot level is network-premier
```

Related Commands

Command	Description
show platform hardware throughput crypto	Displays throughput information on a physical router.

platform hardware throughput level

To change the maximum throughput level on the virtual router, use the **platform hardware throughput level** command in global configuration mode. To return the platform throughput level to the default value, use the **no** form of this command.

Cisco IOS XE Release 3.9S:

platform hardware throughput level {**10000** | **25000** | **50000** | **eval-only**}

Cisco IOS XE Release 3.10S and Later:

platform hardware throughput level MB {**10** | **100** | **1000** | **25** | **250** | **50** | **500**}

Syntax Description

Cisco IOS XE Release 3.9S:	
10000	Sets the maximum throughput to 10,000 Kbps (10 Mbps).
25000	Sets the maximum throughput to 25,000 Kbps (25 Mbps).
50000	Sets the maximum throughput to 50,000 Kbps (50 Mbps).
eval-only	Specifies to use the maximum throughput for the evaluation license only.
Cisco IOS XE Release 3.10S:	
10	Sets the maximum throughput to 10 Mbps.
100	Sets the maximum throughput to 100 Mbps.
1000	Sets the maximum throughput to 1 Gbps.
25	Sets the maximum throughput to 25 Mbps.
250	Sets the maximum throughput to 250 Mbps.
50	Sets the maximum throughput to 50 Mbps.
500	Sets the maximum throughput to 500 Mbps.

Command Default

The default maximum throughput level is determined by the installed base license.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.9S	This command was introduced on the Cisco CSR 1000V Series Cloud Services Router.
Cisco IOS XE 3.10S	The command was updated to change the keywords to units in Mbps, and support for maximum throughput values of 100 Mbps, 250 Mbps, 500 Mbps, and 1 Gbps was added.

Usage Guidelines

The Cisco CSR 1000V requires the installation of base licenses that set the maximum throughput of the platform.

Depending on the configuration and the licenses installed, you may need to manually increase or decrease the maximum throughput level on the Cisco CSR 1000V. The maximum throughput on the router before the license is activated, or if the license is invalidated, is 2.5 Mbps. When you install the base subscription license and accept the EULA, the maximum throughput on the Cisco CSR 1000V will increase to the level allowed by the license.

You may need to manually change the maximum throughput level in the following cases:

- If you are using an evaluation license. When the evaluation license is first installed, the maximum throughput is limited to 2.5 Mbps before the license is activated. You must accept the EULA and enter the **platform hardware throughput level**command to increase the maximum throughput. When the 60-day evaluation license expires, the maximum throughput level reverts to 2.5 Mbps.
- If you want to reduce the maximum throughput level from the maximum permitted by the installed licenses. For example, if you have the 50-Mbps license installed and you want to reduce the maximum throughput to 25 Mbps. You must enter the **platform hardware throughput level** command to reduce the maximum throughput.
- If you previously changed the maximum throughput using the **platform hardware throughput level** command. When you enter the command, it becomes part of the configuration file. You must enter the command again to change the maximum throughput level.

When changing the maximum throughput level, you do not need to reboot the Cisco CSR 1000V for the change to take effect. If you try to increase the throughput level higher than what the installed license supports, you will receive an error message.

Example

The following example changes the maximum throughput level to 500 Mbps:

```
Router(config)# platform hardware throughput level MB 500
```

The following example changes the maximum throughput level to the default level supported by the installed license:

```
Router(config)# no platform hardware throughput level
```

Related Commands

Command	Description
show platform hardware throughput level	Displays the current maximum throughput level for a virtual router.

platform ip features sequential

To enable Internet Protocol (IP) precedence-based or differentiated services code point (DSCP)-based egress quality of service (QoS) filtering to use any IP precedence or DSCP policing or marking changes made by ingress policy feature card (PFC) QoS, use the **platformipfeaturessequential** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

platform ip features sequential [**access-group** {*ip-acl-nameip-acl-number*}]
no platform ip features sequential [**access-group** {*ip-acl-nameip-acl-number*}]

Syntax Description

access-group *ip-acl-name*	(Optional) Specifies the name of the ACL that is used to specify the match criteria for the recirculation packets.
access-group *ip-acl-number*	(Optional) Specifies the number of the ACL that is used to specify the match criteria for the recirculation packets; valid values are from 1 to 199 and from 1300 to 2699.

Command Default

IP precedence-based or DSCP-based egress QoS filtering uses received IP precedence or DSCP values and does not use any IP precedence or DSCP changes made by ingress QoS as the result of policing or marking.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(50)SY	This command was introduced.
12.2(18)SXE	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Caution If the switch is operating in PFC3A mode with egress ACL support for remarked DSCP configured, when the PFC3 processes traffic to apply ingress PFC QoS, it applies ingress PFC QoS filtering and ingress PFC QoS, and incorrectly applies any egress QoS filtering and egress PFC QoS configured on the ingress interface, which results in unexpected behavior if QoS filtering is configured on an interface where egress ACL support for remarked DSCP is enabled. This problem does not occur in other PFC3 modes.

The enhanced egress-QoS filtering enables the IP precedence-based or DSCP-based egress-QoS filtering to use any IP precedence or DSCP policing or marking changes made by ingress QoS.

The nonenhanced egress-QoS filtering behavior is the normal Cisco 7600 series router or the Catalyst 6500 series switch behavior when QoS is applied in the hardware.

The PFC3 provides egress PFC QoS only for Layer 3-switched and routed traffic on egress Layer 3 interfaces (either LAN ports configured as Layer 3 interfaces or VLAN interfaces).

You configure enhanced egress QoS filtering on ingress Layer 3 interfaces (either LAN ports configured as Layer 3 interfaces or VLAN interfaces).

To enable enhanced egress QoS filtering only for the traffic filtered by a specific standard, extended named, or extended numbered IP ACL, enter the IP ACL name or number.

If you do not enter an IP ACL name or number, enhanced egress QoS filtering is enabled for all IP ingress IP traffic on the interface.

Note When you configure enhanced egress-QoS filtering, the PFC3A processes traffic to apply ingress PFC QoS. The PFC3A applies ingress-QoS filtering and Cisco 7600 series router or the Catalyst 6500 series switch hardware ingress QoS. The PFC3A incorrectly applies any egress-QoS filtering and Cisco 7600 series router or the Catalyst 6500 series switch hardware egress QoS that is configured on the ingress interface.

Note If you configure enhanced egress-QoS filtering on an interface that uses Layer 2 features to match the IP precedence or DSCP as modified by ingress-QoS marking, the packets are redirected or dropped and prevented from being processed by egress QoS.

Note If you enable enhanced egress-QoS filtering, the hardware acceleration of NetFlow-based features such as reflexive ACL, NAT, and TCP intercept are disabled.

To verify configuration, use the **showrunning-configinterface** command.

Examples

The following example shows how to enable enhanced egress-QoS filtering:

```
Router(config-if)# platform ip features sequential

Router(config-if)#
```

The following example shows how to disable enhanced egress-QoS filtering:

```
Router(config-if)# no platform ip features sequential

Router(config-if)#
```

Related Commands

Command	Description
show running-config interface	Displays the contents of the currently running configuration file.

platform punt-keepalive

To enable the Punt-Keepalive feature and monitor the status of the punt path between the forwarding processor (FP) and the route processor (RP), use the **platform punt-keepalive** command in the global configuration mode. To disable the Punt-Keepalive feature, use the **no** form of this command.

platform punt-keepalive{**disable-kernel-core** | **settings**{**fatal-count** *fatal-count* | **transmit-interval** *transmit-interval* | **warning-count** *warning-count*}}

no platform punt-keepalive

Syntax Description

disable-kernel-core	Disables Linux kernel crash generation and IOS Daemon (IOSD) crash generation.
settings	Specifies the keepalive parameters.
fatal-count *fatal-count*	Specifies the upper limit of consecutive keepalive warnings for triggering system failures. The range is from 15 to 60. Linux kernel crash generation and IOSD crash generation occur when the fatal count reaches the upper limit.
transmit-interval *transmit-interval*	Specifies the keepalive transmit interval, in seconds. The range is from 2 to 30. The default is 2.
warning-count *warning-count*	Specifies the upper limit of consecutive keepalive message failures for reporting warnings. The range is from 10 to 60. Linux kernel crash generation and IOSD crash generation occur when the warnings reach the upper limit.

Command Default

The Punt-Keepalive feature is enabled, and the Kernel core crash and IOSD crash generation are enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.5S	This command was introduced.

Usage Guidelines

The **platform punt-keepalive** command is available only if all the following conditions are met:

- Device is in an active state.
- FP is present and is online.
- System reload is not in progress.

The punt-keepalive process checks the status of the device and the FP every 30 seconds. However, when the status for the device changes from standby to active, or when the FP goes online, the device waits for another 30 seconds before sending the first keepalive message. Disabling the Linux kernel crash generation and IOS Daemon (IOSD) crash generation allows the system to settle down after the occurrence of critical events.

IOSD or Kernel driver code can cause a keepalive failure; a keepalive failure can force IOSD crash generation and Linux kernel crash generation. The crash generation type depends on the chassis and the operating mode. The following table describes the relationship between chassis, operation mode, and type of crash generation.

Table 27: Relationship Between Chassis, Operation Mode, and Type of Crash Generation

Chassis	Operation Mode	Redundancy Status	Type of Crash Generation
Cisco ASR 1002 Cisco ASR 1002-F	Single IOSD	-	IOSD core Kernel core
Cisco ASR 1001 ASR 1004	Dual IOSD	Not Hot	IOSD core Kernel core
IOSD core Kernel core	Dual IOSD	Hot	IOSD core
Cisco ASR 1006 Cisco ASR 1013	Single or Dual RP	Any	IOSD core Kernel core

Kernel core crash generation takes approximately five minutes. Disable kernel core crash generation for a faster reboot of the system.

Examples

The following example shows how to disable kernel core crash generation and IOSD crash generation by using the **platform punt-keepalive** command:

```
Device(config)# platform punt-keepalive disable-kernel-core
```

Related Commands

Command	Description
show platform software infrastructure punt-keepalive	Displays information about **platform punt-keepalive** command settings.

platform punt-arp-unicast cpu-queue-host

To punt ARP unicast packets through the Routing protocol queue, when packets are forwarded between the forwarding processor (FP) and the route processor (RP), use the **platform punt-arp-unicast cpu-queue-host** command in the global configuration mode. To punt ARP unicast packets through the Broadcast queue, use the **no** form of this command.

Note This command is supported on Cisco IOS XE ASR 920 platforms.

platform punt-arp-unicast cpu-queue-host

no platform punt-arp-unicast cpu-queue-host

Command Default

The platform punt-arp-unicast feature is not enabled by default.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 17.10.1	This command was modified.

platform scp retry interval

To enable Switch-Module Configuration Protocol (SCP) fast retry and set the fast-retry interval, use the **platformscpretryinterval** command in global configuration mode. To disable SCP fast retry, use the **no** form of this command.

platform scp retry interval *timeout-value*
no platform scp retry interval

Syntax Description

timeout-value	Fast retry interval; valid values are from 200 to 2000 milliseconds.

Command Default

2000 milliseconds

Command Modes

Global configuration

Command History

Release	Modification
12.2(18)SXD	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Note Use this command under the direction of the Cisco TAC only.

Examples

This example shows how to enable SCP fast retry and set the fast-retry interval:

```
Router(config)# platform scp retry interval 600
Router(config)#
```

platform smart-sfp

To configure the Gigabit Ethernet or TenGig Ethernet as VCoP smart SFP on OC3 or OC12 or DS3 mode, use the **platform smart-sfp interface** command in SONET/PDH configuration mode. To remove the VCoP smart SFP, use the **no** form of this command.

platform smart-sfp interface gig/tengig*slot/bay/port* **type***OC3/OC12/DS3*

no platform smart-sfp

Syntax Description

Syntax Description

platform	Specifies a platform keyword.
smart sfp	Specifies a smart sfp keyword. SFP stands for Small Form-Factor Pluggable.
interface	Specifies a interface keyword.
gig/tengig	Specifies the Gigabit Ethernet or TenGig Ethernet port where VCoP is inserted.
slot	Slot number of the controller. A forward slash mark (/) is required between the slot argument and the bay argument.
bay	Bay number of the controller. A forward slash mark (/) is required.
port	Port number of the controller. A forward slash mark (/) is required between the bay argument and the port argument.
type	Type of the interface to be configured. The interface type can be OC3/OC12/ DS3.

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on the Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was introduced to support DS3 mode of VCoP Smart SFP for Cisco NCS 4200 Series and Cisco ASR 920 Routers.

Usage Guidelines

This command is used to identify the VCoP OC-n/DS3 smart SFP inserted in the Cisco NCS 4200 Series. This command is used to configure VCoP OC-n smart SFP type i.e. OC3 or OC12 and DS3 mode. Before executing this command for a particular port, the configuration on that port must be deleted or set as default.

This command sets the Gig port as the smart SFP port for configuring the CEP for the given port number.

Examples

The following example shows how to configure VCoP smart SFP on Gig and TenGig ports.

Configruing VCoP smart SFP on OC3 mode

For Gigabit port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface GigabitEthernet 0/0/8 type OC-3
```

For TenGig port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface TenGig 0/0/8 type OC-3
```

Configruing VCoP smart SFP on OC12 mode

For Gigabit port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface GigabitEthernet 0/0/8 type OC-12
```

For TenGig port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface TenGig 0/0/8 type OC-12
```

Configruing VCoP smart SFP on T3 mode

For Gigabit port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface GigabitEthernet 0/0/8 type ds3
```

For TenGig port:

```
Router(config)# configure terminal
Router(config)# platform smart-sfp interface TenGig 0/0/8 type ds3
```

Command	Description
show cem circuit	Displays the circuit emulation (CEM) statistics for the configured CEM circuits.
show controller	Displays SONET/T3 controller configuration.

platform time-source

To initiate Time of Day (ToD) synchronization on a line card, use the **platformtime-source** command in global configuration mode. To disable the platform time-source, use the **no** form of this command.

platform time-source {**ntp** | **ptp**}
no platform time-source

Syntax Description

ntp	Configures Network Time Protocol (NTP) clock source
ptp	Configures Precision Time Protocol (PTP) clock source

Command Default

The **platformtime-source** command is not enabled.

Command Modes

Global configuration

Command History

Release	Modification
15.1(2)S	This command was introduced on the Cisco 7600 routers.
Cisco IOS XE Release 3.12	This command is integrated on the Cisco ASR 900 Series Routers. The **ptp** keyword is not supported on the Cisco ASR 900 Series Routers.

Usage Guidelines

Cisco 7600 Router

Either the 2-Port Gigabit Synchronous Ethernet SPA (PTP) or NTP module on the Route Processor is used to initiate the ToD synchroniztion. The NTP ToD information is converted into PTP format and then synchronized to all the ES+ Linecards.

Cisco ASR 900 Series Routers

This command is used to enable or disable NTP clock (Time of Day) synchronization on the ethernet ports. The ports will use NTP ToD value to timestamp Y.1731 DM packets.

Example

This example shows how to configure platform time-source on the Cisco ASR 900 Series Router.

```
Router (config)# platform time-source ntp
```

Examples

This example shows how to configure the platform time-source on the Cisco 7600 Router.

```
Router (config)#platform time-source ptp 1 master top 6/0/2 slave lo0
or
Router (config)#platform time-source ntp
```

Related Commands

Command	Description
show platform time-source	This command displays the configuration details of the platform time-source.

platform trace boottime process forwarding-manager module interfaces

To enable Forwarding Manager Route Processor and Embedded Service Processor trace messages for the RP forwarding manager process during bootup, use the **platformtraceboottimeprocessforwarding-managermoduleinterfaces**command in the Global configuration mode. To disable debug messages, use the **no** form of this command.

platform trace boottime slot *slot* **bay** *bay* **process forwarding-manager module interfaces level** *level*
no platform trace boottime slot *slot* **bay** *bay* **process forwarding-manager module interfaces**

Syntax Description

slot	Shared Port Adapter (SPA) Interprocessor, Embedded Service Processor or Route Processor slot. Valid options are: • *R0* --Route Processor slot 0 • *R1* --Route Processor slot 1
bay	Chassis bay to be configured. Valid options are: • *0* • *1*
level *level*	Selects the trace level. The trace level determines the amount of information that is to be stored about a module in the trace buffer or file. Valid options are: • **max** --Provides the maximum possible message. • **notice messages** --Provides notice messages.

Command Default

The default tracing level for every module on the Cisco ASR 1000 Series Routers is Notice.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 3.2S	This command was introduced on the Cisco ASR 1000 Routers.

Usage Guidelines

Trace-level settings are leveled that is every setting contains all the messages from the lower setting plus the messages from its own setting. For instance, setting the trace level to 3 (error) ensures that the trace file contains all the output for the 0 (emergencies), 1 (alerts), 2 (critical), and 3 (error) settings. Setting the trace level to 4 (warning) ensures that all the trace output for a specific module is included in that trace file.

All trace levels cannot be configured by users. Specifically, the alert, critical, and notice tracing levels cannot be set by users. To trace these messages, set the trace level to a higher level, which collects these messages.

When setting the trace levels, it is also important to remember that the setting is not done in a configuration mode. As a result of this, trace level settings are returned to their defaults after every router reload.

Caution Setting tracing of a module to the debug level or higher can have a negative performance impact. Setting tracing to the debug level or higher should be done with discretion.

Caution Setting a large number of modules to high tracing levels can severely degrade performance. If a high level of tracing is needed in a specific context, it is almost always preferable to set a single module on a higher tracing level rather than setting multiple modules to high tracing levels.

Examples

In the following example, the trace level for the forwarding processor module in the Forwarding Manager of the ESP processor in slot R0 is set to the informational tracing level (max):

```
Router(config)# platform trace boottime slot R0 bay 1 process forwarding-manager
forwarding-manager level max
```

Related Commands

Command	Description
show platform software trace level	Displays trace levels for specified modules.
show platform software trace message	Displays trace messages.

pm fec threshold

To configure performance monitoring thresholds on the FEC layer, use the **pmfecthreshold**command in DWDM configuration mode. To disable the performance monitoring threshold, use the **no** form of this command.

pm {**15-min** | **24-hour**} **fec** **threshold** {**ec-bits** | **uc-words**} *threshold*
nopm {**15-min** | **24-hour**} **fec** **threshold** {**ec-bits** | **uc-words**} *threshold*

Syntax Description

15-min	Configures the performance monitoring thresholds for 15-minute intervals.
24-hour	Configures performance monitoring thresholds for 24-hour intervals.
ec-bits	Bit errors corrected (BIEC). Indicates the number of bit errors corrected in the DWDM trunk line during the performance monitoring time interval.
uc-words	Uncorrectable Words. Indicates the number of uncorrectable words detected in the DWDM trunk line during the performance monitoring time interval.
threshold	Threshold for the performance monitoring parameter.

Command Default

No threshold is configured.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(3)S	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows how to configure an FEC layer performance monitoring threshold for uncorrectable words:

```
Router(config)# controller dwdm 0/0
Router(config-controller)# pm 15-min fec threshold uc-words 900 enable
```

Related Commands

Command	Description
show controller dwdm pm fec	Displays performance measurement information for the FEC layer.

pm optics report

To enable threshold crossing alert (TCA) generation on the optics layer, use the **pmopticsreport**command in DWDM configuration mode. To disable TCA reporting, use the **no** form of this command.

pm {**15-min** | **24-hour**} **optics report** {**lbc** | **opr** | **opt**} {**max-tca** | **min-tca**} **enable**
nopm {**15-min** | **24-hour**} **optics report** {**lbc** | **opr** | **opt**} {**max-tca** | **min-tca**} **enable**

Syntax Description

15-min	Configures TCA generation for 15-minute intervals.
24-hour	Configures TCA generation for 24-hour intervals.
lbc	Laser bias current.
opr	Optical power on the unidirectional port.
opt	Transmit optical power in dBm.
max-tca	Indicates that the maximum value of the parameter is compared against the threshold to determine if a TCA should be generated.
min-tca	Indicates that the minimum value of the parameter is compared against the threshold to determine if a TCA should be generated.
enable	Enables TCA generation for the specified parameter on the DWDM controller.

Command Default

TCA reporting is not enabled.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(3)S	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows how to enable TCA reporting on the optics layer reporting for the maximum OPT:

```
Router(config)# controller dwdm 0/0
Router(config-controller)# pm 15-min optics report opt max-tca enable
```

Related Commands

Command	Description
show controller dwdm pm optics	Displays performance measurement information for the optics layer.

pm otn report

To enable threshold crossing alert (TCA) generation on the optical transport network (OTN) layer, use the **pmotnreport**command in DWDM configuration mode. To disable TCA reporting, use the **no** form of this command.

pm {**15-min** | **24-hour**} **otn** **report** *otn-parameter* **enable**
nopm {**15-min** | **24-hour**} **otn** **report** *otn-parameter* **enable**

Syntax Description

15-min	Configures TCA generation for 15-minute intervals.
24-hour	Configures TCA generation for 24-hour intervals.
otn-parameter	Specific parameter for which to configure the threshold. OTN parameters can be as follows: • **bbe-pm-fe** --Far-end path monitoring background block errors (BBE-PM). Indicates the number of background block errors recorded in the optical transport network (OTN) path during the performance monitoring time interval. • **bbe-pm-ne** --Near-end path monitoring background block errors (BBE-PM). • **bbe-sm-fe** --Far-end section monitoring background block errors (BBE-SM). Indicates the number of background block errors recorded in the OTN section during the performance monitoring time interval. • **bbe-sm-ne** --Near-end section monitoring background block errors (BBE-SM). • **bber-pm-fe** --Far-end path monitoring background block errors ratio (BBER-PM). Indicates the background block errors ratio recorded in the OTN path during the performance monitoring time interval. • **bber-pm-ne** --Near-end path monitoring background block errors ratio (BBER-PM). • **bber-sm-fe** --Far-end section monitoring background block errors ratio (BBER-SM). Indicates the background block errors ratio recorded in the OTN section during the performance monitoring time interval. • **bber-sm-ne** --Near-end section monitoring background block errors ratio (BBER-SM) • **es-pm-fe** --Far-end path monitoring errored seconds (ES-PM). Indicates the errored seconds recorded in the OTN path during the performance monitoring time interval. • **es-pm-ne** --Near-end path monitoring errored seconds (ES-PM). • **es-sm-fe** --Far-end section monitoring errored seconds (ES-SM). Indicates the errored seconds recorded in the OTN section during the performance monitoring time interval. • **es-sm-ne** --Near-end section monitoring errored seconds (ES-SM). • **esr-pm-fe** --Far-end path monitoring errored seconds ratio (ESR-PM). Indicates the errored seconds ratio recorded in the OTN path during the performance monitoring time interval.

	• **esr-pm-ne** --Near-end path monitoring errored seconds ratio (ESR-PM). • **esr-sm-fe** --Far-end section monitoring errored seconds ratio (ESR-SM). Indicates the errored seconds ratio recorded in the OTN section during the performance monitoring time interval. • **esr-sm-ne** --Near-end section monitoring errored seconds ratio (ESR-SM). • **fc-pm-fe** --Far-end path monitoring failure counts (FC-PM). Indicates the failure counts recorded in the OTN path during the performance monitoring time interval. • **fc-pm-ne** --Near-end path monitoring failure counts (FC-PM). • **fc-sm-fe** --Far-end section monitoring failure counts (FC-SM). Indicates the failure counts recorded in the OTN section during the performance monitoring time interval. • **fc-sm-ne** --Near-end section monitoring failure counts (FC-SM). • **ses-pm-fe** --Far-end path monitoring severely errored seconds (SES-PM). Indicates the severely errored seconds recorded in the OTN path during the performance monitoring time interval. • **ses-pm-ne** --Far-end path monitoring severely errored seconds (SES-PM). • **ses-sm-fe** --Far-end section monitoring severely errored seconds (SES-SM). Indicates the severely errored seconds recorded in the OTN section during the performance monitoring time interval. • **ses-sm-ne** --Near-end section monitoring severely errored seconds (SES-SM). • **sesr-pm-fe** --Far-end path monitoring severely errored seconds ratio (SESR-PM). Indicates the severely errored seconds ratio recorded in the OTN path during the performance monitoring time interval. • **sesr-pm-ne** --Near-end path monitoring severely errored seconds ratio (SESR-PM). • **sesr-sm-fe** --Far-end section monitoring severely errored seconds ratio (SESR-SM). Indicates the severely errored seconds ratio recorded in the OTN section during the performance monitoring time interval. • **sesr-sm-ne** --Near-end section monitoring severely errored seconds ratio (SESR-SM). • **uas-pm-fe** --Far-end path monitoring unavailable seconds (UAS-PM). Indicates the unavailable seconds recorded in the OTN path during the performance monitoring time interval. • **uas-pm-ne** --Near-end path monitoring unavailable seconds (UAS-PM). • **uas-sm-fe** --Far-end section monitoring unavailable seconds (UAS-SM). Indicates the unavailable seconds recorded in the OTN section during the performance monitoring time interval. • **uas-sm-ne** --Near-end section monitoring unavailable seconds (UAS-SM).
enable	Enables TCA generation for the specified parameter on the DWDM controller.

Command Default

TCA generation is not enabled.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(3)S	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows how to enable TCA generation on the OTN layer reporting for the path monitoring errored seconds ratio (ESR-PM):

```
Router(config)# controller dwdm 0/0
Router(config-controller)# pm 15-min otn report esr-pm-fe enable
```

Related Commands

Command	Description
show controller dwdm pm otn	Displays performance measurement information for the OTN layer.

pm optics threshold

To configure performance monitoring thresholds on the optics layer, use the **pmopticsthreshold**command in DWDM configuration mode. To disable the performance monitoring threshold, use the **no** form of this command.

pm {**15-min** | **24-hour**} **optics threshold** {**lbc** | **opr** | **opt**} {**max** | **min**} *threshold*
nopm {**15-min** | **24-hour**} **optics threshold** {**lbc** | **opr** | **opt**} {**max** | **min**} *threshold*

Syntax Description

15-min	Configures performance monitoring thresholds for 15-minute intervals.
24-hour	Configures performance monitoring thresholds for 24-hour intervals.
lbc	Laser bias current.
opr	Optical power on the unidirectional port.
opt	Transmits optical power in dBm.
max	Indicates that the *threshold* is for the maximum value of the parameter.
min	Indicates that the *threshold* is for the minimum value of the parameter.
threshold	Threshold for the performance monitoring parameter.

Command Default

No thresholds are configured.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(3)S	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows how to configure an optics layer performance monitoring threshold for maximum OPT:

```
Router(config)# controller dwdm 0/0
Router(config-controller)# pm 15-min optics threshold opt max 700
```

Related Commands

Command	Description
show controller dwdm pm optics	Displays performance measurement information for the optics layer.

pm otn threshold

To configure performance monitoring thresholds on the optical transport network (OTN) layer, use the **pmotnthreshold**command in DWDM configuration mode. To disable TCA reporting, use the **no** form of this command.

pm {**15-min** | **24-hour**} **otn** **threshold** *otn-parameter* *threshold*
nopm {**15-min** | **24-hour**} **otn** **threshold** *otn-parameter* *threshold*

Syntax Description

15-min	Configures performance monitoring thresholds for 15-minute intervals.
24-hour	Configures performance monitoring thresholds for 24-hour intervals.
otn-parameter	Specific parameter for which to configure the threshold. OTN parameters can be as described in the **pmotnreport** command.
threshold	Threshold for the performance monitoring parameter.

Command Default

No thresholds are configured.

Command Modes

DWDM configuration.

Command History

Release	Modification
15.1(3)S	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows how to configure an OTN layer performance monitoring threshold for path monitoring errored seconds ratio (ESR-PM):

```
Router(config)# controller dwdm 0/0
Router(config-controller)# pm 15-min otn threshold esr-pm-ne 800
```

Related Commands

Command	Description
show controller dwdm pm otn	Displays performance measurement information for the OTN layer.

port (interface)

To enable an interface on a PA-4R-DTR port adapter to operate as a concentrator port, use the **port**command in interface configuration mode. To restore the default station mode, use the **no** form of this command.

port
no port

Syntax Description

This command has no arguments or keywords.

Command Default

Station mode

Command Modes

Interface configuration

Command History

Release	Modification
11.3(3)T	This command was introduced.

Usage Guidelines

By default, the interfaces of the PA-4R-DTR operate as Token Ring stations. Station mode is the typical operating mode. Use this command to enable an interface to operate as a concentrator port.

Examples

The following example configures the PA-4R-DTR ports to operate in concentrator mode on a Cisco 7000 series router:

```
Router(config)# interface tokenring 3/0/0
Router(config-if)# port
```

port access-map

To create a port access map or enter port access-map command mode, use the **portaccess-map** command in global configuration mode. To remove a mapping sequence or the entire map, use the **no** form of this command.

port access-map *name* [*seq#*]
no port access-map *name* [*seq#*]

Syntax Description

name	Port access-map tag.
seq#	(Optional) Map sequence number; valid values are 0 to 65535.

Command Default

This command has no default settings.

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

If you enter the sequence number of an existing map sequence, you enter port access-map mode. If you do not specify a sequence number, a number is automatically assigned. You can enter one match clause and one action clause per map sequence.

If you enter the **noportaccess-mapname** [*seq#*] command without entering a sequence number, the whole map is removed.

Once you enter port access-map mode, the following commands are available:

- **action** -- Specifies the packet action clause; see the **action** command section.
- **default** -- Sets a command to its defaults.
- **end** -- Exits from configuration mode.
- **exit** -- Exits from the port access-map configuration mode.
- **match** -- Specifies the match clause; see the **match** command section.
- **no** -- Negates a command or sets its defaults.

Examples

This example shows how to enter port access-map mode:

```
Router(config)# port access-map ted
Router(config-port-map)#
```

Related Commands

Command	Description
action	Sets the packet action clause.
match	Specifies the match clause by selecting one or more ACLs for a VLAN access-map sequence.

port-channel hash-distribution

To set the hash distribution algorithm method, use the port-channel hash-distribution command in global configuration mode. To return to the default settings, use the **no** or **default** form of this command.

port-channel hash-distribution {**adaptive** | **fixed**}
{**no** | **default**} **port-channel hash-distribution**

Syntax Description

adaptive	Specifies selective distribution of the bundle select register among the port-channel members.
fixed	Specifies fixed distribution of the bundle select register among the port-channel members.
default	Specifies the default setting.

Command Default

The hash distribution algorithm method is set to **fixed.**

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.

Usage Guidelines

The EtherChannel load distribution algorithm uses the bundle select register in the port ASIC to determine the port for each outgoing packet. When you use the **adaptive** algorithm, it does not require the bundle select register to be changed for existing member ports. When you use the **fixed** algorithm and you either add or delete a port from the EtherChannel, the switch updates the bundle select register for each port in the EtherChannel. This update causes a short outage on each port.

Note When you change the algorithm, the change is applied at the next member link event. Example events include link down, up, addition, deletion, no shutdown, and shutdown. When you enter the command to change the algorithm, the command console issues a warning that the command does not take effect until the next member link event.

Examples

The following example shows how to set the hash distribution algorithm method to adaptive:

```
Router(config)# port-channel hash-distribution adaptive
```

port-channel load-balance

To set the load distribution method among the ports in a bundle, use the **port-channelload-balance** command in global configuration mode. To reset the load distribution to the default settings, use the **no** form of this command.

port-channel load-balance *method* **module** *slot*
no port-channel load-balance

Syntax Description

method	Load distribution method; see the "Usage Guidelines" section for a list of valid values.
module	Specifies the module on which the load-distribution method is set. This keyword is supported only on DFC systems.
slot	Number of the slot in the module.

Command Default

The default**method** is **src-dst-ip**.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(14)SX	This command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	This command was modified to support the Supervisor Engine 2.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH	This command was modified. The following keywords were added: **dst-mixed-ip-port**,**src-dst-mixed-ip-port**,**src-mixed-ip-port**,and**excludevlan**. • These keywords are supported on systems that are in PFC3C or PFC3CXL mode (PFC3C or PFC3CXL with no DFC3A or DFC3B/BXL) only. • The **excludevlan**keyword is added only for IP-related load balance options.

Usage Guidelines

Valid *method* values are as follows:

- **dst-ip** --Loads distribution on the destination IP address. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.
- **dst-mac** --Loads distribution on the destination MAC address.
- **dst-mixed-ip-port** --Loads distribution on the destination IP address and TCP or User Datagram Protocol (UDP) port. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.
- **dst-port** --Loads distribution on the destination port.
- **src-dst-ip** --Loads distribution on the source transfer or XOR-destination IP address. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.

- **src-dst-mac** --Loads distribution on the source XOR-destination MAC address.
- **src-dst-mixed-ip-port** --Loads distribution on the source XOR-destination IP address and the TCP or UDP port. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.
- **src-dst-port** --Loads distribution on the source XOR-destination port.
- **src-ip** --Loads distribution on the source IP address. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.
- **src-mac** --Loads distribution on the source MAC address.
- **src-mixed-ip-port** --Loads distribution on the source IP address and the TCP or UDP port. Option to exclude VLAN in the distribution is provided using the **excludevlan**keyword along with this method.
- **src-port** --Loads distribution on the source port.

The **port-channelload-balance***method***module***slot* command is supported on DFC systems only.

The **port-channelper-moduleload-balance** command allows you to enable or disable port-channel load-balancing on a per-module basis. You can enter the **port-channelload-balance***method***module***slot* command to specify the load-balancing method on a specific module after you have entered the **port-channelper-moduleload-balance**command.

The following keywords are supported on systems that are in PFC3C or PFC3CXL mode (PFC3C or PFC3CXL with no DFC3A or DFC3B/BXL) only:

- **dst-mixed-ip-port**
- **src-dst-mixed-ip-port**
- **src-mixed-ip-port**

Note If you change the load-balancing method, EtherChannel ports on DFC-equipped switching modules or an active supervisor engine in a dual supervisor engine configuration will flap.

Examples

The following example shows how to set the load-distribution method to **dst-ip**:

```
Router(config)#
port-channel load-balance dst-ip
```

The following example shows how to set the load-distribution method on a specific module:

```
Router(config)#
port-channel load-balance dst-ip module 2
```

The following example shows how to set the load-distribution method excluding the VLAN option:

```
Router(config)#
port-channel load-balance dst-ip exclude vlan
```

Related Commands

Command	Description
interface port-channel	Creates a port-channel virtual interface and enters interface configuration mode.
port-channel load-balance mpls	Sets the load distribution method among the ports in the bundle for MPLS packets.
show etherchannel	Displays the EtherChannel information for a channel.

port-channel load-balance (interface)

To configure a member link for load balancing, a default service instance weight, or weighted load balancing on port-channel member links, use the **port-channel load-balance** command in interface configuration mode. To cause the default weight to revert to 1 and to disable weighted load balancing, use the **no** form of this command.

port-channel load-balance {**link** *link-id* | **weighted** {**default weight** *weight* | **link** {**all***link-id*} | **rebalance** {**disable***weight*}}}
no port-channel load-balance {**link** *link-id* | **weighted** {**default weight** | **link** | **rebalance**}}

Syntax Description

link	Configures a member link for egress load balancing.
link-id	Integer from 1 to 16 that identifies the member link. • When used with the **weighted** keyword, the *link-id* is a comma-delimited list of member link IDs to use for weighted load balancing.
weighted	Configures weighted load balancing on the port channel.
default weight	Configures a default weight for a service instance.
weight	Integer from 1 to 10000 that is the weight value. The default is 1. • When used with the **rebalance** keyword, this value is the threshold weight used to trigger automatic rebalancing. The default is 4.
all	Configures load balancing across all active member links.
rebalance	Sets or disables the automatic rebalance threshold.
disable	Disables automatic rebalancing.

Command Default

Service instance weight and weighted load balancing are not configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

When weighted load balancing enabled, the weight configured using this command is inherited by all service instances on the port channel that have not been specifically configured with a weight.

Configuring a default weight is optional; the default weight value is 1.

Use of the **weighted**and **link** keywords is required to enable weighted load balancing on a port channel. When the **all** keyword is configured, traffic is distributed across all active member links in the port channel. When one or more member links is specified, traffic is distributed across only those member links. To allow for out-of-order configuration, link IDs not yet assigned to member links may be specified. Issuing this command with the **weighted** and **link** keywords more than once under the same port-channel interface results in overwriting the command settings previously configured.

If this command is configured with a list of link IDs and the member link corresponding to one of those link IDs is later configured with a different ID, a warning is displayed on the console that notifies the user that the action will affect the current load-balancing activity.

When the **disable** keyword is configured, automatic rebalancing is not performed and the operator must manually invoke rebalancing by issuing the **port-channel load-balance weighted rebalance**command in privileged EXEC mode.

When the **disable** keyword is not configured, either the configured or a default weight is used to automatically rebalance service instances. Automatic rebalancing occurs when the average absolute deviation (AAD) of the current distribution exceeds the configured threshold and when the resulting AAD of the rebalanced distribution is less than the current AAD. If automatic rebalancing does not result in a lower AAD, the rebalancing is not done, even if the current AAD exceeds the threshold.

The AAD calculation is (1/*n*)*Sum(|w(*i*) - m|) for all *n* member links where:

n = number of member links

m = mean of member link weights (sum of all Ethernet service instance weights divided by *n*)

w (*i*) = sum of Ethernet service instance weights on member link *i*

Two conditions cause the **port-channel load-balance**command to fail:

- An invalid weight is configured.
- An invalid link ID is provided.

Examples

The following example shows how to configure port-channel load balancing for all port-channel member links:

```
Router(config)# interface port-channel1
Router(config-if)# port-channel load-balance weighted link all
```

port-channel load-balance mpls

To set the load-distribution method among the ports in the bundle for Multiprotocol Label Switching (MPLS) packets, use the **port-channel load-balance mpls**command in global configuration mode. To reset the load distribution to the default settings, use the **no** form of this command.

port-channel load-balance mpls {**label** | **label-ip**}
no port-channel load-balance mpls

Syntax Description

label	Specifies using the MPLS label to distribute packets; see the "Usage Guidelines" section for additional information.
label-ip	Specifies using the MPLS label or the IP address to distribute packets; see the "Usage Guidelines" section for additional information.

Command Default

label-ip

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 2.

If you select **label**, these guidelines apply:

- With only one MPLS label, the last MPLS label is used.
- With two or more MPLS labels, the last two labels (up to the fifth label) are used.

If you select **label-ip**, these guidelines apply:

- With IPv4 and three or fewer labels, the source IP address XOR-destination IP address is used to distribute packets.
- With four or more labels, the last two labels (up to the fifth label) are used.
- With non-IPv4 packets, the distribution method is the same as the **label** method.

Examples

This example shows how to set the load-distribution method to **label-ip**:

```
Router(config)#
port-channel load-balance mpls label-ip
Router(config)#
```

Related Commands

Command	Description
interface port-channel	Creates a port-channel virtual interface and enters interface configuration mode.
show etherchannel	Displays the EtherChannel information for a channel.

port-channel load-balance weighted rebalance

To perform a rebalancing of all port-channel interfaces configured with weighted load balancing, use the **port-channel load-balance weighted rebalance** command in privileged EXEC mode.

port-channel load-balance weighted rebalance [**interface port-channel** *number*]

Syntax Description

interface	(Optional) Specifies a port channel enabled for weighted load balancing.
port-channel	(Optional) Specifies an Ethernet channel of interfaces.
number	(Optional) Integer from 1 to 564 that identifies the port-channel interface.

Command Default

Load rebalancing is not performed.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

If a port-channel interface is specified, only that interface is rebalanced; otherwise all port channels with weighted load balancing enabled are rebalanced.

This command may be used when automatic rebalancing is disabled via the **port-channel load-balance weighted rebalance disable** command or when a rebalancing of service instances is desired prior to reaching the automatic rebalance threshold.

If the specified interface is not a port channel enabled for weighted load balancing, the **port-channel load-balance weighted rebalance**command has no effect on load balancing on that interface.

Examples

The following example shows how to force a rebalancing of service instances, based on their assigned weights, for all port channels with weighted load balancing enabled:

```
Router# port-channel load-balance weighted rebalance
```

Related Commands

Command	Description
port-channel load-balance (interface)	Configures a member link for load balancing, a default service instance weight, or weighted load balancing on port-channel member links.

port-channel load-balancing vlan-manual

To apply the VLAN-manual load-balancing method globally to all Gigabit EtherChannel (GEC) interfaces, use the **port-channelload-balancingvlan-manual**command in global configuration mode. To reset to the default, use the **no** form of this command.

port-channel load-balancing vlan-manual
no port-channel load-balancing

Syntax Description

This command has no arguments or keywords.

Command Default

Flow-based load balancing is enabled.

Command Modes

Global configuration (config)

Command History

Release	Modification
Cisco IOS XE Release 2.1	This command was introduced.
Cisco IOS XE Release 2.5	This command was modified. The default was changed from no load balancing is enabled to flow-based load balancing.

Usage Guidelines

The **port-channelload-balancingvlan-manual** command applies the VLAN-manual load-balancing method globally to all port channels on the router. If you do not use this command to explicitly set the global load-balancing method to VLAN-manual, the load-balancing method is set to flow-based.

The load-balancing method enabled on a port channel with the **load-balancing**command takes precedence over this command.

Load balancing uses the concept of buckets to map traffic flows to the member links of a port channel. The different traffic flows are mapped to the buckets and each bucket has one active member link associated with it. All flows that are mapped to a bucket use the member link associated with that bucket.

There are two methods of load balancing on a GEC interface:

- VLAN-manual--All packets forwarded over the same VLAN subinterface are considered part of the same flow and are mapped to the member link specified in the configuration.
- Flow-based--Traffic flows are mapped to different member links based on the packet header.

Examples

This example shows how to set the load-balancing method to VLAN-manual:

```
Router(config)# port-channel
load-balancing vlan-manual
```

Related Commands

Command	Description
interface port-channel	Creates a port-channel virtual interface.
load-balancing	Applies a load-balancing method to a GEC interface.

Command	Description
show interfaces port-channel etherchannel	Displays the load-balancing bucket distribution currently in use for a GEC interface.
show etherchannel load-balancing	Displays the load-balancing method applied to GEC interfaces.

port-channel load-defer

To configure the port load share deferral interval for all port channels, use the **port-channelload-defer** command in global configuration mode. To reset the port defer interval to the default setting, use the **no** form of this command.

port-channel load-defer *seconds*
no port-channel load-defer *seconds*

Syntax Description

seconds	Sets the time interval in seconds by which load sharing will be deferred on the switch. Valid range is from 1 to 1800 seconds. The default deferal interval is 120 seconds

Command Default

The port defer interval is 120 seconds.

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
12.2(50)SY	This command was introduced. Added the *seconds* variable for use in Cisco IOS Release 12.2(50)SY.

Usage Guidelines

To reduce data loss following a stateful switchover (SSO), port load share deferral can be enabled by entering the **port-channelportload-defer** command on a port channel of a switch that is connected by a multichassis EtherChannel (MEC) to a virtual switching system (VSS). Port load share deferral temporarily prevents the switch from forwarding data traffic to MEC member ports on a failed chassis of the VSS while the VSS recovers from the SSO.

The load share deferral interval is determined by a single global timer configurable by the **port-channelload-defer** command. After an SSO switchover, a period of several seconds to several minutes can be required for the reinitialization of line cards and the reestablishment of forwarding tables, particularly multicast topologies.

The valid range of *seconds* is 1 to 1800 seconds; the default is 120 seconds.

Examples

This example shows how to set the global port deferral interval to 60 seconds:

```
Router(config)#
port-channel load-defer 60
Router(config)#
```

This example shows how to verify the configuration of the port deferral interval on a port channel:

```
Router# show etherchannel 50 port-channel

                Port-channels in the group:
                ----------------------
Port-channel: Po50    (Primary Aggregator)
------------
Age of the Port-channel   = 0d:00h:22m:20s
```

```
Logical slot/port   = 46/5          Number of ports = 3
HotStandBy port = null
Port state          = Port-channel Ag-Inuse
Protocol            =   LACP
Fast-switchover     = disabled
Load share deferral = enabled   defer period = 60 sec
   time left = 57 sec
Router#
```

Related Commands

Command	Description
interface port-channel	Creates a port channel virtual interface and enters interface configuration mode.
port-channel port load-defer	Enables the port load share deferral feature on a port channel.
show etherchannel	Displays the EtherChannel information for a channel.

port-channel min-links

To specify that a minimum number of bundled ports in an EtherChannel is required before the channel can be active, use the **port-channelmin-links** command in interface configuration mode. To return to the default settings, use the **no** form of this command.

port-channel min-links *min-num*
no port-channel min-links

Syntax Description

min-num	Minimum number of bundled ports in a channel that is required before the channel can be active; valid values are from 2 to 8.

Command Default

min-num is **1**

Command Modes

Interface configuration

Command History

Release	Modification
12.2(18)SXF	Support for this command was introduced on the Supervisor Engine 720.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is supported on LACP (802.3ad) ports only. More than one LACP secondary-port channel can belong to the same channel group. This command is applied to all port channels in the same group.

If fewer links than the specified number are available, the port-channel interface does not become active.

Use the **showrunning-config** command to verify the configuration.

Examples

This example shows how to specify that a minimum number of bundled ports in an EtherChannel is required before the channel can be active:

```
Router(config-if)#
port-channel min-links 3
Router(config-if)#
```

Related Commands

port-channel per-module load-balance

To enable load balance on a per-module basis among the ports in a bundle, use the port-channel per-module load-balance command in global configuration mode. To return to the default settings, use the **no** form of this command.

port-channel per-module load-balance
no port-channel per-module load-balance

Syntax Description

This command has no arguments or keywords.

Command Default

The load balance method is not enabled per module**.**

Command Modes

Global configuration (config)

Command History

Release	Modification
12.2(18)ZY	This command was introduced.
12.2(33)SXH	This command was integrated into Cisco IOS Release 12.2(33)SXH.

Usage Guidelines

The **port-channelper-moduleload-balance** command allows you to enable or disable port-channel load balancing on a per-module basis. You can use the **port-channelload-balancemodule**command to specify the load balancing method on a specific module after you have entered the **port-channelper-moduleload-balance** command.

Examples

The following example shows how to enable load balancing on a per-module basis:

```
Router(config)# port-channel per-module load-balance
```

Related Commands

Command	Description
port-channel hash-distribution	Sets the hash distribution algorithm method among the ports in a bundle.
port-channel load-balance	Sets the load balance method among the ports in a bundle.

port-channel port load-defer

To enable the temporary deferral of port load sharing during the connection or reconnection of a port channel, use the **port-channelportload-defer** command in interface configuration mode. To disable the deferral of port load sharing on a port channel, use the **no** form of this command.

port-channel port load-defer
no port-channel port load-defer

Syntax Description

This command has no keywords or arguments.

Command Default

The port load share deferral feature is not enabled on a port channel .

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXH	This command was introduced.
12.2(50)SY	This command was introduced.

Usage Guidelines

To reduce data loss following a stateful switchover (SSO), a port load share deferral can be enabled on a port channel of a switch that is connected by a multichassis EtherChannel (MEC) to a virtual switching system (VSS). The load share deferral interval prevents the switch from forwarding data traffic to MEC member ports on a failed chassis of the VSS while the VSS recovers from the SSO.

When load share deferral is enabled on a port channel, the assignment of a member port's load share is delayed for a period that is configurable globally by the **port-channelload-defer** command. During the deferral period, the load share of a deferred member port is set to 0. In this state, the deferred port is capable of receiving data and control traffic, and of sending control traffic, but the port is prevented from sending data traffic over the MEC to the VSS. Upon expiration of the global deferral timer, the deferred member port exits the deferral state and the port assumes its normal configured load share.

Load share deferral is applied only if at least one other member port of the port channel is currently active with a nonzero load share. If a port enabled for load share deferral is the first member bringing up the EtherChannel, the deferral feature does not apply and the port will forward traffic immediately.

The load share deferral interval is determined by a single global timer configurable from 1 to 1800 seconds by the **port-channelload-defer** command. The default interval is 120 seconds. After an SSO switchover, a period of several seconds to several minutes can be required for the reinitialization of line cards and the reestablishment of forwarding tables, particularly multicast topologies.

Examples

This example shows how to enable the load share deferral feature on port channel 50 of a switch that is an MEC peer to a VSS:

```
Router(config)#
interface port-channel 50
Router(config-if)#
port-channel port load-defer

This will enable the load share deferral feature on this port-channel.
```

```
The port-channel should connect to a Virtual Switch (VSS).
Do you wish to proceed? [yes/no]:
yes
Router(config-if)#
```

This example shows how to verify the state of the port deferral feature on a port channel:

```
Router# show etherchannel 50 port-channel

                Port-channels in the group:
                ----------------------
Port-channel: Po50    (Primary Aggregator)
------------
Age of the Port-channel   = 0d:00h:22m:20s
Logical slot/port   = 46/5          Number of ports = 3
HotStandBy port = null
Port state          = Port-channel Ag-Inuse
Protocol            =   LACP
Fast-switchover     = disabled
Load share deferral = enabled   defer period = 120 sec   time left = 57 sec
Router#
```

Related Commands

Command	Description
interface port-channel	Creates a port channel virtual interface and enters interface configuration mode.
port-channel load-defer	Configures the global port load share deferral time interval for port channels.
show etherchannel	Displays the EtherChannel information for a channel.

port-channel standalone-disable

To disable the EtherChannel standalone option in a port channel, use the **port-channel standalone-disable** command in interface configuration mode. To enable this option, use the **no** form of this command.

port-channel standalone-disable
no port-channel standalone-disable

Syntax Description

This command has no arguments or keywords.

Command Default

The EtherChannel standalone option is enabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.2(33)SXI3	This command was introduced.
15.1(1)SG	This command was integrated into Cisco IOS Release 15.1(1)SG.
Cisco IOS XE Release 3.3SG	This command was integrated into Cisco IOS XE Release 3.3SG.

Usage Guidelines

The **port-channel standalone-disable** command is supported on the Catalyst 6000 series switches. This command can be used only when the port-channel protocol type is Link Aggregation Control Protocol (LACP). This command enables you to change the current behavior when a physical port cannot bundle an LACP EtherChannel.

Examples

The following example shows how to disable the EtherChannel standalone option in a port channel:

```
Device(config-if)# port-channel standalone-disable
```

Related Commands

Command	Description
show etherchannel	Displays the EtherChannel information for a channel.

pos ais-shut

To send the line alarm indication signal (LAIS) when the Packet-over-SONET (POS) interface is placed in any administrative shutdown state, use the pos ais-shut command in interface configuration mode.

pos ais-shut

Syntax Description

This command has no arguments or keywords.

Command Default

No LAIS is sent.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In Automatic Protection Switching (APS) environments, LAIS can be used to force a protection switch. This command forces an APS switch when the interface is placed in the administrative shutdown state.

For more information on APS, refer to the “Configuring Serial Interfaces” chapter in the Cisco IOS Interface and Hardware Component Configuration Guide.

This command does not have a **no** form.

Examples

The following example forces the alarm indication on POS OC-3 interface 0 in slot 3:

```
Router(config)# interface pos 3/0
Router(config-if)# shutdown
Router(config-if)# pos ais-shut
```

pos delay triggers

To enable a POS alarm trigger delay, or to enable path level alarms as triggers to bring the POS line card protocol to down, use the pos delay triggers command in POS interface configuration mode. To disable POS alarm trigger delays, use the **no** form of this command.

pos delay triggers [{**line** *ms* | **path** *ms*}]
no pos delay triggers [{**line** *ms* | **path** *ms*}]

Syntax Description

line	Specifies the delay for SONET line level triggers. The following alarms are considered line level triggers: section loss of signal, section loss of frame, line alarm indication signal. SONET line level triggers bring the line protocol down by default
path	Specifies that SONET path level alarms should trigger the line protocol to go down.
ms	Specifies the time, in milliseconds, that POS trigger should wait before setting the line protocol to down. If no *ms* value is entered, the default value of 100 ms is used.

Command Default

POS line level alarm triggers are enabled by default. If a POS line level alarm trigger occurs and no configuration changes have been made using the**posdelaytriggersline***ms*command, the line protocol is set to down immediately with no delay.

POS path level alarm triggers are disabled by default. A path level alarm will not set the line protocol to down unless the **posdelaytriggerspath** command has been entered.

If no *ms* value is entered but **posdelaytriggersline** command is configured, the default *ms* value for line level triggers is 100 ms.

If no *ms* value is entered and **posdelaytriggerspath** is enabled, the default *ms* value is set at 100 ms for path level triggers.

Command Modes

POS interface configuration

Command History

Release	Modification
12.1(12c)EX1	This command was introduced for Cisco 7304 routers.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command was integrated into Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4	This command was integrated into Cisco IOS Release 12.4 Mainline. This command supports Cisco 7200 Series, Cisco 7304 Series, and Cisco 7600 Series routers.
12.4(24)T	This command was integrated into a release earlier than Cisco IOS Release 12.4(24)T. This command supports Cisco 7200 Series, Cisco 7304 Series, and Cisco 7600 Series routers.

Usage Guidelines

A trigger is an alarm that, when asserted, causes the line protocol to go down.

When one or more triggers are asserted, the line protocol of the interface goes down. The POS Alarm Trigger Delay feature provides the option to delay triggering of the line protocol of the interface from going down when an alarm triggers the line protocol to go down. For instance, if you configure the POS alarm delay for 150 ms, the line protocol will not go down for 150 ms after receiving the trigger. If the trigger alarm stays up for more than 150 ms, the link is brought down as it is now. If the trigger alarm clears before 150 ms, the line protocol is not brought down.

By default, the following line and section alarms are triggers for the line protocol to go down:

- Section loss of signal
- Section loss of frame
- Line alarm indication signal

For line and section alarm triggers, the line protocol of the POS card is brought down immediately if a trigger is received and no POS alarm trigger delay is specified. The delay can be set anywhere from 50 to 10000 ms. If POS alarm triggering is configured but no *ms* value is entered, the POS alarm trigger delay is 100 ms.

The following path alarms are not triggers by default. These path alarms, however, can be configured as triggers:

- Path alarm indication signal
- Path remote defect indication

The POS Alarm Trigger Delay feature can be used to configure these alarms as triggers, as well as to configure the exact POS alarm trigger delay for these triggers. The default delay values for these triggers, if no value is specified, is also 100 ms.

Examples

In the following configuration example, the POS line card will wait 50 ms after receiving a line level trigger before setting the line protocol to down. If the alarm that began the line level trigger clears during that 50 ms, the line protocol will remain up. If the alarm that began the line trigger remains after that 50 ms, the line protocol will go down.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# interface pos 1/0
Router(config-if)# pos delay triggers line 50
```

In the following configuration example, the POS line card will wait 110 ms after receiving a path trigger before setting the line protocol to down. If the alarm that began the path trigger clears during that 110 ms, the line protocol will remain up. If the alarm that began the path trigger remains after 110 ms, the line protocol will go down.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# interface pos 1/0
Router(config-if)# pos delay triggers path 110
```

In the following example, the **showcontrollerspos***slot*/*interface-number***detail** command is used to verify the POS alarm trigger delay. In this particular example, the delay is 100 ms (italicized for emphasis below) for both line level triggers and path level triggers.

```
Router# show controllers pos 4/0 detail
```

Command	Description
show controllers pos *slot* / *interface-number* **detail**	Shows the content of POS controllers, including the amount of delay for line triggers.

pos flag

To set the SONET overhead bytes in the frame header to meet a specific standards requirement or to ensure interoperability with the equipment of another vendor, use the **posflag**command in interface configuration mode. To remove the setting of the SONET overhead bytes, use the **no** form of this command.

pos flag commandpos flag {**c2** | **j0** | **s1s0**} *value*
no pos flag {**c2** | **j0** | **s1s0**} *value*

Syntax Description

c2 *value*	Path signal identifier used to identify the payload content type. The default value is 0xCF.
j0 *value*	Section trace byte (formerly the C1 byte). For interoperability with Synchronous Digital Hierarchy (SDH) equipment in Japan, use the value 0x1. The byte value can be 0 to 255.
sls0 *value*	S1 and S0 bits (bits 5 and 6 of the H1 #1 payload pointer byte). Use the following values to tell the SONET transmission equipment the SS bit: • For OC-3c, use 0 (this is the default). • For AU-4 container in SDH, use 2. The S1 and S0 bits can be 0 to 3. Values 1 and 3 are undefined. The default value is 0.

Command Default

The default **c2** value is 0xCF. The default **sls0** value is 0.

Command Modes

Interface configuration

Command History

Release	Modification
11.2 GS	This command was introduced to support the Cisco 12000 series Internet routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the following values to tell the SONET transmission equipment the payload type:

- For PPP, or High-Level Data Link Control (HDLC) when required, use 0xCF (this is the default).
- For ATM, use 0x13.
- For other equipment, use any nonzero value.
- The byte value can be 0 to 255.

Examples

The following example sets the path signal identifier used to identify the payload content type to ATM on the **pos** interface in slot 9:

```
Router(config)# interface pos 9/0
```

```
Router(config-if)# pos flag c2 0x13
Router(config-if)# end
```

pos flag s1-byte rx-communicate

To direct the router to switch to internal clocking when it receives an S1 SONET overhead byte with a value of 0xF, use the pos flag s1-byte rx-communicate command in interface configuration mode. To disable this capability, use the **no** form of this command.

pos flag s1-byte rx-communicate
no pos flag s1-byte rx-communicate

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced on the Cisco 10000 series router.

Usage Guidelines

The pos flag s1-byte rx-communicate command directs the router to switch the clock source to internal when it receives an S1 SONET overhead byte with a value of 0xF. When the S1 SONET overhead byte changes from 0xF to any other value, the clock source reverts back to the clock source specified in the user configuration.

The S1 SONET overhead byte is ignored by the receiving router unless the pos flag s1-byte rx-communicate command is issued.

Examples

The following example directs the router to switch to internal clocking when it receives an S1 SONET overhead byte with a value of 0xF:

```
pos flag s1-byte rx-communicate
```

Related Commands

Command	Description
pos flag	Assigns values for specific elements of the frame header. This command is typically used to meet a standards requirement or to ensure interoperability with another vendor's equipment.
pos flag s1-byte tx	Controls the transmission of the S1 SONET overhead byte.

pos flag s1-byte tx

To control the transmission of the S1 SONET overhead byte, use the pos flag s1-byte tx command in interface configuration mode.

pos flag s1-byte tx *value*

Syntax Description

value	Set the S1 SONET overhead byte to a value in the range of 0x0 to 0xF.

Command Default

The default is 0x0.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(28)SB	This command was introduced on the Cisco 10000 series router.

Usage Guidelines

In most situations, the default value for the S1 SONET overhead byte does not need to be changed. Refer to the SONET standards for information about the possible values for the S1 SONET overhead byte and the definition of each value.

Examples

The following example sets the S1 SONET overhead byte to 0xF:

```
pos flag s1-byte tx 0xF
```

Related Commands

Command	Description
pos flag	Assigns values for specific elements of the frame header. This command is typically used to meet a standards requirement or to ensure interoperability with another vendor's equipment.
pos flag s1-byte rx-communicate	Directs the router to switch to internal clocking when it receives an S1 SONET overhead byte with a value of 0xF.

pos framing

To specify the framing used on the POS (Packet-over-SONET) interface, use the **posframing** command in interface configuration mode. To return to the default SONET STS-3c framing mode, use the **no** form of this command.

pos framing commandpos framing {**sdh** | **sonet**}
no pos framing

Syntax Description

sdh	Selects SDH STM-1 framing. This framing mode is typically used in Europe.
sonet	Selects SONET STS-3c framing. This is the default.

Command Default

SONET STS-3c framing

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
11.3	This command was modified to change the **posiframing-sdh** command to **posframing-sdh**.
11.2GS	The command syntax was changed from **posframing-sdh** to **posframing**. The **sonet** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example configures the interface for SDH STM-1 framing:

```
Router(config)# interface pos 3/0
Router(config-if)# pos framing sdh
Router(config-if)# no shutdown
```

Related Commands

Command	Description
clock source (interface)	Controls the clock used by a G.703-E1 interface.
interface	Configures an interface type, and enters interface configuration mode.

pos report

To permit selected SONET alarms to be logged to the console for a POS (Packet-over-SONET) interface, use the **posreport**command in interface configuration mode. To disable logging of select SONET alarms, use the **no** form of this command.

pos report commandpos report {**b1-tca** | **b2-tca** | **b3-tca** | **lais** | **lrdi** | **pais** | **plop** | **prdi** | **rdool** | **sd-ber** | **sf-ber** | **slof** | **slos**}
no pos report {**b1-tca** | **b2-tca** | **b3-tca** | **lais** | **lrdi** | **pais** | **plop** | **prdi** | **rdool** | **sd-ber** | **sf-ber** | **slof** | **slos**}

Syntax Description

b1-tca	Reports B1 bit-error rate (BER) threshold crossing alarm (TCA) errors.
b2-tca	Reports B2 BER crossing TCA errors.
b3-tca	Reports B3 BER crossing TCA errors.
lais	Reports line alarm indication signal errors.
lrdi	Reports line remote defect indication errors.
pais	Reports path alarm indication signal errors.
plop	Reports path loss of pointer errors.
prdi	Reports path remote defect indication errors.
rdool	Reports receive data out of lock errors.
sd-ber	Reports signal degradation BER errors.
sf-ber	Reports signal failure BER errors.
slof	Reports section loss of frame errors.
slos	Reports section los of signal errors.

Command Default

The following alarms are reported by default:

- **b1-tca**
- **b2-tca**
- **b3-tca**
- **plop**
- **sf-ber**
- **slof**
- **slos**

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Reporting an alarm means that the alarm can be logged to the console. Just because an alarm is permitted to be logged does not guarantee that it is logged. SONET alarm hierarchy rules dictate that only the most severe alarm of an alarm group is reported. Whether an alarm is reported or not, you can view the current state of a defect by checking the "Active Defects" line from the **showcontrollerspos**command output. A defect is a problem indication that is a candidate for an alarm.

For B1, the bit interleaved parity error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B1 byte of the following frame. Differences indicate that section level bit errors have occurred.

For B2, the bit interleaved parity error report is calculated by comparing the BIP-8/24 code with the BIP-8 code extracted from the B2 byte of the following frame. Differences indicate that line level bit errors have occurred.

For B3, the bit interleaved parity error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B3 byte of the following frame. Differences indicate that path level bit errors have occurred.

PAIS is sent by line terminating equipment (LTE) to alert the downstream path terminating equipment (PTE) that it has detected a defect on its incoming line signal.

PLOP is reported as a result of an invalid pointer (H1, H2) or an excess number of new data flag (NDF) enabled indications.

SLOF is detected when a severely error framing (SEF) defect on the incoming SONET signal persists for 3 milliseconds.

SLOS is detected when an all-zeros pattern on the incoming SONET signal lasts 19 plus or minus 3 microseconds or longer. This defect might also be reported if the received signal level drops below the specified threshold.

To determine the alarms that are reported on the interface, use the **showcontrollerspos**command.

Examples

The following example enables reporting of SD-BER and LAIS alarms on the interface:

```
Router(config)# interface pos 3/0/0
Router(config-if)# pos report sd-ber
Router(config-if)# pos report lais
Router(config-if)# end
```

Related Commands

Command	Description
interface	Configures an interface type, and enters interface configuration mode.
show controllers pos	Displays information about the POS controllers.

pos scramble-atm

To enable SONET payload scrambling on a POS (Packet-over-SONET) interface, use the **posscramble-atm**command in interface configuration mode. To disable scrambling, use the **no** form of this command.

pos scramble-atm commandpos scramble-atm
no pos scramble-atm

Syntax Description

This command has no arguments or keywords.

Command Default

Scrambling is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

SONET payload scrambling applies a self-synchronous scrambler (x43+1) to the Synchronous Payload Envelope (SPE) of the interface to ensure sufficient bit transition density. Both ends of the connection must use the same scrambling algorithm. When enabling POS scrambling on a VIP2 POSIP on the Cisco 7500 series router that has a hardware revision of 1.5 or higher, you can specify CRC 16 only (that is, CRC 32 is currently not supported).

To determine the hardware revision of the POSIP, use the **showdiag** command.

To determine whether scrambling is enabled on the interface, use the **showinterfacepos** command or the **showrunning-config** command.

Note SONET payload scrambling is enabled with the **posscramble-atm** command. SONET payload scrambling applies a self-synchronous scrambler (x43+1) to the Synchronous Payload Envelope (SPE) of the interface to ensure sufficient bit transition density. Both sides of the connection must be configured using the **posscramble-atm** command. Currently, when connecting to a Cisco 7500 series router and using the **posscramble-atm** command, you must specify the **crc16** command rather than the **crc32** command.

Examples

The following example enables scrambling on the interface:

```
Router(config)# interface pos 3/0
Router(config-if)# pos scramble-atm
Router(config-if)# no shutdown
Router(config-if)# end
```

Related Commands

Command	Description
crc	Sets the length of the CRC on an FSIP or HIP of the Cisco 7500 series routers or on a 4-port serial adapter of the Cisco 7200 series routers.
interface	Configures an interface type, and enters interface configuration mode.
show diag	Displays hardware information for the router.
show interfaces pos	Displays information about the Packet OC-3 interface in Cisco 7500 series routers.

pos threshold

To set the bit-error rate (BER) threshold values of the specified alarms for a POS (Packet-Over-SONET) interface, use the **posthreshold**command in interface configuration mode. To return to the default setting, use the **no** form of this command.

pos threshold {**b1-tca** | **b2-tca** | **b3-tca** | **sd-ber** | **sf-ber**} *rate*
no pos threshold {**b1-tca** | **b2-tca** | **b3-tca** | **sd-ber** | **sf-ber**} *rate*

Syntax Description

b1-tca	B1 BER threshold crossing alarm. The default rate is 6.
b2-tca	B2 BER threshold crossing alarm. The default rate is 6.
b3-tca	B3 BER threshold crossing alarm. The default rate is 6.
sd-ber	Signal degrade BER threshold. The default rate is 6.
sf-ber	Signal failure BER threshold. The default rate is 3 (10e-3).
rate	Bit-error rate from 3 to 9 (10-n).

Command Default

The default rate is 6 for **b1-tca**, **b2-tca**, **b3-tca**, and **sd-ber**. The default rateis 3 (10e-3) for **sf-ber**.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

For B1, the bit interleaved parity error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B1 byte of the following frame. Differences indicate that section level bit errors have occurred.

For B2, the bit interleaved parity error report is calculated by comparing the BIP-8/24 code with the BIP-8 code extracted from the B2 byte of the following frame. Differences indicate that line level bit errors have occurred.

For B3, the bit interleaved parity error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B3 byte of the following frame. Differences indicate that path level bit errors have occurred.

SF-BER and SD-BER are sourced from B2 BIP-8 error counts (as is B2-TCA). However, SF-BER and SD-BER feed into the automatic protection switching (APS) machine and can lead to a protection switch (if APS is configured).

B1-TCA, B2-TCA, and B3-TCA do nothing more than print a log message to the console (if reports for them are enabled).

To determine the BER thresholds configured on the interface, use the **showcontrollerspos**command.

Examples

The following example configures thresholds on the interface:

```
Router(config)# interface pos 3/0/0
Router(config-if)# pos threshold sd-ber 8
Router(config-if)# pos threshold sf-ber 4
Router(config-if)# pos threshold b1-tca 4
Router(config-if)# end
```

Related Commands

Command	Description
interface	Configures an interface type, and enters interface configuration mode.
pos report	Permits selected SONET alarms to be logged to the console for a POS interface.
show controllers pos	Displays information about the POS controllers.

power inline

To determine how inline power is applied to the device on the specified switch port, use the **powerinline** command in interface configuration mode. To return the setting to its default, use the **no** form of this command.

power inline {**auto** [**max** *max-milliwatts*] | **never** | **police** | **static** [**max** *max-milliwatts*]}
no power inline [**police**]

Cisco Integrated Services Routers Generation 2 (ISR G2) with Cisco Gigabit EtherSwitch enhanced high-speed WAN interface cards (EHWICs)
power inline {**auto** | **never** | **port max** *max-milliwatts*}
no power inline {**auto** | **never** | **port max** *max-milliwatts*}

Cisco 4451-X Integrated Services Router
power inline
auto | [**max** *max-milliwatts*] | **never** | **redundant**
no power inline
auto | [**max** *max-milliwatts*] | **never** | **redundant**

Syntax Description

auto	Turns on the device discovery protocol and applies power to the device, if found.
max *max-milliwatts*	(Optional) Specifies the maximum amount of power, in milliwatts, that a device connected to a port can consume. Range: 4000 to 16800. Default: 15400.
never	Turns off the device discovery protocol and stops supplying power to the device.
police	Turns on inline power policing; optional if entering the **no** form of the command. Default is disabled.
static	Allocates power from the system power pool to a port.
port max *max-milliwatts*	Specifies the maximum power allocated to the port. The maximum power can be set between 4,000 to 20,000 milliwatts.
redundant	Puts the inline power supply in redundant mode (default mode). (For boost mode, use the no form of the command; for example, **no power inline redundant**.)

Command Default

Power is applied when a telephone is detected on the port (**auto**).*max-milliwatts* is 15400 milliwatts. Inline power policing is disabled.

Power is applied when a telephone is detected on the port (auto). The maximum power limit is 20000 milliwatts. Inline power policing is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
12.0(5)XU	This command was introduced.
12.2(2)XT	This command was integrated to support switchport creation on Cisco 2600 series, Cisco 3600 series, and Cisco 3700 series routers.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T to support switchport creation .
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17b)SXA	This command was changed to include the **static** and **max***max-milliwatts* keywords and arguments.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SXH	This command was changed to include the **police** keyword .
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH2	This command was changed to increase the *max-watts* maximum to 16800 milliwatts for the WS-F6K-48-AF and the WS-F6K-GE48-AF modules. The default setting remains 15400 milliwatts. See the "Usage Guidelines" section for additional information.
15.1(2)T	This command was modified. The **portmax**keyword and *max-milliwatts* argument were added.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Usage Guidelines

The **police**keyword appears if you have a WS-F6K-48-AF or other inline power daughter card that supports power monitoring and inline power policing.

Inline power is supported only on switch ports that are connected to an IP phone. Before you enable inline power on a switch port, you must enter the **switchport** command.

The following information applies to WS-F6K-48-AF and WS-F6K-GE48-AF inline power cards:

- In Cisco IOS Release 12.2(33)SXH2 and later releases, the configurable range of maximum power using the max keyword is 4000 to 16800 milliwatts. For earlier releases, the configurable range for maximum power is 4000 to 15400 milliwatts. For all releases, if no maximum power level is configured, the default maximum power is 15400 milliwatts.

Note To support a large number of inline-powered ports using power levels above 15400 milliwatts on an inline power card, we recommend using the static keyword so that the power budget is deterministic.

- In Cisco IOS Release 12.2(33)SXH2 and later releases, when you enter the auto keyword and CDP is enabled on the port, an inline-powered device that supports CDP can negotiate a power level up to 16800 milliwatts unless a lower maximum power level is configured. For earlier releases, the inline-powered device can negotiate a power level up to 15400 milliwatts or the configured maximum power level, if it is configured lower than 15400 milliwatts.

Cisco ISR G2 with Cisco Gigabit EHWICs

- The **portmax**keyword and *max-milliwatts* argument are available only on the Firebee cards with Power-over-Ethernet (PoE).

Examples

The following example shows how to set the inline power to the off mode on a switch port:

```
Router(config)# interface fastethernet5/1
Router(config-if)# switchport
Router(config-if)# power inline never
```

The following example shows how to allocate power from the system power pool to a switch port:

```
Router(config)# interface fastethernet5/1
Router(config-if)# switchport
Router(config-if)# power inline static max 15000
```

The following example shows how to turn on inline power policing to a switch port:

```
Router(config)# interface gigabitethernet6/3
Router(config-if)# switchport
Router(config-if)# power inline police
```

Cisco ISR G2 with Cisco Gigabit EtherSwitch EHWICs

The following example shows how to turn on inline power to a switch port:

```
Router(config)# interface gigabitethernet
0/1/3
Router(config-if)#
power inline
auto{!-condition!}
```

The following example shows how to set maximum inline power to a switch port:

```
Router(config)# interface
 gigabitethernet
0/1/3
```

The following example shows how to disable inline power to the switch port:

```
Router(config)# interface
 gigabitethernet

0/1/3
Router(config-if)# power inline
 never{!-condition!}
```

Cisco 4451-X Integrated Service Router

The following example shows auto option for power inline command configured on the front panel Gigabit Ethernet port.

```
Router(config)# interface gigabitEthernet 0/0/0
Router(config-if)# power inline auto
```

In this example, an attempt is made to configure the inline power to be in boost mode by using the **no** form of the **power inline redundant** command. The inline power mode is not changed to boost mode because that requires a total power available in redundant mode of 1000W.

```
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 2000 Watts
POE Module :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1000 Watts
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# no power inline redundant
*Jan 31 03:42:40.947: %PLATFORM_POWER-6-MODEMISMATCH: Inline power not in Boost mode
Router(config)# exit
*Jan 31 03:36:13.111: %SYS-5-CONFIG_I: Configured from console by console
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1450 Watts
POE Module :
Configured Mode : Boost
Current runtime state same : No
Total power available : 500 Watts
```

In this example, power for the main power supply is configured to be in boost mode by using the **no** form of the **power main redundant** command. This sets the power for the main power supply in boost mode to be 1450 W and the inline power in redundant mode as 500W.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# no power main redundant
Router(config)#
*Jan 31 03:35:22.284: %PLATFORM_POWER-6-MODEMATCH: Inline power is in Redundant mode
Router(config)#
Router(config)# exit
Router#
*Jan 31 03:36:13.111: %SYS-5-CONFIG_I: Configured from console by console
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1450 Watts
POE Module :
Configured Mode : Redundant
Current runtime state same : Yes
Total power available : 500 Watts
Router#
```

Related Commands

Command	Description
show power inline	Displays the power status for the specified port or for all ports.
switchport priority extend	Determines how the telephone connected to the specified port handles priority traffic received on its incoming port.
switchport voice vlan	Configures the voice VLAN on the port.

power enable

To turn on power for the modules, use the **power enable**command in global configuration mode. To power down a module, use the **no** form of this command.

power enable module *slot*
no power enable module *slot*

Syntax Description

module *slot*	Specifies a module slot number; see the "Usage Guidelines" section for valid values.

Command Default

Enabled

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXD	This command was changed to allow you to disable power to empty slots.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

When you enter the **no power enable module** *slot* command to power down a module, the module's configuration is not saved.

When you enter the **no power enable module** *slot* command to power down an empty slot, the configuration is saved.

The *slot* argument designates the module number. Valid values for *slot*depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values for the module number are from 1 to 13.

Examples

This example shows how to turn on the power for a module that was previously powered down:

```
Router(config)#
power enable module 5
Router(config)#
```

This example shows how to power down a module:

```
Router(config)#
no power enable module 5
Router(config)#
```

Related Commands

Command	Description
show power	Displays information about the power status.

power inline

To determine how inline power is applied to the device on the specified switch port, use the **powerinline** command in interface configuration mode. To return the setting to its default, use the **no** form of this command.

power inline {**auto** [**max** *max-milliwatts*] | **never** | **police** | **static** [**max** *max-milliwatts*]}
no power inline [**police**]

Cisco Integrated Services Routers Generation 2 (ISR G2) with Cisco Gigabit EtherSwitch enhanced high-speed WAN interface cards (EHWICs)
power inline {**auto** | **never** | **port max** *max-milliwatts*}
no power inline {**auto** | **never** | **port max** *max-milliwatts*}

Cisco 4451-X Integrated Services Router
power inline
auto | [**max** *max-milliwatts*] | **never** | **redundant**
no power inline
auto | [**max** *max-milliwatts*] | **never** | **redundant**

Syntax Description

auto	Turns on the device discovery protocol and applies power to the device, if found.
max *max-milliwatts*	(Optional) Specifies the maximum amount of power, in milliwatts, that a device connected to a port can consume. Range: 4000 to 16800. Default: 15400.
never	Turns off the device discovery protocol and stops supplying power to the device.
police	Turns on inline power policing; optional if entering the **no** form of the command. Default is disabled.
static	Allocates power from the system power pool to a port.
port max *max-milliwatts*	Specifies the maximum power allocated to the port. The maximum power can be set between 4,000 to 20,000 milliwatts.
redundant	Puts the inline power supply in redundant mode (default mode). (For boost mode, use the no form of the command; for example, **no power inline redundant**.)

Command Default

Power is applied when a telephone is detected on the port (**auto**).*max-milliwatts* is 15400 milliwatts. Inline power policing is disabled.

Power is applied when a telephone is detected on the port (auto). The maximum power limit is 20000 milliwatts. Inline power policing is disabled.

12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17b)SXA	This command was changed to include the **static** and **max***max-milliwatts* keywords and arguments.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(33)SXH	This command was changed to include the **police** keyword .
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXH2	This command was changed to increase the *max-watts* maximum to 16800 milliwatts for the WS-F6K-48-AF and the WS-F6K-GE48-AF modules. The default setting remains 15400 milliwatts. See the "Usage Guidelines" section for additional information.
15.1(2)T	This command was modified. The **portmax**keyword and *max-milliwatts* argument were added.
Cisco IOS XE Release 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Usage Guidelines

The **police**keyword appears if you have a WS-F6K-48-AF or other inline power daughter card that supports power monitoring and inline power policing.

Inline power is supported only on switch ports that are connected to an IP phone. Before you enable inline power on a switch port, you must enter the **switchport** command.

The following information applies to WS-F6K-48-AF and WS-F6K-GE48-AF inline power cards:

- In Cisco IOS Release 12.2(33)SXH2 and later releases, the configurable range of maximum power using the max keyword is 4000 to 16800 milliwatts. For earlier releases, the configurable range for maximum power is 4000 to 15400 milliwatts. For all releases, if no maximum power level is configured, the default maximum power is 15400 milliwatts.

Note To support a large number of inline-powered ports using power levels above 15400 milliwatts on an inline power card, we recommend using the static keyword so that the power budget is deterministic.

- In Cisco IOS Release 12.2(33)SXH2 and later releases, when you enter the auto keyword and CDP is enabled on the port, an inline-powered device that supports CDP can negotiate a power level up to 16800 milliwatts unless a lower maximum power level is configured. For earlier releases, the inline-powered device can negotiate a power level up to 15400 milliwatts or the configured maximum power level, if it is configured lower than 15400 milliwatts.

Cisco ISR G2 with Cisco Gigabit EHWICs

- The **portmax**keyword and *max-milliwatts* argument are available only on the Firebee cards with Power-over-Ethernet (PoE).

Examples

The following example shows how to set the inline power to the off mode on a switch port:

```
Router(config)# interface fastethernet5/1
Router(config-if)# switchport
Router(config-if)# power inline never
```

The following example shows how to allocate power from the system power pool to a switch port:

```
Router(config)# interface fastethernet5/1
Router(config-if)# switchport
Router(config-if)# power inline static max 15000
```

The following example shows how to turn on inline power policing to a switch port:

```
Router(config)# interface gigabitethernet6/3
Router(config-if)# switchport
Router(config-if)# power inline police
```

Cisco ISR G2 with Cisco Gigabit EtherSwitch EHWICs

The following example shows how to turn on inline power to a switch port:

```
Router(config)# interface gigabitethernet
0/1/3
Router(config-if)#
power inline
auto{!-condition!}
```

The following example shows how to set maximum inline power to a switch port:

```
Router(config)# interface
 gigabitethernet
0/1/3
```

The following example shows how to disable inline power to the switch port:

```
Router(config)# interface
 gigabitethernet

0/1/3
Router(config-if)# power inline
 never{!-condition!}
```

Cisco 4451-X Integrated Service Router

The following example shows auto option for power inline command configured on the front panel Gigabit Ethernet port.

```
Router(config)# interface gigabitEthernet 0/0/0
Router(config-if)# power inline auto
```

In this example, an attempt is made to configure the inline power to be in boost mode by using the **no** form of the **power inline redundant** command. The inline power mode is not changed to boost mode because that requires a total power available in redundant mode of 1000W.

```
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 2000 Watts
POE Module :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1000 Watts
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# no power inline redundant
*Jan 31 03:42:40.947: %PLATFORM_POWER-6-MODEMISMATCH: Inline power not in Boost mode
Router(config)# exit
*Jan 31 03:36:13.111: %SYS-5-CONFIG_I: Configured from console by console
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1450 Watts
POE Module :
Configured Mode : Boost
Current runtime state same : No
Total power available : 500 Watts
```

In this example, power for the main power supply is configured to be in boost mode by using the **no** form of the **power main redundant** command. This sets the power for the main power supply in boost mode to be 1450 W and the inline power in redundant mode as 500W.

```
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router(config)# no power main redundant
Router(config)#
*Jan 31 03:35:22.284: %PLATFORM_POWER-6-MODEMATCH: Inline power is in Redundant mode
Router(config)#
Router(config)# exit
Router#
*Jan 31 03:36:13.111: %SYS-5-CONFIG_I: Configured from console by console
Router# show power
Main PSU :
Configured Mode : Boost
Current runtime state same : Yes
Total power available : 1450 Watts
POE Module :
Configured Mode : Redundant
Current runtime state same : Yes
Total power available : 500 Watts
Router#
```

Related Commands

Command	Description
show power inline	Displays the power status for the specified port or for all ports.
switchport priority extend	Determines how the telephone connected to the specified port handles priority traffic received on its incoming port.
switchport voice vlan	Configures the voice VLAN on the port.

power redundancy-mode

To set the power-supply redundancy mode, use the **power redundancy-mode** command in global configuration mode.

power redundancy-mode {**combined** | **redundant**}

Syntax Description

combined	Specifies no redundancy (combine power-supply outputs).
redundant	Specifies redundancy (either power supply can operate the system).

Command Default

redundant

Command Modes

Global configuration

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to set the power supplies to the no-redundancy mode:

```
Router(config)#
power redundancy-mode combined
Router(config)#
```

This example shows how to set the power supplies to the redundancy mode:

```
Router(config)#
power redundancy-mode redundant
Router(config)#
```

Related Commands

Command	Description
show power	Displays information about the power status.

ppp link

To generate the Point-to-Point Protocol (PPP) Link Control Protocol (LCP) down and keepalive-failure link traps or enable calls to the interface-reset vector, use the **ppplink**command in interface configuration mode. To disable the PPP LCP down and keepalive-failure link traps or calls to the interface-reset vector, use the **no** form of this command.

ppp link {**reset** | **trap**}
no ppp link {**reset** | **trap**}

Syntax Description

reset	Specifies calls to the interface reset vector.
trap	Specifies the PPP LCP down and keepalive-failure link traps.

Command Default

The defaults are as follows:

- The calls are sent to the interface-reset vector.
- The traps are sent when the LCP goes down.

Command Modes

Interface configuration

Command History

Release	Modification
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported on Cisco 7600 series routers that are configured with a Supervisor Engine 720.

The **noppplinktrap** command disables the sending of the link traps when the LCP goes down.

In the event that the PPP calls the interface-reset vector while the LCP is configured or closed, Up/Down status messages will display on the console. If a leased-line configuration is up but the peer is not responding, PPP may call the interface-reset vector once per minute. This situation may result in the Up/Down status messages on the console. Use the **noppplinkreset**command to disable calls to the interface-reset vector. PPP will continue to attempt to negotiate with the peer, but the interface will not be reset between each attempt.

Examples

This example shows how to enable calls to the interface-reset vector:

```
Router(config-if)#
ppp link reset
Router(config-if)#
```

This example shows how to disable calls to the interface-reset vector:

```
Router(config-if)#
no ppp link reset
Router(config-if)#
```

This example shows how to generate the PPP LCP down/keepalive-failure link traps:

```
Router(config-if)#
ppp link trap
Router(config-if)#
```

This example shows how to disable the sending of the link traps when the LCP goes down:

```
Router(config-if)#
no ppp link trap
Router(config-if)#
```

ppp loopback no-backoff

To enable continuous Link Control Protocol (LCP) negotiation of loopback links with PPP sessions, use the **ppp loopback no-backoff** command in interface configuration mode. To restrict negotiation of loopback links with PPP sessions to ten LCP Configure Request (CONFREQ) messages, use the **no** form of this command.

ppp loopback no-backoff

no ppp loopback no-backoff

Command Default

Loopback links with PPP sessions disconnect after ten LCP CONFREQ messages are sent for negotiation.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
Cisco IOS XE Release 3.10.1S	This command was introduced.

Usage Guidelines

A circuit loopback indicates wiring issues in a device or faults with external switching equipment. The default functionality of the PPP protocol is to check for loopbacks and disconnect the session link when a loopback is detected. The PPP protocol includes a mechanism that detects a circuit loopback; that is, it detects a situation when a circuit feeds back upon itself, which results in the device reading its own output on that link. The first phase of loopback detection occurs during LCP negotiation when the circuit is being established. If you enable keepalives on a link, the second phase of loopback detection occurs after the connection is established.

Note Loopback detection depends upon successful negotiation of the LCP magic number during link establishment. LCP magic numbers are used in PPP to avoid frame loopbacks.

Use the **ppp loopback no-backoff** command when it becomes essential to prevent disconnection of session links whenever a loopback is detected. This ensures that the link does not go down and that there is a continuous attempt to establish connection. Link negotiations continue until a unique LCP magic number is received. The **no** form of this command restores the default behavior in which the loopback links with PPP sessions disconnect after only ten LCP CONFREQ messages are sent for negotiation.

Example

The following example shows how to enable the **ppp loopback no-backoff** command on a serial interface:

```
Device> enable
Device# configure terminal
Device(config)# interface Serial1/0/0:1
Device(config-if)# no ip address
Device(config-if)# encapsulation ppp
Device(config-if)# ppp loopback no-backoff
Device(config-if)# end
```

Related Commands

Command	Description
encapsulation ppp	Enables PPP on an interface.
no ip address	Removes an IP address or disables IP processing.
ppp loopback ignore	Disables PPP loopback detection.

ppp multilink mrru

To configure the maximum receive reconstructed unit (MRRU) value negotiated on a Multilink PPP (MLP) bundle, use the **pppmultilinkmrru**command in interface configuration mode. To remove the configured MRRU, use the **no** form of this command.

ppp multilink mrru [{**local** | **remote**}] **bytes**
no ppp multilink mrru [{**local** | **remote**}] **bytes**

Syntax Description

local	(Optional) Configures the local MRRU value.
remote	(Optional) Configures the minimum value that the software will accept from the peer when it advertises its MRRU.
bytes	MRRU value, in bytes. Valid value range is 128 to 16384.

Command Default

The default values for the local MRRU are the value of the multilink group interface maximum transmission unit (MTU) for multilink group members, and 1524 bytes for all other interfaces.

Command Modes

Interface configuration

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.0(28)S	This command was integrated into Cisco IOS Release 12.0(28)S.
12.2(27)SB	This command was integrated into Cisco IOS Release 12.2(27)SB.
12.2(28)S	This command was integrated into Cisco IOS Release 12.2(28)S.
12.2(31)SB	This command was integrated into Cisco IOS Release 12.2(31)SB.
12.2(33)SRB1	This command was integrated into Cisco IOS Release 12.2(33)SRB1.
12.2(33)SRC	This command was integrated into Cisco IOS Release 12.2(33)SRC.
15.2(2)SNI	This command was implemented on the Cisco ASR 901 Series Aggregation Services Routers.

Usage Guidelines

This command allows the MRRU value to be configured on MLP interfaces and member links. This command is useful for interfaces running an application such as IP Security (IPsec), where the addition of the IPsec header causes the packet to exceed the 1500-byte MTU of a typical IP packet.

When using a large-bundle interface MTU size, you must ensure that the individual frames-per-fragment size passed to the link interfaces is not greater than the link interface MTU setting or the peer MRRU setting. This size limit can be achieved in one of the following two ways:

- Configure the link interface MTU setting appropriately.
- Configure fragmentation such that the link MTU settings will never be violated.

When MLP is configured, several physical interfaces can constitute one logical connection to the peer. To represent the logical connection, software provides a logical interface, often called the bundle interface. This interface will have the IP address, for instance, and the MTU setting of the interface that IP uses when it is deciding whether to fragment an IP datagram that needs to be forwarded. The physical interfaces forward individual MLP fragments or frames that are given to them by the bundle interface.

The result of having to decide whether to fragment a packet is that, whereas with simple PPP the interface MTU must not exceed the peer's MRRU, with MLP the MTU size of the bundle interface must not exceed the MRRU setting of the peer.

The MRRU settings on both sides need not be equal, but the "must not exceed" rule just specified must be followed; otherwise a system might send several fragments that, when reconstructed as a frame, will be too large for the peer's receive buffer.

Once you configure the MRRU on the bundle interface, you enable the router to receive large reconstructed MLP frames. You may want to configure the bundle MTU so that the router can send large MLP frames, although it is not strictly necessary. The maximum recommended value for the bundle MTU is the value of the peer's MTU. The software will automatically reduce the bundle interface MTU if necessary to avoid violating the peer's MRRU.

When the bundle interface MTU is tuned to a higher number, then depending upon the fragmentation configuration, the link interface may be given larger frames to send. There are two possible solutions to this problem, as follows:

- Ensure that fragmentation is performed such that fragments are sized less than the link interface MTU (refer to the command pages for the **pppmultilinkfragmentdisable** and **pppmultilinkfragmentdelay** commands for more information about packet fragments).
- Configure the MTUs of the link interfaces such that they can send the larger frames.

Note Be careful when configuring MLP MRRU negotiation in a virtual private dialup network (VPDN) environment when an L2TP network server (LNS) is not running Cisco IOS Release 12.3(7)T. The software performs strict matching on the MRRU values in earlier versions of Cisco IOS software.

Examples

The following example shows how to configure MRRU negotiation on a virtual template with synchronous serial interfaces. The example also applies to asynchronous serial interfaces.

```
multilink virtual-template 1
!
interface virtual-template 1
 ip address 10.13.1.1 255.255.255.0
 mtu 1600
!
interface serial 0/0
 ppp multilink
 ppp multilink mrru local 1600
 mtu 1600
!
interface serial 0/1
 ppp multilink
 ppp multilink mrru local 1600
```

mtu 1600

The following example shows how to configure MRRU negotiation on multilink groups:

```
interface multilink 10
 ip address 10.13.1.1 255.255.255.0
 ppp multilink mrru local 1600
 mtu 1600
!
interface serial 0/0
 ppp multilink
 multilink-group 10
 mtu 1600
!
interface serial 0/1
 ppp multilink
 multilink-group 10
 mtu 1600
```

The following example shows how to configure MRRU negotiation on dialer interfaces:

Note Dialer interfaces are not supported on the Cisco 7600 series router.

```
interface dialer 1
 ip address 10.13.1.1 255.255.255.0
 encapsulation ppp
 dialer remote-name 2610-2
 dialer idle-timeout 30 inbound
 dialer string 5550101
 dialer pool 1
 dialer-group 1
 no cdp enable
 ppp multilink
 ppp multilink mrru local 1600
```

Related Commands

Command	Description
encapsulation ppp	Sets the PPP encapsulation method.
interface dialer	Defines a dialer rotary group.
mtu	Adjusts the maximum packet size or MTU size.
multilink virtual-template	Specifies a virtual template from which the specified MLP bundle interface can clone its interface parameters.
ppp multilink	Enables MLP on an interface.
ppp multilink fragment delay	Specifies a maximum time for the transmission of a packet fragment on an MLP bundle.
ppp multilink fragment disable	Disables packet fragmentation.
ppp multilink fragmentation	Sets the maximum number of fragments a packet will be segmented into before being sent over the bundle.

Command	Description
ppp multilink group	Restricts a physical link to joining only a designated multilink-group interface.
ppp multilink interleave	Enables MLP interleaving.

pri-group

To specify ISDN PRI on a channelized E1 or T1 card on a Cisco 7500 series router, use the **pri-group** command in controller configuration mode. To remove the ISDN PRI, use the **no** form of this command.

pri-group commandpri-group [**timeslots** *range*]
no pri-group

Syntax Description

timeslots *range*	(Optional) Specifies a single range of values from 1 to 23.

Command Default

Disabled

Command Modes

Controller configuration

Command History

Release	Modification
11.0	This command was introduced.
12.2(13)T	This command is no longer supported in Cisco IOS Mainline or Technology-based releases. It may conintue to appear in Cisco IOS 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When you configure ISDN PRI, you must first specify an ISDN switch type for PRI and an E1 or T1 controller.

Examples

The following example specifies ISDN PRI on T1 slot 1, port 0:

```
Router# isdn switch-type primary-4ess
Router(config)# controllers t1 1/0
Router(config-controller)# framing esf
Router(config-controller)# linecode b8zs
Router(config-controller)# pri-group timeslots 2-6
```

Related Commands

Command	Description
controller	Configures a T1 or E1 controller and enters controller configuration mode.
interface serial	Specifies a serial interface created on a channelized E1 or channelized T1 controller (for ISDN PRI, CAS, or robbed-bit signaling).
isdn switch-type (PRI)	Specifies the central office switch type on the ISDN PRI interface.

priority1

To set a preference level for a Precision Time Protocol clock, use the **priority1** command in PTP clock configuration mode. To remove a priority1 configuration, use the **no** form of this command.

priority1 *priorityvalue*
no priority1 *priorityvalue*

Syntax Description

priorityvalue	Number value of the preference level. The range is from 0 to 255; lower values indicate a higher precedence. The default value is 128.

Command Default

The default preference level is 128.

Command Modes

PTP clock configuration (config-ptp-clk)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Subordinate devices use the priority1 value when selecting a primary clock. The priority1 value has precedence over the priority2 value.

Examples

The following example shows how to configure a ptp priority1 value:

```
Device> enable
Device# configure terminal
Device# ptp clock ordinary domain 0
Device(config-ptp-clk)# priority1 128
Device(config-ptp-clk)# end
```

Related Commands

Command	Description
priority2	Sets the PTP priority2 value.

priority2

To set a set a secondary preference level for a Precision Time Protocol clock, use the **priority2** command in PTP clock configuration mode. To remove a priority2 configuration, use the **no** form of this command.

priority2 *priorityvalue*
no priority2 *priorityvalue*

Syntax Description

priorityvalue	The number value of the preference level. The range is from 0 to 255; lower values indicate a higher precedence. The default value is 128.

Command Default

The default preference level is 128.

Command Modes

PTP clock configuration (config-ptp-clk)

Command History

Release	Modification
15.0(1)S	This command was introduced.
15.1(2)SNG	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Usage Guidelines

Subordinate devices use the priority2 value to select a primary clock; the priority2 value is only considered when the device cannot use priority1 and other clock attributes to select a clock.

Examples

The following example shows how to configure the ptp priority2 value:

```
Device> enable
Device# configure terminal
Device# ptp clock ordinary domain 0
Device(config-ptp-clk)# priority2 128
Device(config-ptp-clk)# end
```

Related Commands

Command	Description
priority1	Sets the PTP priority1 value.

proactive enable

To enable automatic triggering of Forward Error Correction-Fast Re-Route (FEC-FRR), use the **proactive enable** command in DWDM configuration mode. To disable automatic triggering, use the no form of this command.

proactive enable

This command has no arguments or keywords.

Command Modes

DWDM Controller (config-controller)

Command History

Release	Modification
15.2(1)S	This command was introduced on the Cisco 7600 series routers.

Usage Guidelines

Examples

This example shows how to enable automatic triggering of Forward Error Correction-Fast Re-Route (FEC-FRR):

```
Router# configure terminal
Router(config)# controller dwdm 0/1
Router(config-controller)# proactive enable
```

Related Commands

Command	Description
proactive trig-threshold	Configures the trigger threshold of Forward Error Correction-Fast Re-Route (FEC-FRR).
proactive trig-window	Configures the trigger window (in milliseconds) in which Fast Re-Route may be triggered.
proactive rvrt-threshold	Configures the revert threshold to trigger reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route.
proactive rvrt-window	Configures the revert window in which reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route is triggered.

proactive rvrt-threshold

To configure the revert threshold to trigger reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route, use the **proactive rvrt-threshold** command in DWDM configuration mode. To remove the revert threshold, use the **no** form of this command.

proactive rvrt-threshold *x-coeff y-power*
no proactive rvrt-threshold *x-coeff y-power*

Syntax Description

x-coeff	Bit error rate coefficient (x of xE-y). The range is 1 to 9.
y-power	Bit error rate exponent (y of xE-y). The range is 3 to 9.

Command Default

Standard FEC mode: 1E-5

Enhanced FEC Mode: 1E-4

Command Modes

DWDM Controller (config-controller)

Command History

Release	Modification
15.2(1)S	This command was introduced on the Cisco 7600 series routers.

Examples

This example shows how to configure the revert threshold for FEC-FRR:

```
Router>enable
Router# configure terminal
Ruter(config)# controller dwdm 0/1
Router(config-controller)# proactive rvrt-threshold 1 6
```

Related Commands

Command	Description
proactive enable	Enables automatic triggering of Forward Error Correction-Fast Re-Route (FEC-FRR).
proactive trig-threshold	Configures the trigger threshold of Forward Error Correction-Fast Re-Route (FEC-FRR).
proactive trig-window	Configures the trigger window in which Fast Re-Route may be triggered.
proactive rvrt-window	Configures the revert window in which reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route is triggered.

proactive rvrt-window

To configure the revert window in which reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route is triggered, use the **proactive rvrt-window** command in DWDM configuration mode. To remove the revert window, use the no form of this command.

proactive rvrt-window *window*
no proactive rvrt-window *window*

Syntax Description

window	The length of time (in milliseconds) of the window in which reverting from FEC-FRR may be triggered. The range is 2000 to 100000.

Command Default

The default value of time is 2000.

Command Modes

DWDM configuration (config-controller)

Command History

Release	Modification
15.2(1)S	This command was introduced on the Cisco 7600 series routers.

Examples

This example shows how to configure the window in which reverting from FEC-FRR may be triggered:

```
Router# configure terminal
Router(config)# controller dwdm 0/1
Router(config-controller)# proactive rvrt-window 20345
```

Related Commands

proactive rvrt-threshold	Configures the revert threshold to trigger reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route.

proactive trig-threshold

To configure the trigger threshold of Forward Error Correction-Fast Re-Route (FEC-FRR), use the **proactive trig-threshold** command in DWDM configuration mode. To remove the trigger threshold, use the**no** form of this command.

proactive trig-threshold *x-coeff y-power*
no proactive trig-threshold *x-coeff y-power*

Syntax Description

x-coeff	Bit error rate coefficient (x of xE-y). The range is 1 to 9. Default is 1.
y-power	Bit error rate exponent (y of xE-y). The range is 3 to 9.

Command Default

Standard FEC mode: 6E-5

Enhanced FEC Mode: 6E-4

Command Modes

DWDM Controller (config-controller)

Command History

Release	Modification
15.2(1)S	This command was introduced on the Cisco 7600 series routers.

Examples

This example shows how to configure the trigger threshold of Forward Error Correction-Fast Re-Route (FEC-FRR).

```
Router# configure terminal
Router(config)# controller dwdm 0/1
Router(config-controller)#proactive trig-threshold 1 9
```

Related Commands

Command	Description
proactive enable	Enables automatic triggering of Forward Error Correction-Fast Re-Route (FEC-FRR).
proactive trig-window	Configures the trigger window (in milliseconds) in which Fast Re-Route may be triggered.
proactive rvrt-threshold	Configures the revert threshold to trigger reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route.

Command	Description
proactive rvrt-window	Configures the revert window in which reverting from the Forward Error Correction-Fast Re-Route (FEC-FRR) route back to the original route is triggered.

protection-group

Use this command to configure virtual protection group interface.

protection-group *group id type STS48c*

Syntax Description

Syntax Description:

group id	Identifier for the interface that is created
type	Protection group type It can be STS, STS3c, STS12c, and STS48c

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	Support for this command was introduced for the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

This command is used for configuring protection group parameters.

Examples

The following example shows how to configure protection group:

```
enable
configure terminal
protection-group 401 type STS48c
controller protection group 401
type STS48c
cem-group 19001 cep
end
```

Related Commands

Command	Description
show protection-group	Verifies the protection group configuration.

protection-group [working | protect]

Use this command to configure protection group roles.

protection-group *group id* [**working** | **protect**]

Syntax Description

Syntax Description:

group id	Identifier for the interface that is created
working	The working interface for protection group
protect	The protect interface for protection group

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
Cisco IOS XE Everest 16.5.1	Support for this command was introduced for the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

Define the role either working interface or protect interface in the protection group.

Examples

The following example shows how to configure UPSR work path protection:

```
enable
configure terminal
controller mediatype 0/3/6
mode sonet
controller sonet 0/3/6
rate oc48
sts-1 1-48 mode sts-48c
protection-group 401 working
end
```

Related Commands

Command	Description
show protection-group	Verifies the protection group configuration.

protocol gre

To specify GRE as the tunnel mode and to set the GRE key for configuring the L3VPN encapsulation profile, use the **protocolgre** command in L3 VPN encapsulation configuration mode. To remove the transport source, use the **no** form of this command.

protocol gre [**key** *gre key*]
no protocol [**gre**]

Syntax Description

key	(Optional) Specifies the key for GRE tunnel interface.
gre key	(Optional) The GRE key value. The range is from 0 to 4294967295.

Command Default

The tunnel mode and GRE key are not specified.

Command Modes

L3VPN Encapsulation Configuration (config-l3vpn-encap-ip)

Command History

Release	Modification
12.2(33)SRE	This command was introduced.

Examples

The following example shows how to specify GRE as the tunnel mode and to set the GRE key:

```
Router(config-l3vpn-encap-ip)# protocol gre key 500
```

Related Commands

Command	Description
l3vpn encapsulation ip	Configures the L3VPN encapsulation profile.
transport ipv4	Specifies IPv4 transport source mode and the transport source interface.
show l3vpn encapsulation ip	Displays the profile health and the underlying tunnel interface.

ptp clock

To create a Precision Time Protocol clock and specify the clock mode, use the **ptpclock** command in the global configuration mode. To remove a ptp clock configuration, use the **no** form of this command.

ptp clock {**ordinary** | **transparent**} **boundary domain** *domain*
no ptp clock {**ordinary** | **transparent**} **boundary domain** *domain*

Syntax Description

ordinary	Sets the PTP clock to ordinary clocking mode.
transparent	Sets the PTP clock to transparent clock mode; the router modifies outgoing PTP sync and delay-request messages to account for residence time using the correction field in the follow-up message.
boundary	Sets the PTP clock to boundary clock mode; the router participates in selecting the best master clock and can act as the master clock if no better clocks are detected.
domain	The PTP clocking domain number. Valid values are from 0 to 127.

Command Default

No default behavior or values.

Command Modes

Global configuration (config)

Command History

Release	Modification
15.0(1)S	This command was introduced.

Usage Guidelines

This command creates a new PTP clock and enters clock configuration mode.

Examples

The following example shows how to configure a PTP clock and enter clock configuration mode:

```
Router# configure terminal
Router# ptp clock ordinary domain 0
Router(config-ptp-clk)#
```

Related Commands

Command	Description
clock-port	Specifies the mode of a PTP clock port.

pulse-time

To enable pulsing data terminal ready (DTR) signal intervals on the serial interfaces, use the **pulse-time** command in interface configuration mode. To restore the default interval, use the **no** form of this command.

pulse-time[{**msec***seconds*}]
no pulse-time

Syntax Description

msec	(Optional) Specifies the use of milliseconds for the DTR signal interval.
seconds	Integer that specifies the DTR signal interval in seconds. If the **msec** keyword is configured, the DTR signal interval is specified in milliseconds. The default is 0.

Command Default

0 seconds

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.1(5)T	The optional **msec** keyword was added to configure the interval in milliseconds.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

When the serial line protocol goes down (for example, because of loss of synchronization), the interface hardware is reset and the DTR signal is held inactive for at least the specified interval. This function is useful for handling encrypting or other similar devices that use the toggling of the DTR signal to resynchronize.

Use the optional **msec** keyword to specify the DTR signal interval in milliseconds. A signal interval set to milliseconds is recommended on High-Speed Serial Interfaces (HSSIs).

Note

Whenever the **pulse-time** command is configured for the synchronous serial interface, do one of the following after every interface state transition. This ensures that the DTR is pulsed down for the configured interval:

- In exec mode, issue the **clear interface serial** *x*/*y*/[*z*] command.
- In config mode of the serial interface, issue a **shutdown**, followed by **no shutdown**.

If you do not clear/reset the interface with one of these procedures, the **pulse-time** command will have no effect.

Optionally, you can automate this procedure using an EEM or Tcl script. The following example EEM script clears the serial interface after a disconnection:

```
event manager applet CLEAR_INIT_S000
 event syslog pattern "Line protocol on Interface Serial0/0/0, changed state to down"
 action 2.0 cli command "enable"
 action 2.1 cli command "clear int Serial0/0/0"
 action 3.0 syslog msg "clear int Serial0/0/0"
```

Examples

The following example enables DTR pulse signals for 3 seconds on serial interface 2:

```
Router(config)# interface serial 2
Router(config-if)# pulse-time 3
```

The following example enables DTR pulse signals for 150 milliseconds on HSSI interface 2/1/0:

```
Router(config)# interface hssi 2/1/0
Router(config-if)# pulse-time msec 150
```

rate

Use this command to enable the rate for SONET and SDH ports.

For SONET:

rate [*OC3* | *OC12* | *OC48* | *OC192*

For SDH:

rate [*STM-1* | *STM-4* | *STM-16* | *STM-64*

Syntax Description

Syntax Description:

OC3	Configures OC-3 port.
OC12	Configures OC-12 port.
OC-48	Configures OC-48 port.
OC-192	Configures OC-192 port.
STM-1	Configures STM-1 port.
STM-4	Configures STM-4 port.
STM-16	Configures STM-16 port.
STM-64	Configures STM-64 port.

Command Default

None

Command Modes

Controller configuration

Command History

Release	Modification
XE 3.18SP	Support for this command was introduced on NCS 4200 Series for SONET.
XE Everest 16.6.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series for SDH.

Usage Guidelines

Configuration of this command is mandatory.

Examples

The following example shows how to configure Mediatype controller mode:

```
enable
configure terminal
controller MediaType 0/5/0
mode sonet
controller sonet 0/5/0
rate oc3
end
```

To configure mode VC4 CEP:

```
enable
configure terminal
controller sdh 0/5/0
rate stm 4
aug mapping au-4
au-4 1
mode vc4
cem-group 100 cep
end
```

Related Commands

Command	Description
controller sonet	Configures the SONET mode.
show controller sonet	Displays SONET controller configuration.

recovered-clock

To configure an associated clock ID with the corresponding CEM circuit, use the **recovered-clock** command in global configuration mode.

recovered-clock *bay slot*

Syntax Description

bay	Identifies the bay where the CEM circuit is inserted. On NCS4200 series bay value is 0 always.
slot	Physical slot number. The slot number is in a range either from 0 to 5 or 8 to 13, depending on the slot in which the STM-1 card resides. The slot is always 0 for Cisco NCS 4200 Series. The physical slot ranges from 0 to 5 for Cisco ASR 900 Series Routers. The value of physical slot supported for Cisco ASR 920 Routers is 1.

Command Default

None

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18SP	This command was integrated into Cisco NCS 4200 Series
XE Everest 16.5.1	This command was integrated into Cisco NCS 4200 Series. This command was introduced into Cisco ASR 900 Series routers.

Usage Guidelines

This command will be used when the clock needs to be recovered by the same CEM circuit.

The following example shows how to configure an associated clock ID with the corresponding CEM circuit.

```
recovered-clock 0 3
 clock recovered 1 differential cem 0 1
```

Related Commands

Command	Description
clock recovered adaptive/differential cem	Associates the clock recovered ID to the CEM group.

redundancy

To enter redundancy configuration mode, use the **redundancy**command in global configuration mode. This command does not have a **no** form.

redundancy

Syntax Description

This command has no arguments or keywords.

Command Default

None

Command Modes

Global configuration (config)

Command History

Release	Modification
12.1(5)XV1	This command was introduced on the Cisco AS5800 universal access server.
12.2(4)XF	This command was introduced for the Cisco uBR10012 router.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
12.0(9)SL	This command was integrated into Cisco IOS Release 12.0(9)SL.
12.0(16)ST	This command was implemented on the Cisco 7500 series Internet routers.
12.2(14)S	This command was integrated into Cisco IOS Release 12.2(14)S.
12.2(14)SX	Support for this command was added for the Supervisor Engine 720.
12.2(18)S	This command was implemented on the Cisco 7500 series Internet routers.
12.2(20)S	This command was implemented on the Cisco 7304 router.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.3(7)T	This command was implemented on the Cisco 7500 series Internet routers.
12.2(8)MC2	This command was implemented on the MWR 1900 Mobile Wireless Edge Router (MWR).
12.3(11)T	This command was implemented on the MWR 1900 MWR.
12.3BC	This command was integrated into Cisco IOS Release 12.3BC.
12.0(22)S	This command was implemented on the Cisco 10000 series Internet routers.
12.2(18)SXE2	This command was integrated into Cisco IOS Release 12.2(18)SXE2.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(44)SQ	This command was integrated into Cisco IOS Release 12.2(44)SQ. Support for the Cisco RF Gateway 10 was added.

Release	Modification
12.2(33) SRE	This command was modified. The interchassis subconfiguration mode was added.

Usage Guidelines

Use the **redundancy** command to enter redundancy configuration mode, where you can define aspects of redundancy such as shelf redundancy for the Cisco AS5800 universal access server.

Cisco 10000 Series Router

Before configuring line card redundancy, install the Y-cables. Before deconfiguring redundancy, remove the Y-cables.

The following restrictions apply to line card redundancy on the Cisco 10000 series router:

- Port-level redundancy is not supported.
- Redundant cards must occupy the two subslots within the same physical line card slot.
- The line card that will act as the primary line card must be the first line card configured, and it must occupy subslot 1.

Cisco 7600 Series Router

From redundancy configuration mode, you can enter the main CPU submode to manually synchronize the configurations that are used by the two supervisor engines.

From the main CPU submode, you can use the **auto-sync** command to use all the redundancy commands that are applicable to the main CPU.

To select the type of redundancy mode, use the **mode** command.

Nonstop forwarding (NSF) with stateful switchover (SSO) redundancy mode supports IPv4. NSF with SSO redundancy mode does not support IPv6, Internetwork Packet Exchange (IPX), and Multiprotocol Label Switching (MPLS).

After you enter redundancy configuration mode, you can use the **interchassis** command to specify the redundancy group number and enter interchassis redundancy mode. In the interchassis redundancy configuration mode, you can do the following:

- Specify a backbone interface for the redundancy group using the **backbone** command.
- Exit from interchassis configuration mode using the **exit** command.
- Specify the IP address of the remote redundancy group member using the **member ip** command.
- Specify the multichassis LACP (mLACP) node ID, system MAC address, and system priority using the **node-id**, **system-mac**, and **system-priority** commands.
- Define the peer monitoring method using the **monitor** command.

Cisco uBR10012 Universal Broadband Router

After you enter redundancy configuration mode, you can use the **main-cpu** command to enter main-CPU redundancy configuration mode, which allows you to specify which files are synchronized between the active and standby Performance Routing Engine (PRE) modules.

Cisco RF Gateway 10

At the redundancy configuration mode, you can do the following:

- Set a command to its default mode using the **default** command.
- Exit from a redundancy configuration using the **exit** command.
- Enter the line card group redundancy configuration using the **linecard-group** command.
- Enter main-CPU redundancy configuration mode using the **main-cpu** command, which allows you to specify which files are synchronized between the active and standby Supervisor cards.
- Configure the redundancy mode for the chassis using the **mode** command.
- Enforce a redundancy policy using the **policy** command.

Examples

The following example shows how to enable redundancy mode:

```
Router(config)# redundancy
Router(config-red)#
```

The following example shows how to assign the configured router shelf to the redundancy pair designated as 25. This command must be issued on both router shelves in the redundant router-shelf pair:

```
Router(config)# redundancy
Router(config-red)# failover group-number 25
```

Cisco 10000 Series Router

The following example shows how to configure two 4-port channelized T3 half eight line cards that are installed in line card slot 2 for one-to-one redundancy:

```
Router(config)# redundancy
Router(config-r)# linecard-group 1 y-cable
Router(config-r-lc)# member subslot 2/1 primary
Router(config-r-lc)# member subslot 2/0 secondary
```

Cisco 7600 Series Router

The following example shows how to enter the main CPU submode:

```
Router(config)#
redundancy
Router(config-r)#
main-cpu
Router(config-r-mc)#
```

Cisco uBR10012 Universal Broadband Router

The following example shows how to enter redundancy configuration mode and display the commands that are available in that mode on the Cisco uBR10012 router:

```
Router# configure terminal
```

```
Router(config)# redundancy

Router(config-r)# ?

Redundancy configuration commands:
  associate  Associate redundant slots
  exit       Exit from redundancy configuration mode
  main-cpu   Enter main-cpu mode
  no         Negate a command or set its defaults
```

The following example shows how to enter redundancy configuration mode and displays its associated commands on the Cisco RFGW-10 chassis:

```
Router# configure terminal
Router(config)# redundancy
Router(config-r)#?
Redundancy configuration commands:
  default         Set a command to its defaults
  exit            Exit from redundancy configuration mode
  linecard-group  Enter linecard redundancy submode
  main-cpu        Enter main-cpu mode
  mode            redundancy mode for this chassis
  no              Negate a command or set its defaults
  policy          redundancy policy enforcement
```

The following example shows how to enter redundancy configuration mode and its associated commands in the interchassis mode:

```
Router# configure terminal
Router(config)# redundancy
```

Router(config-r)#?

```
Redundancy configuration commands:
  exit          Exit from redundancy configuration mode
  interchassis  Enter interchassis mode
  no            Negate a command or set its defaults
Router(config-r)# interchassis group 100

R1(config-r-ic)# ?
Interchassis redundancy configuration commands:
  backbone  specify a backbone interface for the redundancy group
  exit      Exit from interchassis configuration mode
  member    specify a redundancy group member
  mlacp     mLACP interchassis redundancy group subcommands
  monitor   define the peer monitoring method
  no        Negate a command or set its defaults
```

Related Commands

Command	Description
associate slot	Logically associates slots for APS processor redundancy.
auto-sync	Enables automatic synchronization of the configuration files in NVRAM.
clear redundancy history	Clears the redundancy event history log.
linecard-group y-cable	Creates a line card group for one-to-one line card redundancy.

Command	Description
main-cpu	Enters main-CPU redundancy configuration mode for synchronization of the active and standby PRE modules or Supervisor cards.
member subslot	Configures the redundancy role of a line card.
mode (redundancy)	Configures the redundancy mode of operation.
redundancy force-switchover	Switches control of a router from the active RP to the standby RP.
show redundancy	Displays information about the current redundant configuration and recent changes in states or displays current or historical status and related information on planned or logged handovers. In the redundancy configuration of Cisco ASR 920 Series Routers, the commands related to MR-APS feature are only supported.

redundancy all-active replicate

To enable all-active pseudowire redundancy mode with traffic replication, use the **redundancy all-active replicate** command in global or interface configuration mode. To disable this functionality, use the **no** form of this command.

redundancy all-activereplicate
no redundancy all-activereplicate

Syntax Description

replicate	Replicates the pseudowire state on the router.

Command Default

No default behavior or values.

Command Modes

Global configuration (config)

Interface configuration (config-if)

Command History

Release	Modification
Cisco IOS XE Release 3.18.1SP	This command was introduced on the Cisco ASR 900 Series Routers.

Usage Guidelines

The **redundancy all-active replicate** command maintains the working ad protect pseudowires in a pseudowire redundancy configuration with MR-APS configuration to remain in the UP state.

Examples

The following example shows the configuration at global level:

```
pseudowire-class 2G-PW
encapsulation mpls
status peer topology dual-homed

controller E1 0/1
framing unframed
cem-group 8 unframed
```

The following examples shows the configuration at interface level:

```
interface CEM0/1
no ip address
cem 8
xconnect 10.10.10.1 8 encapsulation mpls pw-class 2G-PW
backup peer 10.10.10.2 8 pw-class 2G-PW
redundancy all-active replicate
```

Related Commands

Command	Description
pseudowire class	Configures the pseudowire class on the router.
template typepseudowire	Configures the pseudowire template on the router.

redundancy force-switchover

To force the standby Route Processor (RP) or Supervisor card to assume the role of the active RP or Supervisor card, use the **redundancy force-switchover** command in privileged EXEC mode.

redundancy force-switchover [**main-cpu**]

Syntax Description

main-cpu	(Optional) Forces switchover to the main CPU.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.0(16)ST	This command was introduced.
12.1(10)EX2	This command was integrated into Cisco IOS Release 12.1(10)EX2.
12.0(17)ST	This command was implemented on the Cisco 12000 series routers.
12.0(22)S	This command replaces the **force-failover**command on the Cisco 10000 series routers.
12.2(14)SX	Support for this command was added for the Supervisor Engine 720.
12.2(18)S	This command was implemented on the Cisco 7500 series routers.
12.2(20)S	Support was added for the Cisco 7304 router.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Cisco IOS Release 12.2(17d)SXB.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SCA	This command was integrated into Cisco IOS Release 12.2(33)SCA.
12.2(44)SQ	This command was integrated into Cisco IOS Release 12.2(44)SQ. Support for the Cisco RF Gateway 10 was added.

Usage Guidelines

Use the **redundancy force-switchover** command to switch control of a router from the active RP or Supervisor card to the standby RP or Supervisor card. Both the active and standby RPs or Supervisor cards must have a high availability Cisco IOS image installed and must be configured for Route Processor Redundancy (RPR) mode before the **redundancy force-switchover** command can be used. Before the system switches over, it verifies that the standby RP or Supervisor card is ready to take over.

When you use the **redundancy force-switchover**command and the current running configuration is different from the startup configuration, the system prompts you to save the running configuration before the switchover is performed.

Note All line cards will reset in RPR mode on a switchover.

Note Before using this command in Cisco 7600 series routers, refer to the "Performing a Fast Software Upgrade" section of the *Cisco 7600 Series Router Cisco IOS Software Configuration Guid*e for additional information.

On Cisco 7600 series routers, the **redundancy force-switchover** command conducts a manual switchover to the redundant supervisor engine. The redundant supervisor engine becomes the new active supervisor engine running the new Cisco IOS image. The modules are reset and the module software is downloaded from the new active supervisor engine.

The active and redundant supervisor engines do not reset on a Route Processor Redundancy Plus (RPR+) switchover. The old active supervisor engine reboots with the new image and becomes the redundant supervisor engine.

Beginning with Cisco IOS Release 12.2(33)SCA, you can force a Performance Routing Engine (PRE) switchover using the **redundancy force-switchover main-cpu** command from either the primary or standby PRE. If you force a switchover from the active PRE, both PREs synchronize and the active PRE reloads normally. When you force a switchover from the standby PRE, a crash dump of the active PRE occurs for troubleshooting purposes. Forcing a switchover from the standby PRE should only be done if you cannot access the active PRE.

Examples

The following example shows a switchover from the active RP to the standby RP on a Cisco 7513 router with RPR configured:

```
Router# configure terminal
Router(config)# hw-module slot 7 image slot0:rsp-pv-mz
Router(config)# hw-module slot 6 image slot0:rsp-pv-mz
Router(config)# slave auto-sync config
Router(config)# redundancy
Router(config-r)# mode rpr
Router(config-r)# end
Router# copy running-config startup-config
Router# redundancy force-switchover
```

The following example shows how to perform a manual switchover from the active to the standby RP when the running configuration is different from the startup configuration:

```
Router# redundancy force-switchover
System configuration has been modified. Save? [yes/no]:y
Building configuration...
...
...
[OK]
Proceed with switchover to standby NSE? [confirm]y
00:07:35:%SYS-5-SWITCHOVER:Switchover requested
```

The following example shows how to perform a manual switchover from the active to the standby RP when the running configuration is the same as the startup configuration:

```
Router# redundancy force-switchover
Proceed with switchover to standby NSE? [confirm]
00:07:35:%SYS-5-SWITCHOVER:Switchover requested
```

Cisco RF Gateway 10

The following example shows how to perform a manual switchover from the active to the standby RP when the running configuration is different from the startup configuration:

```
Router# redundancy force-switchover
System configuration has been modified. Save? [yes/no]:y
Building configuration...
...
...
[OK]
Proceed with switchover to standby NSE? [confirm]y
00:07:35:%SYS-5-SWITCHOVER:Switchover requested
```

The following example shows how to perform a manual switchover from the active to the standby RP when the running configuration is the same as the startup configuration:

```
Router# redundancy force-switchover
Proceed with switchover to standby NSE? [confirm]
00:07:35:%SYS-5-SWITCHOVER:Switchover requested
```

Related Commands

Command	Description
clear redundancy history	Clears the redundancy event history log.
hw-module sec-cpu reset	Resets and reloads the standby RP with the specified Cisco IOS image and executes the image.
hw-module slot image	Specifies a high availability Cisco IOS image to run on an active or standby RP.
mode (HSA redundancy)	Configures the High System Availability (HSA) redundancy mode.
mode (redundancy)	Configures the redundancy mode of operation.
redundancy	Enters redundancy configuration mode.
show redundancy	Displays current active and standby Performance Routing Engine (PRE) redundancy status.

redundancy handover

To hand over control of resources (slots and cards) from a route-switch-controller (RSC) card to its peer RSC card, use the **redundancyhandover** command in privileged EXEC mode.

redundancy handover {**cancel** | {**peer-resources** | **shelf-resources**} [**busyout-period** *mins*] [**at** *hh* **:** *mm* [{*day month* | *month day*} *year*]]}

Syntax Description

cancel	Any pending handover is canceled.
peer-resources	Resources to be handed over are those on the side of the peer RSC. This parameter applies only when the system is in extraload.
shelf-resources	Resources to be handed over are those on the side of the RSC from which the command is run.
busyout-period *mins*	(Optional) Time period for which all slots in the selected resources are to be busied out before handover. If time options are omitted, handover or busyout period begins immediately.
at *hh* **:** *mm day month year*	(Optional) Time of the handover or start of the busyout period, in 24-hour time format; hour and minute are required; day, month, and year are optional.

Command Default

Control remains with the assigned RSC.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XB1	This command was introduced.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.

Usage Guidelines

To use this command, you must have two RSC cards installed on your Cisco AS5850 and you must be connected to one of them in handover-split mode. This command can be run from either RSC and can specify that slots be handed over to the peer RSC.

After handover and subsequent restoration of the failed RSC, connect to the active RSC and use this command to return control of cards to the previously failed but now restored RSC.

Note that when you enter the command with the **shelf-resources** option, the RSC reloads.

Examples

The following example hands over control, to the peer RSC, of the slots and cards on the corresponding side of the chassis. Note the prompt to confirm clearing of calls, handover, and reload on the last line.

```
Router# redundancy handover shelf-resources busyout-period 10 at 22:00 3 Sep 2005

Newly entered handover schedule:
Busyout period at 22:00:00 PDT Sat Sep 3 2005 for a duration of 10 minutes
```

```
Handover pending at 22:10:00 PDT Sat Sep 3 2005
Clear calls, handover and reload as specified above? y
```

Related Commands

Command	Description
show redundancy debug-log	Displays up to 256 relevant debug entries.
show redundancy handover	Displays details of any pending handover (that is, a handover command that was entered previously and is not yet completed).
show redundancy history	Displays logged handover events.

redundancy stateful

To configure stateful failover for tunnels using IP Security (IPSec), use the **redundancystateful**command in crypto map configuration mode. To disable stateful failover for tunnel protection, use the **no** form of this command.

redundancy *standby-group-name* **stateful**
no redundancy *standby-group-name* **stateful**

Syntax Description

standby-group-name	Refers to the name of the standby group as defined by Hot Standby Router Protocol (HSRP) standby commands. Both routers in the standby group are defined by this argument and share the same virtual IP (VIP) address.

Command Default

Stateful failover is not enabled for IPSec tunnels.

Command Modes

Crypto map configuration

Command History

Release	Modification
12.3(11)T	This command was introduced.

Usage Guidelines

The **redundancystateful**command uses an existing IPSec profile (which is specified via the **cryptoipsecprofile**command) to configure IPSec stateful failover for tunnel protection. (You do not configure the tunnel interface as you would with a crypto map configuration.) IPSec stateful failover enables you to define a backup IPSec peer (secondary) to take over the tasks of the active (primary) router if the active router is deemed unavailable.

The tunnel source address must be a VIP address, and it must not be an interface name.

Examples

The following example shows how to configure stateful failover for tunnel protection:

```
crypto ipsec profile peer-profile
  redundancy HA-out stateful

interface Tunnel1
 ip unnumbered Loopback0
 tunnel source 209.165.201.3
 tunnel destination 10.0.0.5
 tunnel protection ipsec profile peer-profile
!
interface Ethernet0/0
 ip address 209.165.201.1 255.255.255.224
 standby 1 ip 209.165.201.3
 standby 1 name HA-out
```

Related Commands

Command	Description
crypto ipsec profile	Defines the IPSec parameters that are to be used for IPSec encryption between two routers and enters crypto map configuration mode.

remote command

To execute a Cisco 7600 series router command directly on the switch console or a specified module without having to log into the Cisco 7600 series router first, use the **remote command** command in privileged EXEC mode.

remote command {**module** *num* | **standby-rp** | **switch**} *command*

Syntax Description

module *num*	Specifies the module to access; see the “Usage Guidelines” section for valid values.
standby-rp	Specifies the standby route processor.
switch	Specifies the active switch processor.
command	Command to be executed.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXD	The **standby-rp** keyword was added.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **module** *num* keyword and argument designate the module number. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values are from 1 to 13. The **module** *num* keyword and argument are supported on DFC-equipped modules and the standby supervisor engine only.

When you execute the **remote command switch**command, the prompt changes to Switch-sp#.

This command is supported on DFC-equipped modules and the supervisor engine only.

This command does not support command completion, but you can use shortened forms of the command (for example, entering **sh** for **show**).

Examples

This example shows how to execute the **show calendar** command from the standby route processor:

```
Router#
remote command standby-rp show calendar
Switch-sp#
09:52:50 UTC Mon Nov 12 2001
Router#
```

Related Commands

Command	Description
remote login	Accesses the Cisco 7600 series router console or a specific module.

remote-span

To configure a virtual local area network (VLAN) as a remote switched port analyzer (RSPAN) VLAN, use the **remote-span** command in config-VLAN mode. To remove the RSPAN designation, use the **no** form of this command.

remote-span
no remote-span

Syntax Description

This command has no arguments or keywords.

Command Default

This command has no default settings.

Command Modes

Config-VLAN mode

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

This command is not supported in the VLAN database mode.

You can enter the **show vlan remote-span** command to display the RSPAN VLANs in the Cisco 7600 series router.

Examples

This example shows how to configure a VLAN as an RSPAN VLAN:

```
Router(config-vlan)# remote-span
Router(config-vlan)
```

This example shows how to remove the RSPAN designation:

```
Router(config-vlan)# no remote-span
Router(config-vlan)
```

Related Commands

Connect	Description
show vlan remote-span	Displays a list of RSPAN VLANs.

remote login

To access the Cisco 7600 series router console or a specific module, use the **remote login** command in privileged EXEC mode.

remote login {**module** *num* | **standby-rp** | **switch**}

Syntax Description

module *num*	Specifies the module to access; see the "Usage Guidelines" section for valid values.
standby-rp	Specifies the standby route processor.
switch	Specifies the active switch processor.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXD	This command was changed to include the **standby-rp** keyword.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Caution When you enter the **attach** or **remote login** command to access another console from your switch, if you enter global or interface configuration mode commands, the switch might reset.

The **module** *num* keyword and argument designate the module number. Valid values depend on the chassis that is used. For example, if you have a 13-slot chassis, valid values are from 1 to 13. The **module** *num* keyword and argument are supported on DFC-equipped modules and the standby supervisor engine only.

When you execute the **remote login module** *num* command, the prompt changes to Router-dfcx# or Switch-sp#, depending on the type of module to which you are connecting.

When you execute the **remote login standby-rp** command, the prompt changes to Router-sdby#.

When you execute the **remote login switch** command, the prompt changes to Switch-sp#.

The **remote login module** *num* command is identical to the **attach** command.

There are two ways to end the session:

- You can enter the **exit** command as follows:

```
Switch-sp# exit
```

```
[Connection to Switch closed by foreign host]
Router#
```

- You can press **Ctrl-C** three times as follows:

```
Switch-sp# ^C
Switch-sp# ^C
Switch-sp# ^C
Terminate remote login session? [confirm] y
[Connection to Switch closed by local host]
Router#
```

Examples

This example shows how to perform a remote login to a specific module:

```
Router# remote login module 1
Trying Switch ...
Entering CONSOLE for Switch
Type "^C^C^C" to end this session
Switch-sp#
```

This example shows how to perform a remote login to the Cisco 7600 series router processor:

```
Router# remote login switch
Trying Switch ...
Entering CONSOLE for Switch
Type "^C^C^C" to end this session
Switch-sp#
```

This example shows how to perform a remote login to the standby route processor:

```
Router# remote login standby-rp
Trying Switch ...
Entering CONSOLE for Switch
Type "^C^C^C" to end this session
Router-sdby#
```

Related Commands

Command	Description
attach	Connects to a specific module from a remote location.

reset (alarm-interface)

To reset the CPU in the alarm interface controller (AIC), use the **reset**command in alarm-interface mode.

reset

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Alarm-interface

Command History

Release	Modification
12.2(2)XG	This command was introduced on the Cisco 2600 series and Cisco 3600 series.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.

Usage Guidelines

A change in the AIC IP configuration might not take effect until the next time the card is started. Use the **reset** command to restart the card. This command does not have a **no** form.

Examples

The following example shows a message that might be returned after the **reset** command is entered:

```
Router(alarm-aic)# reset
Selected card in slot 1 restarted
```

Related Commands

Command	Description
alarm-interface	Enters alarm-interface mode and configures the AIC.

retry

To define the amount of time that must elapse before a connection is attempted to a failed server, use the **retry** command in interface configuration mode. To change the connection-reassignment threshold and client threshold to the default settings, use the **no** form of this command.

retry *retry-value*
no retry

Syntax Description

retry-value	Amount of time, in seconds, that must elapse after the detection of a server failure before a new connection is attempted to the server; valid values are from 1 to 3600.

Command Default

retry-value is **60**

Command Modes

real server configuration submode

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Examples

This example shows how to specify a retry timer of 30 seconds:

```
Router(config)# ip slb serverfarm serverfarm-name
Router(config-slb-sfarm)# real 10.1.1.1
Cisco-7600(config-slb-real)# retry 30
```

This example shows how to revert to the default value:

```
Cisco-7600(config-slb-real)# no
 retry
Router(config-if)#
```

Related Commands

Command	Description
faildetect numconns	Specifies the conditions that indicate a server failure.
inservice (real server)	Enables the real server for use by the IOS SLB feature.
maxconns	Limits the number of active connections to the real server.

ring-speed

To set the ring speed for the CSC-1R and CSC-2R Token Ring interfaces, use the **ring-speed** command in interface configuration mode.

ring-speed commandring-speed *speed*

Syntax Description

speed	Integer that specifies the ring speed, either 4 for 4-Mbps operation or 16 for 16-Mbps operation . The default is 16.

Command Default

16-Mbps operation

Caution Configuring a ring speed that is wrong or incompatible with the connected Token Ring causes the ring to beacon, which makes the ring nonoperational.

Command Modes

Interface configuration

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command does not have a **no** form.

Examples

The following example shows how to sets the ring speed to 4 Mbps on a Token Ring interfaces:

```
Router(config)# interface tokenring 0
Router(config-if)# ring-speed 4
```

rj45-auto-detect-polarity

To enable or disable polarity detection for 10 Mbps full-duplex links, use the **rj45-auto-detect-polarity** command in interface configuration mode.

rj45-auto-detect-polarity {**enable** | **disable**}

Syntax Description

enable	Enables polarity detection on the RJ45 interface.
disable	Disables polarity detection on the RJ45 interface.

Command Default

Polarity detection is disabled for 10 Mbps, full duplex links.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.0(1)M3	This command was introduced.

Usage Guidelines

This command is available only for 10 Mbps, full-duplex links. The polarity detection feature helps to detect reversed polarity and provide correction; however, there is a risk of cyclic redundancy check (CRC) errors if polarity detection is enabled.

The polarity detection feature is disabled by default. Use the **rj45-auto-detect-polarityenable**to enable polarity detection.

It is recommended to leave polarity detection disabled.

Examples

The following example shows how to enable polarity detection on the RJ45 interface:

```
router(config-if)# rj45-auto-detect-polarity enable
```

Related Commands

Command	Description
media-type auto-failover	Assigns the RJ45 or the SFP port as the primary and secondary failover media.

scramble through service-module t1 lbo

scramble

To enable scrambling (encryption) of the payload on a T3 or E3 controller or on the PA-T3 and PA-E3 port adapters, use the **scramble** command in interface configuration mode. To disable scrambling, use the **no** form of this command.

scramble
no scramble

Syntax Description

This command has no arguments or keywords.

Command Default

Scrambling is disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.1CA	This command was introduced.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

T3/E3 scrambling is used to assist clock recovery on the receiving end. Scrambling is designed to randomize the pattern of 1s and 0s carried in the physical layer frame. Randomizing the digital bits can prevent continuous, nonvariable bit patterns--in other words, long strings of all 1s or all 0s. Several physical layer protocols rely on transitions between 1s and 0s to maintain clocking.

Scrambling can prevent some bit patterns from being mistakenly interpreted as alarms by switches placed between the Data Service Units (DSUs).

The local interface configuration must match the remote interface configuration. For example, if you enable scrambling on the local port, you must also do the same on the remote port.

To verify that scrambling is configured on the interface, use the **showcontrollersserial**or the **showinterfacesserial**commands.

For T3 controllers, all the DSU modes support scrambling except Clear mode.

For E3 controllers, only Kentrox mode supports scrambling.

Examples

The following example enables scrambling on the PA-E3 port adapter in slot 1, port adapter slot 0, interface 0:

```
Router(config)# interface serial 1/0/0
Router(config-if)# scramble
```

The following example enables scrambling on the controller in slot 1, port 0:

```
Router(config)# interface serial 1/0
Router(config-if)# scramble
```

Related Commands

Command	Description
show controllers serial	Displays information that is specific to the serial controllers.
show interfaces serial	Displays information that is specific to the interface hardware.

serial restart-delay

To set the amount of time that the router waits before trying to bring up a serial interface when it goes down, use the **serialrestart-delay** command in interface configuration mode. To restore the default, use the **no** form of the command.

serial restart-delay *count*
no serial restart-delay

Syntax Description

count	Frequency, in milliseconds, at which the hardware is reset. Range is from 0 to 900. Default is 0.

Command Default

0 milliseconds

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
11.2 P	This command was introduced.
12.2(4)T	The *count* value was changed to set time in milliseconds rather than in seconds.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.1(2)S	This command was integrated into Cisco IOS Release 15.1(2)S.

Usage Guidelines

The router resets the hardware each time the serial restart timer expires. This command is often used with the dial backup feature and with the **pulse-time** command, which sets the amount of time to wait before redialing when a DTR dialed device fails to connect.

When the*count*value is set to the default of 0, the hardware is not reset when it goes down. In this way, if the interface is used to answer a call, it does not cause DTR to drop, which can cause a communications device to disconnect.

Examples

The following example shows how to set the restart delay on serial interface 0 to 0:

```
Router(config)# interface serial 0
Router(config-if)# serial restart-delay 0
```

Related Commands

Command	Description
pulse-time	Enables pulsing DTR signal intervals on the serial interfaces.
show interfaces serial	Displays information about a serial interface.

server ip address

To configure a static IP address for the Cisco E-Series Server, use the **server ip address** command in interface configuration mode.

server ip address [*ip_address subnet_mask*]
no server ip address

Syntax Description

ip_address	Configures a static IP address for the Cisco E-Series Server.
subnet_mask	The subnet mask associated with the IP address.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.2(4)M	This command was introduced.

Usage Guidelines

Use this command from interface configuration mode:

```
Router(config)# interface ucse slot/port
```

Examples

The following example shows how to configure a static IP address for the Cisco E-Series Server:

```
Router(config)# interface ucse 2/0
Router(config-if)# server ip address 10.0.0.2 100.1.1.31
```

service alarm persistency interval

To configure alarm history that helps in defining the periodicity or the interval at which the alarm entries are saved in the designated file., use the **service alarm persistency interval** command.

Syntax Description

Syntax Description

service alarm persistency interval *value*	Configures the alarm history helps in defining the periodicity or the interval at which the alarm entries are saved in the designated file. When alarm history is configured, two log files are created in bootflash:tracelogs.

Command Default

This default is 20 seconds.

Command Modes

Global configuration

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on NCS 4200 Series.
XE Everest 16.5.1	This command was integrated on the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Examples

The following example shows the configuration of alarm history:

```
enable
configure terminal
service alarm persistency interval 20-600
end
```

Related Commands

Command	Description
show process | include persis	Verifies the validity of the process during alarm history configuration.

service declassify

To enable the declassification function to monitor the auxiliary (AUX) port Clear To Send (CTS) pin, use the **servicedeclassify** command in global configuration mode. To disable, use the **no** form of this command.

service declassify [{**erase-flash** | **erase-nvram** | **erase-all**}]
no service declassify [{**erase-flash** | **erase-nvram** | **erase-all**}]

Syntax Description

erase-flash	(Optional) Erases all files in the Flash memory file system when declassification is invoked.
erase-nvram	(Optional) Erases all files in the NVRAM file system when declassification is invoked.
erase-all	(Optional) Scrubs and erases all files on the router when declassification is invoked.

Note The **servicedeclassify** command is supported on the Cisco 3200 series routers only.

Command Default Zeroization is disabled.

Command Modes Global configuration

Command History

Release	Modification
12.3(8)YD	This command was introduced.
12.4(2)T	This command was integrated into Cisco IOS Release 12.4(2)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The network interfaces are shut down when declassification is invoked.

No command-line interface (CLI) command invokes the declassification process. Declassification is invoked by using an external signal that appears on the AUX port of the router. When declassification is complete, the ROMMON prompt appears on the console.

The output that appears on the console when declassification is initiated depends on what options have been configured. Because of the complex interactions between the declassification process and the logging process during declassification, it is not possible to document exactly what appears on the screen.

Examples

The following example shows the console output when declassification is invoked:

The erase-all Keyword

The output on the console when the **erase-all** keyword is used resembles the following:

```
Router# service declassify erase-all
*Mar  5 17:44:28.347:
Declassification initiated...
*Mar  5 17:44:30.647: %LINK-5-CHANGED: Interface FastEthernet0/0, changed state to
administratively down
*Mar  5 17:44:31.647: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet0/0,
changed state to down
System Bootstrap, Version 12.2(1r) [hftseng-MRC_RM 100], DEVELOPMENT SOFTWARE
Copyright (c) 1994-2002 by cisco Systems, Inc.
C3200 platform with 131072 Kbytes of main memory
rommon 1 >
```

Note If the **servicedeclassifyerase-all** command is configured and the Flash file system is erased, error recovery actions must be initiated to load a bootable image on the router. The startup configuration file is also erased; the router boots from the factory default configuration the next time it is booted.

The erase-flash Keyword

The output on the console when the **erase-flash** keyword is used resembles the following:

```
Router# service declassify erase-flash
*Mar  1 00:01:30.091:
Declassification initiated...
*Mar  1 00:01:34.347: %LINK-5-CHANGED: Interface FastEthernet0/0, changed state to
administratively down
*Mar  1 00:01:35.371: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet0/0,
changed state to down
System Bootstrap, Version 12.2(1r) [hftseng-MRC_RM 100], DEVELOPMENT SOFTWARE
Copyright (c) 1994-2002 by cisco Systems, Inc.
C3200 platform with 131072 Kbytes of main memory
rommon 1 >
```

Note The Flash file system is erased and there will not be a bootable image for the router in the Flash file system if the **servicedeclassifyerase-flash** command is configured. Error recovery actions must be initiated to load a bootable image. The startup configuration file is not erased if the **servicedeclassifyerase-flash** command is configured. When the router is booted, it is configured using its startup configuration file in NVRAM.

The erase-nvram Keyword

The output on the console when the **erase-nvram** keyword is used resembles the following:

```
Router# service declassify erase-nvram
System Bootstrap, Version 12.2(1r) [hftseng-MRC_RM 100], DEVELOPMENT SOFTWARE
Copyright (c) 1994-2002 by cisco Systems, Inc.
C3200 platform with 131072 Kbytes of main memory
rommon 1 >
```

Note If the **servicedeclassifyerase-nvram** command is configured, the Flash file system is not erased. The bootable image in the Flash file system remains, and the router can be booted. The startup configuration file is erased; because the router has no configuration file, it boots from the default configuration

Related Commands

Command	Description
show declassify	Displays the state of the **servicedeclassify** command.

service-engine default-gateway

To define a default gateway router IP address for the Cisco WebEx Node SPA in a Cisco ASR 1000 Series Router, use the **service-enginedefault-gateway**command in interface configuration mode. To remove the default-gateway IP address, use the **no** form of this command.

service-engine default-gateway *gateway-ip-address*
no service-engine default-gateway *gateway-ip-address*

Syntax Description

gateway-ip-address	IP address of the router default gateway.

Command Default

No gateway IP address is configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

The **service-enginedefault-gateway** command specifies the IP address for the default gateway router to be used for the Cisco WebEx Node SPA.

A service-engine interface on the Cisco WebEx Node SPA has two IP addresses:

- Router-side IP address--Configured with the **ipaddress**command. The IP address on the router side acts like a gateway to the WebEx services running on the SPA side. This router-side IP address must match the IP address configured in the **service-enginedefault-gateway** command.
- Internal SPA interface IP address--Configured with the**service-engineipaddress**command.

You must configure the **service-engineipaddress** command before configuring the default gateway.

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Examples

The following example defines the gateway on IP address 10.200.72.17 as the default router for the SPA in slot 1/0/0, which corresponds to the IP address configured on the router side in the**ipaddress**command:

```
Router(config) interface Service-Engine1/0/0
Router(config-if) shutdown
Router(config-if) ip address 10.200.72.17 255.255.255.252
Router(config-if) service-engine ip address 10.200.72.18 255.255.255.252
Router(config-if) service-engine default-gateway 10.200.72.17
```

Related Commands

Command	Description
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and key that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine hostname

To specify or modify the hostname or domain name associated with a Cisco WebEx Node SPA on a Cisco ASR 1000 Series Router, use the **service-enginehostname**command in interface configuration mode. To remove the hostname and domain name association, use the **no** form of this command.

service-engine hostname *module-side-hostname module-side-domain-name*
no service-engine hostname *module-side-hostname module-side-domain-name*

Syntax Description

module-side-hostname	Name of the hostname associated with a Cisco WebEx Node SPA.
module-side-domain- name	Name of the domain associated with a Cisco WebEx Node SPA

Command Default

No hostname or domain name is configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

The **service-enginehostname**command specifies the hostname and domain names given to a Cisco WebEx Node SPA. It is an optional configuration and is only used if a Domain Name System (DNS) entry was created for the IP address assigned to the SPA.

To display the configured hostname and domain name for a Cisco WebEx Node SPA, use the **showhw-modulesubslotservice-enginestatus** command.

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Examples

The following example shows how to specify the hostname and domain name for a Cisco WebEx Node SPA:

```
Router(config)# interface service-engine 1/0
Router(config-if)# shutdown
Router(config-if)# service-engine hostname wma-spa-1 cisco.com
```

Related Commands

Command	Description
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.

Command	Description
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and key that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine ip address

To select and configure the internal interface for management traffic for the WebEx Node SPA on a Cisco ASR 1000 Series Router, use the **service-engineipaddress**command in interface configuration mode. To delete the IP address associated with this interface, use the **no** form of this command.

service-engine ip address *module-side-ip-address subnet-mask*
no service-engine ip address *module-side-ip-address subnet-mask*

Syntax Description

module-side-ip-address	Specifies the IP address of the internal network module-side interface.
subnet-mask	Specifies the subnet mask to append to the IP address.

Command Default

No IP address is configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

A service-engine interface on the Cisco WebEx Node SPA has two IP addresses:

- Router-side IP address--Configured with the **ipaddress**command. The IP address on the router side acts like a gateway to the WebEx services running on the SPA side. This router-side IP address must match the IP address configured in the **service-enginedefault-gateway** command.
- Internal SPA interface IP address--Configured with the**service-engineipaddress**command.

To successfully configure the service-engine IP address, consider the following guidelines:

- The router-side IP address must be configured using the **ipaddress** command.
- The service-engine IP address must be on the same subnet as the router-side IP address for the service-engine interface (configured using the **ipaddress**command.)
- The **service-engineipaddress**command must be configured before you configure the **service-enginedefault-gateway** command.

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Examples

The following example shows how to define an IP address for the internal SPA-side interface on the WebEx Node SPA in slot 1 using the **service-engineipaddress**command. The example shows the service-engine IP address on the same subnet as the router-side IP address that is configured with the **ipaddress** command:

```
Router(config) interface Service-Engine1/0/0
Router(config-if) shutdown
Router(config-if) ip address 10.200.72.17 255.255.255.252
Router(config-if) service-engine ip address 10.200.72.18 255.255.255.252
Router(config-if) service-engine default-gateway 10.200.72.17
```

Related Commands

Command	Description
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and key that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine nameserver

To specify the primary and secondary Domain Name System (DNS) used by the Cisco WebEx Node SPA in a Cisco ASR 1000 Series Router, use the **service-enginenameserver**command in interface configuration mode. To remove a DNS name server from the list, use the **no** form of this command.

service-engine nameserver *name-server1-ip-address name-server2-ip-address*
no service-engine nameserver *name-server1-ip-address name-server2-ip-address*

Syntax Description

name-server1-ip- address	IP address of the primary DNS name server for the WebEx Node SPA.
name-server2-ip- address	IP address of a secondary DNS name server for the WebEx Node SPA.

Command Default

No name servers are configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Examples

The following example shows how to specify the hosts at 192.168.2.111 and 192.168.2.112 as the primary and secondary name servers for the WebEx Node SPA in slot 1/0:

```
Router(config)# interface service-engine 1/0
Router(config-if)# shutdown
Router(config-if)# service-engine nameserver 192.168.2.111
 192.168.2.112
```

Related Commands

Command	Description
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.

Command	Description
service-engine wma-passcode	Configures the name and key that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine wma-passcode

To configure the name and key that is used for authentication for a Cisco WebEx Node SPA in a Cisco ASR 1000 Series Router, use the **service-enginewma-passcode** command in interface configuration mode. To disable this function, use the **no** form of this command.

service-engine wma-passcode *name-string key-string*
no service-engine wma-passcode

Syntax Description

name-string	Specifies the authentication name for the WebEx Node SPA.
key-string	Specifies the authentication passcode for the WebEx Node SPA.

Command Default

The name and key used for authentication for a Cisco WebEx Node SPA is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

The **service-enginewma-passcode**command is used to configure the Cisco WebEx Node SPA name and passcode key to identify the node. Both the passcode and the token (configured using the **service-enginewma-token** command) are used together for authentication of the Cisco WebEx Node SPA.

Before you can configure this command, you must first provision the Cisco WebEx Node SPA at the WebEx Data Center. The value of the passcode string provisioned in the Cisco WebEx Node Management System for the SPA must match the value of the passcode string configured in the **service-enginewma-passcode**command. For more information, refer to the “Configuring the Cisco WebEx Node for ASR 1000 Series” chapter of the Cisco ASR 1000 Series Aggregation Services Routers SIP and SPA Software Configuration Guide .

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Once you configure the **service-enginewma-passcode** command and enter the *key-string* into the running configuration, the *key-string* is encrypted. Therefore, you cannot successfully copy the passcode from the running configuration or a backup version of your configuration file to running-configuration. The **service-enginewma-passcode** command must be re-entered.

Examples

The following example defines the authentication SPA name and passcode for the Cisco WebEx Node SPA in slot 1/0:

```
Router(config)# interface service-engine 1/0
Router(config-if)# shutdown
Router(config-if)# service-engine wma-passcode wma-spa-1 spa1pass
```

Related Commands

Command	Description
service-engine default-gateway	Defines a default gateway router IP address for the Cisco WebEx Node SPA.
service-engine ip address	Selects and configures the internal interface for management traffic on a Cisco WebEx Node SPA.
service-engine hostname	Specifies or modifies the hostname or domain name associated with a Cisco WebEx Node SPA.
service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-token	Configures an encrypted token on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine wma-token

To configure an encrypted token for a Cisco WebEx Node SPA in a Cisco ASR 1000 Series Router, use the **service-enginewma-token**command in interface configuration mode. To disable this function, use the **no** form of this command.

service-engine wma-token *token-string*
no service-engine wma-token

Syntax Description

token-string	Specifies the encrypted token for the WebEx Node SPA.

Command Default

The encrypted token for a Cisco WebEx Node SPA is disabled.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

The **service-enginewma-token**command is used to configure an encrypted token for the Cisco WebEx Node SPA. Both the token and the passcode (configured using the **service-enginewma-passcode**command) are used together for authentication of the Cisco WebEx Node SPA.

Before you can configure this command, you must first provision the Cisco WebEx Node SPA at the WebEx Data Center. The value of the token string provisioned in the Cisco WebEx Node Management System for the SPA must match the value of the passcode string configured in the **service-enginewma-token**command. For more information, refer to the “Configuring the Cisco WebEx Node for ASR 1000 Series” chapter of the Cisco ASR 1000 Series Aggregation Services Routers SIP and SPA Software Configuration Guide .

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown**command.

Examples

The following example specifies the token for the Cisco WebEx Node SPA in slot 1/0:

```
Router(config)# interface service-engine 1/0
Router(config-if)# shutdown
Router(config-if)# service-engine wma-token 123456789
```

Related Commands

Command	Description

service-engine nameserver	Specifies the primary and secondary domain name server used by the Cisco WebEx Node SPA.
service-engine wma-passcode	Configures the name and key that are used for authentication on a Cisco WebEx Node SPA.
service-engine wma-url	Specifies the URL to which the Cisco WebEx Node SPA must connect to enable WebEx meetings.
show hw-module subslot service-engine status	Displays the Cisco WebEx Node SPA application status.

service-engine wma-url

To specify the URL to which the Cisco WebEx Node SPA in a Cisco ASR 1000 Series Router must connect to enable WebEx meetings, use the **service-enginewma-url**command in interface configuration mode. To disable this function, use the **no** form of this command.

service-engine wma-url *url-string*
no service-engine wma-url

Syntax Description

url-string	Specifies the URL to connect to the WebEx MediaTone Center.

Command Default

No URL string is configured.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
IOS XE Release 2.4	This command was introduced.

Usage Guidelines

The**service-enginewma-url** command is used to configure the URL that enables connectivity to the WebEx Data Center.

Before you can configure this command, you must first provision the Cisco WebEx Node SPA at the WebEx Data Center. The URL string provisioned in the Cisco WebEx Node Management System for the SPA must match the value of the URL configured in the **service-enginewma-url**command. For more information, refer to the "Configuring the Cisco WebEx Node for ASR 1000 Series" chapter of the Cisco ASR 1000 Series Aggregation Services Routers SIP and SPA Software Configuration Guide .

Note Before you can configure the Cisco WebEx Node SPA, you must shut down the service-engine interface using the **shutdown** interface configuration command. To activate the service-engine interface, use the **noshutdown** command.

Examples

The following example specifies the URL to which the Cisco WebEx Node SPA in slot 1/0 must connect:

```
Router(config)# interface service-engine 1/0
Router(config-if)# shutdown
Router(config-if)# service-engine wma-url https://spa.webex.com
```

service single-slot-reload-enable

To enable single line card reloading for all line cards in the Cisco 7500 series router, use the **servicesingle-slot-reload-enable**command in global configuration mode. To disable single line card reloading for the line cards in the Cisco 7500 series router, use the **no** form of this command.

service single-slot-reload-enable
no service single-slot-reload-enable

Syntax Description

This command has no arguments or keywords.

Command Default

Single line card reloading is disabled.

Command Modes

Global configuration

Command History

Release	Modification
12.0(13)S	This command was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

In the following example, single line card reloading is enabled for all lines cards on the Cisco 7500 series router:

```
Router(config)# service single-slot-reload-enable
```

Related Commands

Command	Description
show diag	Displays hardware information for a networking device.
show running-config	Displays configuration information.

service-module

To set service module parameters, use the **service-module**commandinprivilegedEXEC mode.

service-module GigabitEthernet *interface-number* {**heartbeat-reset** {**disable** | **enable**} | **password-reset** | **reload** | **reset** | **session** [**clear**] | **shutdown** [**no-confirm**] | **statistics** [**clear**] | **status**}

Syntax Description

GigabitEthernet *interface-number*	Specifies the Gigabit Ethernet interface number.
heartbeat-reset	Specifies the heartbeat failure to reset the service module.
disable	Disables the heartbeat reset.
enable	Enables the heartbeat reset.
password-reset	Specifies the password reset for the service module.
reload	Reloads the service module.
reset	Resets the service module hardware.
session	Specifies the service module session.
clear	(Optional) Clears the existing service module session when used with the **session** keyword. Clears the service module statistics when used with the **statistics** keyword.
shutdown	Shuts down the service module.
no-confirm	(Optional) Configures the system not to confirm before the shutdown.
statistics	Specifies service module statistics.
status	Specifies service module status information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced in a release earlier than Cisco IOS Release 15.0(1)M.

Usage Guidelines

Use this command with the **reset** keyword only to recover from the shutdown or failed state. Use the **shutdown** keyword for online removal of a service module. When you shut down a service module on switch modules, the line protocol on the GigabitEthernet interface goes down. If the line protocol does not go down, first shut down the interface using the **shutdown** command in interface configuration mode and then shut down the service module using the **service-moduleGigabitEthernet***interface-number***shutdown** command.

Examples

The following example shows how to disable the heartbeat reset:

```
Router# service-module GigabitEthernet 1/0 heartbeat-reset disable
```

The following example shows the status of the service module:

Router# **service-moduleGigabitEthernet1/0status**

```
Service Module is Cisco GigabitEthernet1/0
Service Module supports session via TTY line 66
Service Module is Shutdown
Service Module reset on error is disabled
Service Module heartbeat-reset is enabled
Service Module status is not available
```

The following example shows how to shut down an interface before shutting down the service module:

```
Router(config)# interface GigabitEthernet 1/0
Router(config-if)# shutdown
```

The following example shows how to shut down a service module:

```
Router# service-module GigabitEthernet 1/0 shutdown
```

Related Commands

Command	Description
show interfaces sm	Displays basic interface configuration information for service modules.
shutdown (interface)	Disables an interface.

service-module 56k clock rate

To configure the network line speed for a serial interface on a 4-wire, 56/64-kbps CSU/DSU module, use the **service-module56kclockrate**command in interface configuration mode. To enable a network line speed of 56 kbps, which is the default, use the **no** form of this command.

service-module 56k clock rate commandservice-module 56k clock rate *speed*
no service-module 56k clock rate *speed*

Syntax Description

speed	Network line speed in kbps. The default speed is 56 kbps. Choose from one of the following optional speeds: • **2.4** -- 2.4 kbps • **4.8** -- 4.8 kbps • **9.6** -- 9.6 kbps • **19.2** -- 19.2 kbps • **38.4** -- 38.4 kbps • **56** -- 56 kbps (default) • **64** -- 64 kbps • **auto** --Automatic line speed mode. Configure this option if your line speed is constantly changing.

Command Default

56 kbps

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The 56-kbps line speed is available in switched mode, which is enabled using the **service-module56knetwork-type** interface configuration command on the 4-wire CSU/DSU. If you have a 2-wire CSU/DSU module, the default is automatically set to switched mode.

The 64-kbps line speed cannot be used with back-to-back digital data service (DDS) lines. The subrate line speeds are determined by the service provider.

The **auto**keyword enables the CSU/DSU to decipher current line speed from the sealing current running on the network. Use the **auto** keyword only when transmitting over telco DDS lines and the clocking source is taken from the line.

Examples

The following example displays two routers connected in back-to-back DDS mode. However, notice that at first the configuration fails because the **auto** option is used. Later in the example the correct matching configuration is issued, which is 38.4 kbps.

```
Router1(config)# interface serial 0
Router1(config-if)# service-module 56k clock source internal
Router1(config-if)# service-module 56k clock rate 38.4
Router2(config-if)# service-module 56k clock rate auto
Router1# ping 10.1.1.2
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.1.2, timeout is 2 seconds:
.....
Success rate is 0 percent (0/5)
Router2(config-if)# service-module 56k clock rate 38.4

Router1# ping 10.1.1.2
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.1.2, timeout is 2 seconds:
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 52/54/56 ms
```

When transferring from DDS mode to switched mode, you must set the correct clock rate, as shown in the following example:

```
Router2(config-if)# service-module 56k network-type dds
Router2(config-if)# service-module 56k clock rate 38.4
Router2(config-if)# service-module 56k network-type switched
% Have to use 56k or auto clock rate for switched mode
% Service module configuration command failed: WRONG FORMAT.
Router2(config-if)# service-module 56k clock rate auto
% WARNING - auto rate will not work in back-to-back DDS.
Router2(config-if)# service-module 56k network-type switched
```

Related Commands

Command	Description
service-module 56k clock source	Sets up the clock source on a serial interface for a 4-wire, 56/64-kbps CSU/DSU module.
service-module 56k network-type	Sends packets in switched dial-up mode or DDS mode using a serial interface on a 4-wire, 56/64-kbps CSU/DSU module.

service-module 56k clock source

To set up the clock source on a serial interface for a 4-wire, 56/64-kbps CSU/DSU module, use the **service-module56kclocksource**command in interface configuration mode. To specify that the clocking come from the line, use the **no** form of this command.

service-module 56k clock source commandservice-module 56k clock source {**line** | **internal**}
no service-module 56k clock source {**line** | **internal**}

Syntax Description

line	Uses the clocking provided by the active line coming in to the router. This is the default.
internal	Uses the internal clocking provided by the hardware module.

Command Default

Line clock

Command Modes

Interface configuration

Command History

Release	Modification
11.1	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In most applications, the CSU/DSU should be configured with the **clocksourceline** command. For back-to-back configurations, configure one CSU/DSU with the **clocksourceinternal** command and the other with **clocksourceline** command.

Examples

The following example configures internal clocking and transmission speed at 38.4 kbps.

```
Router(config)# interface serial 0
Router(config-if)# service-module 56k clock source internal
Router(config-if)# service-module 56k clock rate 38.4
```

Related Commands

Command	Description
clock source (interface)	Controls the clock used by a G.703-E1 interface.
service-module 56k clock rate	Configures the network line speed for a serial interface on a 4-wire, 56/64-kbps CSU/DSU module.

service-module 56k data-coding

To prevent application data from replicating loopback codes when operating at 64 kbps on a 4-wire CSU/DSU, use the **service-module56kdata-coding** command in interface configuration mode. To enable normal transmission, use the **no** form of this command.

service-module 56k data-coding {**normal** | **scrambled**}
no service-module 56k data-coding {**normal** | **scrambled**}

Syntax Description

normal	Specifies normal transmission of data. This is the default.
scrambled	Scrambles bit codes or user data before transmission. All control codes such as out-of-service and out-of-frame are avoided.

Command Default

Normal data transmission

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Enable the scrambled configuration only in 64-kbps digital data service (DDS) mode. If the network type is set to switched, the configuration is refused.

If you transmit scrambled bit codes, both CSU/DSUs must have this command configured for successful communication.

Examples

The following example s crambles bit codes or user data before transmission :

```
Router(config)# interface serial 0
Router(config-if)# service-module 56k clock rate 64
Router(config-if)# service-module 56k data-coding scrambled
```

Related Commands

Command	Description
service-module 56k clock rate	Configures the network line speed for a serial interface on a 4-wire, 56/64-kbps CSU/DSU module.

service-module 56k network-type

To transmit packets in switched dial-up mode or digital data service (DDS) mode using a serial interface on a 4-wire, 56/64-kbps CSU/DSU module, use the **service-module56knetwork-type**command in interface configuration mode. To transmit from a dedicated leased line in DDS mode, use the **no** form of this command.

service-module 56k network-type {**dds** | **switched**}
no service-module 56k network-type {**dds** | **switched**}

Syntax Description

dds	Transmits packets in DDS mode or through a dedicated leased line. The default is DDS enabled for the 4-wire CSU/DSU.
switched	Transmits packets in switched dial-up mode. On a 2-wire, switched 56-kbps CSU/DSU module, this is the default and only setting.

Command Default

DDS is enabled for the 4-wire CSU/DSU. Switched is enabled for the 2-wire CSU/DSU.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

In switched mode, you need additional dialer configuration commands to configure dial-out numbers. Before you enable the **service-module56knetwork-typeswitched** command, both CSU/DSUs must use a clock source coming from the line and have the clock rate configured to **auto** or **56** kbps. If the clock rate is not set correctly, this command will not be accepted.

The 2-wire and 4-wire, 56/64-kbps CSU/DSU modules use V.25 *bis* dial commands to interface with the router. Therefore, the interface must be configured using the**dialerin-band** command. Data terminal ready (DTR) dial is not supported.

Note Any loopbacks in progress are terminated when switching between modes.

Examples

The following example configures transmission in switched dial-up mode :

```
Router(config)# interface serial 0
Router(config
-if)#
 service-module 56k clock rate auto
Router(config
-if)#
```

```
 service-module 56k network-type switched
Router(config
-if)#
 dialer in-band
Router(config
-if)#
 dialer string 5550111
Router(config
-if)#
 dialer-group 1
```

Related Commands

Command	Description
dialer in-band	Specifies that DDR is to be supported.
service-module 56k clock rate	Configures the network line speed for a serial interface on a 4-wire, 56/64-kbps CSU/DSU module.
service-module 56k clock source	Sets up the clock source on a serial interface for a 4-wire, 56/64-kbps CSU/DSU module.
service-module 56k switched-carrier	Selects a service provider to use with a 2- or 4-wire, 56/64-kbps dial-up serial line.

service-module 56k remote-loopback

To enable the acceptance of a remote loopback request on a serial interface on a 2- or 4-wire, 56/64-kbps CSU/DSU module, use the **service-module56kremote-loopback** command in interface configuration mode. To disable the module from entering loopback, use the **no** form of this command.

service-module 56k remote-loopback commandservice-module 56k remote-loopback
no service-module 56k remote-loopback commandservice-module 56k remote-loopback

Syntax Description

This command has no arguments or keywords.

Command Default

Enabled

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **noservice-module56kremote-loopback** command prevents the local CSU/DSU from being placed into loopback by remote devices on the line. The line provider is still able to put the module into loopback by reversing sealing current. Unlike the T1 module, the 2- or 4-wire, 56/64-kbps CSU/DSU module can still initiate remote loopbacks with the **no** form of this command configured.

Examples

The following example enables transmitting and receiving remote loopbacks:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module 56k remote-loopback
```

Related Commands

Command	Description
loopback remote (interface)	Loops packets through a CSU/DSU, over a DS3 link or a channelized T1 link, to the remote CSU/DSU and back.

service-module 56k switched-carrier

To select a service provider to use with a 2- or 4-wire, 56/64-kbps dial-up serial line, use the **service-module56kswitched-carrier** command in interface configuration mode. To enable the default service provider, use the **no** form of this command.

service-module 56k switched-carrier {**att** | **sprint** | **other**}
no service-module 56k switched-carrier {**att** | **sprint** | **other**}

Syntax Description

att	AT&T or other digital network service provider. This is the default on the 4-wire, 56/64-kbps CSU/DSU module.
sprint	Sprint or other service provider whose network requires echo cancelers. This is the default on the 2-wire, switched 56-kbps CSU/DSU module.
other	Any other service provider.

Command Default

ATT is enabled on the 4-wire, 56/64-kbps CSU/DSU module. Sprint is enabled on the 2-wire, switched 56-kbps CSU/DSU module.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

On a Sprint network, echo-canceler tones are sent during call setup to prevent the echo cancelers from damaging digital data. The transmission of echo-canceler tones may increase call setup times by 8 seconds on the 4-wire module. Having echo cancellation enabled does not affect data traffic.

This configuration command is ignored if the network type is DDS.

Examples

The following example configures AT&T as a service provider :

```
Router(config)# interface serial 0
Router(config
-if)
# service-module 56k network-type switched
Router(config
-if)
# service-module 56k switched-carrier att
```

Related Commands

Command	Description
service-module 56k network-type	Sends packets in switched dial-up mode or DDS mode using a serial interface on a 4-wire, 56/64-kbps CSU/DSU module.

service-module analysis-module reload

To perform a graceful halt and reboot of the Network Analysis Module (NAM) software on the NM-NAM network module, use the **service-moduleanalysis-modulereload** command in privileged EXEC mode.

service-module **analysis-module** *slot/unit* **reload**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For the NM-NAM, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

The **service-moduleanalysis-modulereload**command is the Cisco IOS equivalent of the **reboot** NAM CLI command. These commands can be used to initiate the NAM software upgrade process or to access the NAM helper image.

Examples

The following example shows how to gracefully halt and reboot the NAM application software:

```
Router# service-module analysis-module 1/0 reload

Do you want to proceed with reload?[confirm]
Trying to reload Service Module Analysis-Module1/0.
```

Related Commands

Command	Description
service-module analysis-module reset	Resets the hardware on the NM-NAM.
service-module analysis-module shutdown	Gracefully halts the operating system on the NM-NAM.
service-module analysis-module status	Displays hardware and software status information about the NM-NAM.

service-module analysis-module reset

To reset the hardware on the Network Analysis Module (NM-NAM), use the **service-moduleanalysis-modulereset** command in privileged EXEC mode.

service-module analysis-module *slot/unit* **reset**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For the NM-NAM, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

Use the **service-moduleanalysis-modulereset** command to bring up the NM-NAM after it has been shut down using the **service-moduleanalysis-moduleshutdown** command.

Examples

The following example shows how to reset the hardware on the NM-NAM:

```
Router# service-module analysis-module 1/0 reset

Use reset only to recover from shutdown or failed state
Warning:May lose data on the hard disc!
Do you want to reset?[confirm]
Trying to reset Service Module Analysis-Module1/0.
```

Related Commands

Command	Description
service-module analysis-module reload	Gracefully halts and reboots the software on the NM-NAM.
service-module analysis-module shutdown	Gracefully halts the operating system on the NM-NAM.
service-module analysis-module status	Displays hardware and software status information about the NM-NAM.

service-module analysis-module session

To access the Network Analysis Module (NAM) console from the router, use the **service-moduleanalysis-modulesession** command in privileged EXEC mode.

service-module analysis-module *slot/unit* **session** [**clear**]

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For the NM-NAM, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.
clear	(Optional) Clears the NAM console line.

Command Default

The router cannot access the NAM console.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

When entered without the **clear** keyword, this command opens a NAM console session from the router.

Examples

Opening a NAM console Session

The following example shows how to open a NAM console session when the NM-NAM is installed in router slot 2:

```
Router# service-module analysis-module 2/0 session

Trying 10.1.1.1, 2065 ... Open
<Press Return>

Cisco Network Analysis Module (NM-NAM)
nam1.cisco.com login: root

Password: <password>

Terminal type: vt100
Cisco Network Analysis Module (NM-NAM) Console, 3.2(0.9)
Copyright (c) 1999-2003 by Cisco Systems, Inc.
```

```
WARNING! Default password has not been changed!
root@nam1.cisco.com#
```

Clearing the NAM Console Line

The following example shows how to clear the NAM console line when the NM-NAM is installed in router slot 1:

```
Router# service-module analysis-module 1/0 session clear

[confirm]
 [OK]
```

Related Commands

Command	Description
ssh	Starts an encrypted session with a remote networking device.
telnet	Logs in to a host that supports Telnet.

service-module analysis-module shutdown

To gracefully halt the operating system on the Network Analysis Module (NM-NAM), use the **service-moduleanalysis-moduleshutdown** command in privileged EXEC mode.

service-module analysis-module *slot/unit* **shutdown** [**no-confirm**]

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For the NM-NAM, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.
no-confirm	(Optional) No confirmation message appears before shutdown.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

The **service-moduleanalysis-moduleshutdown** command properly brings down the operating system of the Network Analysis Module (NM-NAM) to protect the network module's hard drive. When the operating system has been shut down, the NM-NAM can be removed from the router.

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

If you enter the **no-confirm** keyword, the confirmation prompt does not appear.

Examples

Gracefully Halt the Operating System with Confirmation

The following example shows how to gracefully halt the operating system of the NM-NAM in slot 1:

```
Router# service-module analysis-module 1/0 shutdown

Shutdown is used for Online removal of Service Module.
Do you want to proceed with shutdown?[confirm]
Use service module reset command to recover from shutdown.
```

Gracefully Halt the Operating System -- No Confirmation

The following example shows how to gracefully halt the operating system of the NM-NAM in slot 2 without any user confirmation:

```
Router# service-module analysis-module 2/0 shutdown no-confirm
Use service module reset command to recover from shutdown.
```

Related Commands

Command	Description
service-module analysis-module reload	Gracefully halts and reboots the software on the NM-NAM.
service-module analysis-module reset	Resets the hardware on the NM-NAM.
service-module analysis-module status	Displays hardware and software status information about the NM-NAM.

service-module analysis-module status

To display hardware and software status information about the Network Analysis Module (NM-NAM), use the **service-moduleanalysis-modulestatus** command in privileged EXEC mode.

service-module analysis-module *slot/unit* **status**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For the NM-NAM, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

Use the **service-moduleanalysis-modulestatus** command to:

- Display the NAM software release version.
- Check the NAM status (steady or down).

Examples

The command in the following example displays information about the NM-NAM in router slot 1:

```
Router# service-module analysis-module 1/0 status

Service Module is Cisco Analysis-Module1/0
Service Module supports session via TTY line 33
Service Module is in Steady state
Getting status from the Service Module, please wait...
Cisco Network Analysis Module (NM-NAM), version 3.2(0.8)
```

Related Commands

Command	Description
show controllers analysis-module	Displays controller information for the analysis module interface.
show interfaces analysis-module	Displays status, traffic data, and configuration information about the analysis module interface.

service-module backup interface

To configure an interface as a secondary or dial backup to the satellite interface, use the **servicemodulebackupinterface** command in satellite interface configuration mode. To remove the backup interface configuration, use the **no** form of this command.

service module backup interface *interface*
no service module backup interface *interface*

Syntax Description

interface	Interface type and number.

Command Default

No default behavior or values

Command Modes

Satellite interface configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Examples

The following example shows how to set interface async 1 as the backup to the satellite link:

```
Router(config-if)# service-module backup interface async1
```

Related Commands

Command	Description
service-module backup mode	Sets the terrestrial backup mode for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

service-module backup mode

To set the terrestrial dial backup mode for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **service-modulebackupmode** command in satellite interface configuration mode. To return to the router (default) dial backup mode, use the **no** form of this command.

service-module backup mode [{**hub** | **router**}]
no service-module backup mode

Syntax Description

hub	Hub dial backup mode.
router	Router dial backup mode.

Command Default

Router dial backup mode

Command Modes

Satellite interface configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Hub Dial Backup Mode

Hub dial backup mode maintains TCP connections during transitions between primary and backup links. Note, however, that hub dial backup mode provides backup for the satellite *link* , but not for the NM-1VSAT-GILAT network module hardware, the router satellite interface, or other router interfaces. If the satellite link goes down (for example, because of rain fade) in hub dial backup mode, the NM-1VSAT-GILAT network module connects to the hub using dial-on-demand routing (DDR). Common DDR backup links use ISDN BRIs, modems on auxiliary ports, and T1/E1 lines.

The NM-1VSAT-GILAT network module always encapsulates packets using a satellite backbone protocol before sending the packets over the satellite link. In hub dial backup mode, the NM-1VSAT-GILAT network module continues to encapsulate the packets using the satellite backbone protocol before sending the packets over the dial backup link to the hub; this is how hub dial backup mode maintains TCP connections during transitions between the primary satellite link and the dial backup link. Therefore, hub dial backup mode works only when the NM-1VSAT-GILAT network module itself is functioning properly.

Router Dial Backup Mode

If the satellite link goes down in router dial backup mode, the router uses DDR to send data out a different interface. Unlike hub dial backup mode, router dial backup mode does these things:

- Tears down and reestablishes TCP connections during transitions between primary and backup links
- Does not require that the NM-1VSAT-GILAT network module work properly while the backup link is in use

Examples

The following example shows how to specify hub backup mode:

```
Router(config-if)# service-module backup mode hub
```

The following example shows how to specify router backup mode:

```
Router(config-if)# service-module backup mode router
```

Related Commands

Command	Description
service-module backup interface	Specifies the interface to use to back up the satellite interface.

service-module content-engine reload

To perform a graceful halt and reboot of a content engine (CE) network module operating system, use the **service-modulecontent-enginereload** command in privileged EXEC mode.

service-module content-engine *slot/unit* **reload**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example gracefully halts and reboots the CE network module operating system in slot 1:

```
Router# service-module content-engine 1/0 reload
Do you want to proceed with reload?[confirm]
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
service-module content-engine reset	Resets the hardware on a CE network module.
service-module content-engine shutdown	Gracefully halts a CE network module.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module content-engine reset

To reset the hardware on a content engine (CE) network module, use the **service-modulecontent-enginereset** command in privileged EXEC mode.

service-module content-engine *slot/unit* **reset**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Note Use the **service-modulecontent-enginereset** command only to recover from a shutdown or failed state because you may lose data.

Examples

The following example resets the hardware on the CE network module in slot 1:

```
Router# service-module content-engine 1/0 reset
Use reset only to recover from shutdown or failed state
Warning: May lose data on the hard disc!
Do you want to reset?[confirm]
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
service-module content-engine reload	Performs a graceful halt and reboot of a CE network module operating system.
service-module content-engine shutdown	Gracefully halts a CE network module.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module content-engine session

To access a content engine (CE) network module console and begin a configuration session, use the **service-modulecontent-enginesession** command in privileged EXEC mode.

service-module content-engine *slot* / *unit* **session** [**clear**]

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.
clear	(Optional) Clears the CE configuration session.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

Only one session at a time is allowed into the content engine from the internal CE network-module-side interface. This interface provides console access to the CE network module from the router command-line interface (CLI) by initiating a reverse Telnet connection that uses the IP address of the CE interface and the terminal (TTY) line associated with the CE network module. The TTY line number is calculated using the formula (n*32) + 1, where *n* is the number of the chassis slot that contains the CE network module. The CE interface must be up before you can use this command.

Once a session is started, you can perform any CE configuration task. You first access the CE console in a user-level shell. To access the privileged EXEC command shell, where most commands are available, use the **enable** command. Note that this is a Cisco Application and Content Networking System (ACNS) software command, not a Cisco IOS software command.

CE configuration tasks are described in the documentation for Cisco Application and Content Networking Software, *Release 4.2. Initial CE configuration tasks are covered in the* Cisco Content Delivery Networking Products Getting Started Guide, *section 6, "Perform an Initial Startup Configuration."*

After you finish CE configuration and exit the CE console session, use this command with the **clear** keyword to clear the session. At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows a CE session being opened for a CE network module in slot 2:

```
Router# service-module content-engine 2/0 session
Trying 10.10.10.1, 2129 ... Open
CE-netmodule con now available
Press RETURN to get started!
CE-netmodule> enable
CE-netmodule#
```

The following example clears the session that had been used to configure the CE in the network module in slot 1:

```
Router# service-module content-engine 1/0 session clear
[confirm]
 [OK]
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module content-engine shutdown

To gracefully halt a content engine (CE) network module, use the **service-modulecontent-engineshutdown** command in privileged EXEC mode.

service-module content-engine *slot/unit* **shutdown**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

The **service-modulecontent-engineshutdown** command brings down the operating system of the specified content engine network module in an orderly fashion to protect the network module's hard drive. When the system has been shut down, the network module can be removed from the router.

Examples

The following example gracefully halts the CE network module in slot 1:

```
Router# service-module content-engine 1/0 shutdown
Shutdown is used for Online removal of Service Module.
Do you want to proceed with shutdown?[confirm]
Use service module reset command to recover from shutdown.
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
service-module content-engine reload	Performs a graceful halt and reboot of a CE network module operating system.
service-module content-engine reset	Resets the hardware on a CE network module.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module content-engine status

To display configuration information related to the hardware and software on the content engine (CE) side of a CE network module, use the **service-modulecontent-enginestatus**command in privileged EXEC mode.

service-module content-engine *slot* / *unit* **status**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Usage Guidelines

Use the **service-modulecontent-enginestatus** command to:

- Display the CE network module software release version.
- Check the CE network module status (steady or down).
- Display hardware information for the CE network module including CPU, memory, interface, and disk drive information.

Examples

The following example displays information for a CE network module in router slot 1:

```
Router# service-module content-engine 1/0 status
Service Module is Cisco Content-Engine1/0
Service Module supports session via TTY line 33
Service Module is in Steady state
Getting status from the Service Module, please wait..
Application and Content Networking Software (ACNS)

```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module external ip address

To define the IP address for the external LAN interface on a content engine (CE) network module, use the **service-moduleexternalipaddress**command in content-engine interface configuration mode. To delete the IP address associated with this interface, use the **no** form of this command.

service-module external ip address *external-ip-addr subnet-mask*
no service-module external ip address

Syntax Description

external-ip-addr	IP address of the external LAN interface on a CE network module.
subnet-mask	Subnet mask to append to the IP address.

Command Default

No default behavior or values

Command Modes

Content-engine interface configuration

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Examples

The following example defines an IP address for the external LAN interface on the CE network module in slot 1:

```
Router(config)# interface content-engine 1/0
Router(config-if)# service-module external ip address
 172.18.12.28 255.255.255.0
Router(config-if)# exit
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module heartbeat-reset disable

To disable the service module from being reset when the heartbeat is lost, use the service-module heartbeat-reset disable command in configuration interface mode. To allow a reset of the service module when no heartbeat is received, use the **no** form of this command.

service-module heartbeat-reset disable
no service-module heartbeat-reset disable

Syntax Description

This command has no arguments or keywords.

Command Default

Heartbeat reset is enabled.

Command Modes

Configuration interface (config-if)

Command History

Release	Modification
15.1(4)M	This command was introduced.

Usage Guidelines

With the existing IOS code, if no heartbeat is received from a service module after a period of time, the IOS resets the service module. For some applications, this reset function should be disabled because it blocks normal operations.

This command, being a configuration mode command, persists through router reloads.

Alternatively, the service-module ism heartbeat-reset disable command and the service-module sm heartbeat-reset disable command can prevent Cisco IOS software from rebooting the internal service module (ISM) and the SM-SRE service module, respectively, when the heartbeat is lost. However, both these commands are EXEC mode commands and they are lost when the router reboots.

Examples

The following example shows how to disable the heartbeat reset:

```
Router(config)# interface sm 1/0
Router(config-if)# service-module heartbeat-reset disable
```

Related Commands

Command	Description
service-module	Sets service module parameters.
service-module ism heartbeat-reset	Prevents Cisco IOS software from rebooting the ISM when the heartbeat is lost.
service-module sm heartbeat-reset	Prevents Cisco IOS software from rebooting the SM-SRE service module when the heartbeat is lost.

service-module ids-sensor

To reboot, reset, enable console access to, shutdown, and monitor the status of the Cisco Intrusion Detection System (IDS) network module, use the **service-moduleids-sensor** command in privileged EXEC mode.

service-module ids-sensor *slot/port* {**reload** | **reset** | **session** | **shutdown** | **status**}

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *port*	Port number of the network module. For Cisco IDS network modules, always use 0. The slash mark is required between the *slot* argument and the *unit*argument.
reload	Performs a graceful halt and reboot of the operating system on a Cisco IDS network module.
reset	Resets the hardware on the Cisco IDS network module. This command is usually used to recover from a shutdown.
session	Enables console access to the Cisco IDS network module from the router.
shutdown	Shuts down the IDS applications that are running on a Cisco IDS network module.
status	Provides information on the status of the Cisco IDS software.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)T	This command was introduced.

Usage Guidelines

If a confirmation prompt is displayed, press **Enter** to confirm the action or **n** to cancel.

The Cisco IDS network module is also referred to as the NM-CIDS.

Examples

The following example gracefully halts and reboots the operating system on the Cisco IDS network module in slot 1:

```
Router# service-module ids-sensor 1/0 reload
Do you want to proceed with reload?[confirm]
```

The following example resets the hardware on the Cisco IDS network module in slot 1. A warning is displayed.

```
Router# service-module ids-sensor 1/0 reset
Use reset only to recover from shutdown or failed state
Warning: May lose data on the hard disk!
Do you want to reset?[confirm]
```

Caution Hard-disk drive data loss occurs only if you issue the reset command without first shutting down the Cisco IDS network module. You can use the reset command safely in other situations.

The following example enables console access to the Cisco IDS network module operating system in slot 1:

```
Router# service-module ids-sensor 1/0 session
```

The following example shuts down IDS applications that are running on the Cisco IDS network module in slot 1:

```
Router# service-module ids-sensor 1/0 shutdown
Trying 10.10.10.1, 2129 ... Open
%SERVICEMODULE-5-SHUTDOWN2:Service module IDS-Sensor1/0 shutdown complete
```

The following example shows the status of the Cisco IDS software:

```
Router# service-module ids-sensor 1/0 status
Service Module is Cisco IDS-Sensor1/0
Service Module supports session via TTY line 33
Service Module is in Steady state
Getting status from the Service Module, please wait...
Service Module Version information received, Major ver = 1, Minor ver= 1
Cisco Systems Intrusion Detection System Network Module
Software version: 4.1(1)S42(0.3)
Model: NM-CIDS
Memory: 254676 KB
```

Related Commands

Command	Description
ids-service-module monitoring	Enables IDS monitoring on a specified interface.

service-module integrated-service-engine default-boot

To configure the integrated-service-engine (ISE) network module to use the default BIOS and bootloader, use the service-module integrated-service-engine **default-boot** command in privileged EXEC mode.

service-module integrated-service-engine slot/unit default-boot

Syntax Description

slot	Number of the router chassis slot for the network module.
unit	Number of daughter cards on the network module, if included. For ISE network modules, always use 0.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for the ISE network module.

Examples

After a downtime event or failed upgrade, use the service-module integrated**-service-engineslot/unitdefault-boot** command to configure the network module to use the primary BIOS and primary bootloader to perform startup routines.

The following is sample output from the **integrated-service-engineslot/unitdefault-boot** command for a port adapter in chassis slot 2 on a Cisco router:

```
Router# service-module integrated-service-engine 2/0 default-boot
clear  Clear Default Boot
set    Set Default Boot

Router# service-module integrated-service-engine 2/0 default-boot clear
Router# service-module integrated-service-engine 2/0 default-boot set
```

service-module integrated-service-engine reload

To perform a graceful shutdown and reboot of the integrated-service-engine (ISE) network module operating system, use the **service-moduleintegrated-service-enginereload** command in privileged EXEC mode.

service-module integrated-service-engine *slot/unit* **reload**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For ISE network modules, always use 0. The slash mark (/) is required between the *slot* argument and the *unit*argument.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example gracefully shuts down and reboots the ISE network module's operating system in slot 1:

```
Router# service-module integrated-service-engine 1/0 reload
Do you want to proceed with reload?[confirm]
```

Related Commands

Command	Description
interface integrated-service-engine	Configures an interface for ISE network modules and enters interface configuration mode.
service-module integrated-service-engine reset	Resets the hardware on ISE network modules.
service-module integrated-service-engine shutdown	Gracefully shuts down ISE network modules.
show diag	Displays controller information for ISE network modules.
show interfaces integrated-service-engine	Displays basic interface configuration information for ISE network modules.

service-module integrated-service-engine reset

To reset the integrated-service-engine (ISE) network module hardware, use the **service-moduleintegrated-service-enginereset** command in privileged EXEC mode.

service-module integrated-service-engine *slot/unit* **reset**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For ISE network modules, always use 0. The slash mark (/) is required between the *slot* argument and the *unit*argument.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Caution Because you may lose data, use the **service-moduleintegrated-service-enginereset** command only to recover from a shutdown or failed state.

Examples

The following example resets the hardware on the ISE network module in slot 1:

```
Router# service-module integrated-service-engine 1/0 reset
Use reset only to recover from shutdown or failed state
Warning: May lose data on the hard disk!
Do you want to reset?[confirm]
```

Related Commands

Command	Description
interface integrated-service-engine	Configures an interface for ISE network modules and enters interface configuration mode.
service-module integrated-service-engine reload	Performs a graceful shutdown and reboot on the ISE network module operating system.
service-module integrated-service-engine shutdown	Gracefully shuts down ISE network modules.
show diag	Displays controller information for ISE network modules.

Command	Description
show interfaces integrated-service-engine	Displays basic interface configuration information for ISE network modules.

service-module integrated-service-engine session

To begin a configuration session with an integrated-service-engine (ISE) network module through a console connection, use the **service-moduleintegrated-service-enginesession** command in privileged EXEC mode.

service-module integrated-service-engine *slot/unit* **session** [**clear**]

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For ISE network modules, always use 0. The slash mark (/) is required between the *slot* argument and the *unit*argument.
clear	(Optional) Clears the ISE configuration session.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Usage Guidelines

Only one session at a time is allowed into the network module from the internal ISE network-module-side interface.

After starting a session, you can perform any ISE configuration task. You first access the ISE console in a user-level shell. To access the privileged EXEC command shell, where most commands are available, use the **enable** command.

After you finish ISE configuration and exit the ISE console session, use this command with the **clear** keyword to clear the session. At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows an ISE session being opened for an ISE network module in slot 2:

```
Router# service-module integrated-service-engine 2/0 session
Trying 10.10.10.1, 2129 ... Open
ISE-netmodule con now available
Press RETURN to get started!
ISE-netmodule> enable
ISE-netmodule#
```

The following example clears the session that had been used to configure the ISE in the network module in slot 2:

```
Router# service-module integrated-service-engine 1/0 session clear
[confirm]
 [OK]
```

Related Commands

Command	Description
enable	Enters prviledged EXEC mode.
interface	Configures an interface and enters interface configuration mode.
show diag	Displays controller information for a network module.
show interface integrated-service engine	Displays basic interface configuration information for network modules.

service-module integrated-service-engine shutdown

To gracefully shut down an integrated-service-engine (ISE) network module, use the **service-moduleintegrated-service-engineshutdown** command in privileged EXEC mode.

service-module integrated-service-engine *slot/unit* **shutdown**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For ISE network modules, always use 0. The slash mark (/) is required between the *slot* argument and the *unit*argument.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

The **service-moduleintegrated-service-engineshutdown** command brings down the operating system of the specified integrated-service-engine network module in an orderly fashion to protect the hard drive. When the system has been shut down, the module can be removed from the router.

Examples

The following example gracefully shuts down the ISE network module in slot 1:

```
Router# service-module integrated-service-engine 1/0 shutdown
Shutdown is used for Online removal of Service Module.
Do you want to proceed with shutdown?[confirm]
Use service module reset command to recover from shutdown.
```

Related Commands

Command	Description
interface integrated-service-engine	Configures an interface for ISE network modules and enters interface configuration mode.
service-module integrated-service-engine reload	Performs a graceful shut down and reboot of an ISE network module operating system.
service-module integrated-service-engine reset	Resets the hardware on ISE network modules.
show diag	Displays controller information for ISE network modules.
show interfaces integrated-service-engine	Displays basic interface configuration information for ISE network modules.

service-module integrated-service-engine status

To display configuration information related to the hardware and software on the integrated-service-engine (ISE) side of a network module, use the **service-moduleintegrated-service-enginestatus**command in privileged EXEC mode.

service-module integrated-service-engine *slot*/*unit* **status**

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For ISE network modules, always use 0. The slash mark (/) is required between the *slot* argument and the *unit*argument.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Usage Guidelines

Use the **service-moduleintegrated-service-enginestatus** command to

- Display the ISE network module's software release version
- Check the ISE network module status (steady or down)
- Display hardware information for the ISE network module, including CPU, memory, interface, and disk drive information

Examples

The following example displays information for an ISE network module in router slot 1:

```
Router# service-module integrated-service-engine 1/0 status
Service Module is Cisco integrated-service-engine1/0
Service Module supports session via TTY line 33
Service Module is in Steady state
Getting status from the Service Module, please wait..

Related Commands

Command	Description
interface integrated-service-engine	Configures an interface for ISE network modules and enters interface configuration mode.
show diag	Displays controller information for ISE network modules.
show interfaces integrated-service-engine	Displays basic interface configuration information for ISE network modules.

service-module integrated-service-engine statistics

To display reset and reload information for an integrated-service-engine (ISE) network module and its Cisco IOS software, use the **service-moduleintegrated-service-enginestatistics**command in EXEC mode.

service-module integrated-service-engine *slot/port* **statistics**

Syntax Description

module	Designates a specific ISE network module installed in the router.
slot	Designates the slot where the selected ISE network module is installed in the router.

Command Default

none

Command Modes

User EXEC

Privileged EXEC

Command History

Release	Modification
12.4(9)T	This command was introduced for ISE network modules.

Examples

The following example displays information for an ISE network module in an access router for slot 2:

```
Router# service-module integrated-service-engine 2/0 statistics
Module Reset Statistics:
  CLI reset count = 1
  CLI reload count = 0
  Registration request timeout reset count = 0
  Error recovery timeout reset count = 0
  Module registration count = 2
The last IOS initiated event was a cli reset at *13:34:33.847 UTC Sun Dec 18 2005
```

service-module ip address

To define the IP address for the internal network-module-side interface on a content engine network module (NM-CE-BP), Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), Cisco cable modem high-speed WAN interface card (HWIC-CABLE-D-2, HWIC-CABLE-E/J-2), or the Cisco Services Ready Engine (Cisco SRE) modules (SM-SRE-XXX-K9, ISM-SRE-XXX-K9) use the **service-moduleipaddress** command in content-engine interface configuration mode, satellite interface configuration mode, content-engine configuration mode, or service-module interface configuration mode. To delete the IP address associated with this interface, use the **no** form of this command.

service-module ip address *nm-side-ip-addr subnet-mask* [*"string"*]
no service-module ip address [*"string"*]

Syntax Description

nm-side-ip-addr	IP address of the internal network-module-side interface on a CE network module (NM-CE-BP), Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), or Cisco cable modem high-speed WAN interface card (HWIC-CABLE-D-2, HWIC-CABLE-E/J-2).
subnet-mask	Subnet mask to append to the IP address.
string	(Optional) Name of the virtual interface on the module side that will be assigned the IP address. The string must be in quotes. This argument is available on Cisco SRE modules only.

Command Default

The well-known diagnostic IP address of 192.168.100.1, is supported on all physical interfaces associated with the cable modem to CPE interface (CMCI).

Command Modes

Content-engine interface configuration Satellite interface configuration Cable-modem interface configuration Service-module interface configuration

Command History

Release	Modification
12.2(11)YT	This command was introduced for the CE network module.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.
12.3(14)T	This command was implemented for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
12.4(6)XE	This command was implemented for the Cisco cable modem high-speed WAN interface card (HWIC-CABLE-D-2, HWIC-CABLE-E/J-2).
15.1(4)M	The optional *string* argument was added on Cisco SRE modules only.

Usage Guidelines

Content Engine Network Module (NM-CE-BP)

There are no usage guidelines for this command.

Cisco IP VSAT Satellite WAN Network Module (NM-1VSAT-GILAT)

For the NM-1VSAT-GILAT network module, the **service-moduleipaddress** command is typically not used. The NM-1VSAT-GILAT network module IP address is automatically configured when you enter the **ipaddress** command in satellite interface configuration mode to configure the IP address and subnet mask of the router satellite interface with these conditions:

- The IP address leaves a remainder of 2 when the last octet is divided by 4.
- The subnet mask has /30 or fewer masking bits.

If you use this method to configure the IP address for the router satellite interface, the system automatically configures the IP address and subnet mask on the NM-1VSAT-GILAT network module with these results:

- The IP address is 1 less than the IP address you configured for the router satellite interface.
- The subnet mask is /30.

You can override the automatically configured IP address and mask by manually entering the **service-moduleipaddress** command.

Note The automatically configured IP address does not appear in the router configuration, because the **service-moduleipaddress** command is considered to be set to its default value. Similarly, if you manually configure an IP address and subnet mask that are identical to the automatically configured IP address and subnet mask, the **service-moduleipaddress** command does *not* appear in the router configuration.

Cisco Cable Modem High-Speed WAN Interface Card (HWIC-CABLE-D-2, HWIC-CABLE-E/J-2)

There are no usage guidelines for this command.

Cisco SRE Modules (SM-SRE-XXX-K9, ISM-SRE-XXX-K9)

In Cisco IOS Release 15.1(4)M and later releases, the Cisco SRE modules support an optional "*string*" argument to this command to allow for multiple IP addresses to be configured on the module side. The application running on the SRE module can accept or reject the applied configuration.

Examples

This section provides the following examples:

Content Engine Network Module (NM-CE-BP) Example

The following example shows how to define an IP address for the internal network-module-side interface on the CE network module in slot 1:

```
Router(config)# interface content-engine 1/0
Router(config-if)# service-module ip address 172.18.12.26 255.255.255.0
Router(config-if)# exit
```

Cisco IP VSAT Satellite WAN Network Module (NM-1VSAT-GILAT) Example--Manually Configuring the IP Address

In the following example, the router satellite interface is assigned an IP address (10.0.0.7), the last octet of which does *not* leave a remainder of 2 when divided by 4. The system displays a message to manually configure the IP address for the NM-1VSAT-GILAT network module. Notice that the IP addresses for both the router satellite interface and the NM-1VSAT-GILAT network module appear in the running configuration.

```
Router(config)# interface satellite 1/0

Router(config-if)# ip address 10.0.0.7 255.255.255.0

%VSAT-6-PIMINCOMPADDR:The IP address configured on Satellite1/0
      requires a manually configured IP address for the satellite module
Router(config-if)# service-module ip address 10.0.0.6 255.255.255.0
Router(config-if)# end

Router# show running-config | begin Satellite

interface Satellite 1/0
   ip address 10.0.0.7 255.255.255.0
   service-module ip address 10.0.0.6 255.255.255.0
```

Cisco IP VSAT Satellite WAN Network Module (NM-1VSAT-GILAT) Example--Using the Automatically Configured IP Address

In the following example, the router satellite interface IP address is configured as 10.0.0.6. Because the last octet of the IP address leaves a remainder of 2 when divided by 4, the system automatically configures the IP address for the NM-1VSAT-GILAT network module.

Although the NM-1VSAT-GILAT network module IP address and mask do not appear in the router configuration, you know that the IP address is 1 less than the IP address of the router satellite interface and has a subnet mask of /30. In this case, the NM-1VSAT-GILAT network module is automatically configured with the following IP address and mask: 10.0.0.5 255.255.255.252.

```
!
interface Satellite 1/0
 ip address 10.0.0.6 255.255.255.0
!
```

Cisco IP VSAT Satellite WAN Network Module (NM-1VSAT-GILAT) Example--Overriding the Automatically Configured IP Address

In the following example, the router satellite interface IP address is configured as 10.0.0.6. Because the last octet of the IP address leaves a remainder of 2 when divided by 4, the system automatically configures the IP address and mask for the NM-1VSAT-GILAT network module as 10.0.0.5 255.255.255.252.

Nevertheless, the NM-1VSAT-GILAT network module IP address and mask are manually configured as 10.0.0.1 255.255.255.0 to override the automatically derived IP address and mask. Notice that the IP addresses for both the router satellite interface and the NM-1VSAT-GILAT network module appear in the running configuration.

```
!
interface Satellite 1/0
 ip address 10.0.0.6 255.255.255.0
 service-module ip address 10.0.0.1 255.255.255.0
!
```

Cisco Cable Modem High-Speed WAN Interface Cards (HWIC-CABLE-D-2, HWIC-CABLE-E/J-2) Example

The following example shows how to define an IP address for the cable modem interface in slot 0:

```
Router(config)# interface cable-modem 0

Router(config-if)# service-module ip address 172.18.12.26 255.255.255.0

Router(config-if)# exit
```

Cisco SRE Module (ISM-SRE-XXX-K9, SM-SRE-XXX-K9) Example

The following example shows how to define an IP address for the service module interface in slot 3:

```
Router(config)# interface SM 3/0

Router(config-if)# service-module ip address 172.18.12.26 255.255.255.0

Router (config-if)# service-module ip address 172.18.12.27 255.255.255.0 “VirtualMachine1”
Router (config-if)# service-module ip address 172.18.12.28 255.255.255.0 “VirtualMachine2”
Router(config-if)# exit
```

Related Commands

Command	Description
show controllers content-engine	Displays controller information for CE network modules.
show controllers satellite	Displays controller information about the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
show interfaces satellite	Displays general interface settings and traffic rates for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module ip default-gateway

To define a default gateway (router) for a content engine (CE) network module, use the **service-moduleipdefault-gateway**command in content-engine interface configuration mode. To remove the default gateway from the CE configuration, use the **no** form of this command.

service-module ip default-gateway *gw-ip-addr*
no service-module ip default-gateway

Syntax Description

gw-ip-addr	IP address of the default gateway.

Command Default

No default behavior or values

Command Modes

Content-engine interface configuration

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Examples

The following example configures a default gateway for the CE network module in slot 1:

```
Router(config)# interface content-engine
 1/0
Router(config-if)# service-module ip default-gateway
 172.18.12.1
Router(config-if)# exit
```

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show controllers content-engine	Displays controller information for CE network modules.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

service-module ip redundancy

To link the primary HSRP interface status to that of the satellite interface, use the **service-module ip redundancy** command in satellite interface configuration mode. To remove the link between the primary HSRP interface status and the satellite interface status, use the **no** form of this command.

service-module ip redundancy *group-name*
no service-module ip redundancy *group-name*

Syntax Description

group-name	Name of the hot standby group. This name must match the hot standby group name configured for the primary HSRP interface, which is typically an Ethernet interface.

Command Default

HSRP is disabled.

Command Modes

Satellite interface configuration (config-if)

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **service-module ip redundancy** command only when you have two Cisco IP VSAT satellite WAN network modules (NM-1VSAT-GILAT) on separate HSRP-redundant routers that connect to the same outdoor unit (ODU).

This command enables the satellite interface to spoof the line protocol UP state.

Examples

The following example shows how to link the primary HSRP interface status to that of the satellite interface:

```
Router (config-if)# service-module ip redundancy grp-hsrp
```

Related Commands

Command	Description
standby ip	Activates HSRP.
standby name	Configures the name of the hot standby group.
standby preempt	Enables preemption on the router and optionally configures a preemption delay.
standby track	Configures an interface so that the hot standby priority changes based on the availability of other interfaces.

service-module ism default-boot

To configure the internal service module (ISM) to use the default BIOS and bootloader, use the **service-moduleismdefault-boot** command in privileged EXEC mode.

service-module ism *slot/port* **default-boot**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Default

The default BIOS and bootloader are not used by the ISM.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

After a downtime event or failed upgrade, use this command to configure the service module to use the primary BIOS and primary bootloader to perform startup routines.

Examples

The following is sample output for an ISM:

```
Router# service-module ism 0/0 default-boot
clear  Clear Default Boot
set    Set Default Boot

Router# service-module ism 0/0 default-boot clear
Router# service-module ism 0/0 default-boot set
```

service-module ism heartbeat-reset

To prevent Cisco IOS software from rebooting the internal service module (ISM) when the heartbeat is lost, use the **service-moduleismheartbeat-reset** command in privileged EXEC mode.

service-module ism *slot/port* **heartbeat-reset** {**disable** | **enable**}

Syntax Description

slot	Number of the router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.
disable	Disables reset of the ISM if the heartbeat is lost.
enable	Enables reset of the ISM if the heartbeat is lost.

Command Default

ISM is reset when heartbeat is lost.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

When the ISM is booted in fail-safe mode or is undergoing an upgrade, this command prevents a reboot during the process.

When the ISM heartbeat is lost, the router applies a fail-open or fail-close configuration option to the module, stops sending traffic to the module, and sets the module to error state. The router performs a hardware reset on the ISM and monitors it until the heartbeat is reestablished.

Examples

The following example shows how to disable the ISM from being reset if the heartbeat is lost:

```
Router# service-module ism 0/0 heartbeat-reset disable
```

You can display the status of the heartbeat reset feature with the **service-moduleismstatus**command:

```
Router# service-module ism 0/0 status

Service Module is Cisco IDS-Sensor 0/0
Service Module supports session via TTY line 194
Service Module heartbeat-reset is enabled <=====
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
service-module ism reload	Performs a graceful shutdown and reboot of the ISM.

Command	Description
service-module ism reset	Resets the ISM hardware.
service-module ism shutdown	Performs a graceful shutdown of the ISM.
service-module ism status	Displays configuration information related to the hardware and software on an ISM.

service-module ism install

To use Cisco SRE to install an application on a internal service module (Cisco ISM-SRE), use the **service-moduleisminstall**command in privileged EXEC configuration mode.

service-module ism *slot/port* **install url** *url* [**script** *filename*] [**argument** *"string"*] [**force**]

Syntax Description

slot/port	Location of the services engine module in the router. For internal service modules, the slot and port number must be 0.
url *url*	Address of FTP or HTTP server, as defined in RFC 2396, on which application packages and Tcl scripts are located.
script	(Optional) Changes name of Tcl script to be run from default value to script specified by *filename* argument.
filename	Name of Tcl script.
argument	(Optional) Installer will not present options for the variable specified in the *string* argument.
“ *string* **”**	Alphanumeric characters of variable to be passed directly to the Tcl script via the command line. Variable must be enclosed in quotation marks (“ ”)
force	(Optional) Tcl script automatically proceeds with install without prompting for user input.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command uses a common module-dependent bootloader to install a Linux-based application, such as Cisco Unity Express or Cisco AXP, on an internal service module (Cisco ISM-SRE).

The slash mark (/) is required between the *slot* argument and the *port* argument.

You can only issue one instance of this command at a time on a router. You cannot use this command to install an application on two or more services engine modules in the same router at a time.

The Tcl script to be run must reside in the same FTP or HTTP server and directory as the application packages to be installed. If a credential is required, the user name and password must be imbedded in the url as shown in the following example:

```
Router# service-module ism 0/0 install url ftp://username:passwd@server.com/axp
```

If two or more of the optional keyword/argument combinations are used with this command, they must be issued in the order presented in the command syntax. For example, you cannot use the **force** keyword before the **script** or**argument** keywords, nor the **argument** keyword before the **script** keyword, when you issue this command.

Use the **script***filename* keyword/argument combination with this command to specify that the Cisco IOS software use some Tcl script other than the default installer during the installation.

Use the **argument“***string***”** keyword/argument combination with this command to manually provide variables during installation process and bypass the user interaction feature of the installer. The variable must include the left and right quotation marks (“ ”).

Use the **force** keyword with this command to install an application without prompting for user input. If you use this keyword and if the application requires you to provide certain variables during the installation, you should also use the **argument“***string***”** keyword/argument combination to manually provide the required variables because the **force** keyword will direct the installer to bypass all user interaction during the installation.

To stop the install while the Tcl script is being downloaded, use the **service-moduleisminstallabort**command. This command cannot be used once the actual installation begins.

Examples

The following example shows how to use this command to run the “help.sre” Tcl script rather than the default installation Tcl script:

```
Router# service-module ism 0/0 install url ftp://server.com/cue script help.sre
Router#
```

The following example shows how to direct the installer to use the specified language variable for US English instead of prompting you with language options for Cisco Unity Express:

```
Router# service-module ism 0/0 install url ftp://server.com/cue argument “lang=en_us”
Router#
```

The following example shows the messages displayed on the module console during a successful installation using Cisco SRE:

```
Feb  6 19:09:22.526 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-ISM 0/0 PROGRESSING:
Validating package signature ...1 .
Feb  6 19:09:23.058 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-ISM 0/0 PROGRESSING: Parsing
 package manifest files ...1 .
Feb  6 19:09:44.742 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-ISM 0/0 PROGRESSING:
Starting payload download1 .
Feb  6 19:09:52.022 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-ISM 0/0 PROGRESSING:
Performing Hot install ...1 .
Install successful on Service-Module-ISM 0/0 Feb  6 19:10:28.826 EDT: %SM_INSTALL-6-INST_SUCC:
 Service-Module-ISM 0/0 SUCCESS: install-completed .
```

Related Commands

Command	Description
service-module ism install abort	Stops the install process and returns to the boot-loader prompt.
service-module ism uninstall	Uses Cisco SRE to uninstall an SRE-supported application on an SRE-enabled services engine module.

service-module ism install abort

To abort the Cisco SRE install process on a Cisco ISM-SRE, use the **service-moduleisminstallabort**command in privileged EXEC configuration mode.

service-module ism *slot/port* **install abort** [**force**]

Syntax Description

slot/port	Location of the services engine module in the router. For internal service modules, the slot and port number must be 0.
force	(Optional) Tcl script automatically stops the installation without prompting for confirmation.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command stops the installation during the downloading portion of the process only. You cannot use this command to stop the process once the actual installation has begun.

Use the **force** keyword with this command to stop the process without first prompting for confirmation.

Examples

The following example shows how to use this command to stop an application installation without first prompting for confirmation:

```
Router# service-module ism 0/0 install abort force
.
.
.
boot-loader>
```

Related Commands

Command	Description
service-module ism install	Uses Cisco SRE to install an SRE-supported application on an SRE-enabled services engine module.

service-module ism reload

To perform a graceful shutdown and reboot of the internal service module (ISM) operating system, use the **service-moduleismreload** command in privileged EXEC mode.

service-module ism *slot*/*port* **reload**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced for ISMs.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows how to gracefully shut down and reboot the ISM operating system:

```
Router# service-module ism 0/0 reload

Do you want to proceed with reload?[confirm]
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
service-module ism reset	Resets the ISM hardware.
service-module ism shutdown	Gracefully shuts down the ISM.
show diag	Displays controller information for ISMs.
show interfaces ism	Displays basic interface configuration information for ISMs.

service-module ism reset

To reset the internal service module (ISM) hardware, use the **service-moduleismreset** command in privileged EXEC mode.

service-module **ism** *slot*/*port* **reset**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced for ISMs.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Caution Because you may lose data, use the **service-moduleismreset** command only to recover from a shutdown or failed state.

Examples

The following example shows how to reset the ISM hardware:

```
Router# service-module ism 0/0 reset

Use reset only to recover from shutdown or failed state
Warning: May lose data on the the NVRAM, nonvolatile file system or unsaved configuration!
Do you want to reset?[confirm]
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
service-module ism reload	Performs a graceful shutdown and reboot of the ISM operating system.
service-module ism shutdown	Gracefully shuts down the ISM.
show diag	Displays controller information for ISMs.
show interfaces ism	Displays basic interface configuration information for ISMs.

service-module ism session

To begin a configuration session for an internal service module (ISM) through a console connection, use the **service-moduleismsession** command in privileged EXEC mode.

service-module ism *slot/port* **session** [**clear**]

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.
clear	(Optional) Clears the ISM configuration session.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Only one session at a time is allowed into the service module from the ISM interface.

After starting a session, you can perform any ISM configuration task. You first access the ISM console in a user-level shell. To access the privileged EXEC command shell, where most commands are available, use the **enable** command.

After you finish configuration tasks and exit the ISM console session, use this command with the **clear** keyword to clear the session. At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows a session being opened for an ISM:

```
Router# service-module ism 0/0 session

Trying 10.10.10.1, 2129 ... Open

ISE-netmodule con now available
Press RETURN to get started!

ISE-netmodule> enable
ISE-netmodule#
```

The following example clears the session that had been used to configure the ISM in slot 0:

```
Router# service-module ism 0/0 session clear
[confirm]
 [OK]
```

Related Commands

Command	Description
enable	Enters privileged EXEC mode.

Command	Description
interface	Configures an interface and enters interface configuration mode.
show diag	Displays controller information for a service module.
show interface ism	Displays basic interface configuration information for service modules.

service-module ism shutdown

To gracefully shut down an internal service module (ISM), use the **service-moduleismshutdown** command in privileged EXEC mode.

service-module ism *slot*/*port* **shutdown**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

This command brings down the operating system of the specified ISM in an orderly fashion to protect the hard drive. When the system has been shut down, the module can be removed from the router.

Examples

The following example shows how to gracefully shut down the ISM:

```
Router# service-module ism 0/0 shutdown

Do you want to proceed with shutdown?[confirm]
Use service module reset command to recover from shutdown.

WARNING: Confirm that the service-module status shows 'is Shutdown' before removing the
module or powering off the system !
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
service-module ism reload	Performs a graceful shut down and reboot of the ISM operating system.
service-module ism reset	Resets the hardware on the ISM.
show diag	Displays controller information for ISMs.
show interfaces ism	Displays basic interface configuration information for ISMs.

service-module ism statistics

To display reset and reload information for an internal service module (ISM) and its Cisco IOS software, use the **service-moduleismstatistics**command in EXEC mode.

service-module ism *slot* / *port* **statistics**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Examples

The following example displays information for an ISM:

```
Router# service-module ism 0/0 statistics

Module Reset Statistics:
 CLI reset count = 0
 CLI reload count = 0
 Registration request timeout reset count = 0
 Error recovery timeout reset count = 0
 Module registration count = 1
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
service-module ism reload	Performs a graceful shutdown and reboot of the ISM operating system.
service-module ism reset	Resets the ISM hardware.
service-module ism shutdown	Gracefully shuts down the ISM.
show interfaces ism	Displays basic interface configuration information for ISMs.

service-module ism status

To display configuration information related to the hardware and software on an internal service module (ISM), use the **service-moduleismstatus**command in privileged EXEC mode.

service-module ism *slot*/*port* **status**

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Use this command to:

- Display the ISMs software release version
- Check the ISM status (steady or down)
- Display hardware information for the ISM, including CPU, memory, and interface information

Examples

The following example displays information for an ISM:

```
Router# service-module ism 0/0 status

Service Module is Cisco ISM0/0
Service Module supports session via TTY line 323
Service Module is in Steady state
Service Module heartbeat-reset is enabled
Getting status from the Service Module, please wait..
Cisco Foundation Software 1.0
FNDN Running on ISM
No install/uninstall in progress
```

Related Commands

Command	Description
interface ism	Configures an interface for an ISM and enters interface configuration mode.
show diag	Displays controller information for service modules.
show interfaces ism	Displays basic interface configuration information for ISMs.

service-module ism uninstall

To use Cisco SRE to uninstall an application on an internal service module (Cisco ISM-SRE), use the **service-moduleismuninstall**command in privileged EXEC configuration mode.

service-module ism *slot/port* **uninstall** [**force**]

Syntax Description

slot / *port*	Location of the services engine module in the router. For internal service modules, the slot and port number must be 0.
force	(Optional) Tcl script automatically proceeds with uninstall without prompting for confirmation.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command completely erases the disk or compact flash on the SRE-enabled services engine module and removes the application keys. It does not remove application licenses.

The slash mark (/) is required between the *slot* argument and the *port*argument.

You can only issue one instance of this command at a time on a router. You cannot use this command to uninstall an application on two or more services engine modules in the same router at a time.

Use the **force** keyword with this command to uninstall an application without first prompting for confirmation.

Examples

The following example shows how to use this command to uninstall an application without first prompting for confirmation:

```
Router# service-module ism 0/0 uninstall force
Router#
```

Related Commands

Command	Description
service-module ism install	Uses Cisco SRE to install an SRE-supported application on an SRE-enabled services engine module.

service-module mgf ip address

To place the service module (Cisco SM-SRE or Cisco ISM-SRE) on a subnet, use the **service-modulemgfipaddress**command in interface configuration mode.

service-module mgf ip address *ip-address subnet-mask* [**vlan** *vlan-id*]

Syntax Description

ip-address	IP address of the module's MGF interface.
subnet-mask	Subnet mask to append to the IP address.
vlan *vlan-id*	(Optional) Number of the VLAN to be assigned. The valid range is from 2 to 4094.

Command Default

Service module is not placed on a subnet.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use this command without the **vlan***vlan-id*argument to configure the IP address on the module side for the default VLAN (VLAN 1). Use this command with the **vlan***vlan-id*argument to configure the IP address on the module side for VLANs other than VLAN 1.

Examples

The following example assigns IP addresses to the default VLAN of the port and VLAN 20:

```
Router(config)# interface sm 1/0
Router(config-if)# service-module mgf ip address 192.0.2.0
Router(config-if)# service-module mgf ip address 192.0.2.1 vlan 20
```

service-module mgf ip default-gateway

To define a default gateway (router) for a service module (Cisco SRE SM or Cisco SRE ISM), use the **service-modulemgfipdefault-gateway**command in interface configuration mode.

service-module mgf ip default-gateway *gateway-ip-address* [**vlan** *vlan-id*]

Syntax Description

gateway-ip-address	IP address of the module's default gateway.
vlan *vlan-id*	(Optional) Number of the VLAN to be assigned. The valid range is from 2 to 4094.

Command Default

Default gateway is not defined for a service module.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use this command without the **vlan***vlan-id*argument to configure the default gateway on the module side for the default VLAN (VLAN 1). Use this command with the **vlan***vlan-id*argument to configure the default gateway on the module side for VLANs other than VLAN 1.

Examples

The following example assigns 192.0.2.0 as the default gateway for VLAN 1:

```
Router(config)# interface sm 2/0
Router(config-if)# service-module mgf ip default-gateway 192.0.2.0
```

service-module mgf ipv6 address

To place the service module (Cisco SM-SRE or Cisco ISM-SRE) on a subnet, use the **service-modulemgfipv6address**command in interface configuration mode.

service-module mgf ipv6 address *ipv6-address* [**vlan** *vlan-id*]

Syntax Description

ipv6-address	IPv6 address of the module's MGF interface.
vlan-id	(Optional) Number of the VLAN to be assigned. The valid range is from 2 to 4094.

Command Default

IPv6 address is not configured on the service module.

Command Modes

Interface configuration (config-if)

Command History

Release	Modification
15.1(3)T	This command was introduced.

Usage Guidelines

Use this command without the **vlan***vlan-id*argument to configure the IPv6 address on the module side for the default VLAN (VLAN 1). Use this command with the **vlan***vlan-id*argument to configure the IPv6 address on the module side for VLANs other than VLAN 1.

Examples

The following example assigns IPv6 addresses to the default VLAN of the port and VLAN 20:

```
Router(config)# interface sm 2/0
Router(config-if)# service-module mgf ipv6 address 2001:0DB8::/48
Router(config-if)# service-module mgf ipv6 address 2001:0DB8::/48 vlan 20
```

service-module routing redistribute

To enable the router to send its routing database to the satellite network central hub, use the **service-moduleroutingredistribute** command in satellite interface configuration mode. To prevent the router from sending its routing database over the satellite network, use the **no** form of this command.

service-module routing redistribute
no service-module routing redistribute

Syntax Description

This command has no arguments or keywords.

Command Default

The router is enabled to send its routing database to the hub.

Command Modes

Satellite interface configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **service-moduleroutingredistribute** command is used on a VSAT router, that is, an earthbound modular access router equipped with a Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT) that connects to a satellite network. When VSAT route updates are enabled, the NM-1VSAT-GILAT network module uses Router Blade Configuration Protocol (RBCP) messages to communicate VSAT routing table changes to the hub.

Entering the **noservice-moduleroutingredistribute** command is useful when you do not want the hub to be aware of all the routes known by the VSAT router, such as when Network Address Translation (NAT) is configured on the router.

The hub must learn the remote VSAT routing database for the satellite network to function properly. Therefore, if you enter the **noservice-moduleroutingredistribute** command, then one of the following actions is required:

- You use RIPv2 as the only routing protocol on your VSAT router. The hub can understand and track RIPv2 route updates.
- On the hub router, configure static routes to the VSAT router networks.

Examples

The following example shows how to prevent the VSAT router from sending its routing database to the satellite network central hub:

```
Router(config-if)# no service-module routing redistribute
```

service-module satellite backup

To test the hub dial backup connection for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **service-modulesatellitebackup** command in privileged EXEC mode.

service module satellite *slot/unit* **backup** {**initiate** | **terminate**}

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
initiate	Initiates a hub dial backup connection.
terminate	Terminates a hub dial backup connection.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The **service-modulesatellitebackup** command is used only when you configure *hub* dial backup for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

Normally, the hub dial backup connection comes up only when the satellite link goes down (for example, because of a rain-fade event). The **service-modulesatellitebackup** command allows you to artificially bring down the satellite link to test the hub dial backup connection.

Examples

The following example shows how to initiate a satellite backup test:

```
Router# service-module satellite 1/0 backup initiate
```

The following example shows how to terminate a running satellite backup test:

```
Router# service-module satellite 1/0 backup terminate
```

Related Commands

Command	Description
service-module backup interface	Specifies the interface to use to back up the satellite interface on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
service-module backup mode	Sets the terrestrial backup mode for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

service-module satellite configuration

To enter satellite initial configuration mode, use the **service-modulesatelliteconfiguration**command in user EXEC or privileged EXEC mode.

service-module satellite *slot/unit* **configuration**

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.

Command Default

No default behavior or values.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

You need a password from your satellite service provider to enter satellite initial configuration mode.

The parameters that you configure in satellite initial configuration mode are saved directly to the network module and do not appear in the router configuration, even though you configure the parameters through the Cisco IOS CLI.

To view the parameter values that were configured in satellite initial configuration mode, use one of the following commands:

- **show** command in satellite initial configuration mode
- **service-module satellite** *slot* **/0** **status** command in privileged EXEC mode

Note This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

Examples

The following example shows how to enter satellite initial configuration mode:

```
Router> service-module satellite 1/0 configuration
Password: <mypassword>
Reminder:changing any parameters will result in a software reset of the module.
Router(sat-init-config)>
```

Related Commands

Command	Description
end (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
exit (satellite initial configuration)	Exits satellite initial configuration mode, saves any new or changed parameters, and resets the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
service-module satellite status	Displays status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters.
show (satellite initial configuration)	Displays the initial configuration parameters for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

service-module satellite cw-mode

To enable or disable continuous wave mode, use the **service-modulesatellitecw-mode** command in satellite interface configuration mode.

service-module satellite *slot/unit* **cw-mode** {**off** | **on frequency** *frequency* [**time** *time*]}

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
off	Disables continuous wave mode.
on	Enables continuous wave mode.
frequency *frequency*	Frequency, in kilohertz, in the range from 900000 to 1650000.
time *time*	Length of time, in seconds, that continuous wave mode is enabled. The *time* argument is a number in the range from 60 to 1800.

Command Default

Continuous wave mode is disabled.

If the time is not specified, continuous wave mode continues until turned off.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.
12.4(2)T	A password challenge was added to the command-line interface when continuous wave mode is enabled.

Usage Guidelines

Continuous wave mode can be enabled only when the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT) is in boot mode.

When continuous wave mode is enabled, the NM-1VSAT-GILAT network module transmits unmodulated carrier waves that can be used for dish antenna orientation adjustments and for signal quality measurements.

Note This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to do so.

Note You need a password from your satellite service provider to enable continuous wave mode.

Examples

The following example shows how to enable continuous wave mode for 2 minutes, at 900000 kilohertz:

```
Router# service-module satellite 1/0 cw-mode on frequency 900000 time 120

Password: <mypassword>
CW mode obtained.
```

The following example shows how to disable continuous wave mode:

```
Router# service-module satellite 1/0 cw-mode off

CW mode released.
```

The following example shows the message that appears when you try to enable continuous wave mode while the NM-1VSAT-GILAT network module is *not* in boot mode:

```
Router# service-module satellite 1/0 cw-mode on frequency 900000 time 120

Password <mypassword>
% CW mode NOT obtained!  Valid during boot mode only.
```

service-module satellite status

To display status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters, use the**service-modulesatellitestatus** command in privileged EXEC mode.

service-module satellite *slot/unit* **status** [**log**]

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.
log	Extends the output to include the last ring of messages from the firmware and the last crash dump available from the NM-1VSAT-GILAT network module.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

Use the **service-modulesatellitestatus** command to troubleshoot the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

Examples

See the table below for **service-modulesatellitestatus** command output field descriptions.

This section provides the following examples:

Normal Operation Example

The following example shows that the link to the hub (backbone status) is up, as is expected in normal working conditions:

```
Router# service-module satellite 2/0 status

```

Software Reset Example

The following example shows what appears during the beginning stages of a software reset:

```
Router# service-module satellite 2/0 status

   Getting status from the satellite module, please wait..
   % Satellite2/0 card is busy.  Status is not available.  Try later.
```

Hub Dial Backup Example

The following example shows that the hub dial backup link is being used instead of the satellite link. Note, however, that hub dial backup keeps the backbone status up. In hub dial backup mode, the NM-1VSAT-GILAT network module connects to the hub over a specified dial backup link and maintains TCP connections.

```
Router# service-module satellite 1/0 status

Getting status from the satellite module, please wait..

The table below describes the significant fields shown in the displays.

Table 28: service-module satellite status Field Descriptions

Field	Description
Software Versions HW Version	Software (not Cisco IOS) and hardware versions on the NM-1VSAT-GILAT network module. Useful for technical support.
CPA Number HPS CPA HSP Link AA Group SW Group Download	VSAT-to-hub link parameters.
Oper Mode	Operational mode; one of the following values: • OPERATIONAL--Boot complete and running operational code. • BOOT HOLD--Held in boot mode. • BOOT--In boot mode after a reset. • IDLE--Transitional state. • UNKNOWN--Indicates an error.

Field	Description
In Dial Backup	YES indicates that the satellite link is down and that the hub dial backup connection is in use. NO means that the hub dial backup connection is not in use or not configured. **Note** This field does not indicate whether *router* dial backup mode is in use.
Standby	YES indicates that the router in which the NM-1VSAT-GILAT network module is installed is in standby mode for Hot Standby Router Protocol (HSRP). NO indicates that the router in which the NM-1VSAT-GILAT network module is installed is either in active mode for HSRP, or HSRP is not configured.
One-Way	YES indicates one-way operational mode. NO indicates two-way operational mode.
RBCP Received Packets RBCP Sent Packets	Number of sent and received Router Blade Configuration Protocol (RBCP) packets.
IP Address/Mask	IP address and subnet mask of the NM-1VSAT-GILAT network module.
RX Lock Sync Lock	Corresponds to the following LEDs on the NM-1VSAT-GILAT network module faceplate: • RX LOCK--Indicates whether or not the DVB (outbound) receiver is locked. • SYNC--Indicates whether or not the NM-1VSAT-GILAT network module is synchronized with the hub timing. For both fields: • LOCKED indicates that the initial connection to the hub was successful. This means that the dish antenna is positioned correctly and the satellite initial configuration parameters are valid. • NOT LOCKED indicates that the NM-1VSAT-GILAT network module is in a transitional state during the boot process. If NOT LOCKED does not eventually become LOCKED, then the satellite initial configuration parameters are incorrect, there is a hardware problem, or the satellite signal has faded because of rain-fade or obstruction.
BackBone Status	Backbone link to the hub, either fully established (UP) or not fully established (DOWN). Corresponds to the ON LINE LED on the NM-1VSAT-GILAT network module faceplate.

Field	Description
Two-Way Mode	YES indicates two-way operational mode. NO indicates one-way operational mode.
DA/RA Mode	Indicates whether the satellite link is operating in random access (RA) or dedicated access (DA) mode. DA mode is required for VoIP calls.
Outbound Modulation Type OB Code Rate Outbound ID OB PID OB Freq OB Bit Rate Outbound Sync IP address	Satellite initial configuration parameters: • Outbound modulation type • Outbound Viterbi code rate • Outbound VSAT ID • Outbound packet identifier (PID) • Outbound frequency • Outbound data rate • Outbound synchronization IP address
Internal Software State parameters	Internal states that are useful for technical support.
VOIP DA calls	Information about VoIP calls, which use DA mode. **Note** This field appears only on routers that run VoIP-enabled Cisco IOS software images.
Last forced reset log from card	Debug information used by technical support.

Related Commands

Command	Description
show (satellite initial configuration)	Displays the initial configuration parameters for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
show controllers satellite	Displays controller information about the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).
show interfaces satellite	Displays general interface settings and traffic rates for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

service-module service-engine

To enter the Cisco Unity Express command environment using a network module (NM) or an advanced Integration Module (AIM) card module, use the **service-moduleservice-engine** command in privileged EXEC mode.

service-module service-engine *slot/port* **session**

Syntax Description

slot	Slot number of the NM or AIM.
port	Port number of the NM or AIM.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(15)ZJ	This command was introduced for NMs.
12.3(4)T	This command was integrated into Cisco IOS Release 12.3(4)T.
12.3(7)T	Support was added for AIMs.

Usage Guidelines

This command may only be used for NMs and AIMs running Cisco Unity Express. If your system does not have this hardware, then you will be unable to enter this command.

The **no** form of this command (**nointerfaceservice-engine**) is not available. You can enter the **exit** command to return to the router.

Examples

The following example shows the command for enabling Cisco Unity Express command environment using either a NM or AIM located in slot 4, port 0:

```
Router# service-module service-engine 4/0 session
Router# Trying 172.18.106.66, 2129 ... Open
```

service-module sm default-boot

To configure the SM-SRE service module to use the default BIOS and bootloader, use the **service-modulesmdefault-boot** command in privileged EXEC mode.

service-module sm *slot*/*port* **default-boot**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

After a downtime event or failed upgrade, use this command to configure the service module to use the primary BIOS and primary bootloader to perform startup routines.

Examples

The following is sample output for a service module:

```
Router# service-module sm 1/0 default-boot
clear  Clear Default Boot
set    Set Default Boot

Router# service-module sm 1/0 default-boot clear
Router# service-module sm 1/0 default-boot set
```

service-module sm heartbeat-reset

To prevent Cisco IOS software from rebooting the SM-SRE service module when the heartbeat is lost, use the **service-modulesmheartbeat-reset** command in privileged EXEC mode.

service-module sm *slot/port* **heartbeat-reset** {**disable** | **enable**}

Syntax Description

slot	Number of the router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.
disable	Disables reset of the service module if the heartbeat is lost.
enable	Enables reset of the service module if the heartbeat is lost.

Command Default

Service module is reset when heartbeat is lost.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

When the service module is booted in failsafe mode or is undergoing an upgrade, this command prevents a reboot during the process.

When the service module heartbeat is lost, the router applies a fail-open or fail-close configuration option to the module, stops sending traffic to the module, and sets the module to error state. The router performs a hardware reset on the service module and monitors it until the heartbeat is reestablished.

Examples

The following example shows how to disable the service module from being reset if the heartbeat is lost:

```
Router# service-module sm 1/0 heartbeat-reset disable
```

You can display the status of the heartbeat reset feature with the **service-modulesmstatus**command:

```
Router# service-module sm 1/0 status

Service Module is Cisco IDS-Sensor 1/0
Service Module supports session via TTY line 194
Service Module heartbeat-reset is enabled <=====
```

Related Commands

Command	Description
interface sm	Configures an interface for a service module and enters interface configuration mode.
service-module sm reload	Performs a graceful shutdown and reboot of the service module.

Command	Description
service-module sm reset	Resets the service module hardware.
service-module sm shutdown	Performs a graceful shutdown of the service module.
service-module sm status	Displays configuration information related to the hardware and software on a service module.

service-module sm install

To use Cisco SRE to install an application on a service module (Cisco SM-SRE), use the **service-modulesminstall**command in privileged EXEC configuration mode.

service-module sm *slot/port* **install url** *url* [**script** *filename*] [**argument** *"string"*] [**force**]

Syntax Description

slot / port	Location of the services engine module in the router. For service modules, the slot number is 1 to 4 and the port number must be 0.
url *url*	Address of FTP or HTTP server, as defined in RFC 2396, on which application packages and Tcl scripts are located.
script	(Optional) Changes name of Tcl script to be run from default value to script specified by *filename* argument.
filename	Name of Tcl script.
argument	(Optional) Installer will not present options for the variable specified in the *string* argument.
string	Alphanumeric characters of variable to be passed directly to the Tcl script via the command line. Variable must be enclosed in quotation marks (“ ”)
force	(Optional) Tcl script automatically proceeds with install without prompting for user input.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command uses a common module-dependent bootloader on Cisco SRE to install a Linux-based application, such as Cisco Unity Express or Cisco AXP, on a service module (Cisco SM-SRE).

The slash mark (/) is required between the *slot* argument and the *port* argument.

You can only issue one instance of this command at a time on a router. You cannot use this command to install an application on two or more services engine modules in the same router at a time.

The Tcl script to be run must reside in the same FTP or HTTP server and directory as the application packages to be installed. If a credential is required, the user name and password must be imbedded in the url as shown in the following example:

```
Router# service-module sm 1/0 install url ftp://username:passwd@server.com/axp
```

If two or more of the optional keyword/argument combinations are used with this command, they must be issued in the order presented in the command syntax. For example, you cannot use the **force** keyword before the **script** or**argument** keywords nor the **argument** keyword before the **script** keyword when you issue this command.

Use the **script***filename* keyword/argument combination with this command to specify that the Cisco IOS software use some Tcl script other than the default installer during the installation.

Use the **argument"***string***"** keyword/argument combination with this command to manually provide variables during installation process and bypass the user interaction feature of the installer. The variable must include the left and right quotation marks (" ").

Use the **force** keyword with this command to install an application without prompting for user input. If you use this keyword and if the application requires you to provide certain variables during the installation, you should also use the **argument"***string***"** keyword/argument combination to manually provide the required variables because the **force** keyword will direct the installer to bypass all user interaction during the installation.

To stop the install while the Tcl script is being downloaded, use the **service-modulesminstallabort** command. This command cannot be used once the actual installation begins.

Examples

The following example shows how to use this command to run a "help.sre" Tcl script rather than the default installation Tcl script:

```
Router# service-module sm 1/0 install url ftp://server.com/cue script help.sre
Router#
```

The following example shows how to direct the installer to use the specified language variable for US English instead of prompting you with language options for Cisco Unity Express:

```
Router# service-module sm 1/0 install url ftp://server.com/cue argument "lang=en_us"
Router#
```

The following example shows the messages displayed on the module console during a successful installation using Cisco SRE:

```
Feb  6 19:09:22.526 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-SM 1/0 PROGRESSING:
Validating package signature ...1 .
Feb  6 19:09:23.058 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-SM 1/0 PROGRESSING: Parsing
 package manifest files ...1 .
Feb  6 19:09:44.742 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-SM 1/0 PROGRESSING: Starting
 payload download1 .
Feb  6 19:09:52.022 EDT: %SM_INSTALL-6-INST_PROG: Service-Module-SM 1/0 PROGRESSING:
Performing Hot install ...1 .
Install successful on Service-Module-SM 1/0 Feb  6 19:10:28.826 EDT: %SM_INSTALL-6-INST_SUCC:
 Service-Module-SM 1/0 SUCCESS: install-completed .
```

Related Commands

Command	Description
service-module sm install abort	Stops the install and returns to the boot-loader prompt.
service-module sm uninstall	Uses Cisco SRE to uninstall an SRE-supported application on an SRE-enabled services engine module.

service-module sm install abort

To abort the Cisco SRE install process on a Cisco SM-SRE, use the **service-modulesminstallabort**command in privileged EXEC configuration mode.

service-module sm *slot/port* **install abort** [**force**]

Syntax Description

slot/port	Location of the services engine module in the router. For service modules, the slot number is 1 to 4 and the port number must be 0.
force	(Optional) Tcl script automatically stops the installation without prompting for confirmation.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command stops the installation during the downloading portion of the process only and returns the console to the boot-loader prompt. You cannot use this command to stop the process once the actual installation has begun.

Use the **force** keyword with this command to stop the process without first prompting for confirmation.

Examples

The following example shows how to use this command to stop an application installation without first prompting for confirmation:

```
Router# service-module sm 4/0 install abort force
.
.
.
boot-loader>
```

Related Commands

Command	Description
service-module sm install	Uses Cisco SRE to install an SRE-supported application on an SRE-enabled services engine module.

service-module sm reload

To perform a graceful shutdown and reboot of the SM-SRE service module operating system, use the **service-modulesmreload** command in privileged EXEC mode.

service-module **sm** *slot*/*port* **reload**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows how to gracefully shut down the module and reboot the operating system:

```
Router# service-module sm 1/0 reload

Do you want to proceed with reload?[confirm]
```

Related Commands

Command	Description
interface sm	Configures an interface for a service module and enters interface configuration mode.
service-module sm reset	Resets the service module hardware.
service-module sm shutdown	Gracefully shuts down the service module.
show diag	Displays controller information for service modules.
show interfaces sm	Displays basic interface configuration information for service modules.

service-module sm reset

To reset the SM-SRE service module hardware, use the **service-modulesmreset** command in privileged EXEC mode.

service-module sm *slot/port* **reset**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Caution Because you may lose data, use the **service-modulesmreset** command only to recover from a shutdown or failed state.

Examples

The following example shows how to reset the service module hardware:

```
Router# service-module sm 1/0 reset

Use reset only to recover from shutdown or failed state
Warning: May lose data on the the NVRAM, nonvolatile file system or unsaved configuration!
Do you want to reset?[confirm]
```

Related Commands

Command	Description
interface sm	Configures an interface for a service module and enters interface configuration mode.
service-module sm reload	Performs a graceful shutdown and reboot of the service module operating system.
service-module sm shutdown	Gracefully shuts down the service module.
show diag	Displays controller information for service modules.
show interfaces sm	Displays basic interface configuration information for service modules.

service-module sm session

To begin a configuration session for an SM-SRE service module through a console connection, use the **service-modulesmsession** command in privileged EXEC mode.

service-module sm *slot/port* **session** [**clear**]

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.
clear	(Optional) Clears the service module configuration session.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Only one session at a time is allowed into the service module from the service module interface.

After starting a session, you can perform any service module configuration task. You first access the service module console in a user-level shell. To access the privileged EXEC command shell, where most commands are available, use the **enable** command.

After you finish configuration tasks and exit the service module console session, use this command with the **clear** keyword to clear the session. At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

Examples

The following example shows a session being opened for an SM-SRE:

```
Router# service-module sm 1/0 session

Trying 10.10.10.1, 2129 ... Open

SE-Module con now available
Press RETURN to get started!

SE-Module> enable
```

The following example clears the session that had been used to configure the SM-SRE in slot 1:

```
Router# service-module sm 1/0 session clear
[confirm]
 [OK]
```

Related Commands

Command	Description
enable	Enters privileged EXEC mode.

Command	Description
interface	Configures an interface and enters interface configuration mode.
show diag	Displays controller information for a service module.
show interface sm	Displays basic interface configuration information for service modules.

service-module sm shutdown

To gracefully shut down an SM-SRE service module, use the **service-modulesmshutdown** command in privileged EXEC mode.

service-module sm *slot*/*port* **shutdown**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action or **n** to cancel.

This command brings down the operating system of the specified service module in an orderly fashion to protect the hard drive. When the system is shut down, the module can be removed from the router.

Examples

The following example shows how to gracefully shut down the service module:

```
Router# service-module sm 1/0 shutdown

Do you want to proceed with shutdown?[confirm]
Use service module reset command to recover from shutdown.

WARNING: Confirm that the service-module status shows 'is Shutdown' before removing the
module or powering off the system !
```

Related Commands

Command	Description
interface sm	Configures an interface for an SM-SRE and enters interface configuration mode.
service-module sm reload	Performs a graceful shut down and reboot of the SM-SRE operating system.
service-module sm reset	Resets the hardware on the SM-SRE.
show diag	Displays controller information for service modules.
show interfaces sm	Displays basic interface configuration information for SM-SREs.

service-module sm statistics

To display reset and reload information for an SM-SRE service module and its Cisco IOS software, use the **service-modulesmstatistics**command in EXEC mode.

service-module sm *slot/port* **statistics**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Examples

The following example displays information for a service module in slot 1:

```
Router# service-module sm 1/0 statistics

Module Reset Statistics:
 CLI reset count = 0
 CLI reload count = 0
 Registration request timeout reset count = 1
 Error recovery timeout reset count = 1
 Module registration count = 1
```

Related Commands

Command	Description
interface sm	Configures an interface for an SM-SRE and enters interface configuration mode.
service-module sm reload	Performs a graceful shutdown and reboot of the SM-SRE operating system.
service-module sm reset	Resets the SM-SRE hardware.
service-module sm shutdown	Gracefully shuts down the SM-SRE.
show interfaces sm	Displays basic interface configuration information for SM-SREs.

service-module sm status

To display configuration information related to the hardware and software on an SM-SRE service module, use the **service-modulesmstatus**command in privileged EXEC mode.

service-module sm *slot*/*port* **status**

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

Use this command to:

- Display the SM-SREs software release version
- Check the SM-SRE status (steady or down)
- Display hardware information for the SM-SRE, including CPU, memory, and interface information

Examples

The following example displays information for an SM-SRE:

```
Router# service-module sm 1/0 status

Service Module is Cisco SM1/0
Service Module supports session via TTY line 67
Service Module is in Steady state
Service Module heartbeat-reset is enabled
Getting status from the Service Module, please wait..
Cisco Foundation Software 1.0
FNDN Running on SM
No install/uninstall in progress
```

Related Commands

Command	Description
interface sm	Configures an interface for an SM-SRE and enters interface configuration mode.
show diag	Displays controller information for service modules.
show interfaces sm	Displays basic interface configuration information for SM-SREs.

service-module sm uninstall

To use Cisco SRE to uninstall an application on a service module (Cisco SM-SRE), use the **service-modulesmuninstall**command in privileged EXEC configuration mode.

service-module sm *slot/port* **uninstall** [**force**]

Syntax Description

slot / *port*	Location of the services engine module in the router. For service modules, the slot number is 1 to 4 and port number must be 0.
force	(Optional) Tcl script automatically proceeds with uninstall without prompting for confirmation.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

This command completely erases the disk or compact flash of the SRE-enabled services engine module and removes the application keys. It does not remove application licenses.

The slash mark (/) is required between the *slot* argument and the *port* argument.

You can only issue one instance of this command at a time on a router. You cannot use this command to uninstall an application on two or more services engine modules in a router at a time.

Use the **force** keyword with this command to uninstall an appliction without first prompting for confirmation.

Examples

The following example shows how to use this command to uninstall an application without first prompting for confirmation:

```
Router# service-module
 sm uninstall 1/0 force
Router#
```

Related Commands

Command	Description
service-module sm install	Uses Cisco SRE to install an SRE-supported application on an SRE-enabled services engine module.

service-module t1 cablelength short

To set transmission attenuation for shorter cable lengths, use the **service-modulet1cablelengthshort** command in interface configuration mode. To disable transmission attenuation for shorter cable lengths, use the **no** form of this command.

service-module t1 cablelength short {**110ft** | **220ft** | **330ft** | **440ft** | **550ft** | **660ft**}
no service-module t1 cablelength short

Syntax Description

110ft	Sets a cable length from 0 to 110 feet.
220ft	Sets a cable length from 111 to 220 feet.
330ft	Sets a cable length from 221 to 330 feet.
440ft	Sets a cable length from 331 to 440 feet.
550ft	Sets a cable length from 441 to 550 feet.
660ft	Sets a cable length from 551 to 660 feet.

Command Default

No default behavior or values

Command Modes

Interface configuration

Command History

Release	Modification
12.2(15)ZL	This command was introduced.
12.3(2)T	This command was integrated into Cisco IOS Release 12.3(2)T.

Usage Guidelines

This command is intended only for the Version 2 card, WIC-1-DSU-T1 V2, as part of the **service-modulet1** configuration options.

Use this command to configure the transmission (tx) attenuation for cables whose length is shorter than or equal to 660 feet. The related command, **service-modulet1lbo**, is used to define the line-build-out values for cable lengths longer than 660ft. At any time, only one, either the short configuration or the lbo configuration, can exist. They cannot co-exist. The configuration of one command will cause the effect of the other command to cease and only the new command will be in effect.

Examples

The following example shows how to set the short cablelength to 220 feet.

```
Router(config)# interface serial 0/0
Router(config-if)# service-module t1 cablelength short 220ft
```

Related Commands

Command	Description
service-module t1 lbo	Configures the CSU line-build-out (lbo) on a fractional T1/T1 DSU/CSU module.

service-module t1 clock source

To specify the clock source for the fractional T1/T1 CSU/DSU module, use the **service-modulet1clocksource** command in interface configuration mode. To return to the default line clock, use the **no** form of this command.

service-module t1 clock source {**internal** | **line**}
no service-module t1 clock source

Syntax Description

internal	Specifies the CSU/DSU internal clock.
line	Specifies the line clock. This is the default.

Command Default

Line clock

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following example sets an internal clock source on serial line 0:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 clock source internal
```

Related Commands

Command	Description
service-module 56k clock source	Sets up the clock source on a serial interface for a 4-wire, 56/64-kbps CSU/DSU module.

service-module t1 data-coding

To guarantee the ones density requirement on an alternate mark inversion (AMI) line using the fractional T1/T1 module, use the **service-modulet1data-coding**command in interface configuration mode. To enable normal data transmission, use the**no**form of this command.

service-module t1 data-coding {**inverted** | **normal**}
no service-module t1 data-coding

Syntax Description

inverted	Inverts bit codes by changing all 1 bits to 0 bits and all 0 bits to 1 bits.
normal	Requests that no bit codes be inverted before transmission. This is the default.

Command Default

Normal transmission

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Data inversion is used to guarantee the ones density requirement on an AMI line when using bit-oriented protocols such as High-Level Data Link Control (HDLC), PPP, X.25, and Frame Relay. If the time slot speed is set to 56 kbps, this command is rejected because line density is guaranteed when transmitting at 56 kbps. Use this command with the 64-kbps line speed.

If you transmit inverted bit codes, both CSU/DSUs must have this command configured for successful communication.

Examples

The following example inverts bit codes using a time slot speed of 64 kbps:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 timeslots all speed 64
Router(config
-if)
# service-module t1 data-coding inverted
```

Related Commands

Command	Description
service-module t1 linecode	Selects the linecode for the fractional T1/T1 module.
service-module t1 timeslots	Defines time slots that constitute a fractional T1/T1 (FT1/T1) channel.

service-module t1 fdl

To set the facilities data link (FDL) parameter to either ATT or ANSI, use the**service-modulet1fdl** command in interface configuration mode. To ignore the FDL parameter, use the **no** form of this command.

service-module t1 fdl {**ansi** | **att**}
no service-module t1 fdl

Syntax Description

ansi	Sets the FDL parameter to ANSI.
att	Sets the FDL parameter to ATT.

Command Default

Determined by the telephone company

Command Modes

Interface configuration

Command History

Release	Modification
11.2 P	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The default is **noservice-modulet1fdl**. The **ansi** or **att** options are determined by your service provider or telephone company.

Examples

The following example sets the FDL parameter to ANSI:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 fdl ansi
```

service-module t1 framing

To select the frame type for a line using the fractional T1/T1 (FT1/T1) module, use the **service-modulet1framing** command in interface configuration mode. To revert to the default, Extended Super Frame, use the **no**form of this command.

service-module t1 framing commandservice-module t1 framing {**esf** | **sf**}
no service-module t1 framing commandservice-module t1 framing {**esf** | **sf**}

Syntax Description

esf	Specifies extended super frame (ESF) as the T1 frame type. This is the default.
sf	Specifies D4 super frame (SF) as the T1 frame type.

Command Default

esf

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command in configurations in which the router communicates with FT1/T1 data lines. The service provider determines which framing type, either **esf** or **sf**, is required for your circuit.

Examples

The following example enables Super Frame as the FT1/T1 frame type:

```
Router(config
-if)
# service-module t1 framing sf
```

service-module t1 lbo

To configure the CSU line-build-out (LBO) on a fractional T1/T1 CSU/DSU module, use the **service-modulet1lbo**command in interface configuration mode. To disable line-build-out, use the **no**form of this command.

service-module t1 lbo {**-15 db** | **-7.5 db** | **none**}
no service-module t1 lbo {**-15 db** | **-7.5 db** | **none**}

Syntax Description

-15 db	Decreases outgoing signal strength by 15 dB.
-7.5 db	Decreases outgoing signal strength by 7.5 dB.
none	Transmits packets without decreasing outgoing signal strength.

Command Default

Disabled

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use this command to decrease the outgoing signal strength to an optimum value for a fractional T1 line receiver. The ideal signal strength should be -15 dB to -22 dB, which is calculated by adding the phone company loss, cable length loss, and line build out.

You may use this command in back-to-back configurations, but it is not needed on most actual T1 lines.

Examples

The following example sets the LBO to -7.5 dB:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 lbo -7.5 db
```

service-module t1 linecode through show controllers satellite

service-module t1 linecode

To select the line code for the fractional T1/T1 module, use the **service-modulet1linecode**command in interface configuration mode. To select the default, the B8ZS line code, use the**no** form of this command.

service-module t1 linecode {**ami** | **b8zs**}
no service-module t1 linecode {**ami** | **b8zs**}

Syntax Description

ami	Specifies alternate mark inversion (AMI) as the line code.
b8zs	Specifies binary 8 zero substitution (B8ZS) as the line code. This is the default.

Command Default

The default line code is B8ZS.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Configuring B8ZS is a method of ensuring the ones density requirement on a T1 line by substituting intentional bipolar violations in bit positions four and seven for a sequence of eight zero bits. When the CSU/DSU is configured for AMI, you must guarantee the ones density requirement in your router configuration using the **service-modulet1data-codinginverted** command or the **service-modulet1timeslotsspeed56**command.

Your T1 service provider determines which line code, either **ami**or **b8zs**, is required for your T1 circuit.

Examples

The following example specifies AMI as the line code:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 linecode ami
```

Related Commands

Command	Description
service-module t1 data-coding	Guarantees the ones density requirement on an AMI line using the fractional T1/T1 module.
service-module t1 timeslots	Defines time slots that constitute a fractional T1/T1 (FT1/T1) channel.

service-module t1 remote-alarm-enable

To generate remote alarms (yellow alarms) at the local CSU/DSU or detect remote alarms sent from the remote CSU/DSU, use the **service-modulet1remote-alarm-enable**command in interface configuration mode. To disable remote alarms, use the**no** form of this command.

service-module t1 remote-alarm-enable
no service-module t1 remote-alarm-enable

Syntax Description

This command has no arguments or keywords.

Command Default

Remote alarms are disabled.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Remote alarms are transmitted by the CSU/DSU when it detects an alarm condition, such as a red alarm (loss of frame) or blue alarm (unframed ones). The receiving CSU/DSU then knows that there is an error condition on the line.

With D4 Super Frame configured, a remote alarm condition is transmitted by setting the bit 2 of each time slot to zero. For received user data that has the bit 2 of each time slot set to zero, the CSU/DSU interprets the data as a remote alarm and interrupts data transmission, which explains why remote alarms are disabled by default. With Extended Super Frame configured, the remote alarm condition is signalled out of band in the facilities data link.

You can see if the FT1/T1 CSU/DSU is receiving a remote alarm (yellow alarm) by issuing the **showservice-moduleserial** command.

Examples

The following example enables remote alarm generation and detection:

```
Router(config)# interface serial 0
Router(config
-if)
# service-module t1 remote-alarm-enable
```

Related Commands

Command	Description
service-module t1 framing	Selects the frame type for a line using the fractional T1/T1 (FT1/T1) module.
show service-module serial	Displays performance statistics for an integrated CSU/DSU.

service-module t1 remote-loopback

To specify that the fractional T1/T1 DSU/CSU module enters loopback mode when it receives a loopback code on the line, use the **service-modulet1remote-loopback** command in interface configuration mode. To disable remote loopbacks, use the **no** form of this command.

service-module t1 remote-loopback {**full** | **payload v54**}
no service-module t1 remote-loopback {**full** | **payload v54**}

Syntax Description

full	Configures the remote loopback code used to transmit or accept CSU loopback requests.
payload	Configures the loopback code used by the local CSU/DSU to generate or detect payload-loopback commands.
v54	Industry standard loopback code. Use this keyword for CSU/DSUs that may not support the Accunet loopup standards. This keyword is used only with a payload request, not a full request.

Use the **full**keyword to enable the standard loopup codes, which use a 1-in-5 pattern for loopup and a 1-in-3 pattern for loopdown. Use the **payloadv54**keywords to enable the v54 pseudo-random loopup codes for loopup and v54 pseudo-random loopdown codes for loopdown.

Command Default

Full and payload loopbacks with standard loopup codes

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.3(2)T	The provision for an **alternate** loopback code was removed.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The **no** form of this command disables loopback requests. For example, the **noservice-modulet1remote-loopbackfull** command ignores all full-bandwidth loopback transmissions and requests.

Configuring the **no** form of the command might not prevent telco line providers from looping your router in extended super frame (esf) mode because fractional T1/T1 lines use facilities data link messages to initiate loopbacks.

To have the loopback remote commands on the FT1/T1 CSU/DSU module function successfully, you need to enable the **service-modulet1remote-loopback** command.

Note Use the **full**keyword to enable the standard loopup codes, which use a 1-in-5 pattern for loopup and a 1-in-3 pattern for loopdown. Use the **payloadv54**keywords to enable the v54 pseudorandom codes for loopup and v54 pseudorandom codes for loopdown.

Examples

The following example shows how to configure two routers connected back-to-back through a fractional T1/T1 line to enter loopback mode:

```
Router(config)# interface serial 0/0
Router(config-if)# service-module t1 remote-loopback full

Router(config-if)# loopback remote full
!
%SERVICE_MODULE-5-LOOPUPREMOTE: Unit Serial0/0 - Remote unit placed in loopback
Router(config-if)# no loopback remote
%SERVICE_MODULE-5-LOOPDOWNREMOTE: Unit Serial0/0 - Remote loopback test cancelled
The following example shows how to configure two routers connected back-to-back through a
fractional T1/T1 line to enter loopback mode and generate or detect payload-loopback commands:
Router(config-if)# service-module t1 remote-loopback payload v54

Router(config-if)# loopback remote payload
%%SERVICE_MODULE-5-LOOPUPREMOTE: Unit Serial0/0 - Remote unit placed in loopback
```

Related Commands

Command	Description
loopback remote (interface)	Loops packets through a DSU/CSU to a remote DSU/CSU and back over a channelized T1 link.

service-module t1 timeslots

To define time slots that constitute a fractional T1/T1 (FT1/T1) channel , use the **service-modulet1timeslots**command in interface configuration mode. To resume the default setting (all FT1/T1 time slots transmit at 64 kbps), use the **no** form of this command.

service-module t1 timeslots {*range* | **all**} [**speed** {**56** | **64**}]
no service-module t1 timeslots {*range* | **all**}

Syntax Description

range	The DS0 time slots that constitute the FT1/T1 channel. The range is from 1 to 24, where the first time slot is numbered 1 and the last time slot is numbered 24. Specify this field by using a series of subranges separated by commas.
all	Selects all FT1/T1 time slots.
speed	(Optional) Specifies the time slot speed.
56	(Optional) 56 kbps.
64	(Optional) 64 kbps. This is the default.

Command Default

64 kbps is the default for all time slots.

Command Modes

Interface configuration

Command History

Release	Modification
11.2	This command was introduced.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command specifies which time slots are used in fractional T1 operation and determines the amount of bandwidth available to the router in each FT1/T1 channel.

The time-slot range must match the time slots assigned to the channel group. Your service provider defines the time slots that comprise a channel group.

To use the entire T1 line, enable the **service-modulet1timeslotsall**command.

Examples

The following example displays a series of time-slot ranges and a speed of 64 kbps:

```
Router(config
-if)
# service-module t1 timeslots 1-10,15-20,22 speed 64
```

Related Commands

Command	Description
service-module t1 data-coding	Guarantees the ones density requirement on an AMI line using the fractional T1/T1 module.
service-module t1 linecode	Selects the linecode for the fractional T1/T1 module.

service-module wlan-ap bootimage

To configure the boot image on the service module, use the **service-module wlan-ap bootimage** command in privileged EXEC mode.

service-module wlan-ap *interface number* **bootimage** [{**autonomous** | **unified**}]

Syntax Description

interface number	The interface number for the wireless device. Always use 0.
autonomous	Autonomous software image.
unified	Upgrade image with Lightweight Access Point Protocol (LWAPP).

Command Default

Autonomous software image

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20) T	This command was introduced for wireless-enabled Cisco 880 Series and Cisco 890 Series Integrated Services Routers.

Usage Guidelines

When running the advanced IP services feature set on either Cisco 880 Series routers or Cisco 890 Series routers, use the **service-module wlan-ap 0 bootimage unified command**to enable the Cisco unified software upgrade image on the embedded wireless access point. After enabling the unified image, use the **service-module wlan-ap 0 reload** command to perform a graceful shutdown and reboot of the access point.

Note The **service-module wlan-ap 0 bootimage**command does not support recovery images on the embedded access point. Use the **service-module wlan-ap 0 reload** command to shutdown and reboot the access point.

Cisco 880 Series and Cisco 890 Series routers with embedded access point running the unified software image require DHCP to obtain an IP address for the access point. An IP address is needed to communicate with the Wireless LAN Controller (WLC) and to download its image upon boot up. The host router can provide DHCP server functionality through the DHCP pool to reach the WLC, and setup option 43 for the controller IP address in the DHCP pool configuration.

Use the following guideline to setup a DHCP pool on the host router.

```
ip dhcp pool embedded-ap-pool
    network 60.0.0.0 255.255.255.0
    default router 60.0.0.1
    option 43 hex f104.0a0a.0a0f  /* Single WLC IP address (10.10.10.15) in HEX format */
int vlan 1  /* Default Vlan */
ip address 60.0.0.1 255.255.255.0
int Wlan-GigabitEthernet0 /* internal switch-port to AP */
switchport access vlan 1
```

Examples

The following example upgrades the embedded access point image from autonomous to unified.

```
Router#configure terminal
Router(config)#service-module wlan-ap 0 bootimage unified
 *Jan 18 05:31:58.172: %WLAN_AP_SM-6-UNIFIED_IMAGE: Embedded AP will change boot image to
mini-IOS also called LWAPP recovery Please check router config to ensure connectivity between
 WLC and AP. Use service-module wlan-ap 0 reload to bootup mini-IOS image on AP
Router(config)#end
Router#
*Jan 18 05:32:04.136: %SYS-5-CONFIG_I: Configured from console by console
Router#service-module wlan-ap 0 reload
 Reload will save AP config....
Do you want to proceed with reload?[confirm] Trying to reload Service Module wlan-ap0.
Router#
Service Module saved config, start reset.
Received reload request from router
Saving configuration...
Building configuration...
```

Related Commands

Command	Description
interface wlan-ap	Enters wireless interface configuration mode to configure an interface.
service-module wlan-ap reload	Performs a graceful shutdown and reboot of the service module.
service-module wlan-ap reset	Resets the service module hardware.

service-module wlan-ap reload

To perform a graceful shutdown and reboot of the service module use the **service-module wlan-ap reload** command in privileged EXEC mode.

service-module wlan-ap *interface number* **reload**

Syntax Description

interface number	The interface number for the wireless device. Always use 0.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20)T	This command was introduced for wireless-enabled Cisco 860, 880, and 890 Integrated Services Routers.

Usage Guidelines

Autonomous Mode

At the confirmation prompt, press **Enter** to confirm the action, or press **n** to cancel.

Note When running in autonomous mode, the reload command saves the configuration before rebooting. If the attempt is unsuccessful, the following message displays: Failed to save service module configuration.

Unified Mode

The service module reload command is usually handled by the Wireless LAN Controller (WLC).

Note When running in Unified mode, the reload command will produce the following message: The embedded wireless device is in Unified mode. Reload/reset is normally handled by WLC controller. Still want to proceed? [yes]

Examples

The following examples show a graceful shut down and reboot of the service module:

Autonomous Mode

```
Router# service-module wlan-ap0 reload
Do you want to proceed with reload?[confirm]
Router# reload
Do you want to reload the internal AP ? [yes/no]:
Do you want to save the configuration of the AP ? [yes/no]:
System configuration has been modified. Save [yes/no]:
Proceed with reload? [confirm]
```

Unified Mode

```
Router# service-module wlan-ap0 reload
The embedded AP is in Unified mode. Reload/reset is normally handled by WLC controller.
Still want to proceed? [yes]
Router# reload
The embedded AP is in Unified mode. Reload/reset is normally handled by WLC controller.
Do you want to reload the internal AP [yes/no]:
System configuration has been modified. Save [yes/no]:
Proceed with reload [Confirm]
```

Related Commands

Command	Description
interface wlan-ap	Enters wireless interface configuration mode to configure an interface.
service-module wlan-ap reset	Resets the service module hardware.

service-module wlan-ap reset

To reset the service module hardware, software, and configuration, use the **service-module wlan-ap reset** command in privileged EXEC mode.

service-module wlan-ap interface number reset [{**bootloader** | **default-config**}]

Syntax Description

interface number	The interface number for the wireless device. Always use 0.
bootloader	Resets the wireless device to the bootloader for manual image recovery.
default-config	Resets the wireless device to the factory default configuration.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20)T	This command was introduced for wireless-enabled Cisco 860, 880, and 890 Integrated Services Routers.

Usage Guidelines

At the confirmation prompt, press **Enter** to confirm the action, or press **n** to cancel.

Caution Because you may lose data, use the **service-module wlan-ap reset** command only to recover from a shutdown or failed state.

Examples

The following example resets a wireless device on a router that is operating in either autonomous mode or LWAPP mode:

Autonomous Mode

```
Router# service-module wlan-ap0 reset
Use reset only to recover from shutdown or failed state.
```

LWAPP Mode

```
Router# service-module wlan-ap0 reset
The embedded device is in LWAPP mode. Reload/reset is normally handled by WLC controller.
Still want to proceed? [yes]
```

Resetting the Factory Default Configuration on the Wireless Device

The following example resets the wireless device to the default configuration.

```
Router#service-module wlan-ap 0 reset default-config
Router#
```

Recovering the Image on the Wireless Device

The following example resets the wireless device down to the bootloader level for manual image recovery.

```
Router#service-module wlan-ap0 reset bootloader
Router#
```

Related Commands

Command	Description
interface wlan-ap	Enters wireless interface configuration mode to configure an interface.
service-module wlan-ap reload	Performs a graceful shutdown and reboot of the service module.

service-module wlan-ap session

To begin a configuration session with a service module through a console connection use the **service-module wlan-ap session** command in privileged EXEC mode.

service-module wlan-ap *interface number* **session** [{**clear** | **disconnect**}]

Syntax Description

interface number	The interface number for the wireless device. Always use 0.
clear	(Optional) Clears the wireless device configuration session.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20)T	This command was introduced for wireless-enabled Cisco 860, 880, and 890 Integrated Services Routers.

Usage Guidelines

Only one session is allowed at a time into the wireless device from a router console-port connection. After starting a session, perform configuration tasks on the wireless device. You first access the router in a user-level shell. To access the privileged EXEC command shell, where most commands are available, use the **enable** command.

When you finish configuring the device, and would like to exit the console session, type Ctrl-Shift 6x to return to the router's console. Type service-module wlan-ap session **clear** or disconnect to close the session with the device. At the confirmation prompt, press **Enter twice**to confirm the action or **n** to cancel.

Note If you do not clear or disconnect the session on the service module, it will remain open in the background after you return to the router's console prompt. When the session is open in the background, pressing Enter will toggle you back to the wireless device prompt.

Examples

The following example shows a session being opened on a service-module in an ISR:

```
Router# service-module wlan-ap 0 session
Trying 1.2.3.4, 2002 ... Open
AP#
```

The following example clears the session on the service-module in the ISR:

```
Router#service-module wlan-ap 0 session clear
[confirm]
 [OK]
```

Related Commands

Command	Description
enable	Enters privileged EXEC mode.
interface wlan-ap	Enters wireless interface configuration mode to configure an interface.

service-module wlan-ap statistics

To display reset and reload information for a service module and its operating system software, use the **service-module wlan-ap statistics**command in privileged EXEC mode.

service-module wlan-ap interface number statistics

Syntax Description

interface number	The interface number for the wireless device. Always use 0.

Command Default

none

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20)T	This command was introduced for wireless-enabled Cisco 860, 880, and 890 Integrated Services Routers.

Examples

The following example displays information for wireless-enabled Cisco ISRs:

```
Router#service-module wlan-ap 0 statistics
Module Reset Statistics:
  CLI reset count = 0
  CLI reload count = 1
  Registration request timeout reset count = 0
  Error recovery timeout reset count = 0
  Module registration count = 10
The last IOS initiated event was a cli reload at *04:27:32.041 UTC Fri Mar 8 2007
```

Related Commands

Command	Description
interface wlan-ap	Enters wireless interface configuration mode and configures a wireless device.
service-module wlan-ap reset	Resets the wireless device.
service-module wlan-ap reload	Performs a graceful shutdown and reboot on the wireless device.

service-module wlan-ap status

To display configuration information related to hardware and software on the service module, use the **service-module wlan-ap status**command in privileged EXEC mode.

service-module wlan-ap *interface number* **status**

Syntax Description

interface number	The interface number for the wireless device. Aways use 0.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(20)T	This command was introduced for wireless-enabled Cisco 860, 880, and 890 Integrated Services Routers.

Usage Guidelines

Use the **service-module wlan-ap status** command to

- Display the wireless device’s software release version
- Check the wireless device’s status (steady or down)
- Display hardware information for the wireless device, including image, memory, interface, and system uptime

Examples

The following example displays information for the wireless device on a Cisco Integrated Services Router:

```
Router#service-module wlan-ap 0 status

Service Module is Cisco wlan-ap0
Service Module supports session via TTY line 2
Service Module is in Steady state
Service Module reset on error is disabled
Getting status from the Service Module, please wait..
Image path = flash:c8xx_19xx_ap-k9w7-mx.acregr/c8xx_19xx_ap-k9w7-mx.acre
gr
System uptime = 0 days, 4 hours, 28 minutes, 5 seconds
Router#d was introduced for embedded wireless LAN access points on Cisco 860 and 880 Series
 Integrated Services Routers.
```

Related Commands

Command	Description
interface wlan-ap	Enters wireless service module's console interface.

session slot

To open a session with a module (for example, the Multilayer Switch Module (MSM), Network Analysis Module (NAM), or Asynchronous Transfer Mode (ATM)), use the **sessionslot** command in EXEC mode.

session slot *mod* **processor** *processor-id*

Syntax Description

mod	Slot number.
processor *processor-id*	Specifies the processor ID.

Command Default

This command has no default settings.

Command Modes

EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

To end the session, enter the **quit** command.

This command allows you to use the module-specific CLI.

Examples

This example shows how to open a session with an MSM (module 4):

```
Router# session slot 4 processor 2
Router#
```

set ip df

To change the Don't Fragment (DF) bit value in the IP header, use the **setipdf** command in route-map configuration mode. To disable changing the DF bit value, use the **no** form of this command.

set ip df {**0** | **1**}
no set ip df {**0** | **1**}

Syntax Description

0	Sets the DF bit to 0 (clears the DF bit) and allows packet fragmentation.
1	Sets the DF bit to 1 which prohibits packet fragmentation.

Command Default

The DF bit value is not changed in the IP header.

Command Modes

Route-map configuration

Command History

Release	Modification
12.1(6)	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Using Path MTU Discovery (PMTUD) you can determine an MTU value for IP packets that avoids fragmentation. If ICMP messages are blocked by a router, the path MTU is broken and packets with the DF bit set are discarded. Use the **setipdf** command to clear the DF bit and allow the packet to be fragmented and sent. Fragmentation can slow the speed of packet forwarding on the network but access lists can be used to limit the number of packets on which the DF bit will be cleared.

Note Some IP transmitters (notably some versions of Linux) may set the identification field in the IP header (IPid) to zero when the DF bit is set. If the router should clear the DF bit on such a packet and if that packet should subsequently be fragmented, then the IP receiver will probably be unable to correctly reassemble the original IP packet.

Examples

The following example shows how to clear the DF bit to allow fragmentation. In this example a router is blocking ICMP messages and breaking the path MTU. Using policy routing both the inbound and outbound packets on interface serial 0 will have their DF bit set to 0 which allows fragmentation.

```
interface serial 0
ip policy route-map clear-df-bit
route-map clear-df-bit permit 10
match ip address 111
set ip df 0
access-list 111 permit tcp any any
```

Related Commands

Command	Description
ip tcp path-mtu-discovery	Enables Path MTU Discovery.
route-map	Defines a route map to control where packets are output.

set platform hardware qfp active feature ipsec event-monitor

To set the threshold for IP Security (IPsec) crypto failure, use the **set platform hardware qfp active feature ipsec event-monitor type <*failure type*> count** command in the user EXEC mode. To reset the IPsec crypto failure threshold, use the **clear** form of this command.

set platform hardware qfp active feature ipsec event-monitor type {**decrypt failed** | **encrypt failed** | **replay**} **count** *value*

clear set platform hardware qfp active feature ipsec event-monitor type {**decrypt failed** | **encrypt failed** | **replay**} **count value**

Syntax Description

type	Sets the type of event monitor failure. The following options are available: • *decrypt failed* • *encrypt failed* • *replay*
count	Sets the monitored event threshold count.
value	The value of the monitored event threshold count. The range is from 1 to 4294967295. The default value is 0.

Command Default

The event monitor is not enabled.

Command Modes

User EXEC (#)

Command History

Release	Modification
Cisco IOS 12.2 XN	This command was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.

The following example shows how to set the threshold for IPsec crypto failure:

```
Device> set platform hardware qfp active feature ipsec event-monitor type replay count 1
```

shdsl annex

To define the single-pair high-bit-rate digital subscriber line (SHDSL) G.991.2 standard, use the **shdslannex**command in config controller DSL group mode.

shdsl annex {*annexstandard*}

Syntax Description

standard	Defines the standard for the selected type of DSL group. The following annex standards are supported: • A • A-B-F-G • A-F • B (Default annexure) • B-G • F • G **IMA Group** • A • A-B • B **M-PAIR Group** • A • A-B • B • F {coding 16 | 32} • F-G {coding 16 | 32} • G {coding 16 | 32} **1-PAIR and 2-PAIR Group** • A • A-B • B • F {coding 16 | 32} • F-G {coding 16 | 32} • G {coding 16 | 32}

Command Default

SHDSL annex B

Command Modes

Config controller DSL group

Command History

Release	Modification
12.4(15)T	This command was introduced for the Cisco HWIC-4SHDSL and HWIC-2SHDSL running on the Cisco 1841 router and on the Cisco 2800 and 3800 series access routers.
15.1(1)T	This command was modified. The argument *annex* was introduced for the Cisco HWIC-4SHDSL-E

Usage Guidelines

Use the dsl-group command to create a DSL group, and then use the shdsl annex command to define the G.991.2 standard for the DSL group.

Examples

The following example uses the shdsl annex command to define the annex standard for a 2-Pair DSL group on a Cisco HWIC-4SHDSL:

```
Router(config-controller-dsl-group)# shdsl annex ?
  A    Annex A of G.991.2 standard
  A-B  Annex A/B of G.991.2 standard
  B    Annex B of G.991.2 standard
  F    Annex F of G.991.2 standard
  F-G  Annex F/G of G.991.2 standard
  G    Annex G of G.991.2 standard
Router(config-controller-dsl-group)# shdsl annex g ?
  coding  16-TCPAM or 32-TCPAM line coding
Router(config-controller-dsl-group)# shdsl annex g coding ?
  16-TCPAM  16-TCPAM line coding
  32-TCPAM  32-TCPAM line coding
Router(config-controller-dsl-group)# shdsl annex g coding 16 ?
  <cr>
```

Example

```
Router(config-controller-dsl-group)#shdsl annex ?
  A        Annex A of G.991.2 standard
  A-B-F-G  Annex A/B/F/G of G.991.2 standard
  A-F      Annex A/F of G.991.2 standard
  B        Annex B of G.991.2 standard
  B-G      Annex B/G of G.991.2 standard
  F        Annex F of G.991.2 standard
  G        Annex G of G.991.2 standard
Router(config-controller-dsl-group)#shdsl annex f ?
coding  16-TCPAM, 32-TCPAM line coding or auto-TCPAM line coding
```

The above TCPAM configurations are valid only in case the termination is "co". In case the termination is CPE, user will see the following output

```
Router(config-controller-dsl-group)#shdsl annex f ?
<cr>
```

Related Commands

Command	Description
dsl-group	Creates a DSL group and enters config controller DSL group mode.
shdsl rate	Defines the SHDSL rate.

shdsl rate

To define the single-pair high-bit-rate digital subscriber line (SHDSL) rate, use the **shdslrate**command in config-controller-dsl-group mode.

shdsl rate {*number* | **auto**}

Syntax Description

number	SHDSL rate for the digital subscriber line (DSL) group. **DSL Group with 1 Pair** Annex A & B--192-2304 kbps Annex F & G (32 TC-PAM)--768-5696 kbps Annex F & G (16 TC-PAM)--2304-3840 kbps **DSL Group with 2 Pairs** Annex A & B--384-4608 kbps Annex F & G (32 TC-PAM)--1536-11392 kbps Annex F & G (16 TC-PAM)-- 4608-7680 kbps **DSL Group with 3 Pairs** Annex A & B--576-6912 kbps Annex F & G (32 TC-PAM)--2304-12288 kbps Annex F & G (16 TC-PAM)-- 6912-11520 kbps **DSL Group with 4 Pairs** Annex A & B--768-9216 kbps Annex F & G (32 TC-PAM)--3072-16384 kbps Annex F & G (16 TC-PAM)-- 9216-15360 kbps

	Data rates supported for each Annex and TC-PAM 2-wire configuration. For EFM bonding configuration with multiple links, multiply the data rate ranges by the number of links in the EFM bonding group. **2-wire, 16-TCPAM** Annex A--192 - 2304 kbps Annex B--192 - 2304 kbps Annex F--2304 - 3840 kbps Annex G--2304 - 3840 kbps Annex A & F--192 - 3840 kbps Annex B & G--192 - 3840 kbps A & B & F & G--192 - 3840 kbps **2-wire, 32-TCPAM** Annex F--768 - 5696 kbps Annex G--768 - 5696 kbps Annex A & F--768 - 5696 kbps Annex B & G--768 - 5696 kbps Annex A & B & F & G--768 - 5696 kbps **2-wire Auto-TCPAM** Annex A--192 - 2304 kbps Annex B--192 - 2304 kbps Annex F--768 - 5696 kbps Annex G--768 - 5696 kbps Annex A & F--192 - 5696 kbps Annex B & G--192 - 5696 kbps Annex A & B & F & G--192 - 5696 kbps
auto	Sets this SHDSL rate to automatic mode.

Command Default

The command default is the maximum annex rate for the selected DSL group.

Command Modes

Config controller DSL group

Command History

Release	Modification
12.4(15)T	This command was introduced for the Cisco HWIC-4SHDSL and HWIC-2SHDSL running on the Cisco 1841 router and on the Cisco 2800 and 3800 series access routers.
15.1(1)T	This command was modified. Support for the for the Cisco HWIC-4SHDSL-E is added.

Usage Guidelines

Use the dsl-group command to create a DSL group, and then use the shdsl annex command to define the G.991.2 standard for the newly created DSL group. Define the SHDSL line rate with the shdsl rate command.

Examples

The following example defines the SHDSL line rate for DSL group 1, pairs 0-1 (2 pairs) on a Cisco HWIC-4SHDSL:

```
Router(config-controller)# dsl-group 1 pairs 0-1 ima
Router(config-controller-dsl-group)#
Sep 22 14:53:46.481: %HWIC_SHDSL-5-DSLGROUP_UPDOWN: SHDSL 0/2/0 dsl-group(1) state changed
 to down.
Sep 22 14:53:48.481: %LINK-3-UPDOWN: Interface ATM0/2/IMA1, changed state to down
Sep 22 14:53:49.481: %LINEPROTO-5-UPDOWN: Line protocol on Interface ATM0/2/IMA1, changed
state to down
Router(config-controller-dsl-group)# shdsl annex ?
  A    Annex A of G.991.2 standard
  A-B  Annex A/B of G.991.2 standard
  B    Annex B of G.991.2 standard
Router(config-controller-dsl-group)# shdsl annex b ?
  <cr>
Router(config-controller-dsl-group)# shdsl rate auto
  <384-4608>  DSL Rate in kbps(line will train at the rate + 16kbps overhead)
  auto        auto rate mode
```

The following example shows adaptive rate configurations.

```
Router(config-controller-dsl-group)#shdsl rate ?
<768-9216>  DSL Rate (excluding DSL overhead) in kbps
auto        auto rate mode
Router(config-controller-dsl-group)#shdsl rate 1024
Router(config-controller-dsl-group)#shdsl rate auto ?
current  Current SNR Margin
snext    Self Near end cross talk

Router(config-controller-dsl-group)#shdsl rate auto current ?
<0 - 10>  0dB to 10dB
Router(config-controller-dsl-group)#shdsl rate auto snext ?
<-10 - 10>  -10dB to 10dB
```

Related Commands

Command	Description
dsl-group	Creates a DSL group and enters config controller DSL group mode.
shdsl annex	Defines the G.991.2 standard for a DSL group.

shelf-id

To change the shelf number assigned to the router shelf or dial shelf on the Cisco AS5800, use the **shelf-id** command in global configuration mode. To return the shelf numbers to the default value, use the **no** form of this command.

shelf-id *number* {**router-shelf** | **dial-shelf**}
no shelf-id *number*

Syntax Description

number	Number to assign to the shelf. Range is from 0 to 9999.
router-shelf	Specified number to the router shelf.
dial-shelf	Specified number to the dial shelf.

Command Default

The default shelf number for the router shelf is 0.

The default shelf number for the dial shelf is 1, or one number higher than the specified router shelf number.

Command Modes

Global configuration

Command History

Release	Modification
11.3(2)AA	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The shelf number is used to distinguish between cards on the router shelf and cards on the dial shelf.

Caution You must reload the Cisco AS5800 for the shelf number to take effect. The shelf numbers are part of the interface names. When you reload the Cisco AS5800, all NVRAM interface configuration information is lost.

You can specify the shelf number through the setup facility during initial configuration of the Cisco AS5800. This is the recommended method to specify shelf numbers.

To display the shelf numbers, use the **showrunning-config** command. If a shelf number has been changed, the pending change is shown in the output of the **showversion** command (for example, the dial-shelf ID is 87; will change to 2 on reload).

Examples

In the following example, the dial shelf is assigned the number 456:

```
Router(config)# shelf-id 456 dial-shelf
Router(config)# exit
```

Related Commands

Command	Description
show version	Displays the configuration of the system hardware, the software version, the names and sources of configuration files, and the boot images.

show (satellite initial configuration)

To display the initial configuration parameters for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **show** command in satellite initial configuration mode.

show

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values

Command Modes

Satellite initial configuration

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

This command is typically used by an installation technician. Do not use this command unless your satellite service provider instructs you to perform the satellite initial configuration and provides all necessary parameter values.

You can view the satellite initial configuration parameters by entering the **service-modulesatellite***slot*/**0status** command in privileged EXEC mode.

Examples

The following example shows the satellite initial configuration parameters for the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT):

```
Router(sat-init-config)# show

!
! Initial Configuration Parameters:
!
id aa-group 298
id software group 598
id vsat 6201
mode download
mode two-way
outbound data-pid 514
outbound data-rate 15000000
outbound frequency 1201000
outbound id 2
outbound modulation-type DVB
outbound sync ip address 172.16.0.3
outbound viterbi-rate 1/2
!
!
Router(sat-init-config)#
```

Related Commands

Command	Description
service-module satellite status	Displays status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters.

show alarm-interface

To display the alarm interface controller (AIC) configuration setting and the information sent to the Cisco IOS software by the AIC, use the **showalarm-interface** command in privileged EXEC mode.

show alarm-interface [*slot-number*] [**summary**]

Syntax Description

slot-number	(Optional) Slot number in which the AIC was placed.
summary	(Optional) Selects the summary format for the output message.

Command Default

Displays verbose message output and displays all AICs in all slot numbers on the router.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(2)XG	This command was introduced on the Cisco 2600 series and Cisco 3600 series.
12.2(8)T	This command was integrated into Cisco IOS Release 12.2(8)T.

Examples

The following is sample output from the **showalarm-interfacesummary** command:

```
Router# show alarm-interface 5 summary
         Alarm Interface Card in Slot 5:
Configured IP address:10.2.130.102
Status: KEEPALIVE TIMER EXPIRED
Alarm Interface Card in Slot 5:
Configured IP address:10.2.130.102
Status:KEEPALIVE TIMER EXPIRED
```

The following is an example of a verbose **showalarm-interface**display:

```
Router# show alarm-interface 4
         Alarm Interface Card in Slot 4:
Configured IP address: 10.10.10.2
Status: RUNNING
Timer expires in < 11 min.
Reported version: 00 00 00 01
Expected version: 00 00 00 01
Last Self Test result: READY
Last Start-Up message:
----------
<AIC>: Hardware Version 1, Revision A Software Version 2, Revision A 1.0.1 Installed and
running, POST passed.
----------
Last Status severity: 0
Last Status message:
----------
Status
----------
```

The table below describes significant fields shown in this output.

Table 29: show alarm-interface Field Descriptions

Field	Description
Alarm Interface Card in Slot	Card type and slot number.
Configured IP address	Configured IP address
Status	AIC card status. Can be one of the following: • HARDWARE DETECTED • RUNNING • HARDWARE NOT PRESENT • KEEPALIVE TIMER EXPIRED
Timer expires in	Current value of the KEEPALIVE TIMER, or states if the timer has been disabled. This line is only active when the status line reads HARDWARE DETECTED or RUNNING. Used in troubleshooting to detect operational failures of the AIC.
Reported version	Active software version number. Comparing the reported version to the expected version may reveal possible incompatibilities between the AIC's software and the IOS image.
Expected version	Expected software version number. Comparing the reported version to the expected version may reveal possible incompatibilities between the AIC's software and the IOS image.
Last Self Test result	Result of the AIC's power on self-test (POST).
Last Start-Up message	Startup messages.
<AIC>	AIC. Includes version and activity information.
Last Status severity	Rates the severity of the status message. Any number other than 0 indicates a need for intervention. The number 1 indicates the most severe condition.
Last Status message	Last status message.

Related Commands

Command	Description
alarm-interface	Enters the alarm interface mode and configures the AIC.

show alarm-profile

To verify the alarm profile configured for chassis, use the **show alarm-profile** command.

Syntax Description

Syntax Description:

There are no keywords.

Command Default

There is no default.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
Cisco IOS XE 16.8.1	Support for this command was introduced on ASR 900 Series.

Examples

```
Router# show alarm profile
Alarm profile CHASSIS:
 SONET/SDH:
  Alarm Name                          Severity   Syslog
  Section Loss of Frame Failure       CRITICAL   Enabled
  Line Alarm Indication Signal        INFO       Enabled
  Line Remote Failure Indication      INFO       Enabled
  Path Alarm Indication Signal        INFO       Enabled
  Path Remote Failure Indication      INFO       Enabled
  Path Loss of Pointer                INFO       Enabled
 DS1:
  Alarm Name                          Severity   Syslog
  Receiver has loss of signal         CRITICAL   Enabled
  Receiver has loss of frame          INFO       Enabled
  Receiver has remote alarm           INFO       Enabled
 DS3:
  Alarm Name                          Severity   Syslog
  Receiver has loss of signal         MAJOR      Enabled
  DS1 Alarm Indication Signal         MINOR      Enabled
  DS1 Loss Of Frame                   INFO       Enabled
  DS1 Remote Alarm Indication         INFO       Enabled
```

show als

To display Automatic Laser Shutdown (ALS) status, use the show als command in privileged EXEC mode.

show als {**all** | **interface** **slot**/**port**}

Syntax Description

all	Displays ALS status for all interfaces.
interface	Displays ALS status for the selected interface .
slot/port	Number of the chassis slot that contains the interface, where: • slot--Chassis slot number. • /port--Port number.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series routers.

Examples

The following example shows the ALS status for the selected interface:

```
Router# show als interface t2/1
TenGigabitEthernet2/1
 Mode ALS_MODE_MANUAL
 Pulse Width 100 sec
 Pulse Interval 150 sec
 Current state ALS_STATE_NORMAL

The following example shows the ALS status for all interfaces:
Router# show als all
TenGigabitEthernet2/1
 Mode ALS_MODE_MANUAL
 Pulse Width 100 sec
 Pulse Interval 150 sec
 Current state ALS_STATE_NORMAL

TenGigabitEthernet2/2
 Mode ALS_MODE_AUTOMATIC
 Pulse Width 100 sec
 Pulse Interval 300 sec
 Current state ALS_STATE_NORMAL
```

Related Commands

Command	Description
als	Enables the ALS mode.

Command	Description
als restart	Requests an ALS restart mode.
als restart mode	Selects the ALS restart mode.
als restart pulse	Select the ALS pulse mode.
hw-module als restart	Requests a restart pulse.

show aps

To display information about the current automatic protection switching (APS) feature, use the **showaps** command in privileged EXEC mode.

show aps commandshow aps

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.1CC	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showaps**command on a router configured with a working interface. In this example, POS interface 0/0/0 is configured as a working interface in group 1, and the interface is selected (that is, active).

```
Router1# show aps
POS0/0/0 working group 1 channel 1 Enabled Selected
```

The following is sample output from the **showaps**command on a router configured with a protect interface. In this example, POS interface 2/0/0 is configured as a protect interface in group 1, and the interface is not selected (the ~ indicates that the interface is not active). The output also shows that the working channel is located on the router with the IP address 10.1.6.1 and that the interface is currently selected (that is, active).

```
Router2# show aps
POS2/0/0 protect group 1 channel 0 bidirectional ~Selected
        Rx_K1= 0, Rx_K2= 0 Tx_K1= 0 Tx_K2= 5
        Working channel 1 at 10.1.6.1 Enabled
```

For the K1 field (8 bits), the first 4 bits indicate the channel number that has made the request, and the last 4 bits map to the requests (local or external) listed in the table below. For the K2 field (8 bits), the first 4 bits indicate the channel number bridged onto the protect line, the next bit is the architecture used, and the last 3 bits indicate the mode of operation or non-APS use listed in the table below.

Table 30: K1 Bit Descriptions

Bits (Hexadecimal)	Description
K1 bits 8765	K1 bits 8 through 5: Channel number that made the request.
K1 bits 4321	K1 bits 4 through 1: Type of request.

Bits (Hexadecimal)	Description
1111 (0xF)	Lockout of protection request.
1110 (0xE)	Forced switch request.
1101 (0xD)	Signal failure (SF)--high priority request.
1100 (0xC)	Signal failure (SF)--low priority request.
1011 (0xB)	Signal degradation (SD)--high priority request.
1010 (0xA)	Signal degradation (SD)--low priority request.
1001 (0x9)	Not used.
1000 (0x8)	Manual switch request.
0111 (0x7)	Not used.
0110 (0x6)	Wait to restore request.
0101 (0x5)	Not used.
0100 (0x4)	Exercised request.
0011 (0x3)	Not used.
0010 (0x2)	Reverse request.
0001 (0x1)	Do not revert request.
0000 (0x0)	No request.

show asic-version

To display the application-specific integrated circuit (ASIC) version for a specific module, use the **showasic-version** command in EXEC mode.

show asic-version slot *number*

Syntax Description

slot	The slot that the ASIC is installed in.
number	Module number.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Cisco 7600 series routers.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

In the **showasic-version**command output, the ASIC types are as follows:

- Lyra--Layer 2 forwarding engine
- Medusa--Crossbar and bus fabric interface
- Polaris--Layer 3 CEF engine
- Pinnacle--4-port Gigabit Ethernet interface
- Titan--Packet rewrite and replication engine
- Vela--Constellation bus interface

Examples

This example shows how to display the ASIC type and version for a specific module:

```
Router# show asic-version slot 1
Module in slot 1 has 3 type(s) of ASICs
        ASIC Name      Count      Version
        ASIC1          (2.0)
        ASIC2          (2.0)
        ASIC3 1        (0.1)
Router#
```

Related Commands

Command	Description
show module	Displays the module status and information.

show c7300

To display the types and status of cards installed in a Cisco 7304 router, use the **showc7300**command in privileged EXEC mode.

show c7300

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.1(10)EX	The output of this command was enhanced to include information about Field-Programmable Gate Array (FPGA) images.
12.1(10)EX2	The output of this command was enhanced to include information about a standby route processor (RP).
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)S.
12.2(20)S	Support was added for the Cisco 7304 router.
12.2(20)S2	Support was added for modular services cards (MSCs) and shared port adapters (SPAs) on the Cisco 7304 router.
12.2(28)SB	This command was integrated into Cisco IOS Release 12.2(28)SB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command displays the types and status of cards installed in a Cisco 7304 router (such as network services engines [NSEs], RPs, line cards, MSCs, and SPAs), and information about incompatible FPGA images. When the bundled and current FPGA images are compatible, they are not displayed.

This command also displays whether your system is in compliance with line card configuration guidelines. For NSEs and line cards, empty slots are not displayed in the output. However, for SPAs, several status values are reported, including an empty subslot, which is reported as “missing.”

If your system contains an unsupported line card or RP with no matching bundled FPGA image in Cisco IOS software, then this command displays “None” instead of the bundled FPGA version number.

Use this command to display information about the status of the active and standby NSEs.

Examples

The following example displays information about a Cisco 7304 router that has current FPGA images:

```
Router# show c7300
Slot      Card Type           Status          Insertion time
```

```
----      ---------           ------          --------------
0,1       NSE-100             Active          00:13:16 ago
4         1OC48-POS           Active          00:01:43 ago
System is compliant with hardware configuration guidelines.
All the FPGAs in the system are up-to-date
Network IO Interrupt Throttling:
 throttle count=3, timer count=3
 active=0, configured=1
 netint usec=3999, netint mask usec=200
```

The following example displays information about a Cisco 7304 router that has incompatible FPGA images that need to be updated. If your system contains an unsupported line card or RP with no matching bundled FPGA image in Cisco IOS software, “None” is displayed instead of a bundled FPGA version number.

```
Router# show c7300
Slot      Card Type           Status          Insertion time
----      ---------           ------          --------------
0,1       NSE-100             Active          00:02:26 ago
4         6T3                 Active          00:02:23 ago
5         6T3                 Active          00:02:23 ago
System is compliant with hardware configuration guidelines.
%WARNING:The following FPGAs in the system may need an update.
Slot      Card Type           Current FPGA    Bundled FPGA
----      ---------           ------------    ------------
0         NSE-100 (MB)        0.12            None
Network IO Interrupt Throttling:
 throttle count=0, timer count=0
 active=0, configured=1
 netint usec=3999, netint mask usec=200
```

The following example displays sample output information about the redundancy status of the NSEs installed in the system. In the following example, the active RP is the NSE-100 installed in slot 0 and slot 1. The standby is the NSE-100 installed in slot 2 and slot 3.

```
Router# show c7300
Slot      Card Type           Status          Insertion time
----      ---------           ------          --------------
0,1       NSE-100             Active          00:02:03 ago
2,3       NSE-100             Standby         00:02:03 ago
4         4OC3-POS            Active          00:01:59 ago
5         6T3                 Active          00:01:59 ago
System is compliant with hardware configuration guidelines.
Network IO Interrupt Throttling:
 throttle count=0, timer count=0
 active=0, configured=1
 netint usec=3999, netint mask usec=200
```

The following example displays information about a Cisco 7304 router with an NSE-100, MSC-100s, and 4-Port 10/100 Fast Ethernet SPAs:

```
Router# show c7300
Slot      Card Type           Status          Insertion time
----      ---------           ------          --------------
0,1       NSE100              Active          00:45:29 ago
2         7304-MSC-100        Active          00:44:36 ago
3         7304-MSC-100        Active          00:44:36 ago
4         7304-MSC-100        Active          00:44:36 ago
5         7304-MSC-100        Active          00:14:39 ago
The FPGA versions for the cards listed above are current
Shared Port Adapter information:
```

```
Slot/Subslot  SPA Type          Status         Insertion time
------------  --------          ------         --------------

2/1           SPA-4FE-7304      ok             00:44:36 ago
3/0           SPA-4FE-7304      ok             00:44:35 ago
3/1           not present       missing        never
4/0           SPA-4FE-7304      ok             00:44:35 ago
4/1           SPA-4FE-7304      ok             00:44:35 ago
5/0           SPA-4FE-7304      ok             00:14:36 ago
5/1           SPA-4FE-7304      ok             00:14:36 ago
Network IO Interrupt Throttling:
 throttle count=1, timer count=1
 active=0, configured=1
 netint usec=3999, netint mask usec=200
```

The table below provides a description for each of the possible status fields for SPAs.

Table 31: SPA Status Field Descriptions

Status Field for SPAs	Description
booting	SPA is initializing.
failed	SPA is powered off due to five automatic recovery failures.
FW mismatch	An FPGA version mismatch with the Cisco IOS software has been detected for the SPA.
missing	SPA is not present in the MSC subslot.
not allowed online	SPA is not supported.
ok	SPA is operational.
stopped	SPA is deactivated by the **hw-modulesubslotstop**command.
unknown	SPA is in unrecognizable state.

Related Commands

Command	Description
show c7300 errorlog	Displays error information about a Cisco 7304 router.
show diag	Displays hardware information for any slot or the chassis.
show redundancy (7300)	Displays redundancy information for the active and standby NSEs.
show version	Displays the configuration of the system hardware, the number of each interface type installed, the Cisco IOS software version, the names and sources of configuration files, and the boot images. Displays the configuration of the ROM monitor.

show c7300 errorlog

To display error information on a Cisco 7304 router running pre-Cisco IOS Release 12.2(25)S software, use the **showc7300errorlog**command in privileged EXEC mode.

show c7300 errorlog [{**slot** *slot-number* | **all**}]

Syntax Description

slot	(Optional) Displays error information for the hardware in a slot.
slot-number	(Optional) Specifies the slot location of the hardware to display error information.
all	(Optional) Displays error information for all hardware in all slots.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2 S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Each line card in a Cisco 7304 router has a serial channel connecting to the processor. There are two serial channel controllers on each serial channel, one for the line card side and one for the processor side. Each serial channel has four serial links labeled as SL0, SL1, SL2 and SL3. This command displays a set of error counters for each serial link.

Use this command to display board-level errors. If you are investigating controller or interface errors, use the **showcontroller** and**showinterface** commands.

Examples

The following example displays error information about a line card in slot 2 on a Cisco 7304 router:

```
Router# show c7300 errorlog slot 2
        Backplane serial channel controller (Santa Ana):
        LC 2, LC Santa Ana, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [   0    0    0    0 ]
        Overrun:            [   0    0    0    0 ]
        Underrun:           [   0    0    0    0 ]
        OOB:                [   0    0    0    0 ]
        Disparity:          [   0    0    0    0 ]
        Missing_Ctrl_Code:  [   0    0    0    0 ]
        Chip access errors: [   0    0    0    0 ]
        LC 2, NSE Santa Ana 0, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [   0    0    0    0 ]
```

```
        Overrun:            [    0    0    0    0 ]
        Underrun:           [    0    0    0    0 ]
        OOB:                [    0    0    0    0 ]
        Disparity:          [    0    0    0    0 ]
        Missing_Ctrl_Code:  [    0    0    0    0 ]
        Chip access errors: [    0    0    0    0 ]
```

The following example displays error information about all hardware in all of the slots on a Cisco 7304 router:

```
Router# show c7300 errorlog slot all
        Backplane serial channel controller (Santa Ana):
        LC 2, LC Santa Ana, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [    0    0    0    0 ]
        Overrun:            [    0    0    0    0 ]
        Underrun:           [    0    0    0    0 ]
        OOB:                [    0    0    0    0 ]
        Disparity:          [    0    0    0    0 ]
        Missing_Ctrl_Code:  [    0    0    0    0 ]
        Chip access errors: [    0    0    0    0 ]
        LC 2, NSE Santa Ana 0, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [    0    0    0    0 ]
        Overrun:            [    0    0    0    0 ]
        Underrun:           [    0    0    0    0 ]
        OOB:                [    0    0    0    0 ]
        Disparity:          [    0    0    0    0 ]
        Missing_Ctrl_Code:  [    0    0    0    0 ]
        Chip access errors: [    0    0    0    0 ]
        Backplane serial channel controller (Santa Ana):
        LC 3, LC Santa Ana, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [    0    0    0    0 ]
        Overrun:            [    0    0    0    0 ]
        Underrun:           [    0    0    0    0 ]
        OOB:                [    0    0    0    0 ]
        Disparity:          [    0    0    0    0 ]
        Missing_Ctrl_Code:  [    0    0    0    0 ]
        Chip access errors: [    0    0    0    0 ]
        LC 3, NSE Santa Ana 0, channel A, error counters:
                              SL0  SL1  SL2  SL3
        Reframe:            [    0    0    0    0 ]
        Overrun:            [    0    0    0    0 ]
        Underrun:           [    0    0    0    0 ]
        OOB:                [    0    0    0    0 ]
        Disparity:          [    0    0    0    0 ]
        Missing_Ctrl_Code:  [    0    0    0    0 ]
        Chip access errors: [    0    0    0    0 ]
```

The table below describes the significant fields shown in the display.

Table 32: show c7300 errorlog Field Descriptions

Field	Description
Reframe	A data frame on a serial link does not align to the designated framing boundary.
Overrun:	Packets are stored in a FIFO buffer when the serial link is overloaded.
Underrun:	A serial link looks for packets in an empty FIFO buffer.

Field	Description
OOB:	Out of band error. An undefined serial link control character is received.
Disparity:	A running disparity error occurs on the link.
Missing_Ctrl_Code:	Missing Control Code. An incorrect number of control codes are received.
Chip access errors:	Access to the serial channel device fails.

Related Commands

Command	Description
show c7300	Displays the types of hardware currently installed in a Cisco 7304 router.
show diag	Displays hardware information for any slot or the chassis.
show platform errorlog	Displays error information.
show version	Displays the configuration of the system hardware, the number of each interface type installed, the Cisco IOS software version, the names and sources of configuration files, and the boot images. Displays the configuration of the ROM monitor.

show c7300 pxf accounting

To display the number and types of packets entering or exiting the PXF processors, use the **showc7300pxfaccounting** command in privileged EXEC mode.

show c7300 pxf accounting

Syntax Description

This command has no arguments or keywords.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.2(14)SZ	This command was modified to **showpxfaccounting** for the Cisco 7304 router. All Cisco IOS releases prior to 12.2(14)SZ that support the Cisco 7304 still require that **showc7300pxfaccounting** be entered to gather PXF accounting output.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(20)S	The **c7300** keyword was removed. Entering **showpxfaccounting** could get the information previously gathered by entering the **showc7300pxfaccounting** command.

Usage Guidelines

Use the **showc7300pxfaccounting** command to display the number of packets entering and exiting the PXF processors.

The c7300 keyword was removed from this command in Cisco IOS Release 12.2(20)S. The**showpxfaccounting** command can be used in post-Cisco IOS Release 12.2(20)S releases to gather information previously gathered by entered the **showc7300pxfaccounting** command.

Examples

The following example displays output of the**showc7300pxfaccounting** command:

```
Router# show c7300 pxf accounting
PXF Utilization:14 %
PXF Packet Counters:
 Ingress from GE :             0      Egress to GE :             8
 Ingress from LCs:      24783520      Egress to LCs:      18387770
 Ingress from RP :            10      Egress to RP :             2
 Priority queue  :            12      Default queue:      18387787
Drop Packet Counters:
    ACL input deny Drop:        6395752
```

The table below describes the significant fields shown in the display.

Table 33: show c7300 pxf accounting Field Descriptions

Field	Description
Ingress from GE:	Packets coming into the PXF processors from the Gigabit Ethernet ports.

Field	Description
Egress to GE:	Packets going to the Gigabit Ethernet ports from the PXF processors.
Ingress from LCs	Packets coming in to the PXF processors from line card ports.
Ingress from RP	Packets coming in to the PXF processors from the Route Processor.
Drop Packet Counters:	Packets dropped by the PXF processors.
ACL input deny Drop:	Packets dropped because of the implicit deny all at the end of all ACLs.

Related Commands

Command	Description
ip pxf	Manually enables the PXF processor.
show pxf accounting	Displays the number and types of packets entering or exiting the PXF processors.
show c7300 pxf interfaces	Displays the status of various interfaces know to the PXF processors.

show c7300 pxf interfaces

Note Effective with Cisco IOS Release 12.2(20)S, the **showc7300pxfinterfaces** command is replaced by the **showpxfinterfaces** command. See the **showpxfinterfaces** command for for information.

To display the status of various interfaces known to the Parallel Express Forwarding (PXF) processors, use the **showc7300pxfinterfaces**command in privileged EXEC mode.

show c7300 pxf interfaces {*interface-index* | **all**}

Syntax Description

interface-index	A number that represents an interface known to the PXF processors. Valid values are 0 to 32767.
all	Specifies all PXF interfaces.

Command Default

No default behaviors or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.1(9)EX	This command was introduced.
12.2(14)SZ	This command was modified to **showpxfinterfaces** for the Cisco 7304 router. All Cisco IOS releases prior to 12.2(14)SZ that support the Cisco 7304 still require that **showc7300pxfinterfaces** be entered to gather PXF interface information.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(20)S	This command was replaced by the show pxf interfaces command.

Examples

The following example shows how to display information about PXF interface 1:

```
Router# show c7300 pxf interfaces 1
PXF-If: 00001  Gi0/0    (Up, Punting to RP - no ip route-cache)
  Features: in=iACL  [0x11],  out=None [0x0]
```

The following example shows how to display information about all PXF interfaces:

```
Router# show c7300 pxf interfaces
 all
PXF-If: 00001  Gi0/0    (Up, Punting to RP - no ip route-cache)
  Features: in=iACL  [0x11],  out=None [0x0]
PXF-If: 00002  Gi0/1    (Down, Punting to RP - no ip route-cache)
  Features: in=None [0x1],  out=None [0x0]
PXF-If: 00007  In Use, Reserved
PXF-If: 00024  PO2/0    (Up, Punting to RP - no ip route-cache)
  Features: in=None [0x1],  out=None [0x0]
PXF-If: 00025  PO2/1    (Down, Punting to RP - no ip route-cache)
```

```
  Features: in=None [0x1],  out=None [0x0]
PXF-If: 00026  PO2/2    (Down, Punting to RP - no ip route-cache)
  Features: in=None [0x1],  out=None [0x0]
PXF-If: 00027  PO2/3    (Down, Punting to RP - no ip route-cache)
  Features: in=None [0x1],  out=None [0x0]
```

The table below describes the significant fields shown in the display.

Table 34: show c7300 pxf interfaces Field Descriptions

Field	Description
PXF-IF:	Internal PXF interface number. This is a unique number assigned by PXF.
Gi 0/0 or PO2/3	Type of interface.
Features:	Ingress and egress features on the PXF interface.
in=	Ingress features.
iACL	Input Access Control Lists is configured on this interface.
[0x11]	Hexadecimal value of features flag for input features on this interface.
out=	Egress features.
[0x0]	Hexadecimal value of feature flag for output features on this interface.
(Up, Punting to RP)	Interface status. Interface is up and packets are being sent to the Route Processor.
(Down, Punting to RP)	Interface status. Interface is down and packets are being sent to the Route Processor.
- no ip route-cache	Reason packets are being sent to the Route Processor. In this display, packets are being sent to the Route Processor because the user has entered the **noiproute-cache** command and CEF is not enabled on the interface. Entering the following commands causes packets to be sent to the Route Processor: • **no ip cef** • **no ip routing** • **no ip route-cache** Other reasons may be displayed: • lineproto down--The line is down. • unsupported feature--Packets from a feature that is not supported by PXF.

Related Commands

Command	Description
ip pxf	Manually enables the PXF processors.
show c7300 pxf accounting	Displays the number of packets entering or exiting the PXF processors.
show pxf interfaces	Displays the status of various interfaces known to the PXF processors.

show c7300 slot

To display various output useful for technical support purposes, enter the **showc7300slot**command in privileged EXEC mode.

show c7300 slot {*slot-number* | **all**}

Syntax Description

slot-number	Displays various information for the hardware in a particular slot. This information is useful for technical support purposes only.
all	Displays various information for all of the hardware in all of the router slots. This information is useful for technical support purposes only.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(20)S	This command replaces the show platform slot command.

Usage Guidelines

This command should not be used. The output gathered from this command is useful for technical support purposes only.

Examples

The following example shows how to display information about the hardware in slot 4 of Cisco 7304 router:

```
Router# show c7300 slot 4
Slot 4 Details
  Card Name: OC12-POS
  Card Present: Yes
  Slot Card Type: 0x377
  Saved Slot Card Type (Persistent after the OIR): 0x377
  Slot State (4): Activated
  Slot Previous State (4): Activated
  Slot Return (Transient) State (3): Analyzing
  Current Event to the OIR FSM: Idle (0)
  Current External Event to the OIR FSM: Idle (0)
  Slot Flags (0x100000):
    FPGA Checked
  Slot Ready: Yes
  Slot Retry Count: 0
  Slot Structure Address: 0x446FAED0
  Slot Sync Data Address : 0x446FB318
Slot 4 Line Card Plugin Details
  Line Card Type: OC12-POS (0x377)
  Number of Ports: 1
  Line Card Plugin Address: 0x45E123C0
  Line Card Compatible S/W Version: 0.0 (0x0)
  Line Card H/W Version: 02.03 (0x203)
  Line Card FPGA Version: 00.20 (0x14)
  Minimum Line Card H/W Version required by the S/W: 00.00 (0x0)
  Minimum Line Card FPGA Version required by the S/W: 00.01 (0x1)
```

```
  Slot 4 Line Card Devices:
  Line Card Common Devices
    Device#0: EEPROM
      Plugin Address 0x433BB830, C2W Control Structure Address 0x433C1138
      Card Bus (4): Address 0x50, Frequency 0x13, Slot 4
    Device#1: CPLD
      Plugin Address 0x433BF9E0, C2W Control Structure Address 0x433C1198
      Card Bus (4): Address 0x30, Frequency 0x13, Slot 4
    Device#2: FPGA Flash
      Plugin Address 0x433BFC30, C2W Control Structure Address 0x433C11F8
      Card Bus (4): Address 0x30, Frequency 0x13, Slot 4
(Output removed for readability)
```

Related Commands

Command	Description
show platform slot	Displays various output useful for technical support purposes.

show cable bundle

To display the forwarding table for the specified interface, use the **showcablebundle** command in privileged EXEC mode.

show cable bundle *bundle-number forwarding-table*

Syntax Description

bundle-number	Specifies the bundle identifier. Valid range is from 1 to 255.
forwarding-table	Displays the forwarding table for the specified interface.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(7)XR	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

In the following example, a cable bundle of 25 is specified:

```
Router# show cable bundle 25 forwarding-table
MAC address         Interface
0050.7366.17ab      Cable3/0
0050.7366.1803      Cable3/0
0050.7366.1801      Cable3/0
```

The table below describes the significant fields shown in the display.

Table 35: show cable bundle Field Descriptions

Field	Description
MAC address	Media Access Control ID for each interface in the bundle.
Interface	The cable interface slot and port number.

Related Commands

Command	Description
cable bundle	Creates an interface bundle.

show cable-diagnostics tdr

To display the test results for the Time Domain Reflectometry (TDR) cable diagnostics, use the **showcable-diagnosticstdr**command in privileged EXEC mode.

show cable-diagnostics tdr interface *interface interface-number*

Syntax Description

interface *interface*	Specifies the interface type; valid values are**fastethernet** and **gigabitethernet**.
interface-number	Module and port number.

Command Default

This command has no default settings.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(17a)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXD	The output was changed as follows: • The Local Pair field was changed to the Pair field. The local pair designations were changed as follows: • Pair A to Pair 1-2 • Pair B to Pair 3-4 • Pair C to Pair 5-6 • Pair D to Pair 7-8 • The Remote Pair field was removed. • The Channel field was added to display the pair designation and are as follows: • Pair A • Pair B • Pair C • Pair D
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **showcable-diagnosticstdr** command is supported on specific modules. See the Release Notes for Cisco IOS Release 12.2 SX on the Catalyst 6500 and Cisco 7600 Supervisor Engine 720, Superivsor Engine 32, and Supervisor Engine 2 for the list of the modules that support TDR.

In the event of an open or shorted cable, the accuracy of length of where the cable is open or shorted is plus or minus 2 meters.

The pair length can be displayed in meters (m), centimeters (cm), or kilometers (km).

If the TDR test has not been run on the port, the following message is displayed:

```
TDR test was never run on Gi2/12
```

Examples

This example shows how to display the information about the TDR test:

```
Router# show cable-diagnostics tdr interface gigabitethernet 8/1
TDR test last run on: February 25 11:18:31
Interface Speed Pair Cable length        Distance to fault   Channel Pair status
--------- ----- ---- ------------------- ------------------- ------- ------------
Gi8/1     1000  1-2  1    +/- 6  m       N/A                 Pair B  Terminated
                3-4  1    +/- 6  m       N/A                 Pair A  Terminated
                5-6  1    +/- 6  m       N/A                 Pair C  Terminated
                7-8  1    +/- 6  m       N/A                 Pair D  Terminated
```

The table below describes the fields in the **showcable-diagnosticstdr**command output.

Table 36: show cable-diagnostics tdr Command Output Fields

Field	Description
Interface	Interface tested.
Speed	Current line speed.
Pair	Local pair name.
Cable Length	Cable length and accuracy. The accuracy unit is displayed in meters (m), centimeters (cm), or kilometers (km).
Channel	Pair designation.
Pair status	Pair status displayed is one of the following: • Terminated--The link is up. • Shorted--A short is detected on the cable. • Open--An opening is detected on the cable. • Not Completed--The test on the port failed. • Not Supported--The test on the port is not supported. • Broken--The pair is bad--either open or shorted. • ImpedanceMis--The impedance is mismatched. • InProgress--The diagnostic test is in progress.

Related Commands

Command	Description
clear cable-diagnostics tdr	Clears a specific interface or clear all interfaces that support TDR.
test cable-diagnostics	Tests the condition of 10-Gigabit Ethernet links or copper cables on 48-port 10/100/1000 BASE-T modules.

show card-protection CPGN detail

To verify card protection configuration, use the **show card-protection CPGN detail** command.

Syntax Description

Syntax Description:

There are no keywords.

Command Default

There is no default.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
XE Everest 16.7.1	This command was integarted into the Cisco NCS 4200 Series and Cisco ASR 900 Series.

Example:

Examples

```
#show card-protection 4 detail
Working(0/1:  ):
    Number of LOS Alarms:0
    ok,Active
    1:1, non-revertive

    Protect(0/2: ):
    Number of LOS Alarms:0
    ok,Inactive
    1:1, non-revertive

Revert Timer : (Not Started)
Last switchover reason: Serdes
```

show catalyst6000

To display the information about the chassis, use the **show catalyst6000** command in user EXEC or privileged EXEC mode.

show catalyst6000 {**all** | **chassis-mac-address** | **switching-clock** | **traffic-meter**}

Syntax Description

all	Displays the MAC-address ranges and the current and peak traffic-meter reading.
chassis-mac-address	Displays the MAC-address range.
switching-clock	Displays the failure recovery mode of the switching clock.
traffic-meter	Displays the percentage of the backplane (shared bus) utilization.

Command Default

The default is **all**

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2(33)SXI	The output of the **show catalyst6000 traffic-meter** command was changed to include traffic monitor status information.

Usage Guidelines

If you enter the **switching-clock** keywords, the output displays whether switching of the redundant clock sources on the backplane is allowed if the active clock source fails.

There are either 64 or 1024 MAC addresses that are available to support the software features. You can enter the **show catalyst6000 chassis-mac-address** command to display the MAC-address range on your chassis.

In Cisco IOS Release 12.2(33)SXI and later releases, the traffic monitor status information is displayed in the output. In earlier releases, only the current and peak traffic-meter readings are displayed.

Examples

This example shows how to display the MAC-address ranges and the current and peak traffic-meter readings:

```
Router>
show catalyst6000 all
chassis MAC addresses: 64 addresses from 0001.6441.60c0 to 0001.6441.60ff
  traffic meter =   0%  Never cleared
           peak =   0%  reached at 08:14:38 UTC Wed Mar 19 2003
  switching-clock: clock switchover and system reset is allowed
Router>
```

This example shows how to display the MAC-address ranges:

```
Router#
show catalyst6000 chassis-mac-address
chassis MAC addresses: 1024 addresses from 00d0.004c.1800 to 00d0.004c.1c00
Router#
```

The following example shows how to display the current and peak traffic-meter readings and the traffic monitor status:

```
Router
>
show catalyst6000 traffic-meter
traffic meter =   0%  Never cleared
           peak =   0%        reached at 10:54:49 UTC Wed Mar 19 2008
     -----= Traffic Utilization Monitor Status ===---
            State  Interval  Threshold  MsgCount  LastMsgTime
-----------------------------------------------------------------------------
Backplane    Off      60s       80%        0     --
Fpoe#0  In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
Fpoe#1  In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
Fpoe#2  In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
Fpoe#3  In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
Fpoe#4  In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
.
.
.
Fpoe#19 In   Off      60s       80%        0     --
       out   Off      60s       80%        0     --
Router
>
```

This example shows how to display the failure recovery mode of the switching clock:

```
Router> show catalyst6000 switching-clock
switching-clock: clock switchover and system reset is allowed
Router>
```

Related Commands

Command	Description
monitor traffic-utilbackplane	Enables the backplane traffic utilization monitor or sets the traffic monitor interval.
monitor traffic-util fpoe	Sets the fabric channel traffic utilization monitor to generate SYSLOG messages.
show environment alarm	Displays the information about the environmental alarm.
show fm summary	Displays a summary of FM Information.
show environment status	Displays the information about the operational FRU status.

show cem

To display circuit emulation (CEM) statistics, use the **showcem** command in privileged EXEC mode.

show cem {*slot* / *port* / *channel* | **summary**}

Syntax Description

slot	Slot number where the Circuit Emulation over IP (CEoIP) network module (NM) is installed on the networking device.
/ *port*	Port number on the CEoIP NM. The slash mark is required between the *slot* argument and the *port* argument.
/ *channel*	Channel number that identifies the channel that you want to configure (T1/E1 only). The channel number on a serial port is always 0. The slash mark is required between the *port* argument and the *channel* argument.
summary	Displays summary CEM statistics.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.3(7)T	This command was introduced.
12.4(2)T	This command was modified. Output was modified to support enhanced adaptive clocking.

Examples

The following example shows a summary of some of the configuration parameters of the CEM channels.

```
Router# show cem summary
cem summary
cem 1/0/1 is up
Line state is up
Operational state is active
Near end ip address: 192.168.55.130, udp port: 15904
Far end ip address: 192.168.55.136, udp port: 15903
IP payload size: 144
IP dscp : 0x2E Idle pattern length: 8 , Idle Pattern: 0x55
Payload compression is disabled
Data protection is enabled
Dejitter buffer size is 120 ms
Channel clock rate is 512000 bps
CEIP header CRC is disabled
Signaling is enabled, onh:0x0 offh:0xF delay:2000 ms
Failure activation time is 2000 ms
Failure deactivation time is 2000 ms
Physical interface is T1 channelized
Ingress packets: 5044607, dropped: 0, overruns: 0, max_ipt: 3
Egress packets: 5039268, dropped: 0, lost pkts: 52792
Egress late pkts: 222
Egress overruns: 0, underruns: 0, ur_delay: 0, ur2pkt: 0
Egress pkts dropped by burst control: 0
Egress corrupt pkts rcvd: 0
```

```
cem info
30 second ingress rate 513523 bits/sec, 445 packets/sec
30 second egress rate 513100 bits/sec, 445 packets/sec
Tx interrupts: 5035243
Reorder queue flush: 3, visited: 6, max wait window: 4
Pkt-to-pkt jitter max: 141 ms, average: 2 ms, min: 0 ms
Dejitter buffer level max: 118 ms, min: 4 ms
Event history: 0x01830000 Pkts dropped by PCI burst limit: 0
```

The table below describes the significant fields shown in the display.

Table 37: show cem summary Field Descriptions

Field	Description
CEM	Displays the slot, port, and channel number of a CEM channel.
Current State	Displays the current state of a CEM channel. The state can be one of the following: • up--The channel is receiving valid packets from a source CEM channel. • down--The channel is receiving no packets (for example, the dejitter buffer is empty). • shutdown--The CEM channel has been administratively shut down.
Line State	Displays the current line state of a CEM channel. The line state can be one of the following: • up--The line is ready. • down--The line is down. A T1 or E1 line is down when the line is experiencing a physical-layer failure, such as loss of signal (LOS), loss of multiframe alignment (OOF), or alarm indication signal (AIS). A serial line is down when no cable is attached to the port.

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>Operational State</td><td>Displays the current operational state of a CEM channel. The operational state can be one of the following:
config-incomplete--The channel is in a config-incomplete state when any of the following conditions exist:
An xconnect is not defined.
A local IP address is not defined.
A local UDP port is not defined.
A remote UDP port is not defined.
The CEM channel is administratively shut down.
enabled--If none of the conditions for the config-incomplete state exists, but the CEM channel is receiving no packets from the remote side, the CEM channel is in an enabled state.
config-mismatch--If packets are arriving from the remote side but with a different payload size, data protection setting, or compression setting, the channel is in the config-mismatch state.
active--The CEM channel is active if none of the conditions outlined above exist.</td></tr>
<tr><td>Payload Size</td><td>Payload size configured for the CEM channel, in bytes.</td></tr>
<tr><td>Payload Compression</td><td>Displays whether payload compression is enabled or disabled for the CEM channel.</td></tr>
<tr><td>Data protection</td><td>Displays whether data protection is enabled or disabled for the CEM channel.</td></tr>
<tr><td>MAX_IPT</td><td>Maximum time between two consecutive ingress packets</td></tr>
<tr><td>Egress late packets</td><td>Number of packets that arrive too late to be queued to the dejitter buffer. A packet identified as late packet is discarded and substituted with an idle pattern.</td></tr>
<tr><td>ur_delay</td><td>Delay in milliseconds from the last packet received to the occurrence of an underrun.</td></tr>
<tr><td>ur2pkt</td><td>Delay in milliseconds from the occurrence of an underrun to the reception of the next packet.</td></tr>
<tr><td>pkt-to-pkt-jitter max</td><td>Maximum time between two consecutive egress packets</td></tr>
<tr><td>Dejitter buffer level max</td><td>Maximum recorded level of the dejitter buffer in milliseconds.</td></tr>
</table>

Related Commands

Commands	Description
cem	Enters circuit emulation configuration mode.
clear cem	Clears CEM statistics.

show cem circuit

To display the circuit emulation (CEM) statistics for the configured CEM circuits, use the**showcemcircuit**command in privileged EXEC mode.

show cem circuit [{*cem-group-id* | **interface** {**CEM** | **Virtual-CEM**} *slot*/*subslot*/*port* *cem-group-id* | **detail** | **summary**}]

Syntax Description

cem-group-id	The group ID specified while creating the CEM group.
interface	Displays detailed statistics for a CEM group configured on the specified CEM interface.
CEM	Circuit emulation interface for the data traffic.
Virtual-CEM	Virtual CEM interface created when out-of-band clock recovery is performed on a CEoP SPA.
slot	Slot where SIP-400 is installed.
/ *subslot*	Slot where CEoP SPA is installed. The slash character is required between the*slot* argument and the *subslot* argument.
/ *port*	Port on the CEoP SPA.The slash character is required between the *subslot* argument and the *port* argument.
detail	Displays detailed statistics for all CEM groups.
summary	Displays a summary of CEM groups, as well as their operational modes.

Command Modes

Privileged EXEC(#)

Command History

Release	Modification
12.2(33)SRB	This command was introduced.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.
Cisco IOS XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series Routers, Cisco ASR 920 Routers and Cisco NCS 4200 Series.
15.1(2)SNG	This command was implemented on Cisco ASR 901 Series Aggregation Services Routers.

Examples

The following is sample output from the **show cem circuit** command:

```
Router# show cem circuit
CEM Int.       ID   Ctrlr     Admin     Circuit         AC
--------------------------------------------------------------
CEM0/0         0    UP        UP        Enabled         UP
CEM0/1         1    UP        UP        Enabled         UP

The table below describes significant fields shown in the **showcemcircuit** command display.

Table 38: show cem circuit Field Descriptions

Field	Description
CEM	Displays the slot, port, and channel number of a CEM channel.
ID	Displays the value assigned to the CEM group while creating the CEM group.
Controller State	Displays the current state of the controller that represents the CEoP SPA.
Idle Pattern	Specifies the idle pattern that is transmitted on the physical link for any CEM packets that are lost or dropped.
Idle CAS	Specifies the default Channel Associated Signalling (CAS) pattern that is transmitted in the CAS bits of the outgoing T1/E1 frames.
Dejitter	Specifies the size of the dejitter buffer used to compensate for variable network delays experienced by CEM packets.
Payload Size	Specifies the number of payload bytes encapsulated into a single CEM packet.
Framing	Specifies whether the CEM group is framed (CESoPSN) or unframed (SAToP).
CEM Defects Set	Lists the defects that are currently active for the specified CEM group.
CEM Counter Details	Lists the various counters for the CEM group.
Pkts Missing	Specifies the total number of missing packets on the CEM group.
Pkts Reordered	Specifies the number of packets that are arrived out of order on the egress node of the CEM pseudowire and successfully reordered by the CEoP SPA.
Pkts Malformed	Specifies the number of CEM packets that are detected as malformed and dropped.
Misorder Drops	Specifies the number of packets that are dropped because they arrived out of order and could not be reordered.
JitterBuf Underrun	Specifies the number of times the CEoP SPA searches the dejitter buffer for a CEM packet and fails.
JitterBuf Overrun	Specifies the number of times a CEM packet arrived from the pseudowire is not accommodated in the dejitter buffer because the buffer is full.
Error Sec	Specifies the number of seconds in which any missing packet, reorder packet, jitter buffer underrun, misorder dropped packet, or malformed packet is detected.
Severly Errored Sec	Specifies the number of seconds in which more than one percent of the received CEM packets are lost.
Unavailable Sec	Specifies the number of seconds for which the CEM circuit is down due to a fault condition.

Field	Description
Failure Counts	Specifies the number of times the CEM circuit entered into the packet loss state.

show chassis

To display processor and memory information, use the **showchassis** command in privileged EXEC mode.

show chassis [{**clocks** | **slot** *slot-number* [**detail**] | **split** | **detail**}]

Syntax Description

clocks	(Optional) Displays trunk (T1/E1) clock information.
slot *slot-number*	(Optional) Displays slot-specific information.
split	(Optional) Displays split-related data.
detail	(Optional) Displays slot information

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(2)XB1	This command was introduced on the Cisco AS5850 universal gateway.
12.2(11)T	This command was integrated into Cisco IOS Release 12.2(11)T.
15.0(1)M	This command was modified in a release earlier than Cisco IOS Release 15.0(1)M. The **detail** keyword was added. The **clocks** and **split** keywords were removed.

Usage Guidelines

You must enter this command from one of the route-switch-controller (RSC) cards.

Use the **showchassis** command to display additional output relevant to handover-split mode. Command output shows the RSC card to be configured with all slots of the entire chassis, regardless of configured ownership. Slots owned by the peer RSC are shown in the ignore state, properly configured and ready to go.

Examples

The following example shows output for a system in handover-split mode. Each RSC is shown to be configured with all slots in the entire chassis, regardless of whether the RSC actually owns the slot. Slots that are not owned by an RSC are shown to be in the ignore state. The RSC from which the command is entered owns slots 0 to 5, but has configured for it all slots (0 to 5 and 8 to 13--all slots except those in which the RSCs are inserted). Entries for slots 8 and 10 show the designator "ignore."

```
Router# show chassis
System is in handover-split mode, RSC in slot 6.
!
  Slots owned: 0 1 2 3 4 5
  Slots configured: 0 1 2 3 4 5 8 9 10 11 12 13
  Slots owned by other: 8 9 10 11 12 13
Slot    Board        CPU       DRAM                I/O Memory         State     Elapsed
        Type         Util      Total (free)        Total (free)                 Time
5       UP324        0%/0%     26814176( 20%)      33554432( 45%)     Up        01:02:54
8       CT3_UP216    0( 0%)    0( 0%)                                 Ignore    01:05:19
10      UP324        0( 0%)    0( 0%)                                 Ignore    01:05:19
```

The following example shows output for a system in classic-split mode. The RSC from which the command is entered owns slots 0 to 5, and has configured for it only those same slots 0 to 5.

```
Router# show chassis
System is in classic-split mode, RSC in slot 6.
  Slots owned: 0 1 2 3 4 5
  Slots configured: 0 1 2 3 4 5
  Slots owned by other: 8 9 10 11 12 13
```

The following example shows details for the card in slot 0:

```
Router# show chassis slot 0
Slot: 0, Type: 24 E1 Ports (700)
CPU utilization: 0%/0% (5 secs); 0% (1 min); 0% (5 mins)
Memory: Total(b) Used(b) Free(b) Lowest(b) Largest(b)
Processor 59304928 16307688 42997240 42817836 42819352
I/O 67108864 8200288 58908576 58515056 58515004
State: IOS up; elapsed time in state: 13:28:35
Flags:
FB_FLAGS_PRESENT
FB_FLAGS_LINECARD
FB_FLAGS_ANALYZED
FB_FLAGS_CHECKPOINT
Inserted: 13:39:30 ago
Last update: 00:00:08 ago
```

The table below describes significant fields shown in this output.

Table 39: show chassis Fields Descriptions

Field	Description
Slot	Slot number.
Type	Card type.
CPU utilization	CPU usage in percentages.
Memory	Current processor and I/O memory values.
State	Current state of slot and time in hours, minutes, and seconds that the slot has spent in current state.
Flags	Displays a sequence of flag states that the slot has been through.
Inserted	Time in hours, minutes, and seconds since the slot was inserted into the chassis.
Last Update	Time in hours, minutes, and seconds since the last update message was sent.

Related Commands

Command	Description
show dial-shelf	Displays information about dial shelves.

show class cem

T o display the cem parameters configured for CEM class, use the **showclasscem**commandin privilege exec mode. A CEM class helps in configuring parameters in a template and applying parameters at the CEM interface level on a CEOPS SPA.

show class cem [{**name** | **all** | **detail**}]

Syntax Description

name	Indicates the class name, specific to which the CEM parameter details are displayed.
all	Displays the CEM parameter configuration details for all the classes.
detail	Displays CEM parameters configured and additionally provides the circuits and interfaces inheriting the respective class.

Command Default

No default behavior or values.

Command Modes

Privilege Exec Mode (Exec)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced.

Usage Guidelines

The **showclasscem**command has been introduced on Cisco ASR 1000 Series Router in Cisco IOS XE Release 3.3. The **showclasscem***name* command is used to view the CEM parameters configured for a specific classname. To view the CEM parameters configured for all the CEM classes, use the **showclasscemall** command. To view the circuits and interfaces inheriting the class and the CEM parameters configured, use the **showclasscemdetail** command from privilege exec mode.

Examples

The following example shows the command output for class parameters configured for a specific class name:

```
Router# show class cem cemqos
Class: DUMMY, Dummy mode: user-defined, Dummy Pattern: 0x77
Class: 0/2/0
Dejitter: 320, Payload Size: 960
```

The following example shows the command output providing details of parameters configured for all the classes and additionally shows the interfaces and circuits inheriting the class:

```
Router# show class cem detail
Class: DUMMY, Dummy mode: user-defined, Dummy Pattern: 0x77
Circuits inheriting this Class:
 None
Interfaces inheriting this Class:
 None
Class: 0/2/0
Dejitter: 320, Payload Size: 960
Circuits inheriting this Class:
 None
```

```
Interfaces inheriting this Class:
 None
```

The following example shows the command output providing details of parameters configured for all the classes:

```
Router# show class cem all

Class: cemqos         , Dummy mode: last-frame
Dejitter: 20, Payload Size: 256
Router#show inter
Router#show interfaces cem 0/1/0
CEM0/1/0 is up, line protocol is up
  Hardware is Circuit Emulation Interface
  MTU 1500 bytes, BW 155520 Kbit/sec, DLY 0 usec,
     reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation CEM, loopback not set
  Keepalive not supported
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/0 (size/max)
  5 minute input rate 1022000 bits/sec, 745 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
     2851672 packets input, 215070144 bytes, 0 no buffer
     Received 0 broadcasts (0 IP multicasts)
     0 runts, 0 giants, 0 throttles
     0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
     0 packets output, 0 bytes, 0 underruns
     0 output errors, 0 collisions, 0 interface resets
     0 unknown protocol drops
```

Related Commands

Command	Description
clear interface cem	Clears the cem channel.

show compress

To display compression statistics, use the **showcompress** command in user EXEC or privileged EXEC mode.

show compressshow compress command

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.3	An example for hardware compression was added as implemented in the Canadian Standards Association (CSA) hardware.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is a sample output from the **showcompress** command when software compression is used on the router:

```
Router# show compress
Serial0
uncompressed bytes xmt/rcv 10710562/11376835
1  min avg ratio xmt/rcv 2.773/2.474
5  min avg ratio xmt/rcv 4.084/3.793
10 min avg ratio xmt/rcv 4.125/3.873
no bufs xmt 0 no bufs rcv 0
resets 0
```

The table below describes the fields shown in the display.

*Table 40: **show compress** Field Descriptions--Software Compression*

Field	Description
Serial0	Name and number of the interface.
uncompressed bytes xmt/rcv	Total number of uncompressed bytes sent and received.
1 min avg ratio xmt/rcv 5 min avg ratio xmt/rcv 10 min avg ratio xmt/rcv	Static compression ratio for bytes sent and received, averaged over 1, 5, and 10 minutes.
no bufs xmt	Number of times buffers were not available to compress data being sent.
no bufs rcv	Number of times buffers were not available to uncompress data being received.

Field	Description
resets	Number of resets (for example, line errors could cause resets).

The following is a sample output from the **showcompress** command when hardware compression is enabled (that is, compression is implemented in the CSA hardware):

```
Router# show compress
 Serial6/1
     Hardware compression enabled
     CSA in slot3 in use
     Compressed bytes sent:     402 bytes     0 Kbits/sec    ratio: 4.092
     Compressed bytes recv:     390 bytes     0 Kbits/sec    ratio: 3.476
     restarts:1
     last clearing of counters: 1278 seconds
```

The table below describes the fields shown in the display. The information displayed by the **showcompress** command is the same for hardware and distributed compression. For Cisco 7200 series routers with multiple CSAs, an additional line is displayed indicating the CSA in use.

Table 41: show compress Field Descriptions--Hardware or Distributed Compression

Field	Description
Serial6/1	Name and number of the interface.
Hardware compression enabled	Type of compression.
CSA in slot3 in use	Identifies the CSA that is performing compression service.
Compressed bytes sent	Total number of compressed bytes sent including the kilobits per second.
Compressed bytes recv	Total number of compressed bytes received including the kilobits per second.
ratio	Compression ratio for bytes sent and received since the link last came up or since the counters were last cleared.
restarts	Number of times the compression process restarted or reset.
last clearing of counters	Duration since the last time the counters were cleared with the **clearcounters**command.

Related Commands

Command	Description
compress	Configures compression for LAPB, PPP, and HDLC encapsulations.

show controllers c3794

To display information about configuration of C37.94 controller, use the **show controllers c3794** command in global configuration mode.

Cisco 900 Series Routers
controllers c3794 *slot/sub-slot/port*

Syntax Description

c3794	Controller type
slot	Backplane slot number. The slot number for C37.94 controller is always 0.
sub-slot	Physical sub-slot number. The range for sub-slot is 0-5.
port	Port number of the controller. Valid numbers are 0 and 3. A forward slash mark (/) is required between the slot argument and the port argument.

Command Modes

Global configuration

Command History

Release	Modification
3.18.1SP	This command was introduced.

Usage Guidelines

This command displays controller status. The information displayed is generally useful for diagnostic tasks performed by technical support personnel only. The command is used to display:

- Number of channels configured
- Number of channels received from tele-protection equipment
- Loss of Signal, if any
- Number of times LOS was set and cleared
- Path of Yellow, if any
- Number of times yellow alarm was set and cleared

Examples

The following is sample output from the **showcontrollers c3794** command on the Cisco 900 Series Router:

```
Router# show controllers c3794
C3794 0/0/0 - (A900-IMA4C3794) is up
Configured Channels: 12
Peer Channels      : 12
Alarm                               : Nil
Sending Y-Alarm to Peer Device      : No
Receiving Y-Alarm from Peer Device : No
```

show controller dsl

To display the DSL controller status and the statistics of a DSL port, use the **showcontrollerdsl** command in privileged EXEC mode.

show controller dsl *slot/port*

Syntax Description

slot	Slot number of the DSL controller.
/ *port*	Port number of the DSL controller. The slash (/) character is required and must be entered when specifying the slot and port arguments.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on Cisco 2600 series and Cisco 3700 series routers.
12.3(4)XG	This command was integrated into Cisco IOS Release 12.3(4)XG on the Cisco 1700 series routers.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T on Cisco 2600 series, Cisco 3631, and Cisco 3700 series routers.
12.3(11)T	This command was implemented on Cisco 2800 and Cisco 3800 series routers.
12.3(14)T	This command was implemented on Cisco 1800 series routers.

Usage Guidelines

This command is used to display the controller mode of the controller in the specified slot and port and to display the statistics. Use this command in troubleshooting. Use the Cisco IOS help to find the valid slot and port numbers.

Examples

Display for DSL Controller Configured in ATM 4-Wire Mode

The following example displays the status and statistics of the DSL controller in slot 1 and port 0 configured in ATM 4-wire mode:

```
Router# show controller dsl 1/0
 DSL 1/0 controller UP
 Globespan xDSL controller chipset
 DSL mode:SHDSL Annex B
 Frame mode:Utopia

 Rcv Clock Status:In the Range
 Loop Attenuation: 0.7800 dB
 Transmit Power: 7.5 dB
 Receiver Gain: 22.5420 dB
 SNR Sampling: 35.6120 dB
 Dying Gasp:Present
```

Annex Display When Line Is Trained

The following example shows the DSL controller annex display when the line is trained:

```
Router# show controller dsl 1/0
 DSL 1/0 controller UP
 SLOT 0: Globespan xDSL controller chipset
 DSL mode: SHDSL Trained with Annex B-ANFP
```

Annex Display When Line Is Not Trained

The following example shows the DSL controller annex display when the line is not trained:

```
Router# show controller dsl 1/0
 DSL 1/0 controller DOWN
 SLOT 0: Globespan xDSL controller chipset
 DSL mode: Not trained
```

The following table describes the significant fields of the **showcontrollerdsl** command.

Table 42: show controller dsl Field Descriptions

Field	Description
DSL ... controller ...	Describes the status of the controller in the indicated slot number.
DSL mode	Displays the DSL mode of the controller.
Frame mode	Displays the frame mode of the controller.
Configured Line rate	Displays the line rate.
LOSW Defect alarm	Displays the status of the LOSW alarm.

Field	Description
CRC per second alarm	Displays the status of the CRC per second alarm.
Line termination	Displays how the line is terminated.
Chipset Version	Displays the version of the chipset.
Firmware Version	Displays the version of the firmware.
Modem Status	Displays the status of the modem.
Last Fail Mode	Displays the last fail mode.
Line rate	Displays the line rate.
Framer Sync Status	Displays the framer synchronization status.
Rcv Clock Status	Displays the revision clock status.
Loop Attenuation	Displays the loop attenuation.
Transmit Power	Displays the transmit power.
Receiver Gain	Displays the receiver gain.
SNR Sampling	Displays the signal-to-noise ratio sampling.

Related Commands

Command	Description
controller dsl	Configures the controller status and the controller number.

show controller vdsl

To display VDSL controller related information, use the **showcontrollervdsl** command in privileged EXEC mode.

show controller vdsl *slot/subslot/portnumber* [**bit-alloc** | **brief** | **console** | **crash** | **datapath** | **delt-data**| **detailed** | **gain-nsc** | **ipc** | **regs**]

Syntax Description

slot/subslot/port number	Slot, subslot, and port number on the VDSL interface.
bit-alloc	(Optional) Displays bit allocation NSC information.
brief	(Optional) Displays brief information only.
console	(Optional) Displays the console buffer.
crash	(Optional) Displays the CPU crash log.
datapath	(Optional) Displays total datapath information.
delt-data	(Optional) Displays the results of the **delt** command.
detailed	(Optional) Displays all detailed information.
gain-nsc	(Optional) Displays gain NSC information.
ipc	(Optional) Displays ipc statistics.
regs	(Optional) Displays the registers.

Command Default

No default behavior or values

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M1	This command was introduced.

Examples

The following example shows output for this command:

```
router# show controller vdsl 0/0/0
Controller VDSL 0/0/0 is UP
Daemon Status:            Up
                         XTU-R (DS)               XTU-C (US)
Chip Vendor ID:          'BDCM'                    'BDCM'
Chip Vendor Specific:    0x0000                    0x0000
Chip Vendor Country:     0xB500                    0xB500
Modem Vendor ID:         'CSCO'                    'BDCM'
Modem Vendor Specific:   0x4602                    0x0000
Modem Vendor Country:    0xB500                    0xB500
Serial Number Near:     FHH1327000CCISCO00000000
Serial Number Far:

```

The table below describes the significant fields of the **showcontrollervdsl** command.

Table 43: show controller vdsl Field Descriptions

Field	Description
Daemon Status	Current state of the VDSL daemon, the application that controls the VDSL2 line and the modem state. The VDSL2 daemon can transition through the following states: Reload, Start, Boot Init, Boot Code Download, Firmware Download, DSL Mgmt Task Init, Admin State Check, Configuration, Establishing Link, DSL Line Ready, and Up. The VDSL2 daemon is in the "Up" state when the line reaches showtime.
Chip Vendor ID	Identification code for the chipset vendor, made up of four ASCII characters. For example, BDCM stands for Broadcom.
Chip Vendor Specific	Chipset vendor-specific code made up of four hexadecimal digits as specified in ITU standard. This field is used for ITU standard modes exclusively.
Chip Vendor Country	Country code where the vendor is located. This field is used for ITU standard modes exclusively.
Modem Vendor ID	Identification code for the modem equipment vendor, made up of four ASCII characters. For example, CSCO stands for Cisco.
Modem Vendor Specific	Modem equipment vendor specific code made up of four hexadecimal digits.

Field	Description
Modem Vendor Country	Country code where the modem system vendor is located. This field is used for ITU standard modes exclusively.
Serial Number Near	Serial identification number, which is made up of 11 characters for serial number, 8 characters for platform id, and 11 characters for the version. For example, FOC135145AS 3925-CHA 15.1(2.10)T The 11 characters for the serial number include the modem equipment serial number, modem equipment model, and modem equipment firmware version.
Serial Number Far	Serial identification number of the DSLAM is displayed if it is available from the DSLAM.
Modem Version Near	Modem equipment software version information. It is the IOS version string.
Modem Version Far	Software version of the DSLAM is displayed if it is available from the DSLAM.
Modem Status	Current state of the VDSL2 modem. It can be one of the following states: Line NOT initialized, Line Exception, Idle Request, Silent Request, Line Silent, Handshake, Line FullInit, Discovery, Training, Analysis, Exchange, No Sync, TC Sync (Showtime!), Fast Retrain, Low Power L2, Loop Diagnostics Active, Loop Diagnostics Data Exchange, Loop Diagnostics Data Request, Loop Diagnostics Complete, Resync, Test, Test Loop, Test Reverb, Test Medley, Low Power L3, or Unknown.
DSL Config Mode	VDSL2 line configuration mode. For the HWIC-1VDSL, only Auto mode is supported.
Trained Mode	ITU-T mode in which the VDSL2 line trained up. For the HWIC-1VDSL only G.993.2 (VDSL2) mode is supported.
TC Mode	Layer 2 mode for the VDSL line. For HWIC-1VDSL, only PTM mode is supported.
DELT configuration	Dual Ended Loop Test configuration status, if the feature is enabled.
DELT state	Actual State of Dual Ended Loop Test. The values can be one of the following: Successful, Failed, Not Running, In Progress, or Unknown.
Trellis	Actual State of Dual Ended Loop Test. The values can be one of the following: Successful, Failed, Not Running, In Progress, or Unknown.
Line Attenuation	Aggregate value of Line Attenuation across the subcarriers of all VDSL2 bands.
Signal Attenuation	Aggregate value of Signal Attenuation across the subcarriers of all VDSL2 bands.
Noise Margin	Aggregate value of Signal-to-Noise Ratios (SNR) values across the subcarriers of all VDSL2 bands.
Attainable Rate	Maximum net data rate, in bits, currently attainable by the CPE receiver and DSLAM transmitter.

Field	Description
Actual Power	Measured total output power when the line is trained up. When the line is down, the last measured power is given.
Line Attenuation (dB)	For a band in the downstream direction, it is the measured difference in the total power transmitted by the DSLAM (xTU-C) and the total power received by the CPE (xTU-R) over all sub-carriers of that band during initialization. For a band in the upstream direction, it is the measured difference in the total power transmitted by the xTU-R and the total power received by the xTU-C over all sub-carriers of that band during initialization.
Signal Attenuation (dB)	For a band in the downstream direction, it is the measured difference in the total power transmitted by the DSLAM(xTU-C) and the total power received by the CPE(xTU-R) over all sub-carriers of that band during Showtime. For a band in the upstream direction, it is the measured difference in the total power transmitted by the xTU-R and the total power received by the xTU-C over all sub-carriers of that band during Showtime
Noise Margin (dB)	SNR Margin is the maximum increase of the noise power (in dB) received at the xTU (xTU-R for a band in the downstream direction and xTU-C for a band in the upstream direction), such that the Bit Error Rate (BER) requirements are met for all bearer channels received at the xTU.
Total FECS	Cumulative count during which there is at least one Forward Error Correction (FEC) event on the VDSL2 line.
Total ES	Cumulative count during which there is at least one Errored Second (ES) event on the VDSL2 line.
Total SES	Cumulative count during which there is at least one Severely Errored Second (SES) event on the VDSL2 line.
Total LOSS	Cumulative count, in seconds, during which there is at least one Loss of Signal (LOS) event on the VDSL2 line.
Modem FW Version	Comprehensive firmware version information for the modem, which includes the Operating System version, the VDSL2 PHY version, and the VDSL2 driver version.
Modem PHY Version	Modem firmware Version information, which includes the VDSL2 PHY and the VDSL2 driver.
Speed (kbps)	Actual trained line rate as measured in kbps.
Reed-Solomon EC	Number of VDSL2 superframes that have at least one Reed-Solomon correction action in one of its data frames. Reed-Solomon ECs do not affect service performance.
CRC Errors	Number of superframes that have an incorrect CRC. CRC errors do affect service performance.

Related Commands

Command	Description
clear controller vdsl	Resets the VDSL line related counters.

show controllers analysis-module

To display controller information for the analysis module interface, use the **showcontrollersanalysis-module** command in user EXEC or privileged EXEC mode.

show controllers analysis-module *slot/unit*

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network analysis module (NAM). For NAM, always use 0. The slash (/) between the *slot* and *unit* arguments is required.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.3(4)XD	This command was introduced on the following platforms: Cisco 2600XM series, Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745.
12.3(7)T	This command was integrated into Cisco IOS Release 12.3(7)T.
12.3(8)T4	This command was implemented on the following platforms: Cisco 2811, Cisco 2821, and Cisco 2851.
12.3(11)T	This command was implemented on the Cisco 3800 series.

Usage Guidelines

The output from this command is generally useful for diagnostic tasks performed by technical support only. Nevertheless, you can use the displayed HARDWARE STATISTICS information to obtain the receive and transmit packet statistics that are collected by the hardware controller during packet processing.

Examples

The following example shows how to display controller information for the analysis module interface when the NAM is installed in router slot 2:

```
Router# show controllers analysis-module 2/0

Interface Analysis-Module2/0
Hardware is Intel 82559 FastEthernet
IDB: 64AD5AB0, FASTSEND: 609A0494, MCI_INDEX: 0

The table below describes the significant fields shown in the display.

Table 44: show controllers analysis-module Field Descriptions

Field	Description
Hardware is	Description of the chip being used.
IDB, FASTSEND	Address in router memory of the Interface Descriptor Block (IDB) and the fastsend routine.
INSTANCE	Device-specific data stored in router memory that lists the memory locations and current indexes of receive (Rx) and transmit (Tx) rings in router I/O memory.
CONTROL AND STATUS REGISTERS (CSR)	Control and status registers that are physically located on the chip itself and that are accessed by the CPU over the Peripheral Component Interconnect (PCI) bus.
PHY REGISTERS	Contents of the PHY registers. PHY is a device that interfaces the physical Ethernet line and that is located between the chip and the physical line.
HARDWARE STATISTICS	Receive (Rx) and transmit (Tx) traffic statistics collected by the chip.
INTERRUPT STATISTICS	Transmit (Tx), Receive (Rx), control, software, and flow control interrupt statistics collected by the chip.

Related Commands

Command	Description
service-module analysis-module status	Displays hardware and software status information about the NM-NAM.
show interfaces analysis-module	Displays status, traffic data, and configuration information about the analysis module interface.

show controllers cbus

To display all information under the cBus controller card including the capabilities of the card and reports controller-related failures, use the **showcontrollerscbus** command in privileged EXEC mode on the Cisco 7500 series routers.

show controllers cbus

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.4(16)	The **showcontrollerscbus** command output display was modified to allow users to monitor IPC buffer limits when **debugcbusipc** is enabled. The **showcontrollerscbus** command output display on the 7500 will now have a new line added under each VIP slot that begins with **ipcacc**. The status line indicates the current ipc accumulator value and its initial limit assigned.

Examples

Cisco 7500 Series Router with VIP2 Card Example

The following is a partial output from the **showcontrollerscbus** command on a Cisco 7500 series router with one Versatile Interface Processor version 2 (VIP2) card. This example does not show output from additional interface processors that are usually installed in a Cisco 7500 series router.

```
Router# show controllers cbus

The table below describes significant fields in the per-slot part of these displays.

*Table 45: **show controllers cbus** Command--Per-Slot Field Descriptions*

Field	Description
slot1	Slot location of the specific interface processor (in this case Packet-over-SONET Interface Processor).
hw	Version number of the card.
sw	Version number of the card's internal software (in ROM).
software loaded from	Source device and file name from which the router software was loaded.
FLASH ROM version VPLD version	Version of Flash ROM.
Pos1/0, applique is SONET	Location of the specific interface and the hardware applique type (in this case a Packet OC-3 interface).
gfreeq	Location of the global free queue that is shared among similar interfaces.
lfreeq	Location of the local free queue, which is a private queue of MEMD buffers.
throttled	Number of times input packet processing has been throttled on this interface.
rxlo	Minimum number of MEMD buffers held on local free queue. When idle, the interface returns buffers from its local queue to the global free queue until only this number of buffers remain in the local queue.
rxhi	Maximum number of MEMD buffers that the interface can remove from the global free queue in order to populate its local queue.
rxcurr	Number of MEMD buffers currently on the local free queue.
maxrxcurr	Maximum number of MEMD buffers that were enqueued on the local free queue.
txq	Address of the transmit queue.
txacc	Address of the transmit queue accumulator.
txlimit	Maximum number of buffers allowed in the transmit queue.

Cisco 7500 Series Router Example

The following is sample output from the **showcontrollerscbus** command on a Cisco 7500 series router:

```
Router# show controllers cbus
cBus 1, controller type 3.0, microcode version 2.0
  128 Kbytes of main memory, 32 Kbytes cache memory
  40 1520 byte buffers, 14 4484 byte buffers
  Restarts: 0 line down, 0 hung output, 0 controller error
HSCI 1, controller type 10.0, microcode version 129.3
  Interface 6 - Hssi0, electrical interface is Hssi DTE
    5 buffer RX queue threshold, 7 buffer TX queue limit, buffer size 1520
    ift 0004, rql 2, tq 0000 0000, tql 7
    Transmitter delay is 0 microseconds
 MEC 3, controller type 5.1, microcode version 130.6
  Interface 18 - Ethernet2, station address 0000.0c02.a03c (bia 0000.0c02.a03c)
    10 buffer RX queue threshold, 7 buffer TX queue limit, buffer size 1520
    ift 0000, rql 10, tq 0000 0000, tql 7
    Transmitter delay is 0 microseconds
  Interface 19 - Ethernet3, station address 0000.0c02.a03d (bia 0000.0c02.a03d)
    10 buffer RX queue threshold, 7 buffer TX queue limit, buffer size 1520
    ift 0000, rql 10, tq 0000 0000, tql 7
    Transmitter delay is 0 microseconds
```

The table below describes the fields shown in the following lines of output.

```
cBus 1, controller type 3.0, microcode version 2.0
  128 Kbytes of main memory, 32 Kbytes cache memory
  40 1520 byte buffers, 14 4484 byte buffers
  Restarts: 0 line down, 0 hung output, 0 controller error
```

*Table 46: **show controllers cbus** Field Descriptions--Part 1*

Field	Description
cBus 1	Card type and number (varies depending on card).
controller type 3.0	Version number of the card.
microcode version 2.0	Version number of the card's internal software (in ROM).
128 Kbytes of main memory	Amount of main memory on the card.
32 Kbytes cache memory	Amount of cache memory on the card.
40 1520 byte buffers	Number of buffers of this size on the card.
14 4484 byte buffers	Number of buffers of this size on the card.
Restarts • 0 line down • 0 hung output • 0 controller error	Count of restarts for the following conditions: • Communication line down • Output unable to transmit • Internal error

The table below describes the fields shown in the following lines of output:

```
HSCI 1, controller type 10.0, microcode version 129.3
  Interface 6 - Hssi0, electrical interface is Hssi DTE
    5 buffer RX queue threshold, 7 buffer TX queue limit, buffer size 1520
```

```
ift 0004, rql 2, tq 0000 0000, tql 7
Transmitter delay is 0 microseconds
```

*Table 47: **show controllers cbus** Field Descriptions--Part 2*

Field	Description
HSCI 1	Card type and number (varies depending on card).
controller type 10.0	Version number of the card.
microcode version 129.3	Version number of the card's internal software (in ROM).
Interface 6	Physical interface number.
Hssi 0	Logical name for this interface.
electrical interface is Hssi DTE	Self-explanatory.
5 buffer RX queue threshold	Maximum number of buffers allowed in the receive queue.
7 buffer TX queue limit	Maximum number of buffers allowed in the transmit queue.
buffer size 1520	Size of the buffers on this card (in bytes).
ift 0004	Interface type code: • 0 = EIP • 1 = FSIP • 4 = HIP • 5 = TRIP • 6 = FIP • 7 = AIP
rql 2	Receive queue limit. Current number of buffers allowed for the receive queue. It is used to limit the number of buffers used by a particular inbound interface. When equal to 0, all of that interface's receive buffers are in use.
tq 0000 0000	Transmit queue head and tail pointers.
tql 7	Transmit queue limit. Current number of buffers allowed for transmit queue. It limits the maximum cBus buffers allowed to sit on a particular interface's transmit queue.
Transmitter delay is 0 microseconds	Transmitter delay between the packets.

ATM Interface Processor Example

The following is a sample output from the **showcontrollerscbus** command for an ATM Interface Processor (AIP) installed in IP slot 4. The running AIP microcode is Version 170.30, the physical layer interface module (PLIM) type is 4B/5B, and the available bandwidth is 100 Mbps:

```
Router# show controllers cbus
Switch Processor 5, hardware version 11.1, microcode version 170.46
  Microcode loaded from system
  512 Kbytes of main memory, 128 Kbytes cache memory
  60 1520 byte buffers, 91 4496 byte buffers
  Restarts: 0 line down, 0 hung output, 0 controller error
 AIP 4, hardware version 1.0, microcode version 170.30
  Microcode loaded from system
  Interface 32 - ATM4/0, PLIM is 4B5B(100Mbps)
    15 buffer RX queue threshold, 36 buffer TX queue limit, buffer size 4496
    ift 0007, rql 12, tq 0000 0620, tql 36
    Transmitter delay is 0 microseconds
```

Service Provider MultiChannel Interface Processor Example

The following is sample output from the **showcontrollerscbus** command for the Service Provider MultiChannel Interface Processor (SMIP):

```
Router# show controllers cbus
SMIP 2, hardware version 1.0, microcode version 10.0
 Microcode loaded from system
 Interface 16 - T1 2/0, electrical interface is Channelized T1
   10 buffer RX queue threshold, 14 buffer TX queue limit, buffer size 1580 ift 0001, rql
   7, tq 0000 05B0, tql 14
   Transmitter delay is 0 microseconds
```

Per-Slot Limits on IPC Example

The following example shows the current value of the IPC accumulator used for RSP-to-VIP communication along with the initial value of the IPC accumulator assigned to that particular VIP. The IPC accumulator shows the buffers for IPC packets and is analogous to the tx accumulator used for data packets.

```
Router# show controllers cbus
MEMD at E0000000, 2097152 bytes (unused 2880, recarves 1, lost/qaerror recoveries 0/0)
  RawQ E8000100, ReturnQ E8000108, EventQ E8000110, IpcackQ E8000118, VIP_CrashinfoQ E8000128

  IpcSlaveackQ E8000120
  BufhdrQ E8000150 (2893 items), LovltrQ E8000168 (64 items, 2016 bytes)
  IpcbufQ E8000178 (32 items, 4096 bytes)
  IpcbufQ_classic E8000170 (8 items, 4096 bytes)
  3569 buffer headers (E8002000 - E800FF00)
  pool0: 9 buffers, 256 bytes, queue E8000158
  pool1: 298 buffers, 1536 bytes, queue E8000160
  pool2: 261 buffers, 4544 bytes, queue E8000180
  pool3: 4 buffers, 4576 bytes, queue E8000188
  slot1: VIP2 R5K, hw 2.00, sw 22.20, ccb F800FF20, cmdq E8000088, vps 8192
    software loaded from system
    Copyright (c) 1986-2005 by Cisco Systems, Inc.
```

```
    ROM Monitor version 115.0

      gfreeq E8000160, lfreeq E8000190 (1536 bytes)
      rxlo 4, rxhi 123, rxcurr 0, maxrxcurr 0
      txq E8001A00, txacc E8001A02 (value 0), txlimit 33
    ATM1/1/0, applique is OC3 (155000Kbps)
      gfreeq E8000180, lfreeq E8000198 (4544 bytes)
      rxlo 4, rxhi 261, rxcurr 0, maxrxcurr 0
      txq E8001A08, txacc E8001A0A (value 0), txlimit 174
  slot2: VIP4-50 RM5271, hw 2.01, sw 22.20, ccb F800FF30, cmdq E8000090, vps 8192
    software loaded from system
    Copyright (c) 1986-2005 by Cisco Systems, Inc.
    ROM Monitor version 103.0
    ipcacc E800008A (value 36), ipclimit 36
    ATM2/0/0, applique is SONET (155000Kbps)
```

show controllers cbus Display With a Filter Applied to Customize the Display

The following example shows the IPC statistics. The **showcontrollerscbus** command output display on the 7500 includes a line under the entry for each VIP slot that begins with **ipcacc**. The status line indicates the current IPC accumulator value and its initial limit assigned.

```
Router# show controllers cbus | include ipc|slot
  slot1: VIP2 R5K, hw 2.00, sw 22.20, ccb F800FF20, cmdq E8000088, vps 8192
    ipcacc E8000082 (value 6), ipclimit 36
  slot2: VIP4-50 RM5271, hw 2.01, sw 22.20, ccb F800FF30, cmdq E8000090, vps 8192
    ipcacc E800008A (value 36), ipclimit 36
  slot3: VIP2 R5K, hw 2.00, sw 22.20, ccb F800FF40, cmdq E8000098, vps 8192
    ipcacc E8000092 (value 6), ipclimit 36
```

When the IPC acc reaches 10% of the IpcbufQ limit, a rate-limited warning message will be displayed if the **debugcbusipc** comamnd is enabled:

```
%RSP-6-IPC_STUCK: Ipcacc for slot 1 has reached 7% of its Ipclimit
```

show controllers content-engine

To display controller information for content engine (CE) network modules, use the **showcontrollerscontent-engine** command in privileged EXEC mode.

show controllers content-engine *slot*/*unit*

Syntax Description

slot	Number of the router chassis slot for the network module.
/ *unit*	Number of the daughter card on the network module. For CE network modules, always use 0. The slash (/) character is required when specifying the *slot* and *unit* arguments.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(11)YT	This command was introduced.
12.2(13)T	This command was integrated into Cisco IOS Release 12.2(13)T.

Examples

The following example displays controller information for the CE network module in router slot 1:

```
Router# show controllers content-engine 1/0
Interface Content-Engine1/0
Hardware is Intel 82559 FastEthernet
IDB: 82A92DC4, FASTSEND: 8021B488, MCI_INDEX: 0

```

The table below describes the significant fields shown in the display.

Table 48: show controllers content-engine Field Descriptions

Field	Description
Hardware	Description of the chip being used.

Field	Description
IDB, FASTSEND	Address in router memory of the Interface Descriptor Block (IDB) and the fastsend routine.
INSTANCE	Device-specific data stored in router memory that lists the memory locations and current indices of receive (Rx) and transmit (Tx) rings in router I/O memory.
CONTROL AND STATUS REGISTERS (CSR)	Control and status registers that are physically located on the chip itself and that are accessed by the CPU over the protocol control information (PCI) bus.
PHY REGISTERS	Contents of the physical layer (PHY) registers. A PHY module is a device that interfaces the physical Ethernet line and that is located between the chip and the physical line.
HARDWARE STATISTICS	Receive (Rx) and transmit (Tx) traffic statistics collected by the chip.
INTERRUPT STATISTICS	Transmit (Tx), Receive (Rx), control, software, and flow control interrupt statistics collected by the chip.

Related Commands

Command	Description
interface content-engine	Configures an interface for a CE network module and enters interface configuration mode.
show interfaces content-engine	Displays basic interface configuration information for a CE network module.

show controllers dsx3

To display digital signal level 3 cross connect (dsx3) information and to display hardware and software driver information for the dsx3 controller, use the **showcontrollersdsx3**command in privileged EXEC mode.

show controllers dsx3 *shelf* / *slot* / *port*

Syntax Description

shelf	Shelf chassis in the Cisco 10000 series router that contains the dsx3 interface card.
/*slot*	Location of the dsx3 interface card in the shelf chassis.
/*port*	Port number.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(31)SB	This command was introduced in a release earlier to Cisco IOS Release 12.2(31)SB.
12.2(33)SB	This command's behavior was modified on the Cisco 10000 series router for the PRE3 and PRE4.

Examples

The following is a sample output show the show controller dsx3 command for 8E3DS3 card:

```
Router# show controllers dsX3 3/0/0
DSX3 3/0/0 is down.  Hardware is C10K ET line card
  ET H/W Version : 0.0.0, ET ROM Version : 0.0, ET F/W Version : 0.0.0
  Applique type is Subrate T3/E3
  Receiver has loss of signal.
  MDL transmission is disabled

  FEAC code received: No code is being received
  Framing is C-BIT Parity (Configured)
  Line Code is B3ZS, Clock Source is Internal
  DSU mode is cisco, DSU bandwidth is 44210
  equipment customer loopback
  Data in current interval (75 seconds elapsed):
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     75 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
     0 AIS Defect Secs, 75 LOS Defect Secs
     0 Near-end path failures
     0 Far-end path failures, 0 FERF Defect Secs
     0 CP-bit Far-End Unavailable Secs, 0 Far-End Coding Violations
     0 Far-End Errored Secs, 0 Far-End Severely Errored Secs
```

The table below describes the significant fields shown in the display.

Table 49: show controllers dsx3 Field Descriptions--Cisco 10000 series router

Field	Description
AIS	The alarm indication signal (AIS).
dsx3 3/0/0 is down	dsx3 controller connected to this Cisco 10000 series router in shelf 3, slot 0, port 0 is down. The controller's state can be up, down, or administratively down. Loopback conditions are shown by Locally Looped or Remotely Looped.
Applique type	Describes the type of controller.
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Receiver has loss of frame (LOF). • Receiver has loss of signal (LOS). • Receiver has no alarms. • Receiver has remote alarm. • Receiver is getting AIS. • Transmitter is sending alarm indication signal (AIS). • Transmitter is sending remote alarm.
MDL transmission	Maintenance Data Link status (either enabled or disabled). Used for carrying performance information and control signals across the network toward the far-end dsx3 unit.
FEAC code received	Whether a far-end alarm code request is being received. Possible values are as follows: • Common Eqpt. Failure (NSA) • DS1 Eqpt. Failure (NSA) • DS1 Eqpt. Failure • DS3 AIS Received • DS3 Eqpt. Failure (NSA) • DS3 Eqpt. Failure (SA) • DS3 IDLE Received • DS3 LOS/HBER • DS3 Out-of-Frame • Multiple DS1 LOS/HBER • No code is being received • Single DS1 LOS/HBER

Field	Description
Framing	Standard dsx3 framing type: M23, C-bit, or Auto-detect.
Line Code	Standard dsx3 line-coding format. In the example, the line-coding format is bipolar 3-zero substitution (B3ZS).
Clock Source	The source of the synchronization signal (clock): Line or Internal. In this example, the line is providing the clock signal.
Data in current interval (seconds elapsed)	Summary statistics for dsx3 signal quality for the current time interval of 900 seconds (15 minutes). In this example, the statistics are for current partial interval. Statistics roll into the 24-hour accumulation buffer every 15 minutes. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Count of both Bipolar Violations (BPVs) and Excessive Zeros (EXZs) that occur over the accumulation period. An EXZ increments the line code violations (LCVs) by one, regardless of the length of the zero string.
P-bit Coding Violation	P-bit parity error event. A P-bit parity error event is the occurrence of a received P-bit code on the DS3 M-frame that is not identical to the corresponding locally calculated code. Referred to as PCV.
C-bit Coding Violation	Count of coding violations reported via the C-bits. For C-bit parity, it is the count of CP-bit parity errors that occur during the accumulation interval. Referred to as CCV.
P-bit Err Secs	Number of seconds with one or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
P-bit Severely Err Secs	Number of seconds with 44 or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
Severely Err Framing Secs	Number of a seconds with one or more out-of-frame defects or a detected incoming AIS.
Unavailable Secs	Number of seconds during which the interface was not available in this interval. Referred to as UAS.
Line Errored Secs	Number of seconds in this interval during which one or more code violations or one or more LOS defects occurred. Referred to as LES.
C-bit Errored Secs	Number of seconds with one or more C-bit code violations (CCV), one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted. Referred to as CES.
C-bit Severely Errored Secs	Number of seconds with 44 or more CCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted.

show controller dwdm

To display ITU-T G.709 alarms, alerts, and counters for a dense wavelength division multiplexing (DWDM) controller, use the **showcontrollerdwdm**command in privileged EXEC mode.

show controller dwdm *slot/port* [**g709**]

Syntax Description

slot	Chassis slot number of the DWDM controller.
/ *port*	Port number of the DWDM controller.
g709	(Optional) Displays G.709 information.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
12.2(33)SRD1	This command was introduced on the Cisco 7600 series routers.

Examples

The following is sample output from the **showcontrollerdwdm**command. The output fields are self-explanatory.

```
Router# show controller dwdm 2/3

 Controller dwdm 2/3, is up (operational state)
G709 status : Enabled

OTU

Related Commands

Command	Description
show platform dwdm alarm history	Displays platform DWDM alarm history.

show controllers e1

To display information about E1 links, use the **showcontrollerse1**command in privileged EXEC mode.

Cisco 4000 Series Routers
show controllers e1 *controller-number*

Cisco 7500 Series Routers and Cisco ASR 901 Series Routers
show controllers e1 [*slot/port*]

Cisco AS5000 Series Access Servers
show controllers e1 {*controller-number* | **clock** | **firmware-status** | **monitor** | **timeslots** *timeslot-range*}

Cisco Series
show controllers e1 [*slot/bay/port*]

Syntax Description

controller-number	Controller number.
slot / *port*	(Optional) Backplane slot number and port number on the interface. Refer to the hardware manuals for your controller type to determine specific slot and port numbers.
slot / *bay* / *port*	Slot number, interface module number in which the slot is inserted, and port number (Cisco series routers).
clock	Displays primary clock change history.
firmware-status	Displays system crash history.
monitor	Displays primary monitor change history.
timeslots *timeslot-range*	Displays DS0 information. Time slot range is 1 through 31 for the E1 controller.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.2	This command was implemented on additional router platforms.
12.1(3)T	This command was implemented on additional access server platforms.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.4(3)S	This command was implemented on the Cisco ASR 901 Series Aggregation Services Router.

Release	Modification
XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series Routers and Cisco NCS 4200 Series.
XE Fuji 16.8.x	This command output was modified on the Cisco Series Routers to display far-end counters for performance monitoring.

Usage Guidelines

This command displays controller status that is specific to the controller hardware. The information displayed is generally useful for diagnostic tasks performed by technical support personnel only.

The Network Processor Module (NPM) on the Cisco 4000 series router or MultiChannel Interface Processor (MIP) on a Cisco 7500 series router can query the port adapters to determine their current status. Issue a **showcontrollerse1** command to display statistics about the E1 link.

On a Cisco 7500 series router, if you specify a slot and port number each 15-minute period will be displayed.

On the Cisco 5000 series access servers use the **showcontrollerse1timeslots** command to display the CAS and ISDN PRI channel state in detail. This command shows whether the DS0 channels of a controller are in idle, in-service, maintenance, or busyout states. Enter the commands to display statistics about the E1 links.

Examples

The following is sample output from the **showcontrollerse1** command on the Cisco 7500 series router:

```
Router# show controllers e1
e1 0/0 is up.
  Applique type is Channelized E1 - unbalanced
  Framing is CRC4, Line Code is HDB3
  No alarms detected.
  Data in current interval (725 seconds elapsed):
     0 Line Code Violations, 0 Path Code Violations
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
  Total Data (last 24 hours)
     0 Line Code Violations, 0 Path Code Violations,
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins,
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

The following is sample output from the **showcontrollerse1**command including the board identifier type:

```
Router#
show controllers e1
E1 4/1 is up.
  No alarms detected.
  Framing is CRC4, Line Code is hdb3
  Data in current interval (0 seconds elapsed):
     0 Line Code Violations, 0 Path Code Violations 0 Slip Secs, 0 Fr Loss Secs,
     0 Line Err Secs, 0 Degraded Mins 0 Errored Secs, 0 Bursty Err Secs,
     0 Severely Err Secs, 0 Unavail Secs
  Total Data (last 79 15 minute intervals):
     0 Line Code Violations, 0 Path Code Violations, 0 Slip Secs, 0 Fr Loss Secs,
     0 Line Err Secs, 0 Degraded Mins, 0 Errored Secs, 0 Bursty Err Secs,
     0 Severely Err Secs, 0 Unavail Secs
```

The table below describes the significant fields shown in the display.

Table 50: show controllers e1 Field Descriptions

Field	Description
e1 0/0 is up	The E1 controller 0 in slot 0 is operating. The controller's state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).
Applique type	The applique type is shown and will indicate balanced or unbalanced.
Framing is	Displays the current framing type.
Linecode is	Displays the current linecode type.
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
Data in current interval (725 seconds elapsed)	Displays the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Indicates the occurrence of either a Bipolar Violation (BPV) or Excessive Zeros (EXZ) error event.
Path Code Violations	Indicates a frame synchronization bit error in the D4 and E1-no-CRC formats, or a cyclic redundancy check (CRC) error in the Extended Superframe (ESF) and E1-CRC formats.
Slip Secs	Indicates the replication or deletion of the payload bits of a DS1 frame. A slip might be performed when there is a difference between the timing of a synchronous receiving terminal and the received signal.
Fr Loss Secs	Indicates the number of seconds an Out Of Frame (OOF) error is detected.
Line Err Secs	Line Errored Seconds (LES) is a second in which one or more Line Code Violation errors are detected.
Degraded Mins	A Degraded Minute is one in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3.

Field	Description
Errored Secs	In ESF and E1 CRC links, an Errored Second is a second in which one of the following are detected: one or more Path Code Violations; one or more Out of Frame defects; one or more Controlled Slip events; a detected AIS defect. For SF and E1 no-CRC links, the presence of Bipolar Violations also triggers an Errored Second.
Bursty Err Secs	A second with fewer than 320 and more than 1 Path Coding Violation error, no Severely Errored Frame defects and no detected incoming AIS defects. Controlled slips are not included in this parameter.
Severely Err Secs	For ESF signals, a second with one of the following errors: 320 or more Path Code Violation errors; one or more Out of Frame defects; a detected AIS defect. For E1-CRC signals, a second with one of the following errors: 832 or more Path Code Violation errors; one or more Out of Frame defects. For E1-nonCRC signals, a second with 2048 Line Code Violations or more. For D4 signals, a count of 1-second intervals with Framing Errors, or an Out of Frame defect, or 1544 Line Code Violations.
Unavail Secs	A count of the total number of seconds on the interface.

The following is sample output from the **showcontrollerse1timeslots** command on a Cisco access server. The information displayed is self-explanatory.

```
Router# show controllers e1 timeslots 1

```

Examples

show controllers e3

To display information about an E3 controller, use the**showcontrollerse3**command in user EXEC or privileged EXEC mode.

show controllers e3 *slot/port* [{**brief** | **tabular**}]

Series
show controllers e3 [*slot/bay/port*]

Syntax Description

slot	Slot number. Refer to the appropriate hardware manual for slot information.
/ *port*	Port number. Refer to the appropriate hardware manual for port information.
brief	(Optional) Displays a list of configurations only.
tabular	(Optional) Displays a list of configurations and MIB information in a tabular format.
slot / bay / port	Slot number, interface module number in which the slot is inserted, and port number (Cisco series routers).

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.1 CC	This command was introduced on the E3 controller.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
XE Fuji 16.8.x	This command output was modified on the Cisco ASR 900 Series and Cisco NCS 4200 Series Routers to display far-end counters for performance monitoring.

Examples

The following are samples of output from the **showcontrollerse3**command:

```
Router# show controllers e3 2/0
E3 2/0 is down.
 Applique type is Subrate E3
 Transmitter is sending remote alarm.
 Receiver has loss of signal.
 Framing is G751, Clock Source is Internal.
 Data in current interval (450 seconds elapsed):
  0 C-bit Coding Violation
  0 P-bit Err Secs, 0 P-bit Severely Err Secs
  0 Severely Err Framing Secs, 450 Unavailable Secs
  0 Line Errored Secs, 0-C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Data in Interval 1:
  0 C-bit Coding Violation
  0 P-bit Err Secs, 0 P-bit Severely Err Secs
```

```
  0 Severely Err Framing Secs, 900 Unavailable Secs
  0 Line Errored Secs, 0-C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Total Data (last 1 15 minute intervals):
  0 C-bit Coding Violation
  0 P-bit Err Secs, 0 P-bit Severely Err Secs
  0 Severely Err Framing Secs, 900 Unavailable Secs
0 Line Errored Secs, 0-C-bit Errored Secs, 0 C-bit Severely Errored Secs
Router# show controllers e3 2/0 brief
E3 2/0 is down.
  Applique type is Subrate E3
  Transmitter is sending remote alarm.
  Receiver has loss of signal.
  Framing is G571, Clock Source is Internal.
Router# show controllers e3 2/0 tabular
E3 2/0 is down.
  Applique type is Subrate E3
  Transmitter is sending remote alarm.
  Receiver has loss of signal.
  Framing is G571, Clock Source is Internal.
  INTERNAL   LCV PCV CCV PES PSES SEFS UAS LES CES CSES
  18:10-18:21 0   0   0   0   0    0   680  0   0    0
  17:55-18:10 0   0   0   0   0    0   900  0   0    0
  Total       0   0   0   0   0    0   900  0   0    0
```

The table below describes the significant fields shown in the display.

Table 51: show controllers e3 Field Descriptions

Field	Description
E3 2/0 is down	The E3 controller in slot 0 shows the state in which it is operating. The controller's state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).
Applique type	Controller type.
Description	User-specified information about the E3 controller.
No alarms detected (not shown in display)	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending alarm indication signal (AIS). • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
Linecode is (not shown in display)	Line coding format on the E3.
Framing	Framing type.

Field	Description
Clock Source	User-specified clock source (Line or Internal).
Data in current interval (450 seconds elapsed)	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
PCV	Path coding violation (PCV) error event is a frame synchronization bit error in the E1-no-CRC formats or a cyclic redundancy check (CRC) error in the E1-CRC formats.
CCV	C-bit coding violation (CCV) error event for C-bit parity. This is the count of coding violations reported via the C-bits occurring in the accumulation interval.
PES	P-bit errored seconds (PES) is a second with one or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
PSES	P-bit severely errored seconds (PSES) is a second with 44 or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
SEFS	Severely errored framing seconds (SEFS) is a second with one or more out-of-frame defects or a detected incoming AIS.
UAS	Unavailable seconds (UAS) are calculated by counting the number of seconds for which the interface is unavailable. For more information, refer to RFC 1407.
LES	Line errored seconds (LES) is a second in which one or more code violations or one or more LOS defects occurred.
CES	C-bit errored seconds (CES) is a second with one or more out-of-frame defects or a detected incoming AIS. This gauge is not incremented when UASs are counted.
CSES	C-bit severely errored seconds (CSES) is a second with one or more out-of-frame defects or a detected incoming AIS. This gauge is not incremented when UASs are counted.
Total	Displays the last 15-minute accumulation period.

Series Router

The following is sample output from the **show controllers e3** command on the Cisco series routers:

```
Router# show controllers e3 0/4/40
E3 0/4/40 is up.
Hardware is -48T3E3-CE
Applique type is Clear Channel e3
No alarms detected.
MDL transmission is disabled
FEAC code received: No code is being received
```

```
Framing is C-BIT Parity, Line Code is B3ZS, Cablelength Short less than 225ft

```

Examples

show controllers ethernet

To display the hardware information specific to the Ethernet interface on Cisco 2500 and Cisco 4000 series routers, use the **showcontrollersethernet** command in user EXEC or privileged EXEC mode.

show controllers ethernet *interface-number*

Syntax Description

interface-number	Interface number of the Ethernet interface.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Examples

The following is sample output from the **showcontrollersethernet** command on Cisco 4000 series routers:

```
Router# show controllers ethernet 0
LANCE unit 0, NIM slot 1, NIM type code 4, NIM version 1
Media Type is 10BaseT, Link State is Up, Squelch is Normal

```

The table below describes the significant fields shown in the display.

Table 52: show controllers ethernet Field Description

Field	Description
Rx Bytes	Number of packets received without any error on the interface.
Tx Bytes	Number of packets transmitted without any error on the interface.
Rx Good Packets	Number of packets received without any error on the interface.
Tx Good Packets	Number of packets transmitted without any error on the interface.
Rx Multicast	Number of multicast packets received on the interface.
Rx Broadcast	Number of broadcast packets received on the interface.
Rx Bad Pkt Errors	Number of bad frames received on the interface.

Field	Description
Rx FCS Errors	Number of valid size frames with Frame Check Sequence (FCS) errors, but not with framing errors.
Rx Runt Errors	Frames received on the interface that are smaller than the minimum IEEE 802.3 frame size (64 bytes for Ethernet).
Rx Oversize Errors	Number of oversize packets received on the interface.
Rx Length Errors	Number of packets received on the interface with errors in the length of the packet.
Tx Collisions	Number of collision events on the interface. This is applicable only in the half-duplex mode.
Rx Code Errors	Number of packets received on the interface with the code error signal.
Tx Late Collisions	Number of late collisions.
Rx Dribble Errors	Number of packets received with the dribble error. When a packet does not contain an integral number of bytes, it is a dribble error .
Excessive Collisions	Number of frames dropped in the transmit direction due to excessive collision. This is applicable only in the half-duplex mode.
Tx Abort Errors	Number of packets that were aborted during transmission.

Related Commands

Command	Description
show controllers	Displays information specific to the hardware on a line card.

show controllers fastethernet

To display information about initialization block, transmit ring, receive ring, Fast Ethernet interface information, applicable MAC destination address and VLAN filtering tables, and errors for the Fast Ethernet controller chip, use the **showcontrollersfastethernet** command in user EXEC or privileged EXEC mode.

Standard Syntax

show controllers fastethernet *number*

Cisco 7200 Series

show controllers fastethernet *slot/port*

Cisco 7500 Series

show controllers fastethernet *slot/port-adaptor/port*

Shared Port Adapter

show controllers fastethernet *slot/sub-slot/port*{[**detail**]}

Syntax Description

number	Port, connector, or interface card number. On a Cisco 4500 or Cisco 4700 router, specifies the network processor module (NPM) number. The numbers are assigned at the factory at the time of installation or when added to a system.
slot	Slot number. Refer to the appropriate hardware manual for slot information.
/ *port*	Port number. Refer to the appropriate hardware manual for port information.
/ *port-adapter*	Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.
subslot	(Optional) Secondary slot number on a jacket card where a SPA is installed.
detail	Specifies display of additional low-level diagnostic information.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
11.2	This command was introduced.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(20)S2	This command was implemented on the 4-Port 10/100 Fast Ethernet SPA on the Cisco 7304 router and introduced a new address format and output.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The output from this command is generally useful for diagnostic tasks performed by technical support.

Shared Port Adapter Usage Guidelines

The output from the **showcontrollersfastethernet**command for the 4-Port 10/100 Fast Ethernet SPA provides several different sections of information and statistics that are organized according to the internal hardware devices and the various paths in the flow of data on the SPA. The following sections are provided:

Several areas of the output are generally useful for diagnostic tasks performed by Cisco Systems technical support personnel only.

Examples

The following is a sample output from the **showcontrollersfastethernet** command on a Cisco 4500 series router:

Shared Port Adapter Examples

The following is sample output from the **showcontrollersfastethernet** command for the first interface (port 0) on a 4-Port 10/100 Fast Ethernet SPA that is located in the top subslot (0), of the MSC that is installed in slot 4 on a Cisco 7304 router:

```
Router# show controllers fastethernet 4/0/0
Interface FastEthernet4/0/0
  Hardware is SPA-4FE-7304
  Connection mode is auto-negotiation
  Interface state is up, link is up
  Configuration is Auto Speed, Auto Duplex
  Selected media-type is RJ45
  Promiscuous mode is off, VLAN filtering is enabled
  MDI crossover status: MDI
  Auto-negotiation configuration and status:
    Auto-negotiation is enabled and is completed
    Speed/duplex is resolved to 100 Mbps, full duplex
    Advertised capabilities: 10M/HD 10M/FD 100M/HD 100M/FD Pause capable (Asymmetric)
    Partner capabilities: 10M/HD 10M/FD 100M/HD 100M/FD Pause capable
MAC counters:
  Input: packets = 15, bytes = 1776
         FIFO full/reset removed = 0, error drop = 0
  Output: packets = 18, bytes = 2622
          FIFO full/reset removed = 0, error drop = 0
  Total pause frames: transmitted = 0, received = 0
FPGA counters:
  Input: Total (good & bad) packets: 15, TCAM drops: 4
         Satisfy (host-backpressure) drops: 0, CRC drops: 0
         PL3 RERRs: 0
  Output: EOP (SPI4) errors: 0
SPA carrier card counters:
  Input: packets = 11, bytes = 1476, drops = 0
  Output: packets = 18, bytes = 2550, drops = 0
  Egress flow control status: XON
  Per bay counters:
  General errors: input = 0, output = 0
  SPI4 errors: ingress dip4 = 0, egress dip2 = 0
SPA Error counters:
  SPI4 TX out of frame error = 2 (00:02:31 ago)
  SPI4 TX Train valid error = 1 (00:02:11 ago)
  SPI4 TX DIP4 error = 1 (00:01:30 ago)
  SPI4 RX out of frame error = 1 (00:00:36 ago)
  SPI4 RX DIP2 error = 1 (00:00:13 ago)
MAC destination address filtering table:
  Table entries: Total = 512, Used = 4, Available = 508
  Index MAC destination address       Mask
  ----- ----------------------  --------------
  1     0007.0ed3.ba80           ffff.ffff.ffff
  2     ffff.ffff.ffff           ffff.ffff.ffff
  3     0100.0000.0000           0100.0000.0000
```

```
  4     0100.0ccc.cccc           ffff.ffff.ffff
VLAN filtering table:
  Number of VLANs configured on this interface = 0
  Table entries: Total = 1024, Used = 2, Available = 1022
  Index  VLAN identifier  Enabled  Tunnel
  -----  ---------------  -------  ------
  1           0             No      No
  2           0             Yes     No
Platform details:
  PXF tif number: 0x10
```

The table below describes the fields shown in the interface configuration section of the display. This section is useful for verifying the status of autonegotiation and configured parameters on the link, and the amount of traffic being handled by the interface.

Table 53: show controllers Command Field Descriptions--Interface Section

Field	Description
Interface	Name of the interface.
Hardware	Type of hardware.
Connection mode	Indicator of autonegotiation used to establish the connection.
Link	State of the link.
Configuration	Configuration of the speed and duplex operation on the interface.
Selected media-type	Interface port media type. RJ-45 is the only type supported on the 4-Port 10/100 Fast Ethernet SPA.
Promiscuous mode	State of promiscuous mode (on or off). When promiscuous mode is on, the SPA disables MAC destination address and VLAN filtering. When promiscuous mode is off, the SPA enables MAC destination address and VLAN filtering.
VLAN filtering	Status of ternary content addressable memory (TCAM) filtering of VLANs (enabled or disabled). By default, the SPA always enables VLAN filtering. The SPA disables VLAN filtering if the TCAM table is full, or if the SPA is operating in promiscuous mode. **Note** VLAN filtering is not enabled or disabled using any command-line interface (CLI) command.
MDI crossover status	State of the media dependent interface (MDI) for the PHY device on the specified interface. The possible values are MDI for straight-through cables or media dependent interface crossover (MDI-X) for crossover cables.
Auto-negotiation	State of autonegotiation (enabled or disabled) on the interface and its current status.
Speed/duplex is resolved to	Results of autonegotiated parameter values (speed and duplex) currently being used on the link.

Field	Description
Advertised capabilities	List of the possible combinations of speed and duplex modes (in *speed*/*duplex* format) and flow control that the local interface has advertised it supports to the remote device: • For speed--10M is 10 Mbps, and 100M is 100 Mbps. • For duplex--HD is half duplex, and FD is full duplex. • For flow control--"Pause capable (Asymmetric)" means that the SPA advertises support of the PAUSE flow control bit and the ASM_DIR (asymmetric) flow control bit.
Partner capabilities	List of the possible combinations of speed and duplex modes (in *speed*/*duplex* format) and flow control that the remote device has advertised it supports to the local interface: • For speed--10M is 10 Mbps, and 100M is 100 Mbps. • For duplex--HD is half duplex, and FD is full duplex. • For flow control--"Pause capable" means that the remote device supports implementation of the PAUSE flow control bit; "Pause capable (Asymmetric)" means that the remote device supports implementation of the PAUSE flow control bit and the ASM_DIR (asymmetric) flow control bit.

The table below describes the fields shown in the MAC counters section of the display. This section is useful for verifying the status of packets processed by the MAC device for the interface. This information is useful for Cisco Systems technical support personnel.

Table 54: show controllers Command Field Descriptions--MAC Counters Section

Field	Description
Input: packets, bytes	Total number of packets and bytes received by the MAC device for the interface since it was activated or cleared. You can clear these counters using the **clearcounters** privileged EXEC command.
Input: FIFO full/reset removed	Total number of packets removed by the MAC device due to a first-in, first-out (FIFO) overflow condition in the input buffer for the interface.
Input: error drop	Total number of input packets with errors that are dropped by the MAC device for the interface.
Output: packets, bytes	Total number of packets and bytes transmitted by the MAC device for the interface since it was activated or cleared. You can clear these counters using the **clearcounters** privileged EXEC command.

Field	Description
Output: FIFO full/reset removed	Total number of packets removed by the MAC device due to a first-in, first-out (FIFO) overflow condition in the output buffer for the interface.
Output: error drop	Total number of output packets with errors that are dropped by the MAC device for the interface.
Total pause frames	Total number of Ethernet 802.3x pause frames transmitted and received by the MAC device for flow control on the interface.

The table below describes the fields shown in the FPGA counters section of the display. This section is useful for verifying the status of packets processed by the FPGA device for the interface. This information is useful for Cisco Systems technical support personnel.

Table 55: show controllers Command Field Descriptions--FPGA Counters Section

Field	Description
Input: Total (good & bad) packets	Total number of packets received by the FPGA device in the ingress direction for the interface.
Input: TCAM drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to a ternary content addressable memory (TCAM) lookup failure. This counter increments when the interface receives a frame with a destination MAC address or VLAN identifier that is not present in the TCAM table.
Input: Satisfy (host-backpressure) drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to back-pressure from the MSC.
Input: CRC drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to cyclic redundancy check (CRC) errors.
Input: PL3 RERRs	Total number of packets with errors received for the interface by the FPGA device in the ingress direction over the System Packet Interface Level 3 (SPI3) (also called PL3) path from the MAC device to the FPGA device.
Output: EOP (SPI4) errors	Total number of packets with end-of-packet (EOP) errors received by the FPGA device in the egress direction for the interface over the System Packet Interface Level 4 (SPI4) path from the MSC to the FPGA device.

The table below describes the fields shown in the SPA carrier card counters section of the display. This section is useful for verifying the status of packets processed by the MSC for the interface. This information is useful for Cisco Systems technical support personnel.

Table 56: show controllers Command Field Descriptions--SPA Carrier Card Counters Section

Field	Description
Input: packets, bytes, drops	Total number of packets, bytes, and packet drops that have occurred on the SPI4 path from the FPGA device to the MSC.

Field	Description
Output: packets, bytes, drops	Total number of packets, bytes, and packet drops that have occurred on the SPI4 path from the MSC to the FPGA device.
Egress flow control status	Status of flow control between the MSC and the Route Processor (RP). The possible values are: • XON--A control frame has been sent by the MSC to the RP to indicate that the MSC is ready to accept data. • XOFF--A control frame has been sent by the MSC to the RP to indicate congestion on the MSC. The MSC cannot accept any more data from the RP during this condition.
General errors	Total number of errors (such as parity) on the MSC in the ingress and egress direction.
SPI4 errors: ingress dip4	Total number of 4-bit Diagonal Interleaved Parity (DIP4) errors in the ingress direction on the SPI4 path from the FPGA device to the MSC. DIP4 is a parity algorithm where a 4-bit odd parity is computed diagonally over control and data words.
SPI4 errors: egress dip2	Total number of 2-bit Diagonal Interleaved Parity (DIP2) errors in the egress direction on the SPI4 path from the FPGA device to the MSC. DIP2 is a parity algorithm where a 2-bit odd parity is computed diagonally over status words.

The table below describes the fields shown in the SPA error counters section of the display. This section appears only when one of the SPI4 transmit or receive errors occurs on the interface. This information is useful for Cisco Systems technical support personnel.

Note None of the SPA SPI4 error counters appear in **showcontrollersfastethernet** command output until at least one of those types of SPI4 errors occurs.

All of the errors in the SPA error counters section are subject to the SPA automatic recovery process when certain thresholds are reached. For more information about this process on the Cisco 7304 router, refer to the “Understanding SPA Automatic Recovery” section of the *Cisco 7304 Router Modular Services Card and Shared Port Adapter Software Configuration Guide*

Table 57: show controllers Command Field Descriptions--SPA Error Counters Section

Field	Description
SPI4 TX out of frame error = 2 (00:02:31 ago)	Number of SPI4 out-of-frame errors (events) detected in the transmit direction (toward the network), from the MSC to the SPA FPGA device. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. This error indicates a loss of synchronization between the synchronization block and the data received on the SPI4 path. When synchronization is reacquired, the error no longer occurs.
SPI4 TX Train valid error = 1 (00:02:11 ago)	Number of times that a low-level synchronization problem was detected in the transmit direction (toward the network), from the MSC to the SPA FPGA device. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected.
SPI4 TX DIP4 error = 1 (00:01:30 ago)	Number of 4-bit Diagonal Interleaved Parity (DIP4) errors in the transmit direction (toward the network), from the MSC to the SPA FPGA device. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. DIP4 is a parity algorithm where a 4-bit odd parity is computed diagonally over control and data words.
SPI4 RX out of frame error = 1 (00:00:36 ago)	Number of SPI4 out-of-frame errors (events) detected in the receive direction (from the network), from the SPA FPGA device to the MSC. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. This error indicates a loss of synchronization between the synchronization block and the data received on the SPI4 path. When synchronization is reacquired, the error no longer occurs.
SPI4 RX DIP2 error = 1 (00:00:13 ago)	Number of 2-bit Diagonal Interleaved Parity (DIP2) errors in the receive direction (from the network), from the SPA FPGA device to the MSC. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. DIP2 is a parity algorithm where a 2-bit odd parity is computed diagonally over status words.

The table below describes the fields shown in the MAC destination address filtering table section of the display. This section is useful for verifying the multicast destination addresses that are in the TCAM table and permitted by the interface. This information is useful for Cisco Systems technical support personnel.

Table 58: show controllers Command Field Descriptions--MAC Destination Address Filtering Table Section

Field	Description
Table entries: Total, Used, Available	Total number of MAC destination address entries possible in the TCAM table for the interface, the number of table entries currently used by the interface, and the number of table entries that remain available. The 4-Port 10/100 Fast Ethernet SPA supports a 512-entry MAC filtering table for each supported interface (2048 entries total on the card).
Index	Table entry identifier.
MAC destination address	MAC destination address (multicast) permitted by the interface and used in the TCAM lookup table for packet filtering. The multicast MAC entries typically come from routing protocols [such as Open Shortest Path First (OSPF) and Enhanced IGRP (EIGRP)], and other protocols including the Hot Standby Router Protocol (HSRP). When the router reloads, three addresses appear by default in the MAC filtering table: the unicast address of the local interface, the Ethernet broadcast address, and the Ethernet multicast address.
Mask	Mask for the corresponding destination address. The SPA uses the bits that are set in the mask to look up the address in the TCAM table.

The table below describes the fields shown in the VLAN filtering table section of the display. This section is useful for verifying the VLANs that are in the TCAM table and are permitted by the interface. This information is useful for Cisco Systems technical support personnel.

Table 59: show controllers Command Field Descriptions--VLAN Filtering Table Section

Field	Description
Number of VLANs configured on this interface	Number of VLANs that are configured on the interface. If the number of VLANs configured on the interface is 1022 or less, then the VLAN filtering table also shows an index entry for every VLAN ID. The number of VLANs configured on the interface can be 0, while the number of used table entries reports 2, because the SPA always uses two entries to provide valid matching criteria for promiscuous mode and non-VLAN packets.
Table entries: Total, Used, Available	Total number of VLAN entries possible in the TCAM filtering table for the interface, the number of table entries currently used by the interface (two are always in use by default), and the number of table entries that remain available. The 4-Port 10/100 Fast Ethernet SPA supports a 1024-entry VLAN filtering table for each supported interface (4096 entries total on the card).
Index	Table entry identifier.
VLAN identifier	Number of the VLAN. Two VLAN ID 0 entries always appear in the table and represent the local interface port for handling of promiscuous mode and non-VLAN packets. Other VLAN entries appear in this table when VLANs are configured on the interface.

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>Enabled</td><td>Status of the VLAN ID for TCAM filtering, with the following possible values:
• No--The entry is disabled for filtering.
• Yes--The entry is enabled for filtering.

The TCAM filter uses the “first-match” rule to filter packets that the SPA receives against entries in the table. The matching assessment begins at the top of the table with the VLAN ID 0 entries.

Note The SPA always supports two VLAN ID 0 entries. The first VLAN ID 0 entry of the TCAM table is used for promiscuous mode. It has a value of “No,” meaning it is disabled, whenever promiscuous mode is disabled for the interface. The second VLAN ID 0 entry is used for filtering of non-VLAN packets.</td></tr>
<tr><td>Tunnel</td><td>Status of tunneling for the interface, with the following possible values:
• No--Tunneling is disabled and the SPA performs MAC destination address filtering.
• Yes--Tunneling is enabled and the SPA does not perform MAC destination address filtering.

Note If promiscuous mode is enabled, then the first VLAN ID 0 entry shows tunnel = Yes. All other VLAN ID entries show tunnel = No.</td></tr>
</table>

The table below describes the fields shown in the Platform details section of the display.

Table 60: show controllers Command Field Descriptions--Platform Details Section

Field	Description
PXF tif number	Number of the interface (in hexadecimal format) used for PXF on the network services engine (NSE) or by the Hyper Transport (HT) FPGA device on the network processing engine (NPE).

Related Commands

Command	Description
show interfaces fastethernet	Displays information about the Fast Ethernet interfaces.

show controllers fddi

To display all information under the FDDI Interface Processor (FIP) on the Cisco 7200 series and Cisco 7500 series routers, use the **showcontrollersfddi** command in user EXEC or privileged EXEC mode.

show controllers fddi

Syntax Description

This command has no arguments or keywords.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command reflects the internal state of the chips and information that the system uses for bridging and routing that is specific to the interface hardware. The information displayed is generally useful for diagnostic tasks performed by technical support personnel only.

Examples

The following is sample output from the **showcontrollersfddi** command:

```
Router# show controllers fddi
Fddi2/0 - hardware version 2.2, microcode version 1.2
  Phy-A registers:
    cr0 4, cr1 0, cr2 0, status 3, cr3 0
  Phy-B registers:
    cr0 4, cr1 4, cr2 0, status 3, cr3 0
  FORMAC registers:
    irdtlb  71C2, irdtneg F85E, irdthtt F5D5, irdmir  FFFF0BDC
    irdtrth F85F, irdtmax FBC5, irdtvxt 5959, irdstmc 0810
    irdmode 6A20, irdimsk 0000, irdstat 8060, irdtpri 0000
  FIP registers
    ccb:   002C  cmd:   0006  fr:   000F  mdptr: 0000  mema: 0000
    icb:   00C0  arg:   0003  app:  0004  mdpg:  0000  af:   0603
    clm:   E002  bcn:   E016  clbn: 0198  rxoff: 002A  en:   0001
    clmbc: 8011  bcnbc: 8011  robn: 0004  park:  0000  fop:  8004
    txchn: 0000  pend:  0000  act:  0000  tail:  0000  cnt:  0000
    state: 0003  check: 0000  eof:  0000  tail:  0000  cnt:  0000
    rxchn: 0000  buf0:  0534  nxt0: 0570  eof:   0000  tail: 0000
    eofch: 0000  buf1:  051C  nxt1: 0528  pool:  0050  err:  005C
    head:  0984  cur:   0000  t0:   0030  t1:    0027  t2:   000F

 Total LEM: phy-a 6, phy-b 13
```

The last line of output indicates how many times the specific PHY encountered an “UNKNOWN LINE STATE” event on the fiber.

show controllers gigabitethernet

To display initialization block information, transmit ring, receive ring, transmission statistics and errors, and applicable MAC destination address and VLAN filtering tables for Gigabit Ethernet interface controllers, use the **showcontrollersgigabitethernet**command in privileged EXEC mode.

Standard Syntax

show controllers gigabitethernet *slot*/*port*

Shared Port Adapters

show controllers gigabitethernet *slot*/*subslot*/*port* [**detail**]

Syntax Description

slot	(Optional) Chassis slot number. Refer to the appropriate hardware manual for slot information. For MSCs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for MSCs and SPAs" topic in the platform-specific SPA software configuration guide.
/ *subslot*	(Optional) Secondary slot number on a MSC where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
/ *port*	(Optional) Port or interface number. Refer to the appropriate hardware manual for port information. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide.
detail	Specifies display of additional low-level diagnostic information.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.1CC	This command was introduced.
12.1(3a)E	Support for the Cisco 7200-I/O-GE+E controller was introduced.
12.1(5)T	This command was integrated into Cisco IOS Release 12.1(5)T.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(20)S2	This command was implemented on the 2-Port 10/100/1000 Gigabit Ethernet SPA on the Cisco 7304 router with a new address format and output.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Release	Modification
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
15.2(02)SA	This command was implemented on the Cisco ME 2600X Series Ethernet Access Switches.

Usage Guidelines

This command is used to display hardware and software information about the Gigabit Ethernet interface. The I/O controller is always found in slot 0.

Shared Port Adapter Usage Guidelines

The output from the **showcontrollersgigabitethernet**command for the 2-Port 10/100/1000 Gigabit Ethernet SPA provides several different sections of information and statistics that are organized according to the internal hardware devices and the various paths in the flow of data on the SPA. Several areas of the output are generally useful for diagnostic tasks performed by technical support only.

Shared Port Adapter Examples

The following is sample output from the **showcontrollersgigabitethernet** command for the first RJ-45 interface (port 0) in a 2-Port 10/100/1000 Gigabit Ethernet SPA located in the top subslot (0) of the MSC that is installed in slot 5 on a Cisco 7304 router. This output also shows the SPA Error counters section that appears only if one of the types of SPI4 errors occurs on the interface:

```
Router#  show controllers gigabitethernet 0/0
Interface GigabitEthernet5/0/0
  Hardware is SPA-2GE-7304
  Connection mode is auto-negotiation
  Interface state is up, link is up
  Configuration is Auto Speed, Auto Duplex
  Selected media-type is RJ45
  Promiscuous mode is off, VLAN filtering is enabled
  MDI crossover status: MDIX
  Auto-negotiation configuration and status:
    Auto-negotiation is enabled and is completed
    Speed/duplex is resolved to 1000 Mbps, full duplex

The following is sample output from the **showcontrollersgigabitethernet** command for the first fiber interface (port 0) in a 2-Port 10/100/1000 Gigabit Ethernet SPA located in the bottom subslot (1) of the MSC that is installed in slot 4 on a Cisco 7304 router:

```
Router# show controllers gigabitethernet 4/1/0
Interface GigabitEthernet4/1/0
  Hardware is SPA-2GE-7304
  Connection mode is auto-negotiation
  Interface state is up, link is up
  Configuration is Auto Speed, Auto Duplex
  Selected media-type is GBIC, GBIC type is 1000BaseSX
  SFP is present, LOS: no, Tx fault: no, Security check status: Pass
  Promiscuous mode is off, VLAN filtering is enabled
  MDI configuration is automatic crossover, status is MDI
  Auto-negotiation configuration and status:
    Auto-negotiation is enabled and is completed
    Speed/duplex is resolved to 1000 Mbps, full duplex
    Advertised capabilities: 1000BaseX/FD Pause capable (Asymmetric)
    Partner capabilities: 1000BaseX/FD Pause capable(Asymmetric)
MAC counters:
  Input: packets = 213, bytes = 21972
         FIFO full/reset removed = 0, error drop = 0
  Output: packets = 216, bytes = 22932
          FIFO full/reset removed = 0, error drop = 0
  Total pause frames: transmitted = 0, received = 0
FPGA counters:
  Input: Total (good & bad) packets: 213, TCAM drops: 183
         Satisfy (host-backpressure) drops: 0, CRC drops: 0
         PL3 RERRs: 0
  Output: EOP (SPI4) errors: 0
SPA carrier card counters:
  Input: packets = 30, bytes = 10140, drops = 0
  Output: packets = 216, bytes = 22068, drops = 0
  Egress flow control status: XON
  Per bay counters:
  General errors: input = 0, output = 0

This table describes the fields shown in the interface configuration section of the display. This section is useful for verifying the status of autonegotiation and configured parameters on the link, and the amount of traffic being handled by the interface.

Table 61: show controllers Command Field Descriptions--Interface Section

Field	Description
Interface	Name of the interface.
Hardware	Type of hardware.

Field	Description
Connection mode	Indicator of autonegotiation used to establish the connection.
Link	State of the link.
Configuration	Configuration of the speed and duplex operation on the interface.
Selected media-type	Interface port media type: RJ45 or Gigabit Interface Converter (GBIC).
GBIC type is	GBIC interface type: 1000BaseSX, 1000BaseLX, or 1000BaseZX
SFP is	Indicates presence of an SFP optical transceiver.
LOS	Indicates whether or not the SFP detects a loss of signal (LOS).
Tx fault	Indicates whether or not the SFP detects a transmission fault.
Security check status	Indicates whether or not the SFP passes the security check. The SPA enables a security check by default to verify whether a Cisco-approved SFP is inserted. If the SFP is not a Cisco-approved device, the link is brought down.
Promiscuous mode	State of promiscuous mode (on or off). When promiscuous mode is on, the SPA disables MAC destination address and VLAN filtering. When promiscuous mode is off, the SPA enables MAC destination address and VLAN filtering.
VLAN filtering	Status of ternary content addressable memory (TCAM) filtering of VLANs (enabled or disabled). By default, the SPA always enables VLAN filtering. The SPA disables VLAN filtering if the TCAM table is full, or if the SPA is operating in promiscuous mode. **Note** VLAN filtering is not enabled or disabled using any command-line interface (CLI) command.
MDI crossover status	State of the media dependent interface (MDI) for the PHY device on the specified interface. The possible values are MDI for straight-through cables or media dependent interface crossover (MDI-X) for crossover cables.
Auto-negotiation	State of autonegotiation (enabled or disabled) on the interface and its current status.
Speed/duplex is resolved to	Results of autonegotiated parameter values (speed and duplex) currently being used on the link.
Advertised capabilities	List of the possible combinations of speed and duplex modes (in *speed*/*duplex* format) and flow control that the local interface has advertised it supports to the remote device: • For speed--10M is 10 Mbps, 100M is 100 Mbps, and 1000M is 1000 Mbps. • For duplex--HD is half duplex, and FD is full duplex. • For flow control--“Pause capable (Asymmetric)” means that the SPA advertises support of the PAUSE flow control bit and the ASM_DIR (asymmetric) flow control bit.

Field	Description
Partner capabilities	List of the possible combinations of speed and duplex modes (in *speed*/*duplex* format) and flow control that the remote device has advertised it supports to the local interface: • For speed--10M is 10 Mbps, 100M is 100 Mbps, and 1000M is 1000 Mbps. • For duplex--HD is half duplex, and FD is full duplex. • For flow control--"Pause capable" means that the remote device supports implementation of the PAUSE flow control bit; "Pause capable (Asymmetric)" means that the remote device supports implementation of the PAUSE flow control bit and the ASM_DIR (asymmetric) flow control bit.

This table describes the fields shown in the MAC counters section of the display. This section is useful for verifying the status of packets processed by the MAC device for the interface. This information is useful for Cisco Systems technical support personnel.

Table 62: show controllers Command Field Descriptions--MAC Counters Section

Field	Description
Input: packets, bytes	Total number of packets and bytes received by the MAC device for the interface since it was activated or cleared. You can clear these counters using the **clearcounters** privileged EXEC command.
Input: FIFO full/reset removed	Total number of packets removed by the MAC device due to a first-in, first-out (FIFO) overflow condition in the input buffer for the interface.
Input: error drop	Total number of input packets with errors that are dropped by the MAC device for the interface.
Output: packets, bytes	Total number of packets and bytes transmitted by the MAC device for the interface since it was activated or cleared. You can clear these counters using the **clearcounters** privileged EXEC command.
Output: FIFO full/reset removed	Total number of packets removed by the MAC device due to a first-in, first-out (FIFO) overflow condition in the output buffer for the interface.
Output: error drop	Total number of output packets with errors that are dropped by the MAC device for the interface.
SPI3: disabled port drop	Total number of packets dropped by the MAC device at the System Packet Interface Level 3 (SPI3) path between the MAC device and FPGA device due to a disabled port condition.
SPI3: sync error drop	Total number of packets dropped by the MAC device at the SPI3 path between the MAC device and FPGA device due to a sync error (synchronization bits altered) condition.

Field	Description
SPI3: short packet drop	Total number of packets dropped by the MAC device at the SPI3 path between the MAC device and FPGA device due to a short packet (packet length is less than 64 bytes) condition.
SPI3: parity error drop	Total number of packets dropped by the MAC device at the path between the MAC device and FPGA device due to a parity error (parity bit is altered during data transmission) condition.
Total pause frames	Total number of Ethernet 802.3x pause frames transmitted and received by the MAC device for flow control on the interface.

This table describes the fields shown in the FPGA counters section of the display. This section is useful for verifying the status of packets processed by the FPGA device for the interface. This information is useful for Cisco Systems technical support personnel.

Table 63: show controllers Command Field Descriptions--FPGA Counters Section

Field	Description
Input: Total (good & bad) packets	Total number of packets received by the FPGA device in the ingress direction for the interface.
Input: TCAM drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to a ternary content addressable memory (TCAM) lookup failure. This counter increments when the interface receives a frame with a destination MAC address or VLAN identifier that is not present in the TCAM table.
Input: Satisfy (host-backpressure) drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to back-pressure from the MSC.
Input: CRC drops	Total number of packets dropped by the FPGA device in the ingress direction for the interface due to cyclic redundancy check (CRC) errors.
Input: PL3 RERRs	Total number of packets with errors received for the interface by the FPGA device in the ingress direction over the SPI3 (PL3) path from the MAC device to the FPGA device.
Output: EOP (SPI4) errors	Total number of packets with end-of-packet (EOP) errors received by the FPGA device in the egress direction for the interface over the System Packet Interface Level 4 (SPI4) path from the MSC to the FPGA device.

The following table describes the fields shown in the SPA carrier card counters section of the display. This section is useful for verifying the status of packets processed by the MSC for the interface. This information is useful for Cisco Systems technical support personnel.

Table 64: show controllers Command Field Descriptions--SPA Carrier Card Counters Section

Field	Description
Input: packets, bytes, drops	Total number of packets, bytes, and packet drops that have occurred on the SPI4 path from the FPGA device to the MSC.
Output: packets, bytes, drops	Total number of packets, bytes, and packet drops that have occurred on the SPI4 path from the MSC to the FPGA device.
Egress flow control status	Status of flow control between the MSC and the Route Processor (RP). The possible values are: • XON--A control frame has been sent by the MSC to the RP to indicate that the MSC is ready to accept data. • XOFF--A control frame has been sent by the MSC to the RP to indicate congestion on the MSC. The MSC cannot accept any more data from the RP during this condition.
General errors	Total number of errors (such as parity) on the MSC in the ingress and egress direction.
SPI4 errors: ingress dip4	Total number of 4-bit Diagonal Interleaved Parity (DIP4) errors in the ingress direction on the SPI4 path from the FPGA device to the MSC. DIP4 is a parity algorithm where a 4-bit odd parity is computed diagonally over control and data words.
SPI4 errors: egress dip2	Total number of 2-bit Diagonal Interleaved Parity (DIP2) errors in the egress direction on the SPI4 path from the FPGA device to the MSC. DIP2 is a parity algorithm where a 2-bit odd parity is computed diagonally over status words.

The following table describes the fields shown in the SPA error counters section of the display. This section appears only when one of the SPI4 transmit or receive errors occurs on the interface. This information is useful for Cisco Systems technical support personnel.

Note None of the SPA SPI4 error counters appear in **showcontrollersgigabitethernet** command output until at least one of those types of SPI4 errors occurs.

All of the errors in the SPA error counters section are subject to the SPA automatic recovery process when certain thresholds are reached. For more information about this process on the Cisco 7304 router, refer to the “Understanding SPA Automatic Recovery” section of the *Cisco 7304 Router Modular Services Card and Shared Port Adapter Software Configuration Guide* .

Table 65: show controllers Command Field Descriptions--SPA Error Counters Section

Field	Description
SPI4 TX out of frame error = (*hh:mm:ss* ago)	Number of SPI4 out of frame errors (events) detected in the transmit direction (toward the network), from the MSC to the SPA FPGA device. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. This error indicates a loss of synchronization between the synchronization block and the data received on the SPI4 path. When synchronization is reacquired, the error no longer occurs.
SPI4 TX Train valid error = (*hh:mm:ss* ago)	Number of times that a low-level synchronization problem was detected in the transmit direction (toward the network), from the MSC to the SPA FPGA device. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected.
SPI4 TX DIP4 error = (*hh:mm:ss* ago)	Number of 4-bit Diagonal Interleaved Parity (DIP4) errors in the transmit direction (toward the network), from the MSC to the SPA FPGAdevice. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. DIP4 is a parity algorithm where a 4-bit odd parity is computed diagonally over control and data words.
SPI4 RX out of frame error = (*hh:mm:ss* ago)	Number of SPI4 out of frame errors (events) detected in the receive direction (from the network), from the SPA FPGA device to theMSC. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. This error indicates a loss of synchronization between the synchronization block and the data received on the SPI4 path. When synchronization is reacquired, the error no longer occurs.
SPI4 RX DIP2 error = (*hh:mm:ss* ago)	Number of 2-bit Diagonal Interleaved Parity (DIP2) errors in the receive direction (from the network), from theSPA FPGA device to the MSC. The time stamp indicates how long ago (in hours:minutes:seconds) from the current system time, that the last error was detected. DIP2 is a parity algorithm where a 2-bit odd parity is computed diagonally over status words.

The following table describes the fields shown in the MAC destination address filtering table section of the display. This section is useful for verifying the multicast destination addresses that are in the TCAM table and permitted by the interface. This information is useful for Cisco Systems technical support personnel.

Table 66: show controllers Command Field Descriptions--MAC Destination Address Filtering Table Section

Field	Description
Table entries: Total, Used	Total number of MAC destination address entries possible in the TCAM table for the interface, and the number of table entries currently used by the interface. The 2-Port 10/100/1000 Gigabit Ethernet SPA supports a 512-entry MAC filtering table for each supported interface (1024 entries total on the card).
Index	Table entry identifier.
MAC destination address	MAC destination address (multicast) permitted by the interface and used in the TCAM lookup table for packet filtering. The multicast MAC entries typically come from routing protocols [such as Open Shortest Path First (OSPF) and Enhanced IGRP (EIGRP)], and other protocols including the Hot Standby Router Protocol (HSRP). When the router reloads, three addresses appear by default in the MAC filtering table: the unicast address of the local interface, the Ethernet broadcast address, and the Ethernet multicast address.
Mask	Mask for the corresponding destination address. The SPA uses the bits that are set in the mask to look up the address in the TCAM table.

The following table describes the fields shown in the VLAN filtering table section of the display. This section is useful for verifying the VLANs that are in the TCAM table and are permitted by the interface. This information is useful for Cisco Systems technical support personnel.

Table 67: show controllers Command Field Descriptions--VLAN Filtering Table Section

Field	Description
Number of VLANs configured on this interface	Number of VLANs that are configured on the interface. If the number of VLANs configured on the interface is 1022 or less, then the VLAN filtering table also shows an index entry for every VLAN ID. The number of VLANs configured on the interface can be 0, while the number of used table entries reports 2, because the SPA always uses two entries to provide valid matching criteria for promiscuous mode and non-VLAN packets.
Table entries: Total, Used, Available	Total number of VLAN entries possible in the TCAM filtering table for the interface, the number of table entries currently used by the interface (two are always in use by default), and the number of table entries that remain available. The 2-Port 10/100/1000 Gigabit Ethernet SPA supports a 1024-entry VLAN filtering table for each supported interface (2048 entries total on the card).
Index	Table entry identifier.
VLAN identifier	Number of the VLAN. Two VLAN ID 0 entries always appear in the table and represent the local interface port for handling of promiscuous mode and non-VLAN packets. Other VLAN entries appear in this table when VLANs are configured on the interface.

<table>
<tr><th>Field</th><th>Description</th></tr>
<tr><td>Enabled</td><td>Status of the VLAN ID for TCAM filtering, with the following possible values:
• No--The entry is disabled for filtering.
• Yes--The entry is enabled for filtering.

The TCAM filter uses the “first-match” rule to filter packets that the SPA receives against entries in the table. The matching assessment begins at the top of the table with the VLAN ID 0 entries.

Note The SPA always supports two VLAN ID 0 entries. The first VLAN ID 0 entry of the TCAM table is used for promiscuous mode. It has a value of “No,” meaning it is disabled, whenever promiscuous mode is disabled for the interface. The second VLAN ID 0 entry is used for filtering of non-VLAN packets.</td></tr>
<tr><td>Tunnel</td><td>Status of tunneling for the interface, with the following possible values:
• No--Tunneling is disabled and theSPA performs MAC destination address filtering.
• Yes--Tunneling is enabled and the SPA does not perform MAC destination address filtering.

Note If promiscuous mode is enabled, then the first VLAN ID 0 entry shows tunnel = Yes. All other VLAN ID entries show tunnel = No.</td></tr>
</table>

The following table describes the fields shown in the platform details section of the display.

Table 68: show controllers Command Field Descriptions--Platform Details Section

Field	Description
PXF tif number	Number of the interface (in hexadecimal format) used for PXF on the network services engine (NSE) or by the Hyper Transport (HT) FPGA device on the network processing engine (NPE).

Related Commands

Command	Description
show interfaces gigabitethernet	Displays software and hardware information about a Gigabit Ethernet interface.

show controllers integrated-service-engine

To show the Cisco wireless LAN controller network module (WLCM) on the router, use the **showcontrollersintegrated-service-engine** command in privileged EXEC mode.

show controllers integrated-service-engine slot / unit

Syntax Description

slot/unit	Specifies the router slot and unit numbers for the WLCM.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(15)T	This command was introduced.

Examples

The following example shows how to display interface information for the WLCM:

```
Router# show controllers integrated-service-engines
 1/0
Interface integrated-service-engine 1/0
Hardware is Intel 82559 FastEthernet
IDB: 67796B08, FASTSEND: 60E073CC, MCI_INDEX: 0

INSTANCE=0x67797BE8
  Rx Ring entries = 64
  Rx Shadow = 0x67797ED0
  Rx Ring = 0x2DCC1840
  Rx Ring Head = 5
  Rx Ring Last = 4
  Rx Buffer Descr = 0x2DCC3040
  Rx Buffer Descr Head = 5
  Rx Buffer Descr Last = 4

(cont...)
Receive All Multicasts = enabled
Receive Promiscuous = disabled
Loopback Mode = disabled

Module Reset Statistics:
  CLI reset count = 0
  CLI reload count = 0
  Registration request timeout reset count = 0
  Error recovery timeout reset count = 0
  Module registration count = 1
```

show controllers ism

To display controller information for the internal service module interface, use the **showcontrollersism** command in user EXEC or privileged EXEC mode.

show controllers ism *slot/port*

Syntax Description

slot	Router slot in which the service module is installed. For internal service modules, always use 0.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

The output from this command is generally useful for diagnostic tasks performed by technical support only. You can, however, use the displayed hardware statistics to obtain the receive and transmit packet statistics that are collected by the hardware controller during packet processing.

Examples

The following example shows how to display information for the ISM installed in the router:

```
Router# show controllers ism 0/0
Interface ISM0/0
Hardware is PSE2
HWIDB: 0x01395BF0 INSTANCE: 0x11E75280, FASTSEND: 0x040D6C44
Init flags: 0x23

The table below describes the significant fields shown in the display.

Table 69: show controllers analysis-module Field Descriptions

Field	Description
Hardware	Description of the chip being used.
IDB, FASTSEND	Address in router memory of the Interface Descriptor Block (IDB) and the fastsend routine.
INSTANCE	Device-specific data stored in router memory that lists the memory locations and current indexes of receive (Rx) and transmit (Tx) rings in router I/O memory.
CONTROL AND STATUS REGISTERS (CSR)	Control and status registers that are physically located on the chip itself and that are accessed by the CPU over the Peripheral Component Interconnect (PCI) bus.
PHY REGISTERS	Contents of the PHY registers. PHY is a device that interfaces the physical Ethernet line and that is located between the chip and the physical line.
HARDWARE STATISTICS	Receive (Rx) and transmit (Tx) traffic statistics collected by the chip.
INTERRUPT STATISTICS	Transmit (Tx), Receive (Rx), control, software, and flow control interrupt statistics collected by the chip.

Related Commands

Command	Description
service-module ism status	Displays hardware and software status information about the ISM.
show interfaces ism	Displays status, traffic data, and configuration information about the ISM interface.

show controllers j1

To display statistics about the J1 link, use the **showcontrollersj1**command in privileged EXEC mode.

show controllers j1 *slot/port*

Syntax Description

slot / port	Backplane slot and port number on the controller.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.2(8)T	The command was introduced on the J1 controller for the Cisco 2600 and Cisco 3600 series.

Examples

The following is sample output from the **showcontrollersj1**command on the Cisco 3660:

```
Router# show controllers j1 3/0
J1 3/0 is up.
  Applique type is Channelized J1 - TTC2M
  No alarms detected.
Version info Firmware: 20010530, FPGA: 1
  Framing is J1-TTC2M MF, Line Code is CMI, Clock Source is Line.
  Data in current interval (344 seconds elapsed):
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
  Total Data (last 24 hours)
     0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins,
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavail Secs
```

The table below describes the fields shown in the display.

Table 70: show controllers j1 Field Descriptions

Field	Description
j1 3/0 is up.	The J1 controller 3 in slot 0 is operating. The controller's state can be up, down, or administratively down.
Applique type	The applique type is shown and is always Channelized.

Field	Description
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
Version	Indicates date of compilation.
Framing is	Shows the current framing type which is always J1-TTC2M MF.
Linecode is	Shows the current line encoding type which is always coded mark inversion (CMI).
Clock Source	Shows the current clock source type.
Data in current interval (344 seconds elapsed)	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Slip Secs	Indicates the replication or deletion of the payload bits of a DS1 frame. A slip might be performed when there is a difference between the timing of a synchronous receiving terminal and the received signal.
Fr Loss Secs	Indicates the number of seconds an Out of Frame (OOF) error is detected.
Line Err Secs	Line errored seconds (LES) is a second in which one or more line code violation errors are detected.
Degraded Mins	A degraded minute is one in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3.
Errored Secs	An errored second is a second in which one of the following are detected: • One or more path code violations. • One or more out of rame defects. • One or more controlled slip events. • A detected alarm indication signal (AIS) defect.

Field	Description
Bursty Err Secs	A second with fewer than 320 and more than 1 path coding violation error, no severely errored frame defects, and no detected incoming AIS defects. Controlled slips are not included in this parameter.
Severely Err Secs	A severely err sec is a second with one of the following errors: 320 or more path code violation errors; one or more out of frame defects; a detected AIS defect.
Unavail Secs	A count of the total number of seconds where the controller did not get a clock.

show controllers lex

To show hardware and software information about the LAN Extender chassis, use the **showcontrollerslex** command in EXEC mode.

show controllers lex [*number*]

Cisco 7500 Series
show controllers lex [*slot*/*port*]

Syntax Description

number	(Optional) Number of the LAN Extender interface about which to display information.
slot	(Optional) Number of the slot being configured. Refer to the appropriate hardware manual for slot and port information.
port	(Optional) Number of the port being configured. Refer to the appropriate hardware manual for slot and port information.

Command Modes

EXEC

Command History

Release	Modification
11.0	This command was introduced.
12.2(15)T	This command is no longer supported in Cisco IOS Mainline or Technology-based releases. It may conintue to appear in Cisco IOS 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **showcontrollerslex** command to display information about the hardware revision level, software version number, Flash memory size, serial number, and other information related to the configuration of the LAN Extender.

Examples

The following is a sample output from the **showcontrollerslex** command:

```
Router# show controllers lex 0
Lex0:
FLEX Hardware revision 1
FLEX Software version 255.0
128K bytes of flash memory
Serial number is 123456789
Station address is 0000.4060.1100
```

The following is a sample output from the **showcontrollerslex** command when the LAN Extender interface is not bound to a serial interface:

```
Router#
```

```
show controllers lex 1
Lex1 is not bound to a serial interface
```

The table below describes the fields shown in the preceding output.

Table 71: show controllers lex Field Descriptions

Field	Description
Lex0:	Number of the LAN Extender interface.
FLEX Hardware revision	Revision number of the Cisco 1000 series LAN Extender chassis.
FLEX Software version	Revision number of the software running on the LAN Extender chassis.
128K bytes of Flash memory	Amount of Flash memory in the LAN Extender.
Serial number	Serial number of the LAN Extender chassis.
Station address	MAC address of the LAN Extender chassis.

show controllers mci

To display all information under the Multiport Communications Interface (MCI) card or the Serial Communications Interface (SCI) card, use the **showcontrollersmci** command in privileged EXEC mode.

show controllers mci

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command displays information that the system uses for bridging and routing that is specific to the interface hardware. The information displayed is generally useful for diagnostic tasks performed by technical support personnel.

The interface type is queried only at startup. If the hardware changes *subsequent* to initial startup, the wrong type is reported. This has *no* adverse effect on the operation of the software. For instance, if a DCE cable is connected to a dual-mode V.35 applique after the unit has been booted, the display presented for the **showinterfaces** command incorrectly reports attachment to a DTE device although the software recognizes the DCE interface and behaves accordingly.

Examples

The following is sample output from the **showcontrollersmci** command:

```
Router# show controllers mci
MCI 0, controller type 1.1, microcode version 1.8
    128 Kbytes of main memory, 4 Kbytes cache memory
22 system TX buffers, largest buffer size 1520
    Restarts: 0 line down, 0 hung output, 0 controller error
Interface 0 is Ethernet0, station address 0000.0c00.d4a6
    15 total RX buffers, 11 buffer TX queue limit, buffer size 1520
    Transmitter delay is 0 microseconds
Interface 1 is Serial0, electrical interface is V.35 DTE
    15 total RX buffers, 11 buffer TX queue limit, buffer size 1520
    Transmitter delay is 0 microseconds
    High speed synchronous serial interface
Interface 2 is Ethernet1, station address aa00.0400.3be4
    15 total RX buffers, 11 buffer TX queue limit, buffer size 1520
    Transmitter delay is 0 microseconds
Interface 3 is Serial1, electrical interface is V.35 DCE
    15 total RX buffers, 11 buffer TX queue limit, buffer size 1520
    Transmitter delay is 0 microseconds
    High speed synchronous serial interface
```

The table below describes significant fields shown in the display.

Table 72: show controllers mci Field Descriptions

Field	Description
MCI 0	Card type and unit number (varies depending on card).
controller type 1.1	Version number of the card.
microcode version 1.8	Version number of the card's internal software (in ROM).
128 Kbytes of main memory	Amount of main memory on the card.
4 Kbytes cache memory	Amount of cache memory on the card.
22 system TX buffers	Number of buffers that hold packets to be transmitted.
largest buffer size 1520	Largest size of these buffers (in bytes).
Restarts • 0 line down • 0 hung output • 0 controller error	Count of restarts for the following conditions: • Communication line down • Output unable to transmit • Internal error
Interface 0 is Ethernet0	Names of interfaces, by number.
electrical interface is V.35 DTE	Line interface type for serial connections.
15 total RX buffers	Number of buffers for received packets.
11 buffer TX queue limit	Maximum number of buffers in transmit queue.
Transmitter delay is 0 microseconds	Delay between outgoing frames.
Station address 0000.0c00.d4a6	Hardware address of the interface.

Related Commands

Command	Description
tx-queue-limit	Controls the number of transmit buffers available to a specified interface on the MCI and SCI cards.

show controllers pcbus

To display all information about the bus interface, use the **showcontrollerspcbus** command in privileged EXEC mode.

show controllers pcbus

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.0	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is valid on LanOptics Branchcard or Stacknet 2000 products only.

Examples

The following is sample output from the **showcontrollerspcbus** command:

```
Router# show controllers pcbus
PCbus unit 0, Name = PCbus0  Hardware is ISA PCbus shared RAM
IDB at 0x3719B0, Interface driver data structure at 0x3735F8
Control/status register at 0x2110008, Shared memory at 0xC000000
Shared memory is initialized

Shared memory interface control block :
Magic no = 0x41435A56 (valid) Version = 1.0
Shared memory size = 64K bytes, Interface is NOT shutdown
Interface state is up, line protocol is up

Tx buffer : (control block at 0xC000010)
Start offset = 0x30, Size = 0x7FE8, Overflows = 1
GET_ptr = 0x4F6C, PUT_ptr = 0x4F6C, WRAP_ptr = 0x3BB0

Rx buffer : (control block at 0xC000020)
Start offset = 0x8018, Size 0x7FE8, Overflows = 22250698
GET_ptr = 0x60, PUT_ptr = 0x60, WRAP_ptr = 0x7FD0

Interrupts received = 567
```

show controllers pos

To display information about the Packet over SONET (POS) controllers, use the **showcontrollerspos** command in privileged EXEC mode.

Cisco 7500 Series Routers
show controllers pos [*slot*/*port-adapter*/*port*] [{**details** | **pm** [*time-interval*]}]

Cisco 12000 Series Routers
show controllers pos [*slot*/*port*] [{**details** | **pm** [*time-interval*]}]

POS Shared Port Adapters
show controllers pos [*slot*/*subslot*/*port* [/*sub_int*]] [{**alarm** | **details** | **pm** [*time-interval*]}]

Syntax Description

slot / *port-adapter* / *port*	**(Optional) Cisco 7500 Series Routers** Number of the chassis slot that contains the POS interface (for example, 2/0/0), where: • *slot* --Chassis slot number. • / *port-adapter*-- Port adapter number. • / *port*-- Port or interface number. Refer to the appropriate hardware manual for slot and port information, and port adapter compatibility.
slot / *port*	**(Optional) Cisco 12000 Series Routers** Number of the chassis slot that contains the POS interface (for example, 4/0), where: • *slot* --Chassis slot number. • / *port*-- Port or interface number. Refer to the appropriate hardware manual for slot and port information.

slot / *subslot* / *port* / *sub_int*	**(Optional) POS Shared Port Adapters** Number of the chassis slot that contains the POS interface (for example 4/3/0), where: • *slot* --Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide. • / *subslot*-- Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information. • / *port* --Port or interface number. For SPAs, refer to the corresponding "Specifying the Interface Address on a SPA" topics in the platform-specific SPA software configuration guide. • / *sub_int* -- (Optional) Subinterface number.
alarm	(Optional) Displays SONET/SDH alarm event counters.
details	(Optional) In addition to the normal information displayed by the **showcontrollerspos** command, the **details** keyword provides a hexadecimal and ASCII "dump" of the path trace buffer.
pm	(Optional) Displays SONET performance monitoring statistics accumulated for a 24-hour period in 15-minute intervals.
time-interval	(Optional) Number of the SONET MIB 15-minute time interval in the range from 1 to 96. If the *time-interval*argument is not specified, the performance monitoring statistics for the current time interval are displayed.

Command Default

If you do not specify any slot addressing, information for all installed POS interfaces is displayed.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.1CC	This command was introduced.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3 to support SPAs on the Cisco 7304 router. The command was modified to support a new addressing format for SPAs on the Cisco 7304 router.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.

Release	Modification
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S to support SPAs on the Cisco 12000 series routers.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **showcontrollerspos** command with the **pm** keyword displays SONET performance monitoring statistics accumulated at 15-minute intervals, and these statistics can be queried using Simple Network Management Protocol (SNMP) tools. The performance monitoring statistics are collected according to the RFC 1595 specification.

The information that this command displays is generally useful only for diagnostic tasks performed by Cisco Systems technical support personnel.

Examples

Example of the show controllers pos Command on the Cisco 7500 Series Router

The following is sample output from the **showcontrollerspos** command on a Cisco 7500 series router:

```
Router# show controllers pos
POS2/0/0

TCA thresholds:  B1 = 10e-7  B2 = 10e-3  B3 = 10e-6
```

The table below describes the fields shown in this display.

Table 73: show controllers pos Field Descriptions

Field	Description
POS*x/y/z*	Slot number of the POS interface.

Field	Description
LOF	Section loss of frame is detected when a severely error framing (SEF) defect on the incoming SONET signal persist for 3 milliseconds.
LOS	Section loss of signal is detected when an all-zeros pattern on the incoming SONET signal lasts 19 plus or minus 3 microseconds or longer. This defect might also be reported if the received signal level drops below the specified threshold.
BIP(B1)/BIP(B2)/BIP(B3)	Bit interleaved parity (BIP). For B1, the BIP error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B1 byte of the following frame. Differences indicate that section-level bit errors have occurred. For B2, the BIP error report is calculated by comparing the BIP-8/24 code with the BIP-8 code extracted from the B2 byte of the following frame. Differences indicate that line-level bit errors have occurred. For B3, the BIP error report is calculated by comparing the BIP-8 code with the BIP-8 code extracted from the B3 byte of the following frame. Differences indicate that path-level bit errors have occurred.
AIS	Alarm indication signal. A line alarm indication signal is sent by the section terminating equipment (STE) to alert the downstream line terminating equipment (LTE) that a loss of signal (LOS) or loss of frame (LOF) defect has been detected on the incoming SONET section. A path alarm indication signal is sent by the LTE to alert the downstream path terminating equipment (PTE) that it has detected a defect on its incoming line signal.
RDI	Remote defect indication. A line remote defect indication is reported by the downstream LTE when it detects LOF, LOS, or AIS. A path remote defect indication is reported by the downstream PTE when it detects a defect on the incoming signal.
FEBE	Far end block errors. Line FEBE (accumulated from the M0 or M1 byte) is reported when the downstream LTE detects BIP(B2) errors. Path FEBE (accumulated from the G1 byte) is reported when the downstream PTE detects BIP(B3) errors.
LOP	Path loss of pointer is reported as a result of an invalid pointer (H1, H2) or an excess number of new data flag (NDF)-enabled indications.
NEWPTR	Inexact count of the number of times that the SONET framer has validated a new SONET pointer value (H1, H2).

Field	Description
PSE	Inexact count of the number of times that the SONET framer has detected a positive stuff event in the received pointer (H1, H2).
NSE	Inexact count of the number of times that the SONET framer has detected a negative stuff event in the received pointer (H1, H2).
Active Defects	List of all currently active SONET defects.
Active Alarms	List of current alarms as enforced by Sonet Alarm Hierarchy.
Alarm reporting enabled for	List of alarms for which you enabled reporting with the **posreport** interface command.
APS	Automatic protection switching.
COAPS	An inexact count of the number of times that a new APS value has been detected in the K1, K2 bytes.
PSBF	An inexact count of the number of times that a protection switching byte failure has been detected (no three consecutive SONET frames contain identical K1 bytes).
PSBF_state	Protection switching byte failure state.
Rx(K1/K2)/Tx(K1/K2)	Contents of the received and transmitted K1 and K2 bytes.
S1S0	The two S bits received in the last H1 byte.
C2	The value extracted from the SONET path signal label byte (C2).
CLOCK RECOVERY	The SONET clock is recovered using information in the SONET overhead. RDOOL is an inexact count of the number of times that Receive Data Out Of Lock has been detected, which indicates that the clock recovery phased lock loop is unable to lock to the receive stream.
PATH TRACE BUFFER	SONET path trace buffer is used to communicate information regarding the remote host name, interface name and number, and IP address. This is a Cisco-proprietary use of the J1 (path trace) byte.
BER thresholds	List of the bit error rate (BER) thresholds that you configured with the **posthreshold** interface command.
TCA thresholds	List of the threshold crossing alarms (TCAs) that you configured with the**posthreshold** interface command.

Example of the show controllers pos Command on a POS Shared Port Adapter

The following is sample output from the **showcontrollerspos** command on a Cisco 7600 series router for POS interface 4/3/0 (which is the interface for port 0 of the SPA in subslot 3 of the SIP in chassis slot 4):

```
Router# show controllers pos 4/3/0

POS4/3/0
SECTION

```

The table below describes the fields shown in the display.

Table 74: show controllers pos pm Field Descriptions

Field	Description
POS*x/y*	Slot number of the POS interface.
Line coding	Shows the current line encoding type, either return to zero (RZ) or nonreturn to zero (NRZ).
Line type	Line type for this interface. Optical line types can be either long range (LONG) or short range (SHORT), and either single mode (SM) or multimode (MM).
Data in current interval	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Errored Secs	An errored second is a second in which one of the following is detected: • One or more coding violations. • One or more incoming defects (for example, a severely errored frame [SEF] defect, an LOS defect, an AIS defect, or an LOP defect).
Severely Err Secs	A severely errored second (SES) is a second with one of the following errors: • A certain number of coding violations. The number is dependent on the line rate and the BER. • A certain number of incoming defects.
Coding Violations	Number of coding violations for the current interval. Coding violations are defined as BIP errors that are detected in the incoming signal. The coding violations counter is incremented for each BIP error detected.
Sev Err Framing Secs	Severely errored framing seconds (SEFS) are seconds with one or more SEF defects.

Field	Description
Unavailable Secs	Total number of seconds for which the interface is unavailable. The interface is considered to be unavailable after a series of ten consecutive SESs.

Related Commands

Command	Description
pos report	Permits selected SONET alarms to be logged to the console for a POS interface.
pos threshold	Sets the BER threshold values of specified alarms for a POS interface.

show controllers satellite

To display controller information about the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), use the **showcontrollerssatellite** command in user EXEC or privileged EXEC mode.

show controllers satellite *slot/unit*

Syntax Description

slot	Router chassis slot in which the network module is installed.
unit	Interface number. For NM-1VSAT-GILAT network modules, always use 0.

Command Default

No default behavior or values.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.3(14)T	This command was introduced.

Usage Guidelines

The output from this command is generally useful for diagnostic tasks performed by technical support.

The **showcontrollerssatellite** command displays information about initialization block, transmit ring, receive ring, and errors for the Fast Ethernet controller chip in the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

Examples

The following example shows how to display controller information about the internal router interface that connects to an installed NM-1VSAT-GILAT network module:

```
Router# show controllers satellite
 2/0

Interface Satellite2/0

The table below describes the significant fields shown in the display.

Table 75: show controllers satellite Field Descriptions

Field	Description
Hardware	Description of the chip being used.
IDB	Address in router memory of the Interface Descriptor Block (IDB).
FASTSEND	Fastsend routine.
INSTANCE	Device-specific data stored in router memory that lists the memory locations and current indices of receive (Rx) and transmit (Tx) rings in router I/O memory.
CONTROL AND STATUS REGISTERS (CSR)	Control and status registers that are physically located on the chip itself and that are accessed by the CPU over the protocol control information (PCI) bus.
PHY REGISTERS	Contents of the physical layer (PHY) registers of the PHY module, which is an internal device that interfaces between the internal physical Ethernet line and the external physical line.
HARDWARE STATISTICS	Receive (Rx) and transmit (Tx) traffic statistics collected by the chip.
INTERRUPT STATISTICS	Receive (Rx), transmit (Tx), control, software, and flow control interrupt statistics collected by the chip.

Related Commands

Command	Description
service-module satellite status	Displays status information related to the hardware and software on the Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT), including the initial configuration parameters.
show interfaces satellite	Displays general interface settings and traffic rates for the internal router interface that connects to an installed Cisco IP VSAT satellite WAN network module (NM-1VSAT-GILAT).

show controllers serial through show hw-module slot proc cpu

show cem circuit

To display information about the circuit state, administrative state, the CEM ID of the circuit, and the interface on which it is configured, use the **show cem circuit** command. If cross connect is configured under the circuit, the command output also includes information about the attachment circuit status.

Syntax Description

Syntax Description

Command Default

There is no default.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
XE 3.18 SP	Support for this command was introduced on Cisco NCS 4200 Series.
XE Everest 16.5.1	This command was integrated into the Cisco NCS 4200 Series and Cisco ASR 900 Series Routers.

Usage Guidelines

The **show cem circuit** command allows you to display information about the circuit state, administrative state, the CEM ID of the circuit, and the interface on which it is configured.

Examples

The following example shows the detailed information about a particular circuit.:

```
Router# show cem circuit 0
CEM0/1/2, ID: 0, Line: UP, Admin: UP, Ckt: ACTIVE
Controller state: up, T1/E1 state: up
Idle Pattern: 0xFF, Idle CAS: 0x8
Dejitter: 5 (In use: 0)
Payload Size: 192
Framing: Unframed
CEM Defects Set
None
Signalling: No CAS
RTP: No RTP
Ingress Pkts: 11060 Dropped: 0
Egress Pkts: 11061 Dropped: 0
CEM Counter Details
Input Errors: 0 Output Errors: 0
Pkts Missing: 0 Pkts Reordered: 0
Misorder Drops: 0 JitterBuf Underrun: 0
Error Sec: 0 Severly Errored Sec: 0
Unavailable Sec: 0 Failure Counts: 0
Pkts Malformed: 0 JitterBuf Overrun: 0
```

show controllers serial

To display serial controller statistics, use the **showcontrollersserial**command in privileged EXEC mode.

Standard Syntax
show controllers serial [*slot*/*port*]

Cisco 7000 Series Routers with the RSP7000 and RSP7000CI and Cisco 7500 Series Routers
show controllers serial [*slot*/*port-adapter*/*port*]

T3/E3 Shared Port Adapters and 2-Port and 4-Port Channelized T3 SPA in Unchannelized Mode
show controllers serial [*slot*/*subslot*/*port*]

Channelized T3 Shared Port Adapters
show controllers serial [*slot*/*subslot*/*port*/*t1-number*]

Syntax Description

slot	(Optional) Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide.
port-adapter	(Optional) On Cisco 7500 series routers and Cisco 7000 series routers with the RSP7000 and RSP7000CI, the location of the port adapter on a Versatile Interface Processor (VIP). The value can be 0 or 1.
/ *subslot*	(Optional) Secondary slot number on a SIP where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information.
/ *port*	(Optional) Port or interface number. Refer to the appropriate hardware manual for port information. For SPAs, refer to the corresponding “Specifying the Interface Address on a SPA” topics in the platform-specific SPA software configuration guide.
t1-number	(Optional) Logical T1 number in channelized mode. For SPAs, refer to the corresponding “Specifying the Interface Address on a SPA” topics in the platform-specific SPA software configuration guide.

Command Default

No default behavior or values

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.

Release	Modification
11.1CA	This command was modified to include support for the PA-E3 and PA-T3 port adapters.
12.2S	This command was integrated into Cisco IOS Release 12.2S.
12.2(25)S3	This command was integrated into Cisco IOS Release 12.2(25)S3.
12.2(18)SXE	This command was integrated into Cisco IOS Release 12.2(18)SXE and introduced a new output for interfaces on the serial SPAs on the Cisco 7600 series routers and Catalyst 6500 series switches.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The output from the **showcontrollersserial**command provides error and alarm information that is useful in troubleshooting line problems.

The information displayed is generally useful for diagnostic tasks performed by Cisco Systems technical support personnel only. For the PA-E3 or PA-T3 port adapters, the **showcontrollersserial** command also displays configuration information such as the framing, clock source, bandwidth limit, whether scrambling is enabled, the national bit, the international bits, and DSU mode configured on the interface. Also displayed are the performance statistics for the current interval and last 15-minute interval and whether any alarms exist.

Examples

Example of the show controllers serial Command on the Cisco 4000 Series Router

The following is sample output from the **showcontrollersserial** command on the Cisco 4000:

```

      0 CP-bit Far-end Unavailable Secs
      0 Near-end path failures, 0 Far-end path failures
      0 Far-end code violations, 0 FERF Defect Secs
      0 AIS Defect Secs, 0 LOS Defect Secs
    No alarms detected.
```

The table below describes the fields shown in the **showcontrollersserial** output.

Note The fields appearing in the output will vary depending on card type, controller configuration, and the status of the controller line.

Table 76: show controllers serial Field Descriptions

Field	Description
Serial	Name of the serial controller.
Framing	Framing type.
Clock source	Source of the synchronization signal (clock).
Bandwidth limit	The allowable bandwidth for the controller.
DSU mode	The Data Service Unit (DSU) interoperability mode.
Cable length	The distance to the first repeater.
rx FEBE since last clear counter	Number of received far-end block errors. **Note** Line far-end block error (accumulated from the M0 or M1 byte) is reported when the downstream LTE detects BIP(B2) errors. Path far-end block error (accumulated from the G1 byte) is reported when the downstream PTE detects BIP(B3) errors.
rx FEBE since last reset	Number of received far-end block errors.

Field	Description
Line Code Violations	Number of Bipolar Violation (BPV) errors or Excessive Zeros (EXZ) errors.
P-bit Coding Violations	Number of P-bit errors encountered between source and destination.
C-bit coding violations	Number of C-bit errors encountered between source and destination.
P-bit Err Secs (PES)	Number of seconds with P-bit errors. **Note** A PES is a second with one or more PCVs or one or more Out of Frame defects or a detected incoming AIS. This gauge is not incremented when UASs are counted.
P-bit Sev Err Secs (PSES)	Number of seconds with P-bit severe errors. **Note** A PSES is a second with 44 or more PCVs or one or more Out of Frame defects or a detected incoming AIS. This gauge is not incremented when UASs are counted.
Sev Err Framing Secs	The number of 1-second intervals in which either a Remote Alarm Indication was received or a Loss Of Frame condition occurred.
Unavailable Secs	The number of 1-second intervals in which the controller was down.
Line Errored Secs	The number of 1-second intervals in which a Line Code Violation occurred.
C-bit Errored Secs (CES)	Number of seconds with C-bit errors. **Note** A CES is a second with one or more CCVs or one or more Out of Frame defects or a detected incoming AIS. This count is only for the SYNTRAN and C-bit Parity DS3 applications. This gauge is not incremented when UASs are counted.
C-bit Sev Err Secs (CSES)	Number of seconds with severe C-bit errors. **Note** A CSES is a second with 44 or more CCVs or one or more Out of Frame defects or a detected incoming AIS. This count is only for the SYNTRAN and C-bit Parity DS3 applications. This gauge is not incremented when UASs are counted.

Field	Description
Severely Errored Line Secs	For ESF signals, this is a second in which one of the following defects is detected: • 320 or more Path Code Violation errors. • One or more Out of Frame defects. • An AIS defect. For E1-CRC signals, this is a second with one of the following errors: • 832 or more Path Code Violation errors. • One or more Out of Frame defects. For E1-nonCRC signals, this is a second with 2048 or more Line Code Violations.
Far-End Errored Secs	Number of seconds of far-end failures.
Far-End Severely Errored Secs	The number of 1-second intervals in which either a Remote Alarm Indication was received or a Loss Of Frame condition occurred.
P-bit Unavailable Secs	Number of seconds the interface is unavailable because of P-bit errors.
CP-bit Unavailable Secs	Number of seconds the interface is unavailable because of CP-bit errors.
CP-bit Far-end Unavailable Secs	Number of seconds the interface is unavailable because of CP-bit errors from the far-end device.
Near-end path failures	Indicates the number of failures at the near end of the path, or device, during the specified trace period.
Far-end path failures	Indicates the number of failures at the remote (or far) end of the path, or device, during the specified trace period.
Far-end code violations	Indicates a frame synchronization bit error in the D4 and E1-no CRC formats, or a CRC error in the Extended Superframe (ESF) and E1-CRC formats has occurred on the remote, or far-end device.
FERF Defect Secs	Number of far-end receive failures detected per second.
AIS Defect Secs	Number of alarm indication signals per second.
LOS Defect Secs	Number of loss of signal alarms per second.
Path Code Violations	Indicates a frame synchronization bit error in the D4 and E1-no CRC formats, or a CRC error in the Extended Superframe (ESF) and E1-CRC formats.
Slip Secs	Indicates the replication or deletion of the payload bits of a domestic trunk interface (DS1) frame. A slip might happen when there is a difference between the timing of a synchronous receiving terminal and the received signal.

Field	Description
Fr Loss Secs	Indicates the number of seconds an Out of Frame (OOF) error is detected.
Line Err Secs	Line Errored Seconds (LES) is a second in which one or more Line Code Violation errors are detected.
Degraded Mins	A degraded minute is one in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3.
Errored Secs	In ESF and E1-CRC links, an errored second is a second in which one of the following defects is detected: • One or more Path Code Violations. • One or more Controlled Slip events. **Note** For SF and E1 no-CRC links, the presence of Bipolar Violations also triggers an errored second.
Bursty Err Secs	A second with more than one but fewer than 320 Path Coding Violation errors, no Severely Errored Frame defects, and no detected incoming AIS defects. Controlled slips are not included in this parameter.

show controllers serial bert

To view the BERT statistics for a completed or in-progress BERT test, enter the **showcontrollersserialbert** in user EXEC or EXEC privileged mode.

show controllers serial *slot/interface-number* **bert**

Syntax Description

slot	Specifies the slot where the serial interface is located.
interface-number	Specifies the number of the serial interface.

Command Default

None

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.1(12c)EX1	This command was introduced for Cisco 7304 routers.
12.2(18)S	This command was introduced on Cisco 7304 routers running Cisco IOS Release 12.2S.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

This command is used to view the results of a user-initiated BERT test.

Examples

In the following example, the **showcontrollersserialbert**command is used to view a BERT test that is still in progress:

```
Router#
show controllers serial 6/0 bert
Interface Serial6/0 (DS3 port 1)
 BERT information:
  State            :enabled (sync'd)
  Pattern          :2^23
  Interval         :10 minutes
  Time remaining   :00:01:44
  Total errors     :0
  Time this sync   :00:08:10
  Errors this sync :0
  Sync count       :1
```

In the following example, the **showcontrollersserialbert**command is used to view a BERT test that is complete:

```
Router# show controllers serial 6/0 bert
Interface Serial6/0 (DS3 port 1)
 BERT information:
  State            :enabled (sync'd)
  Pattern          :2^23
```

```
Interval          :10 minutes
Time remaining    :00:09:44
Total errors      :0
Time this sync    :00:00:10
Errors this sync :0
Sync count        :1
```

Related Commands

Command	Description
bert errors	Inserts intention errors into a BERT test.
bert pattern	Begins a BERT test.

show controllers sm

To display controller information for the service module interface, use the **showcontrollerssm** command in user EXEC or privileged EXEC mode.

show controllers sm *slot*/*port*

Syntax Description

slot	Router slot in which the service module is installed. Range: 1 to 4.
/ *port*	Port number of the module interface. Always use 0. The slash mark (/) is required.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
15.0(1)M	This command was introduced.

Usage Guidelines

The output from this command is generally useful for diagnostic tasks performed by technical support only. You can, however, use the displayed hardware statistics to obtain the receive and transmit packet statistics that are collected by the hardware controller during packet processing.

Examples

The following example shows how to display information for the SM-SRE installed in the router:

```
Router# show controllers sm 1/0
Interface SM1/0
Hardware is PSE2
HWIDB: 0x11E3C8C8 INSTANCE: 0x01323100, FASTSEND: 0x040D6C44

The table below describes the significant fields shown in the display.

Table 77: show controllers analysis-module Field Descriptions

Field	Description
Hardware	Description of the chip being used.
IDB, FASTSEND	Address in router memory of the Interface Descriptor Block (IDB) and the fastsend routine.
INSTANCE	Device-specific data stored in router memory that lists the memory locations and current indexes of receive (Rx) and transmit (Tx) rings in router I/O memory.
CONTROL AND STATUS REGISTERS (CSR)	Control and status registers that are physically located on the chip itself and that are accessed by the CPU over the Peripheral Component Interconnect (PCI) bus.
PHY REGISTERS	Contents of the PHY registers. PHY is a device that interfaces the physical Ethernet line and that is located between the chip and the physical line.
HARDWARE STATISTICS	Receive (Rx) and transmit (Tx) traffic statistics collected by the chip.
INTERRUPT STATISTICS	Transmit (Tx), Receive (Rx), control, software, and flow control interrupt statistics collected by the chip.

Related Commands

Command	Description
service-module sm status	Displays hardware and software status information about the SM-SRE.
show interfaces sm	Displays status, traffic data, and configuration information about the SM-SRE interface.

show controllers sonet

To display information about Synchronous Optical Network (SONET) controllers, use the **showcontrollerssonet** command in user EXEC or privileged EXEC mode with the appropriate parameters for the operating mode of the channelized line.

show controllers sonet[{*slot/bay/port*
[illegible]
slot/bay/port:t1-line-number}][{**bert** | **brief** | **tabular**}]

Cisco Series
show controllers sonet [*slot/bay/port*]

Syntax Description

slot / bay / port	(Optional) Slot, bay, and port number. The slash mark is required between the *slot* argument, the *bay* argument, and the *port* argument. **Note** This form of the syntax is used only for the synchronous transport module-1 (STM-1) trunk card on a Cisco AS5850 universal gateway.
slot / bay / port **.** *sts1 - number / t1 -* number	(Optional) Slot and port number of a T1 line under SONET framing in CT3 mode.
slot / bay / port **.** *vtg1 - number / sts1 - number / t1 - number*	(Optional) Slot and port number of a T1 line under SONET framing in VT-15 mode.
slot / bay / port **.** *au-3-number / tug-2-number / t1-number*	(Optional) Slot and port number of a T1 line under synchronous digital hierarchy (SDH) framing with administrative unit type 3 (AU-3) administrative unit group (AUG) mapping.
slot / bay / port **.** *au - 4 - number / tug - 3 - number / tug - 2 - number / e1 - line - number*	(Optional) Slot and port number of an E1 line under SDH framing with AU-4 AUG mapping.
slot / bay / port **.** *au - 4 - number / vc3 - number*	(Optional) Slot and port number of a DS3/E3 interface under SDH framing with AU-4 mapping.
slot / bay / port **:** *interface - number*	(Optional) Slot and port number of a DS3/E3 interface under SONET framing or SDH framing with AU-3 mapping.
t3 slot / bay / port **:** *t1 - line - number*	(Optional) Displays information for a T1 line under SF or ESF format framing.
bert	(Optional) Displays bit error rate test (BERT) information.
brief	(Optional) Displays summary information about SONET controllers.
tabular	(Optional) Displays SONET controller information in a tabular format.

Command Modes

User EXEC (>) Privileged EXEC (#)

Command History

Release	Modification
12.0(21)S	This command was introduced on Cisco 12000 series Internet routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T, and support was added for the STM-1 trunk card on the Cisco AS5850 platform.
12.3(11)T	This command was modified to support SONET APS on the Cisco AS5850 platform.
Cisco IOS XE Release 3.1	This command was modified to display the Detected Alarms and Asserted/Active Alarms fields.
Cisco IOS XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series Rotuters and Cisco NCS 4200 Series.
XE Fuji 16.8.x	This command output was modified on the Cisco Series Routers to display far-end counters for performance monitoring.

Usage Guidelines

You can enter the **showcontrollerssonet** command at any time during a BERT.

Examples

The following is sample output from the **showcontrollerssonet**command on a T1 line under SONET framing in VT-15 mode. (The table below describes the lines in the BERT portion of the output.)

```
Router# show controllers sonet
 4/0.1/1/1 brief
OC3.STS1 4/0.1 is up. Hardware is GSR 2 port STM1/OC3 (channelized)
  Applique type is VT1.5 in STS-1

 STS-1 1, VTG 1, T1 1 (VT1.5 1/1/1) is up
  timeslots: 1-24
  FDL per AT&T 54016 spec.
  No alarms detected.
  Framing is ESF, Clock Source is Internal
  BERT test result (running)
     Test Pattern : 2^20-QRSS, Status : Sync, Sync Detected : 1
     Interval : 5 minute(s), Time Remain : 4 minute(s)
     Bit Errors (since BERT started): 0 bits,
     Bits Received (since BERT started): 112 Mbits
     Bit Errors (since last sync): 0 bits
     Bits Received (since last sync): 112 Mbits
```

Table 78: show controllers sonet Line Descriptions

Field	Description
BERT test result (running)	Indicates the current state of the test. In this case, “running” indicates that the test is still active. If the test is complete, “done” is displayed.
Test Pattern : 2^20-QRSS, Status : Sync, Sync Detected : 1	Indicates the test pattern that you selected for the test (2^20-QRSS), the current synchronization state (Sync), and the number of times that synchronization was detected during this test (1).

Field	Description
Interval : 5 minute(s), Time Remain : 4 minute(s)	Indicates the time allocated for the test to run and the time remaining for the test to run. For a BERT that you terminate before the time expires, this line indicates the time the test would have taken to run and the time remaining for the test to run had you not terminated it. “unable to complete” is displayed to indicate that you interrupted the test.
Bit Errors (since BERT started): 0 bits Bits Received (since BERT started): 112 Mbits Bit Errors (since last sync): 0 bits Bits Received (since last sync): 112 Mbits	Shows the bit errors that were detected versus the total number of test bits that were received since the test started and since the last synchronization was detected.

The following is sample output from the **showcontrollerssonet**command for an E1 line under SDH framing with AU-4 AUG mapping.

```
Router# show controllers sonet 3/0.1/1/3/5
SONET 3/0 is up. (Configured for Locally Looped)  Hardware is GSR 2 port

The table below describes the significant fields shown in the display.

Table 79: show controllers sonet STM-1 Field Descriptions

Field	Description
SONET 3/0	The SONET controller in slot 3 shows the state in which it is operating. The controller's state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).
Applique type	Controller type.
Clock Source	User-specified clock source (Line or Internal).
AUG mapping	Indicates type of administrative unit group (AUG) mapping.
Line Coding	Shows the current line encoding type, either return to zero (RZ) or non return to zero (NRZ).
Line Type	Line type for this interface. Optical line types can be either long range (LONG) or short range (SHORT), and either single mode (SM) or multimode (MM).
VC-12	Indicates the number of the virtual circuit (VC) and whether the VC has reported any defects.
CVs	Number of coding violation (CV) error events.
ESs	An errored second (ES) is a second in which one of the following is detected: • One or more path code violations. • One or more out of frame defects. • One or more controlled slip events. • A detected alarm indication signal (AIS) defect.
SESs	Severely errored seconds (SESs) are seconds with one or more out-of-frame defects or a detected incoming AIS. This gauge is not incremented when UASs are counted.
SEFSs	Severely errored framing seconds (SEFSs) are seconds with one or more out-of-frame defects or a detected incoming AIS.
UASs	Unavailable seconds (UASs) are calculated by counting the number of seconds for which the interface is unavailable.

The following is partial output from the **showcontrollerssonet**command using an STM-1 card in the Cisco AS5850 with SONET APS configured.

```
Router# show controllers sonet 1/0
SONET 1/0 is up.
  Applique type is Channelized Sonet/SDH
  Clock Source is Line, AUG mapping is AU4.
  MSP 1+1 bi-directional enabled
  Protection fiber (Port 0), No Alarm, traffic in-use
  Working fiber (Port 1), No Alarm, traffic not in-use
  Local request: No Request
  Remote request: No Request
Medium info:
  Type: SDH, Line Coding: NRZ, Line Type: Short SM
Regenerator Section Status:
```

```
  No alarms detected.
Multiplex Section Status:
  No alarms detected.
  No BER failure/degrade detected
  B2 BER_SF threshold power : 3
  B2 BER_SD threshold power : 6
Higher Order Path Status:
  Path# 1 has no defects
Lower Order Path Status:
  VC-12 1/1/1/1 has no defects
  VC-12 1/1/1/2 has no defects
  VC-12 1/1/1/3 has no defects
  .
  .
  .
```

The table below describes the significant fields shown in the display that are different from the fields described in the table above.

Table 80: show controllers sonet STM-1 APS Field Descriptions

Field	Description
MSP 1+1	Indicates whether the SDH multiplex section protection (MSP) is bidirectional or unidirectional.
Protection fiber	Indicates the port location of the protect fiber, whether an alarm has been detected, and whether traffic is flowing through the port.
Working fiber	Indicates the port location of the working fiber, whether an alarm has been detected, and whether traffic is flowing through the port.
Local request	Indicates whether a local request to switch fibers has been received. If a request has been received, the type of request (forced, lockout, or manual) is indicated.
Remote request	Indicates whether a remote request to switch fibers has been received. If a request has been received, the type of request (forced, lockout, or manual) is indicated.
No alarms detected	Alarms detected by the controller are displayed here. The possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending alarm indication signal (AIS). • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
No BERT failure/degrade detected	No bit error rate (BER) failures or degrades detected.

Field	Description
B2 BER_SF threshold power	BER signal failure (SF) threshold configured with the **b2sf-ber** controller command.
B2 BER_SD threshold power	BER signal degrade (SD) threshold configured with the **b2sd-ber** controller command.

The following is a sample output from the **showcontrollerssonet**command using the CHOCX card.

```
Router# show controllers sonet 0/0/0

The table below describes the significant fields shown in the display.

Table 81: show controllers sonet CHOCX Card Field Descriptions

Field	Description
Applique type	The controller type.
Clock Source	The user-specified clock source (line or internal).
Active Defects	List of active SONET defects.
Detected Alarms	List of alarms detected by the controllers.
Asserted/Active Alarms	List of resultant active alarms after SONET alarm hierarchy is enforced on detected alarms.
BER thresholds	BER threshold values of the specified alarms.
TCA thresholds	Threshold crossing alarm (TCA) values of the specified alarms.

The following is sample output from the **showcontrollerssonet**command using a shared port adapter (SPA), SPA-1XCHOC12/DS0 on a Cisco 7600 series router. SPAs such as the SPA-1XCHSTM1/OC3, SPA-1xCE-OC3/STM1, and SPA-1xCHOC12/OC3 are also used on a Cisco 7600 series router to get output on the SONET controller.

show controllers t1 [*slot*/*bay*/*port*]

Syntax Description

number	Network processor number (NPM)) number, in the range 0 through 2.
slot / *port*	(Optional) Backplane slot number and port number on the interface. Refer to your hardware installation manual for the specific slot and port numbers.
slot / *bay* / *port*	Slot number, interface module number in which the slot is inserted, and port number (Cisco series routers).
dial-shelf	Dial shelf chassis in the Cisco AS5800 access server that contains the CT3 interface card.
/ *slot*	Location of the CT3 interface card in the dial shelf chassis.
/ *t3-port*	T3 port number. The only valid value is 0.
: *t1-num*	T1 time slot in the T3 line. The value can be from 1 to 28.
bert	(Optional) Type **bert** to get a specific display for the bit-error rate testing (BERT) results. Otherwise, the display will include all other non-BERT information.

Command Modes

Privileged EXEC

Command History

Release	Modification
11.0	This command was introduced.
12.0(2)XD	The keyword **bert** was added.
12.0(3)T	This command was implemented on the Cisco AS5800 access server.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Release	Modification
XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series and Cisco NCS 4200 Series Routers.
XE Fuji 16.8.x	This command output was modified on the Cisco Series Routers to display far-end counters for performance monitoring.

Usage Guidelines

This command displays controller status that is specific to the controller hardware. The information displayed is generally useful for diagnostic tasks performed by technical support personnel. Use the **showcontrollerst1bert** command to display the results of the BERT feature.

The NPM or MultiChannel Interface Processor (MIP) can query the port adapters to determine their current status. Issue a **showcontrollerst1** command to display statistics about the T1 link.

If you specify a slot and port number, each 15-minute period will be displayed.

Cisco 7500 Series Routers

The following is sample output from the **showcontrollerst1** command on the Cisco 7500 series routers:

```
Router# show controllers t1
T1 4/1 is up.
  No alarms detected.
  Framing is ESF, Line Code is AMI, Clock Source is line
  Data in current interval (10 seconds elapsed):
     0 Line Code Violations, 0 Path Code Violations 0 Slip Secs, 0 Fr Loss Secs,
     0 Line Err Secs, 0 Degraded Mins 0 Errored Secs, 0 Bursty Err Secs,
     0 Severely Err Secs, 0 Unavail Secs
  Total Data (last 79 15 minute intervals):
     0 Line Code Violations, 0 Path Code Violations, 0 Slip Secs, 0 Fr Loss Secs,
     0 Line Err Secs, 0 Degraded Mins, 0 Errored Secs, 0 Bursty Err Secs,
     0 Severely Err Secs, 0 Unavail Secs
```

The table below describes the fields shown in the display.

Table 83: show controllers t1 Field Descriptions--Cisco 7500 Series

Field	Description
T1 4/1 is up	The T1 controller 1 in slot 4 is operating. The controller’s state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).

Field	Description
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
Data in current interval (10 seconds elapsed)	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Indicates the occurrence of either a Bipolar Violation (BPV) or Excessive Zeros (EXZ) error event.
Path Code Violations	Indicates a frame synchronization bit error in the D4 and E1-no-CRC formats, or a CRC error in the ESF and E1-CRC formats.
Slip Secs	Indicates the replication or deletion of the payload bits of a DS1 frame. A slip may be performed when there is a difference between the timing of a synchronous receiving terminal and the received signal.
Fr Loss Secs	Indicates the number of seconds an out-of-frame error is detected.
Line Err Secs	Line Errored Seconds (LES) is a second in which one or more Line Code Violation errors are detected.
Degraded Mins	Degraded Minute is one in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3.
Errored Secs	In ESF and E1-CRC links, an Errored Second is a second in which one of the following are detected: one or more Path Code Violations; one or more out-of-frame defects; one or more Controlled Slip events; a detected AIS defect. For D4 and E1-no-CRC links, the presence of Bipolar Violations also triggers an Errored Second.
Bursty Err Secs	Second with fewer than 320 and more than 1 Path Coding Violation error, no Severely Errored Frame defects and no detected incoming AIS defects. Controlled slips are not included in this parameter.

Field	Description
Severely Err Secs	For ESF signals, a second with one of the following errors: 320 or more Path Code Violation errors; one or more out-of-frame defects; a detected AIS defect. For E1-CRC signals, a second with one of the following errors: 832 or more Path Code Violation errors; one or more out-of-frame defects. For E1-no-CRC signals, a second with 2048 Line Code Violations or more. For D4 signals, a count of 1-second intervals with Framing Errors, or an Out-of-Frame defect, or 1544 Line Code Violations.
Unavail Secs	Count of the total number of seconds on the interface.

Cisco AS5800 Access Server

The following example shows the status of the T1 controllers connected to the Cisco AS5800 access servers:

```
Router# show controllers t1 1/0/0:1
T1 1/0/0:1 is up.
 No alarms detected.
 Framing is ESF, Line Code is AMI, Clock Source is Line.
 Data in current interval (770 seconds elapsed):
     5 Line Code Violations, 8 Path Code Violations
     0 Slip Secs, 0 Fr Loss Secs, 7 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 7 Unavail Secs
 Total Data (last 81 15 minute intervals):
     7 Line Code Violations, 4 Path Code Violations,
     6 Slip Secs, 20 Fr Loss Secs, 2 Line Err Secs, 0 Degraded Mins,
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 2 Unavail Secs
T1 1/0/1:5 is down.
 Transmitter is sending remote alarm.
 Receiver has loss of frame.
 Framing is SF, Line Code is AMI, Clock Source is Line.
 Data in current interval (770 seconds elapsed):
     50 Line Code Violations, 5 Path Code Violations
     0 Slip Secs, 7 Fr Loss Secs, 7 Line Err Secs, 0 Degraded Mins
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 7 Unavail Secs
 Total Data (last 81 15 minute intervals):
     27 Line Code Violations, 22 Path Code Violations,
     0 Slip Secs, 13 Fr Loss Secs, 13 Line Err Secs, 0 Degraded Mins,
     0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 13 Unavail Secs
```

The table below describes the fields shown in the display.

Table 84: show controllers t1 Field Descriptions--Cisco AS5800 Access Server

Field	Description
T1 ... is up	Status of T1 line.
No alarms detected	Access server received no alarms.
Framing is ...	Standard T1 framing type. In this example, the framing is Extended Super Frame (ESF).

Field	Description
Line Code is ...	Standard T1 line-coding format. In this example, the line-coding format is Alternate Mark Inversion (AMI).
Clock Source is ...	Source of the synchronization signal (clock). In this example, the line is providing the clock signal.
Data in current interval ...	Summary statistics for T1 signal quality for the current time interval of 900 seconds. In this example, the statistics are for current partial interval (770 seconds of 900 seconds).
Line Code Violations	Number of T1 line code violations for the current interval.
Path Code Violations	Number of T1 path code violations for the current interval.
Slip Secs	Number of seconds in this interval during which a frame misalignment occurred.
Fr Loss Secs	Number of seconds in this interval during which frame loss occurred.
Line Err Secs	Number of seconds in this interval during which line errors occurred.
Degraded Mins	Number of minutes in this interval during which the signal quality was degraded.
Errored Secs	Number of seconds in this interval during which an error was reported.
Bursty Err Secs	Number of bursty error seconds in this interval.
Severely Err Secs	Number of severely errored seconds in this interval.
Unavail Secs	Number of unavailable seconds in this interval.
Total Data (last ... 15 minute intervals)	Summary statistics for T1 signal quality for 15-minute intervals. Every 24 hours (96 intervals) the counters in this data block clear.

Using the bert Keyword

The following is sample output from the **showcontrollerst1bert** command displaying the BERT status for all ports:

```
Router#
show controllers t1 bert
 Controller T1 0 Profile default : The Test was aborted by User
 Controller T1 0 Profile 2 : Test Never Ran
 Controller T1 1 Profile 3 : Test Never Ran
 Controller T1 1 Profile 3 : Test Failed with a BER of 10^-2
 Controller T1 2 Profile 3 : Current running, BER 0
 Controller T1 2 Profile 2 : Passed with a BER of 0
 Controller T1 3 Profile default : Test Never Ran
 Controller T1 3 Profile 2 : Test Never Ran
 Controller T1 4 Profile default : Test Never Ran
 Controller T1 4 Profile 2 : Test Never Ran
 Controller T1 5 Profile default : Test Never Ran
```

```
 Controller T1 5 Profile 2 : Test Never Ran
 Controller T1 6 Profile default : Test Never Ran
 Controller T1 6 Profile 2 : Test Never Ran
 Controller T1 7 Profile default : Test Never Ran

Controller T1 7 Profile 2 : Test Never Ran
```

The following is sample output from the **showcontrollerst1bert** command with only one T1 port, port 0.

```
Router#
show controllers t1 0 bert
Controller T1 0 Profile default : The Test was aborted by User
Controller T1 0 Profile 2 : Test Never Ran
```

Series Router

The following is sample output from the **show controllers t1** command on the Cisco series routers:

```
Router# show controllers t1 0/2/1
T1 0/2/1 is down.
Applique type is -48T1E1-CE
Cablelength is short 110
No alarms detected.
alarm-trigger is not set
Soaking time: 3, Clearance time: 10
AIS State:Clear LOS State:Clear LOF State:Clear
Framing is ESF, FDL is ansi, Line Code is B8ZS, Clock Source is Line.
BER thresholds: SF = 10e-3 SD = 10e-6
Data in current interval (230 seconds elapsed):
Near End
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavailable Secs
0 Path Failures, 0 SEF/AIS Secs
Far End
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 0 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 0 Unavailable Secs
0 Path Failures
Data in Interval 1:
Near End
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 0 Fr Loss Secs, 14 Line Err Secs, 0 Degraded Mins
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 15 Unavailable Secs
1 Path Failures, 0 SEF/AIS Secs
Far End Data
0 Line Code Violations, 0 Path Code Violations
0 Slip Secs, 4 Fr Loss Secs, 2 Line Err Secs, 0 Degraded Mins
4 Errored Secs, 0 Bursty Err Secs, 4 Severely Err Secs, 0 Unavailable Secs
0 Path Failures
Total Data (last 1 15 minute intervals):
Near End
0 Line Code Violations, 0 Path Code Violations,
0 Slip Secs, 0 Fr Loss Secs, 14 Line Err Secs, 0 Degraded Mins,
0 Errored Secs, 0 Bursty Err Secs, 0 Severely Err Secs, 15 Unavailable Secs
1 Path Failures, 0 SEF/AIS Secs
Far End
0 Line Code Violations, 0 Path Code Violations,
0 Slip Secs, 4 Fr Loss Secs, 2 Line Err Secs, 0 Degraded Mins,
```

```
4 Errored Secs, 0 Bursty Err Secs, 4 Severely Err Secs, 0 Unavailable Secs
0 Path Failures
```

show controllers t1 bert

To get the results of the bit-error rate testing (BERT) run for all ports, use the **showcontrollerst1bert**command in privileged EXEC mode.

show **controllers** *type* [*controller-number*] [**bert**]

Syntax Description

type	Specify either T1 or E1 facility.
controller-number	(Optional) Select a specific controller/port numbers. The range is 0 to 7. If not selected, the display will show all ports.
bert	(Optional) Type **bert** to get a specific display for the BERT results. Otherwise, the display will include all other non-BERT information.

Command Default

No default behavior or values.

Command Modes

Privileged EXEC

Command History

Release	Modification
12.0(2)XD	This command was introduced.
12.0(3)T	This command was modified.
12.2(15)T	This command is no longer supported in Cisco IOS Mainline or Technology-based releases. It may conintue to appear in Cisco IOS 12.2S-family releases.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Use the **showcontrollers** command to display the results of the BERT feature.

Examples

The following example shows how the **showcontrollers** command is used to display the BERT status for all ports:

```
Router#
show controllers t1 bert
 Controller T1 0 Profile default : The Test was aborted by User
 Controller T1 0 Profile 2 : Test Never Ran
 Controller T1 1 Profile 3 : Test Never Ran
 Controller T1 1 Profile 3 : Test Failed with a BER of 10^-2
 Controller T1 2 Profile 3 : Current running, BER 0
 Controller T1 2 Profile 2 : Passed with a BER of 0
 Controller T1 3 Profile default : Test Never Ran
 Controller T1 3 Profile 2 : Test Never Ran
 Controller T1 4 Profile default : Test Never Ran
 Controller T1 4 Profile 2 : Test Never Ran
 Controller T1 5 Profile default : Test Never Ran
```

```
 Controller T1 5 Profile 2 : Test Never Ran
 Controller T1 6 Profile default : Test Never Ran
 Controller T1 6 Profile 2 : Test Never Ran
 Controller T1 7 Profile default : Test Never Ran

Controller T1 7 Profile 2 : Test Never Ran
```

The following example shows how the output display was limited to that of only one T1 port, port 0.

```
Router#
show controllers t1 0 bert
Controller T1 0 Profile default : The Test was aborted by User
Controller T1 0 Profile 2 : Test Never Ran
```

show controllers T1-E1 errors

To show the last nineteen alarms on a controller, use the **showcontrollers**command in privileged EXEC mode.

show controllers {**t1** | **e1**} *slot subslot port* **errors**

Syntax Description

slot	Chassis slot number. Refer to the appropriate hardware manual for slot information. For SIPs, refer to the platform-specific SPA hardware installation guide or the corresponding "Identifying Slots and Subslots for SIPs and SPAs" topic in the platform-specific SPA software configuration guide.
subslot	Secondary slot number on a SPA interface processor (SIP) where a SPA is installed. Refer to the platform-specific SPA hardware installation guide and the corresponding "Specifying the Interface Address on a SPA" topic in the platform-specific SPA software configuration guide for subslot information.
port	Interface number on a SPA.
t1	Clear-channel T1 with integrated data service units (DSUs).
e1	Clear-channel E1 with integrated data service units (DSUs).

Command Modes

Privileged EXEC mode

Command History

Release	Modification
12.2(18)SXE	This command was introduced in Cisco IOS Release 12.2(18)SXE to support SPAs on the Cisco 7600 series router and Catalyst 6500 series switch.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

Use the **showcontrollers**command to show the last nineteen alarms on a controller on a 8-Port T1/E1 SPA.

Examples

The following example displays the alarms on an E1 interface.

```
Router# #show controllers e1 10/2/4 errors
  E1 10/2/4:Alarm Log Information
  present alarm:NONE
  Alarm:OOF 03:54:17 - 03:54:22
  Alarm:OOF 03:53:34 - 03:54:07
```

Related Commands

Command	Description
controller	Configures a T1, E1, or T3 controller and enters controller configuration mode.
show controller	Displays controller configuration.

show controllers t3

To display information about T3 links and to display hardware and software driver information for the T3 controller, use the **showcontrollerst3**command in privileged EXEC mode.

Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 Series, Cisco 3725, and Cisco 3745 Routers
show controllers t3 *slot/port* [{**brief** | **tabular**}]

Cisco 7200 Series Routers
show controllers t3 [*bay/port* [*/t1-channel*]] [{**brief** | **errors** | **tabular** | **remote performance** [{**brief** | **tabular**}]}]

Cisco 7500 Series Routers
show controllers t3 [*slot/bay/port* [*/t1-channel*]] [{**brief** | **errors** | **tabular** | **remote performance** [{**brief** | **tabular**}]}]

Cisco AS5800 Access Servers and Cisco 10000 Series Routers
show controllers t3 *dial-shelf/slot/t3-port*

Cisco Series
show controllers t3 [*slot/bay/port*]

Cisco Series
show controllers t3 [*slot/bay/port path*]

Note This is applicable to 48-Port T3/E3 CEM Interface Module and 1 port OC-48/STM-16 or 4 port OC-12/OC-3 / STM-1/STM-4 + 12 port T1/E1 + 4 port T3/E3 CEM Interface Module.

Syntax Description

slot	Slot number. Refer to the appropriate hardware manual for slot information.
/ *port*	Port number. Refer to the appropriate hardware manual for port information.
slot / *bay* / *port*	Slot number, interface module number in which the slot is inserted, and port number (Cisco series routers).
/ *bay*	(Optional) The port adaptor bay number. Refer to the appropriate hardware manual for bay information
/ *t1-channel*	(Optional) Number from 1 to 28 that represents the T1 channel for the Channelized T3 Interface Processor (CT3IP) on Cisco 7200 series and Cisco 5200 series routers.
dial-shelf	Dial shelf chassis in the Cisco AS5800 access server that contains the CT3 interface card.
/ *slot*	Location of the CT3 interface card in the dial shelf chassis.
/ *t3-port*	T3 port number.

brief	(Optional) Displays a subset of information.
errors	(Optional) Displays a history of alarm events that causes a T3 controller or a T1 controller of a T3 to transition from an Up state to a Down state. The history size is 18 events.
tabular	(Optional) Displays information in a tabular format.
remote performance	(Optional) Displays the far-end ANSI performance monitor information when enabled on the T1 channel with the **t1fdlansi** controller configuration command.
path	Defines the path (sts-1/vc3) information to which the DS3 (T3 or E3) is mapped.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.3	This command was introduced.
12.0(3)T	This command was implemented on the Cisco AS5800 access server.
12.2(11)YT	This command was integrated into Cisco IOS Release 12.2(11)YT and implemented on the following platforms: Cisco 2650XM, Cisco 2651XM, Cisco 2691, Cisco 3660 series, Cisco 3725, and Cisco 3745 routers.
12.2(15)T	This command was integrated into Cisco IOS Release 12.2(15)T.
12.2(19c)	This command was modified to display error throttling and alarm conditions that cause the T3 controller to enter a failure state.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(31)SB	This command was integrated in Cisco IOS Release 12.2(31)SB.
12.2(33)SB	This command's behavior was modified on the Cisco 10000 series router for the PRE3 and PRE4.
XE Everest 16.5.1	This command was implemented on the Cisco ASR 900 Series Routers and Cisco NCS 4200 Series.
XE Fuji 16.8.x	This command output was modified on the Cisco Series Routers to display far-end counters for performance monitoring.
XE Fuji 16.8.x	The path keyword is introduced in Cisco IOS XE Fuji 16.8.x release for Cisco ASR 900 Series Routers and Cisco NCS 4200 Series Routers for 48-Port T3/E3 CEM Interface Module and 1 port OC-48/STM-16 or 4 port OC-12/OC-3 / STM-1/STM-4 + 12 port T1/E1 + 4 port T3/E3 CEM Interface Module.

Usage Guidelines

Cisco 7500 Series Routers

This command displays controller status that is specific to the controller hardware. The information displayed is generally useful for diagnostic tasks performed by technical support personnel only.

When you use the errors keyword, this command displays history that identifies which alarm events caused a T3 or T1 controller of a T3 to go down for the Cisco 7500 and Cisco 7200 series routers.

Note T1 channels on the CT3IP are numbered 1 to 28 rather than the more traditional zero-based numbering scheme (0 to 27) used with other Cisco products. This is to ensure consistency with telco numbering schemes for T1 channels within channelized T3 equipment.

The **showcontrollerst3**command also displays Maintenance Data Link (MDL) information (received strings) if MDL is configured and framing is set to C-bit.

Cisco 10000 Series Router Usage Guidelines

In releases prior to Cisco IOS Release 12.2(33)SB, when you configure the t1 loopback remote command on the local router, the command also displays in the running configuration file of the far-end router. This is due to the Route Processor (RP) updating an incorrect parameter when it receives the loopback event message from the line card for loopback requests from the far end.

In Cisco IOS Release 12.2(33)SB, the RP updates the correct parameter and the show controllers command correctly displays the loopback CLI commands applied on the local end and displays the loopback events and status received from the line card in response to loopback requests from the far end.

This change in behavior affects the following line cards and is documented in the CSCsm84447 caveat:

- 4-port channelized STM1
- 1-port channelized OC-12
- 6-port channelized T3
- 4-port half-height channelized T3

In Cisco IOS Release 12.2(33)SB, the output from the show controller command includes line code information for the 6-port channelized T3 line card and the 8-port E3/DS3 line card. However, because SONET line cards do not have a direct physical link at the T3 or E3 level, the output from the show controller t3 command does not include line code information.

In Cisco IOS Release 12.2(31)SB, the output from the show controller command displays line code information. The output of the show controller t3 command for SONET-based T3 also includes line code information.

Examples

Cisco 7200 Series Routers

The following is partial output from the **showcontrollerst3** errors command for Cisco IOS Release 12.2(19c) for a specific T1 controller of a T3 on a Cisco 7200 series router with a bay/port of 4/1, displaying the T1 1 alarm event of OOF:

```
Router# show controllers t3 4/1/1 errors
  T3 4/1: Error Log Information
  present alarm: NONE
  Error: AIS
  17:28:08-17:29:18
  T1 1 Error Log Information
```

```
  present alarm: OOF
  Since 17:30:55
  Error: OOF
  17:30:09-17:30:46
```

The following is partial output from the **showcontrollerst3** errors command from Cisco IOS Release 12.2(19c) for a T3 controller on a Cisco 7200 series router with a bay/port of 4/1, displaying a history of all alarm events on all 28 T1 channels:

```
Router# show controllers t3 4/1 errors
  T3 4/1: Error Log Information
  present alarm: NONE
  Error: AIS
  17:28:08-17:29:18
  T1 1 Error Log Information
  present alarm: OOF
  Since 17:30:55
  Error: OOF
  17:30:09-17:30:46
  T1 2 Error Log Information
  present alarm: NONE
  T1 3 Error Log Information
  present alarm: NONE
  T1 4 Error Log Information
  present alarm: NONE
  T1 5 Error Log Information
  present alarm: NONE
  T1 6 Error Log Information
  present alarm: NONE
  T1 7 Error Log Information
  present alarm: NONE
  T1 8 Error Log Information
  present alarm: NONE
  T1 9 Error Log Information
  present alarm: NONE
  T1 10 Error Log Information
  present alarm: NONE
  T1 11 Error Log Information
  present alarm: NONE
 .
 .
 .
```

.Cisco 7500 Series Routers

The following is partial output from the **showcontrollerst3** errors command from Cisco IOS Release 12.2(19c) for a T3 controller with a slot/bay/port of 1/4/1, displaying a history of all alarm events on all 28 T1 channels:

```
Router# show controllers t3 1/4/1 errors
  T3 1/4/1: Error Log Information
  present alarm: NONE
  Error: AIS
  17:28:08-17:29:18
  T1 1 Error Log Information
  present alarm: OOF
  Since 17:30:55
  Error: OOF
  17:30:09-17:30:46
  T1 2 Error Log Information
```

```
  present alarm: NONE
  T1 3 Error Log Information
  present alarm: NONE
  T1 4 Error Log Information
  present alarm: NONE
  T1 5 Error Log Information
  present alarm: NONE
  T1 6 Error Log Information
  present alarm: NONE
  T1 7 Error Log Information
  present alarm: NONE
.
.
.
```

The following is partial output from the **showcontrollerst3** errors command from Cisco IOS Release 12.2(19c) for a specific T1 controller of a T3 on a Cisco 7200 series router with a bay/port of 4/1, displaying the T1 1 alarm event of OOF:

```
Router# show controllers t3 4/1/1 errors
  T3 4/1: Error Log Information
  present alarm: NONE
  Error: AIS
  17:28:08-17:29:18
  T1 1 Error Log Information
  present alarm: OOF
  Since 17:30:55
  Error: OOF
  17:30:09-17:30:46
.
.
.
```

The table below describes the error field shown in the display.

*Table 85: **show controllers t3** Error Field Description*

Field	Description
AIS	alarm indication signal. In a T1 transmission, an all-ones signal transmitted in lieu of the normal signal to maintain transmission continuity and to indicate to the receiving terminal that there is a transmission fault that is located either at, or upstream from, the transmitting terminal.
RAI	remote alarm indication. Indicates a yellow alarm from the remote end of the T1 transmission.
OOF	out of frame. An OOF defect is detected when any three or more errors in sixteen or fewer consecutive F-bits occur.
LOS	loss of signal. A loss of signal occurs when n consecutive zeros is detected on an incoming signal.
NONE	No error is detected.

The following is partial output from the **showcontrollerst3** command from Cisco IOS Release 12.2(19c):

```
Router# show controllers t3 2/1/0
T3 2/1/0 is down.  Hardware is 2CT3 single wide port adapter
  CT3 H/W Version:0.2.2, CT3 ROM Version:1.0, CT3 F/W Version:2.5.1
  FREEDM version:1, reset 0 resurrect 0
```

```
  Applique type is Channelized T3
  Transmitter is sending remote alarm.
  Receiver has loss of signal.
  FEAC code received:No code is being received
  Framing is M23, Line Code is B3ZS, Clock Source is Internal
  Rx-error throttling on T1's ENABLED
  Rx throttle total 0, equipment customer loopback
  Data in current interval (545 seconds elapsed):
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs

The table below describes the fields shown in the display.

*Table 86: **show controllers t3** Field Descriptions--Cisco 7500 Series*

Field	Description
T3 3/0/0 is up	T3 controller in slot 3 is operating. The controller's state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).
CT3 H/W Version	Version number of the hardware.
CT3 ROM Version	Version number of the ROM.
CT3 F/W Version	Version number of the firmware.
Mx H/W version	Hardware version number of the HDLC controller chip.
Mx ucode ver	Microcode version of the HDLC controller chip.
Applique type	Controller type.
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.
MDL transmission	Status of the Maintenance Data Link (either enabled or disabled).

Field	Description
FEAC code received	Whether or not a far-end alarm code request is being received. Possible values are as follows: • DS3 Eqpt. Failure (SA) • DS3 LOS/HBER • DS3 Out-of-Frame • DS3 AIS Received • DS3 IDLE Received • DS3 Eqpt. Failure (NSA) • Common Eqpt. Failure (NSA) • Multiple DS1 LOS/HBER • DS1 Eqpt. Failure • Single DS1 LOS/HBER • DS1 Eqpt. Failure (NSA) • No code is being received
Framing	Framing type on the CT3IP. Values are M23, C-Bit, and Auto-detect.
Line Code	Line coding format on the CT3IP.
Clock Source	Clock source on the CT3IP. Values are internal or line.
RX-error throttling	Indicates that error throttling is enabled. The error throttling command disables the T1 level clock in order to stop receiving error data packets on a T1 controller. If any single interface receives a burst of errors over a short duration, such as 400 errors in 100 milliseconds, the T1 clock will be turned off for a period of 100 milliseconds.
RX throttles	The presence of the throttle count indicates that there are many input errors on lines. On the CT3 PA, the T1 is throttled when there are a number of input errors on an interface (400 errors in 100 milliseconds). The T1 is throttled even if one of the interfaces on it sees continuous errors. The 1-second periodic process checks for throttled interfaces and unthrottles them back.

Field	Description
BERT test result	BERT test information is available if the **t1bert** controller configuration command is enabled for the T1 channel on the CT3IP. The BERT results include the following information: • Test Pattern--Type of test pattern selected. • Status--Status of the test. • Sync Detected--Number of times the pattern synch is detected (that is, the number of times the pattern goes from No Sync to Sync). • Interval--Duration selected. • Tim Remain--Time remaining on the BERT test. • Bit Errors (Sync BERT Started)--Number of bit errors during the BERT test. • Bit Errors (Sync last Sync)--Number of bit errors since the last pattern sync was detected. • Bits Received--Total bits received. When the T1 channel has a BERT test running, the line state is DOWN. Also, when the BERT test is running and the Status field is Not Sync, the information in the total bit errors field is not valid. When the BERT test is done, the Status field is not relevant.
Data in current interval (39 seconds elapsed)	Shows the current accumulation period, which rolls into the 24-hour accumulation every 15 minutes. Accumulation period is from 1 to 900 seconds. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Line Code Violations (LCVs) is a count of both Bipolar Violations (BPVs) and Excessive Zeros (EXZs) that occur over the accumulation period. An EXZ increments the LCV by one regardless of the length of the zero string.
P-bit Coding Violation	For all DS3 applications, a P-bit coding violation (PCV) error event is a P-bit parity error event. A P-bit parity error event is the occurrence of a received P-bit code on the DS3 M-frame that is not identical to the corresponding locally calculated code.
C-bit Coding Violation	For C-bit parity and SYNTRAN DS3 applications, the C-bit coding violation (CCV) is the count of coding violations reported via the C-bits. For C-bit parity, it is the count of CP-bit parity errors that occur during the accumulation interval. For SYNTRAN, it is a count of CRC-9 errors that occur during the accumulation interval.
P-bit Err Secs	P-bit errored seconds (PES) is a second with one or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.

Field	Description
P-bit Severely Err Secs	P-bit severely errored seconds (PSES) is a second with 44 or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
Severely Err Framing Secs	Severely errored framing seconds (SEFS) is a second with one or more out-of-frame defects or a detected incoming AIS.
Unavailable Secs	The number of unavailable seconds (UAS) is calculated by counting the number of seconds for which the interface is unavailable. For more information, refer to RFC 1407, *DS3 MIB Variables* .
Line Errored Secs	Line errored seconds (LES) is a second in which one or more code violations or one or more LOS defects occurred.
C-bit Errored Secs	C-bit errored seconds (CES) is a second with one or more C-bit code violations (CCV), one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted.
C-bit Severely Errored Secs	C-bit severely errored seconds (CSES) is a second with 44 or more CCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted.
Total Data (last 1 15 minute intervals)	Shows the last 15-minute accumulation period.
T1 1 is up	T1 channel is operating. The channel's state can be up, down, or administratively down. Loopback conditions are shown by (Locally Looped) or (Remotely Looped).
speed	Speed of the T1 channel, in kbps.
non-inverted data	Indicates if the T1 channel is configured for inverted data.
timeslots	Time slots assigned to the T1 channel.
FDL per ANSI T1.403 and AT&T 54016 spec.	Performance monitoring is via Facility Data Link per ANSI T1.403 and AT&T standard specification number 54016.
No alarms detected	Any alarms detected by the T1 controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending AIS. • Receiver has loss of signal. • Receiver is getting AIS. • Receiver has loss of frame. • Receiver has remote alarm. • Receiver has no alarms.

Field	Description
Framing	Type of framing used on the T1 channel. Values are ESF or SF.
Line Code	Type of line coding used on the T1 channel. Values are B8ZS or AMI.
Clock Source	Clock source on the T1 channel. Values are internal or line.
Path Code Violations	Path coding violation (PCV) error event is a frame synchronization bit error in the D4 and E1-no-CRC formats or a CRC error in the ESF and E1-CRC formats.
Slip Secs	Controlled slip second (CSS) is a 1-second interval that contains one or more controlled slips.
Fr Loss Secs	Frame loss seconds (SELS) is the number of seconds for which an out-of-frame error is detected.
Line Err Secs	Line errored seconds (LES) is a second in which one or more line code violation errors are detected.
Degraded Mins	Degraded minute (DM) is a minute in which the estimated error rate exceeds 1E-6 but does not exceed 1E-3. For more information, refer to RFC 1406, *Definitions of Managed Objects for DS1 and E1 Interface Types* .
Errored Secs	Errored seconds (ES) is a second with one or more path coding violations, one or more out-of-frame defects, or one or more controlled slip events or a detected AIS defect.
Bursty Err Secs	Bursty errored seconds (BES) is a second with fewer than 320 and more than one path coding violation error events, no severely errored frame defects, and no detected incoming AIS defects. Controlled slips are not included in this parameter.
Severely Err Secs	Severely errored seconds (SES) is a second with 320 or more path code violation errors events, one or more out-of-frame defects, or a detected AIS defect.
Unavailable Secs	Number of seconds during which the interface was not available in this interval. Referred to as UAS.
Stuffed Secs	Stuffed seconds (SS) is a second in which one more bit stuffings take place. This happens when the Pulse Density Enforcer detects a potential violation in the output stream and inserts a 1 to prevent it. Such bit stuffings corrupt user data and indicate that the network is configured incorrectly. This counter can be used to help diagnose this situation.

Cisco AS5800 Access Servers

The following example shows the summary status of the T3 controller located in shelf 1, slot 4, port 0:

```
Router# show controllers t3 1/4/0 brief
T3 1/4/0 is up.
 Applique type is Channelized T3
```

```
 No alarms detected.
 MDL transmission is disabled

 FEAC code received: Multiple DS1 LOS/HBER
 Framing is C-BIT Parity, Line Code is B3ZS, Clock Source is Line.
 Data in current interval (491 seconds elapsed):
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Total Data (last 80 15 minute intervals):
     3 Line Code Violations, 4 P-bit Coding Violation,
     2 C-bit Coding Violation, 0 P-bit Err Secs,
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs,
     2 Unavailable Secs, 0 Line Errored Secs,
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
```

The following example shows the detailed status of the T3 controller connected to the Cisco AS5800 in shelf 1, slot 4, port 0. Notice that the detailed information shows the last eighty-six 15-minute time periods.

```
Router# show controllers t3 1/4/0
T3 1/4/0 is up.
 Applique type is Channelized T3
 No alarms detected.
 MDL transmission is disabled

 FEAC code received: Multiple DS1 LOS/HBER
 Framing is C-BIT Parity, Line Code is B3ZS, Clock Source is Line.
 Data in current interval (91 seconds elapsed):
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Data in Interval 1:
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Data in Interval 2:
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Data in Interval 3:
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Data in Interval 4:
     0 Line Code Violations, 0 P-bit Coding Violation
     0 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
.
.
.
```

```
Data in Interval 86:
     3 Line Code Violations, 4 P-bit Coding Violation
     2 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     2 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
 Total Data (last 86 15 minute intervals):
     3 Line Code Violations, 4 P-bit Coding Violation,
     2 C-bit Coding Violation, 0 P-bit Err Secs,
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs,
     2 Unavailable Secs, 0 Line Errored Secs,
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
```

The table below describes the fields shown in the display.

Table 87: show controllers t3 Field Descriptions--Cisco AS5800

Field	Description
T3 1/4/0 is up	T3 controller connected to this Cisco AS5800 access server in shelf 1, slot 4, port 0 is up. The controller's state can be up, down, or administratively down. Loopback conditions are shown by Locally Looped or Remotely Looped.
Applique type	Describes the type of controller.
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Transmitter is sending remote alarm. • Transmitter is sending alarm indication signal (AIS). • Receiver has loss of signal (LOS). • Receiver is getting AIS. • Receiver has loss of frame (LOF). • Receiver has remote alarm. • Receiver has no alarms.
MDL transmission	Maintenance Data Link status (either enabled or disabled). Used for carrying performance information and control signals across the network toward the far-end T3 unit. It is the counterpart of Facility Data Link (FDL) in a T1 link.

Field	Description
FEAC code received	Whether or not a far-end alarm code request is being received. Possible values are as follows: • DS3 Eqpt. Failure (SA) • DS3 LOS/HBER • DS3 Out-of-Frame • DS3 AIS Received • DS3 IDLE Received • DS3 Eqpt. Failure (NSA) • Common Eqpt. Failure (NSA) • Multiple DS1 LOS/HBER • DS1 Eqpt. Failure • Single DS1 LOS/HBER • DS1 Eqpt. Failure (NSA) • No code is being received
Framing	Standard T3 framing type: M23, C-Bit, or Auto-detect.
Line Code	Standard T3 line-coding format. In this example, the line-coding format is bipolar 3-zero substitution (B3ZS).
Clock Source	The source of the synchronization signal (clock): line or internal. In this example, the line is providing the clock signal.
Data in current interval (... seconds elapsed)	Summary statistics for T3 signal quality for the current time interval of 900 seconds (15 minutes). In this example, the statistics are for current partial interval. Statistics roll into the 24-hour accumulation buffer every 15 minutes. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Count of both Bipolar Violations (BPVs) and Excessive Zeros (EXZs) that occur over the accumulation period. An EXZ increments the Line Code Violations (LCVs) by one regardless of the length of the zero string.
P-bit Coding Violation	P-bit parity error event. A P-bit parity error event is the occurrence of a received P-bit code on the DS3 M-frame that is not identical to the corresponding locally calculated code. Referred to as PCV.
C-bit Coding Violation	Count of coding violations reported via the C-bits. For C-bit parity, it is the count of CP-bit parity errors that occur during the accumulation interval. Referred to as CCV.

Field	Description
P-bit Err Secs	Number of seconds with one or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
P-bit Severely Err Secs	Number of seconds with 44 or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
Severely Err Framing Secs	Number of a seconds with one or more out-of-frame defects or a detected incoming AIS.
Unavailable Secs	Number of seconds during which the interface was not available in this interval. Referred to as UAS.
Line Errored Secs	Number of seconds in this interval during which one or more code violations or one or more LOS defects occurred. Referred to as LES.
C-bit Errored Secs	Number of seconds with one or more C-bit code violations (CCV), one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted. Referred to as CES.
C-bit Severely Errored Secs	Number of seconds with 44 or more CCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted.
Total Data (last ... 15 minute intervals)	Summary statistics for T3 signal quality for 15-minute intervals. Every 24 hours (96 intervals) the counters in this data block clear.

Cisco 10000 Series Router Examples

The following examples from the show controller t3 command show the information that displays when the router is running Cisco IOS Release 12.2(33)SB and Cisco IOS Release 12.2(31)SB:

Cisco IOS Release 12.2(33)SB --No Line Code Information (CHSTM1 and 1CHOC12 Cards)

```
Router# show controllers t3 2/0/0.1
T3 2/0/0.1 is up. Hardware is C10K CHSTM1 line card
Applique type is Channelized T3
Controller is in channelized mode
No alarms detected.
MDL transmission is disabled
FEAC code received: No code is being received
Framing is C-BIT Parity (Detected), Clock Source is Internal
equipment customer loopback
Data in current interval (155 seconds elapsed):
290738 P-bit Coding Violation
290736 C-bit Coding Violation, 0 P-bit Err Secs
0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
34 Unavailable Secs, 0 Line Errored Secs
0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
31 AIS Defect Secs, 0 FERF Defect Secs
```

```
1 Near-end path failures, 0 Far-end path failures
0 CP-bit Far-End Unavailable Secs, 107 Far-End Coding Violations
2 Far-End Errored Secs, 1 Far-End Severely Errored Secs
```

Cisco IOS Release 12.2(31)SB --Line Code Information (CHSTM1 and 1CHOC12 Cards)

```
Router# show controllers t3 2/0/0.1
T3 2/0/0.1 is up. Hardware is C10K CHSTM1 line card
Applique type is Channelized T3
Controller is in channelized mode
No alarms detected.
MDL transmission is disabled
FEAC code received: No code is being received
Framing is C-BIT Parity (Detected), Clock Source is Internal
equipment customer loopback
Data in current interval (155 seconds elapsed):
290738 P-bit Coding Violation
290736 C-bit Coding Violation, 0 P-bit Err Secs
0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
34 Unavailable Secs, 0 Line Errored Secs
0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
```

Cisco IOS Release 12.2(33)SB3-- CHSTM1 and 1CHOC12 Cards

```
Router# show controllers t3 2/0/0.1
T3 2/0/0.1 is up.  Hardware is C10K CHSTM1 line card
  Applique type is Channelized T3
  Controller is in channelized mode
  No alarms detected.
  MDL transmission is disabled

  FEAC code received: No code is being received
  Framing is C-BIT Parity (Detected), Clock Source is Internal
  equipment customer loopback
  Data in current interval (155 seconds elapsed):
     290738 P-bit Coding Violation
     290736 C-bit Coding Violation, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     34 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
     31 AIS Defect Secs, 0 FERF Defect Secs
     1 Near-end path failures, 0 Far-end path failures
     0 CP-bit Far-End Unavailable Secs, 107 Far-End Coding Violations
     2 Far-End Errored Secs, 1 Far-End Severely Errored Secs
```

Cisco IOS Release 12.2(33)SB3 --4HHCT3 and 6CHT3 Cards

```
Router# show controllers t3 8/0/0
T3 8/0/0 is down.  Hardware is C10K Half Height CT3 line card
  Applique type is Channelized T3
  Controller is in channelized mode
  Receiver has loss of signal.
  MDL transmission is disabled

  FEAC code received: No code is being received
  Framing is C-BIT Parity (Configured)
```

```
Line Code is B3ZS, Clock Source is Internal
equipment customer loopback
Data in current interval (617 seconds elapsed):
   6120 Line Code Violations, 0 P-bit Coding Violation
   0 C-bit Coding Violation, 0 P-bit Err Secs
   0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
   25 Unavailable Secs, 0 Line Errored Secs
   0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
   0 AIS Defect Secs, 25 LOS Defect Secs
   1 Near-end path failures
   0 Far-end path failures, 0 FERF Defect Secs
   24 CP-bit Far-End Unavailable Secs, 4771 Far-End Coding Violations
   0 Far-End Errored Secs, 0 Far-End Severely Errored Secs
```

The table below describes the significant fields shown in the display.

Table 88: show controllers t3 Field Descriptions--Cisco 10000 series router

Field	Description
AIS	Alarm indication signal.
T3 2/0/0.1 is up	T3 controller connected to this Cisco 10000 series router in shelf 2, slot 0, port 0.1 is up. The controller's state can be up, down, or administratively down. Loopback conditions are shown by Locally Looped or Remotely Looped.
T3 8/0/0 is down	T3 controller connected to this Cisco 10000 series router in shelf 8, slot 0, port 0 is down. The controller's state can be up, down, or administratively down. Loopback conditions are shown by Locally Looped or Remotely Looped.
Applique type	Describes the type of controller.
No alarms detected	Any alarms detected by the controller are displayed here. Possible alarms are as follows: • Receiver has loss of frame (LOF). • Receiver has loss of signal (LOS). • Receiver has no alarms. • Receiver has remote alarm. • Receiver is getting AIS. • Transmitter is sending alarm indication signal (AIS). • Transmitter is sending remote alarm.
MDL transmission	Maintenance Data Link status (either enabled or disabled). Used for carrying performance information and control signals across the network toward the far-end T3 unit. It is the counterpart of Facility Data Link (FDL) in a T1 link.

Field	Description
FEAC code received	Whether a far-end alarm code request is being received. Possible values are as follows: • Common Eqpt. Failure (NSA) • DS1 Eqpt. Failure (NSA) • DS1 Eqpt. Failure • DS3 AIS Received • DS3 Eqpt. Failure (NSA) • DS3 Eqpt. Failure (SA) • DS3 IDLE Received • DS3 LOS/HBER • DS3 Out-of-Frame • Multiple DS1 LOS/HBER • No code is being received • Single DS1 LOS/HBER
Framing	Standard T3 framing type: M23, C-bit, or Auto-detect.
Line Code	Standard T3 line-coding format. In this example, the line-coding format is bipolar 3-zero substitution (B3ZS).
Clock Source	The source of the synchronization signal (clock): Line or Internal. In this example, the line is providing the clock signal.
Data in current interval (617 seconds elapsed)	Summary statistics for T3 signal quality for the current time interval of 900 seconds (15 minutes). In this example, the statistics are for current partial interval. Statistics roll into the 24-hour accumulation buffer every 15 minutes. The oldest 15-minute period falls off the back of the 24-hour accumulation buffer.
Line Code Violations	Count of both Bipolar Violations (BPVs) and Excessive Zeros (EXZs) that occur over the accumulation period. An EXZ increments the line code violations (LCVs) by one, regardless of the length of the zero string.
P-bit Coding Violation	P-bit parity error event. A P-bit parity error event is the occurrence of a received P-bit code on the DS3 M-frame that is not identical to the corresponding locally calculated code. Referred to as PCV.
C-bit Coding Violation	Count of coding violations reported via the C-bits. For C-bit parity, it is the count of CP-bit parity errors that occur during the accumulation interval. Referred to as CCV.
P-bit Err Secs	Number of seconds with one or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.

Field	Description
P-bit Severely Err Secs	Number of seconds with 44 or more PCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when unavailable seconds are counted.
Severely Err Framing Secs	Number of a seconds with one or more out-of-frame defects or a detected incoming AIS.
Unavailable Secs	Number of seconds during which the interface was not available in this interval. Referred to as UAS.
Line Errored Secs	Number of seconds in this interval during which one or more code violations or one or more LOS defects occurred. Referred to as LES.
C-bit Errored Secs	Number of seconds with one or more C-bit code violations (CCV), one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted. Referred to as CES.
C-bit Severely Errored Secs	Number of seconds with 44 or more CCVs, one or more out-of-frame defects, or a detected incoming AIS. This gauge is not incremented when UASs are counted.

Series Router

The following is a sample output from the **show controllers t3** command on the Cisco series routers:

```
Router# show controllers t3 0/4/40
T3 0/4/40 is up.
Hardware is -48T3E3-CE
Applique type is Clear Channel T3
No alarms detected.
MDL transmission is disabled
FEAC code received: No code is being received
Framing is C-BIT Parity, Line Code is B3ZS, Cablelength Short less than 225ft
BER thresholds: SF = 10e-10 SD = 10e-10
Clock Source is internal
Equipment customer loopback
Data in current interval (240 seconds elapsed):
  Near End
     0 Line Code Violations, 0 P-bit Coding Violations
     0 C-bit Coding Violations, 0 P-bit Err Secs
     0 P-bit Severely Err Secs, 0 Severely Err Framing Secs
     0 Unavailable Secs, 0 Line Errored Secs
     0 C-bit Errored Secs, 0 C-bit Severely Errored Secs
     0 Severely Errored Line Secs, 0 Path Failures
     0 AIS Defect Secs, 0 LOS Defect Secs
   Far End
     0 Errored Secs, 0 Severely Errored Secs

show controllers t3 bert

To display BER test statistics, use the show controllers t3 bert command in user EXEC or privileged EXEC mode.

show controllers t3 *slot/subslot/port* [/*t1-number*] **bert**

Syntax Description

slot	Chassis line card slot number.
subslot	Chassis line card subslot number.
port	Interface number on the line card.
t1-number	(Optional) Logical T1 interface number.
bert	Displays BER test statistics.

Command Modes

User EXEC

Privileged EXEC

Command History

Release	Modification
12.2(28)SB	This command was introduced on the Cisco 10000 series routers.

Examples

The following example shows BER test statistics for an unchannelized T3 interface:

```
Router# show controllers t3 6/1/0 bert

T3 6/1/0 is up.
BERT test result (done)
Test Pattern : 2^15, Status : Not Sync, Sync Detected : 1
Interval : 5 minute(s), Time Remain : 0 minute(s)
Bit Errors (since BERT started): 0 bits,
Bits Received (since BERT started): 13025 Mbits
Bit Errors (since last sync): 0 bits
Bits Received (since last sync): 13025 Mbits
```

The following example shows BER test statistics for a channelized T3 interface:

```
Router# show controllers t3 6/1/0 bert

T3 6/1/0 is up.
BERT test result (running)
Test Pattern : 2^15, Status : Sync, Sync Detected : 1
Interval : 3 minute(s), Time Remain : 1 minute(s)
Bit Errors (since BERT started): 0 bits,
Bits Received (since BERT started): 5493 Mbits
Bit Errors (since last sync): 0 bits
Bits Received (since last sync): 5493 Mbits
```

The following example shows BER test statistics for a T1 interface:

```
Router# show controllers t3 6/1/1/1 bert

T3 6/1/1/1 is up. Hardware is C10K Half Height CT3 line card
T1 1
BERT test result (running)
Test Pattern : 2^15, Status : Sync, Sync Detected : 1
Interval : 5 minute(s), Time Remain : 5 minute(s)
Bit Errors (since BERT started): 0 bits,
Bits Received (since BERT started): 36 Mbits
Bit Errors (since last sync): 0 bits
Bits Received (since last sync): 36 Mbits
```

Related Commands

Command	Description
bert	Configures a BER test for an unchannelized or channelized T3 interface.
t1 bert pattern	Configures a BER test for a T1 interface.

show controllers token

To display information about memory management and error counters on the Token Ring Interface Processor (TRIP) for the Cisco 7500 series routers, use the **showcontrollerstoken** command in privileged EXEC mode.

show controllers token

Syntax Description

This command has no arguments or keywords.

Command Modes

Privileged EXEC

Command History

Release	Modification
10.0	This command was introduced.
11.3(3)T	The information was modified to include the PA-4R-FDX full-duplex Token Ring port adapter.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

Depending on the card being used, the output can vary. This command also displays information that is proprietary to Cisco Systems. Thus, the information that the **showcontrollerstoken** command displays is of primary use to Cisco technical personnel. Information that is useful to users can be obtained with the **showinterfacestokenring** command, which is described later in this chapter.

Examples

The following is sample output for the PA-4R-DTR from the **showcontrollerstoken**command. In this example, the current operating mode is classic Token Ring station.

```
Router# show controllers token
Interface TokenRing4/0 state: up
  Data from IDB:
    Current MAC address: 0008.2a36.1a04, Burned in MAC address: 0008.2a36.1a04
    Group address: 80000000
    Functional address: 08000000, enables: CDP
    Ring mode: 0000, enables:
  Last Ring Status: none
    Stats: soft: 0/0, hard: 0/0, sig loss: 0/0, throttle: 0/0

Table 89: show controllers token Field Descriptions

Field	Description
Tokenring4/0	Interface processor type, slot, and port.

Field	Description
Last Ring Status	Last abnormal ring condition. Can be any of the following: • Signal Loss • HW Removal • Remote Removal • Counter Overflow • Only station • Ring Recovery
Current operating mode	Operating mode. Can be one of the following: • Classic token ring station (standard half-duplex Token Ring station) • DTR station (full-duplex Token Ring station) • DTR concentrator (concentrator port)
MAC state	The MAC state indicates the state of the Token Ring MAC layer protocol. Can be one of the following: • Not inserted (not connected to any ring) • Inserting (currently entering a ring) • Inserted (connected to an active Token ring)

Related Commands

Command	Description
show interfaces tokenring	Displays information about the Token Ring interface and the state of source-route bridging.
show source-bridge	Displays the current source bridge configuration and miscellaneous statistics.

show controllers vg-anylan

To display the controller information for the 100VG-AnyLAN port adapter on Cisco 7200 series routers and Cisco 7500 series routers, use the **showcontrollersvg-anylan** command in user EXEC or privileged EXEC mode.

Cisco 7200 Series
show controllers vg-anylan *slot/port*

Cisco 7500 Series with VIP Cards
show controllers vg-anylan *slot/port-adapter/port*

Syntax Description

slot	Slot number. Refer to the appropriate hardware manual for slot and port information.
/ *port*	Port number. Refer to the appropriate hardware manual for slot and port information.
/ *port-adapter*	Port adapter number. Refer to the appropriate hardware manual for information about port adapter compatibility.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
11.3	This command was introduced.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.

Usage Guidelines

The information displayed is generally useful for diagnostic tasks performed by technical support personnel only.

Examples

The following is sample output from the **showcontrollersvg-anylan** command:

```
Router# show controllers vg-anylan 3/0
Interface VG-AnyLAN3/0
Hardware is MC68852

show controllers wanphy

T o display the SPA mode (LAN mode or WAN mode), alarms, and the J1 byte string value, use the **showcontrollerswanphy**commandin Privileged EXEC mode.

show controllers wanphy *slot*/*subslot*/*port*

Syntax Description

slot	The SIP slot number in which the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter has been installed.
subslot	The subslot number in which the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter has been installed.
port	The port number of the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter. **Note** There is only 1 port (0) in the Cisco 1-Port 10 Gigabit Ethernet LAN/WAN-PHY Shared Port Adapter.

Command Default

No default values are available.

Command Modes

Privileged EXEC Mode (EXEC)

Command History

Release	Modification
Cisco IOS XE Release 3.3.0S	This command was introduced on the Cisco ASR 1000 Series Routers.

Usage Guidelines

The **showcontrollerwanphy**command has been introduced on the Cisco ASR 1000 Series Router in Cisco IOS XE Release 3.3.0S. This command is used to display:

- LAN or WAN mode of operation in which the SPA is currently working
- Configured alarms and active alarms (if any)
- Remote J1 byte string value passed to check the connectivity from local SPA to the remote SPA
- SF-BER and SD-BER threshold values

Examples

The following example shows the output of **showcontrollerswanphy** command:

```
Router# show controllers wanphy 0/1/0
TenGigabitEthernet0/1/0
Mode of Operation: WAN Mode
SECTION

TCA thresholds:  B1 = 10e-6  B2 = 10e-6  B3 = 10e-6
```

Related Commands

Command	Description
clear controller wanphy	Clears the counter of alarms generated, and resets it back to zero.

show controllers wlan-controller

To show the Cisco Wireless Local Area Network (WLAN) controller network module on the router, use the **showcontrollerswlan-controller** command in privileged EXEC mode.

show controllers wlan-controller slot/unit

Syntax Description

slot/unit	Specifies the router slot and unit numbers for the WLAN controller network module.

Command Default

None

Command Modes

Privileged EXEC

Command History

Release	Modification
12.4(2)XA1	This command was introduced on the router software.
12.4(6)T	This command was integrated into Cisco IOS Release 12.4(6)T.

Examples

The following example shows how to display interface information for the WLAN controller network module:

```
Router# show controllers wlan-controllers 1/0
Interface wlan-controller1/0
Hardware is Intel 82559 FastEthernet

show counters interface

To display the information about the interface counter, use the **showcountersinterface** command in user EXEC or privileged EXEC mode.

show counters interface *type mod/port* [**delta**]

Syntax Description

type	Interface type; possible valid values are **ethernet**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **port-channel**, **pos**, **atm**, **null**, **tunnel**, and **ge-wan**
mod / port	Module and port number.
delta	(Optional) Displays the interface counters values since the last **clearcounters** command.

Command Default

This command has no default settings.

Command Modes

User EXEC Privileged EXEC

Command History

Release	Modification
12.2(14)SX	Support for this command was introduced on the Supervisor Engine 720.
12.2(17d)SXB	Support for this command on the Supervisor Engine 2 was extended to Release 12.2(17d)SXB.
12.2(18)SXE	This command was changed to support the **delta** keyword on the Supervisor Engine 720 only.
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.

Usage Guidelines

The **showcountersinterface** command is not supported on SVIs.

The **showcountersinterfacedelta**command displays a detailed list of the last-saved counter values.

Examples

This example shows how to display the information about the interface counter:

```
Router# show counters interface fastethernet 5/2
64 bit counters:
 0.                      rxHCTotalPkts = 1
 1.                      txHCTotalPkts = 1

68.                          maxIndex = 0
Router#
```

This example shows how to display the values for the interface counters since the last **clearcounters** command:

```
Router# show counters interface gigabitethernet 5/2 delta

Time since last clear
---------------------
1d08h
64 bit counters:
0. rxHCTotalPkts = 508473
1. txHCTotalPkts = 2366
2. rxHCUnicastPkts = 411611
3. txHCUnicastPkts = 193
4. rxHCMulticastPkts = 81868
5. txHCMulticastPkts = 2155
6. rxHCBroadcastPkts = 14994
7. txHCBroadcastPkts = 18
8. rxHCOctets = 36961992
.
.
.
Router#
```

Related Commands

Command	Description
clear counters	Clears the interface counters.

show diag

To display hardware and diagnostic information for a networking device, line card, processor, jacket card, chassis, or network module, use the **show diag** command in privileged EXEC mode.

show diag [*slot-number*] [{**details** | **summary**}]

Cisco 7304 Router
show diag [{*slot-number* | **chassis** | **subslot** *slot/subslot*}] [{**details** | **summary**}]

Shared Port Adapters
show diag [**subslot** *slot/subslot*] [{**details** | **summary**}]

Network Module
show diag [*slot-number*]

Cisco 10000 Series Router
show diag [*slot/subslot*] [{**details** | **summary**}] [**crashdump**]

Cisco uBR10012 Universal Broadband Router
show diag [{*slot/subslot* | *slot/subslot/port* | **summary**}]

Cisco uBR7225VXR and Cisco uBR7246VXR Universal Broadband Routers
show diag *slot*

Cisco ASR 1000 Series Aggregation Services Routers
show diag [{**all** | **chassis** | **slot** | **subslot**}] **eeprom**

Cisco 4400 Series Integrated Services Router
show diag [{**all** | **chassis** | **slot** | **subslot**}] **eeprom**

Syntax Description

slot-number	(Optional) Slot number of the interface. If a slot number is not specified, diagnostic information for all slots is displayed.
details	(Optional) Displays more details than the normal **show diag** output.
summary	(Optional) Displays a summary (one line per slot) of the chassis.
chassis	(Optional) Specifies the display of diagnostic information about the backplane, power supplies, and fan modules.

subslot *slot* / *subslot*	(Optional) **Shared Port Adapters** Specifies the display of diagnostic information about the shared port adapter (SPA), where: • *slot* --Chassis slot number. See the appropriate hardware manual for slot information. For SPA interface processor (SIP), refer to the platform-specific SPA hardware installation guide or the corresponding “Identifying Slots and Subslots for SIPs and SPAs” topic in the platform-specific SPA software configuration guide. • *subslot* --Secondary slot number on a SIP where a SPA is installed. See the platform-specific SPA hardware installation guide and the corresponding “Specifying the Interface Address on a SPA” topic in the platform-specific SPA software configuration guide for subslot information. (Optional) Specifies subslot location information for the connected network modules and interfaces.
slot / *subslot/port*	(Optional) **Cisco uBR10012 Universal Broadband Router** Displays diagnostic information about the specified line card, where: • *slot* --Slot number of the line card in the uBR10012 router. The range is 0 to 8. • *subslot* --Subslot of the half-height line card in the uBR10012 router. The value t is either 0 or 1. • *port* --Port number on the cable interface. Valid values are 0 to 4 (depending on the cable interface).
slot	(Optional) **Cisco uBR7225VXR and Cisco uBR7246VXR Universal Broadband Routers** Displays diagnostic information about the specified line card, where: • *slot* --Slot number of the line card in the Cisco uBR7225VXR or Cisco uBR7246VXR router. Cisco uBR7246VXR router: The range is 3 to 6. Cisco uBR7225VXR router: The range is 1 to 2.
all	(Optional) Displays all diagnostic information related to EEPROM.

Command Modes

Privileged EXEC (#)

Command History

Release	Modification
11.1CA	This command was introduced.
11.2	This command was integrated into Cisco IOS Release 11.2.

Release	Modification
11.2P	This command output was modified for the PA-12E/2FE port adapter, PA-E3 port adapter, and PA-T3 port adapter.
11.2GS	This command was implemented on the Cisco 12000 series Internet router.
11.3 XA	This command was integrated in Cisco IOS Release 11.3 XA.
12.0	This command was implemented on the Cisco AS5300.
12.0(5)XQ	This command was implemented on the Cisco 1750 router.
12.0(7)T	This command was integrated into Cisco IOS Release 12.0(7)T.
12.1(9)EX	This command was introduced on the Cisco 7300 series routers, and the *slot-number* argument and **chassis** keyword were added.
12.1(10)EX	This command was enhanced to display information about Field-Programmable Gate Array (FPGA) image versions on installed NSEs and line cards on Cisco 7304 routers.
12.2(11)YZ	Support was added for the 7300-CC-PA.
12.2(8)T	This command was implemented for AIC and WIC cards on the Cisco 2600 series routers and the Cisco 3600 series routers.
12.2(13)T	This command was implemented for the AIM-VPN/EPII and AIM-VPN/HPII cards on the Cisco 2691, Cisco 3660, Cisco 3725, and Cisco 3745 routers.
12.2(15)ZJ	This command was implemented for the AIM-VPN/BPII card on the Cisco 2610XM, Cisco 2611XM, Cisco 2620XM, Cisco 2621XM, Cisco 2650XM, and Cisco 2651XM routers.
12.2(18)S	This command was integrated into Cisco IOS Release 12.2(18)S and implemented on the Cisco 7304 router.
12.3(4)T	Support for the AIM-VPN/BPII card on the Cisco 2600XM series was integrated into Cisco IOS Release 12.3(4)T.
12.2(20)S2	This command was integrated into Cisco IOS Release 12.2(20)S2 and the **subslot***slotsubslot*keyword and arguments were added to support SPAs on the Cisco 7304 router.
12.0(31)S	This command was integrated into Cisco IOS Release 12.0(31)S and the **subslot***slotsubslot*keyword and arguments were added to support SIPs and SPAs on the Cisco 12000 series Internet router.
12.4(4)T	This command was implemented for the HWIC-1ADSL and HWIC-1ADSLI interface cards on the following platforms: Cisco 1800 (modular) series, Cisco 2800 series, and Cisco 3800 series routers.
12.4(9)T	This command was implemented for the NME-AON-K9= enhanced network module on the following platforms: Cisco 2811, Cisco 2821, Cisco 2851, Cisco 3725, and Cisco 3745 routers.

Release	Modification
12.2(33)SRA	This command was integrated into Cisco IOS Release 12.2(33)SRA.
12.2SX	This command is supported in the Cisco IOS Release 12.2SX train. Support in a specific 12.2SX release of this train depends on your feature set, platform, and platform hardware.
12.2(33)SB	This command was enhanced with a crashdump option to enable you to display crashdump files collected on the SIP. This was implemented on the Cisco 10000 series router for the PRE3 and PRE4.
12.2(33)SCC	The output for this command was modified to display the diagnostic mode for the Cisco uBR10-MC5X20H cable interface line card on the uBR10012 router, when the field diagnostic image is loaded.
12.2(33)SCD	This command was modified. Support was added for the Cisco uBR7225VXR and Cisco uBR7246VXR routers.
12.2(33)XNE	This command was modified. The **all** keyword was added.
12.2(33)SCG	This command was modified. The output was modified to display all hardware and EEPROM information, including PID and PCB information for the Cisco uBR10-MC5X20H cable interface line card on the Cisco uBR10012 router.
IOS XE 3.9S	This command was integrated into Cisco IOS XE Release 3.9S.

Usage Guidelines

Use this command to determine the type of hardware installed in your router and to show detailed hardware information and EEPROM version information.

This command displays information for the motherboard, WAN interface cards (WICs), voice interface cards (VICs), high-speed WICs (HWICs), ATM interface cards (AICs), advanced integration modules (AIMs), port adapters, shared port adapters (SPAs), modular services cards (MSCs), SPA interface processors (SIPs), and enhanced network modules (NME).

For the Cisco 7304 router, this command applies to NEs, line cards, MSCs, and SPAs.

- To display hardware information for an NSE, line card, or MSC in the specified slot, use the *slot-number*argument. For MSCs, using this argument displays information about the MSC and each of its installed SPAs.
- To display hardware information about the backplane, power supplies, and fan modules, use the **chassis** keyword.

Shared Port Adapter Usage Guidelines

- To display hardware information for an MSC or SIP only in a specified slot, use the *slot-number*argument.
- To display hardware information for a SPA only, use the **show diag subslot***slot*/*subslot*version of this command.

Cisco 10000 Series Router Usage Guidelines

The **crashdump** keyword of the **show diag** command enables you to display any crashdump files collected on the SIP. The SIP stores the crashdump files by a reference number from 1 to 60.

To view a crashdump file, do the following:

1. Determine the most recent crashdump number:
   a. Enter the show diag slot/subslot command.
   b. Look for the latest crashdump number in the following section of the command output:

```
Number of crashdumps : output number
```

   c. Enter the following command to view the crashdump file:

```
show diag slot/subslot crashdump number
```

Note The subslot value is always zero for the SIP.

Cisco uBR10012 Router Usage Guidelines

- In the command syntax, the argument *slot/subslot* refers to a half-height line-card on the Cisco uBR10012 Router.
- This command applies to all cable interface line cards. The output for this command additionally displays the diagnostic mode when the Cisco uBR10-MC5X20H line card is enabled with the Field Diagnostic image.

Examples

1-Port T3 Serial Port Adapter: Example

The following is a sample output from the **show diag** command for a 1-port T3 serial port adapter in chassis slot 1 on a Cisco 7200 series router:

```
Router# show diag 1

Slot 1:
        Physical slot 1, ~physical slot 0xE, logical slot 1, CBus 0
        Microcode Status 0x4
        Master Enable, LED, WCS Loaded
        Board is analyzed
        Pending I/O Status: None
        EEPROM format version 1
        VIP2 controller, HW rev 2.4, board revision D0
        Serial number: 04372053  Part number: 73-1684-03
        Test history: 0x00        RMA number: 00-00-00
        Flags: cisco 7000 board; 7500 compatible

        EEPROM contents (hex):
          0x20: 01 15 02 04 00 42 B6 55 49 06 94 03 00 00 00 00

The table below describes significant fields shown in the display.

Table 90: show diag (AIC) Field Descriptions

Field	Description
C2611 2E Mainboard Port adapter, 2 ports	Line card type; number of ports available.
Port adapter is analyzed	The system has identified the port adapter.
Port adapter insertion time	Elapsed time since insertion.
Hardware Revision	Version number of the port adapter.
PCB Serial Number	Serial number of the printed circuit board.
Part Number	Part number of the port adapter.

Field	Description
RMA History	Counter that indicates how many times the port adapter has been returned and repaired.
RMA Number	Return material authorization number, which is an administrative number assigned if the port adapter needs to be returned for repair.
Board Revision	Revision number (signifying a minor revision) of the port adapter.
Deviation Number	Revision number (signifying a minor deviation) of the port adapter.
EEPROM format version	Version number of the EEPROM format.
EEPROM contents (hex)	Dumps of EEPROM programmed data.

AIM-VPN in a Cisco 2611XM: Example

The following example shows how to obtain hardware information about an installed AIM-VPN on the Cisco 2611XM router.

Router# **show diag 0**

Encryption AIM 1:

Shared Port Adapters on the Cisco 7304 Router: Example

The following is a sample output from the **show diag subslot** command for a 4-Port 10/100 Fast Ethernet SPA located in the bottom subslot (1) of the MSC that is installed in slot 4 on a Cisco 7304 router:

```
Router# show diag subslot 4/1

Subslot 4/1:
        Shared port adapter: SPA-4FE-7304, 4 ports

Shared Port Adapter on a Cisco 12000 Series Internet Router: Example

The following is a sample output from the **show diag subslot** command for the 1-Port OC-192c/STM-64c POS/RPR XFP SPA in subslot 1 of the SIP located in chassis slot 1 on a Cisco 12000 series Internet router:

```
Router# show diag subslot 1/1

SUBSLOT  1/1 (SPA-OC192POS-XFP): 1-port OC192/STM64 POS/RPR XFP Optics Shared Port Adapter
       Product Identifier (PID) : SPA-OC192POS-XFP
       Version Identifier (VID) : V01
       PCB Serial Number        : PRTA1304061
       Top Assy. Part Number    : 68-2190-01
       Top Assy. Revision       : A0
       Hardware Revision        : 2.0
       CLEI Code                : UNASSIGNED
       Insertion Time           : 00:00:10 (13:14:17 ago)
       Operational Status       : ok
```

The table below describes the significant fields shown in the display.

Table 92: show diag subslot Field Descriptions for Cisco 12000 Series Internet Routers

Field	Description
Product Identifier (PID)	Product number of the SPA.
Version Identifier (VID)	Version number of the SPA.
PCB Serial Number	Serial number of the printed circuit board.

Field	Description
Top Assy. Part Number	Part number of the SPA.
Top Assy. Revision	Revision number (signifying a minor revision) of the SPA.
Hardware Revision	Revision number (signifying a minor revision) of the SPA hardware.
CLEI Code	Common Language Equipment Identification number.
Insertion Time	Time when the SPA was installed, and elapsed time between that insertion time and the current time.
Operational Status	Current status of the SPA. For more information about the status field descriptions, refer to the **show hw-module subslot oir** command.

The following is a sample output from the **show diag subslot details**command for the 1-Port OC-192c/STM-64c POS/RPR XFP SPA in subslot 1 of the SIP located in chassis slot 1 on a Cisco 12000 series Internet router:

```
Router# show diag subslot 1/1 details
