Fax: 408 527-0883

THE SPECIFICATIONS AND INFORMATION REGARDING THE PRODUCTS IN THIS MANUAL ARE SUBJECT TO CHANGE WITHOUT NOTICE. ALL STATEMENTS, INFORMATION, AND RECOMMENDATIONS IN THIS MANUAL ARE BELIEVED TO BE ACCURATE BUT ARE PRESENTED WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED. USERS MUST TAKE FULL RESPONSIBILITY FOR THEIR APPLICATION OF ANY PRODUCTS.

THE SOFTWARE LICENSE AND LIMITED WARRANTY FOR THE ACCOMPANYING PRODUCT ARE SET FORTH IN THE INFORMATION PACKET THAT SHIPPED WITH THE PRODUCT AND ARE INCORPORATED HEREIN BY THIS REFERENCE. IF YOU ARE UNABLE TO LOCATE THE SOFTWARE LICENSE OR LIMITED WARRANTY, CONTACT YOUR CISCO REPRESENTATIVE FOR A COPY.

The Cisco implementation of TCP header compression is an adaptation of a program developed by the University of California, Berkeley (UCB) as part of UCB's public domain version of the UNIX operating system. All rights reserved. Copyright © 1981, Regents of the University of California.

NOTWITHSTANDING ANY OTHER WARRANTY HEREIN, ALL DOCUMENT FILES AND SOFTWARE OF THESE SUPPLIERS ARE PROVIDED "AS IS" WITH ALL FAULTS. CISCO AND THE ABOVE-NAMED SUPPLIERS DISCLAIM ALL WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, THOSE OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT OR ARISING FROM A COURSE OF DEALING, USAGE, OR TRADE PRACTICE.

IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THIS MANUAL, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

Any Internet Protocol (IP) addresses and phone numbers used in this document are not intended to be actual addresses and phone numbers. Any examples, command display output, network topology diagrams, and other figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses or phone numbers in illustrative content is unintentional and coincidental.

All printed copies and duplicate soft copies of this document are considered uncontrolled. See the current online version for the latest version.

Cisco has more than 200 offices worldwide. Addresses and phone numbers are listed on the Cisco website at www.cisco.com/go/offices.

Cisco and the Cisco logo are trademarks or registered trademarks of Cisco and/or its affiliates in the U.S. and other countries. To view a list of Cisco trademarks, go to this URL: [www.cisco.com go trademarks](http://www.cisco.com/go/trademarks). Third-party trademarks mentioned are the property of their respective owners. The use of the word partner does not imply a partnership relationship between Cisco and any other company. (1721R)

Full Cisco Trademarks with Software License ?

CHAPTER 1

Using the Command-Line Interface 1

Information About Using the Command-Line Interface 1

Command Modes 1

Understanding Abbreviated Commands 3

No and Default Forms of Commands 3

CLI Error Messages 3

Configuration Logging 4

Using the Help System 4

How to Use the CLI to Configure Features 5

Configuring the Command History 5

Changing the Command History Buffer Size 5

Recalling Commands 6

Disabling the Command History Feature 6

Enabling and Disabling Editing Features 7

Editing Commands Through Keystrokes 7

Editing Command Lines That Wrap 8

Searching and Filtering Output of show and more Commands 9

Accessing the CLI 9

Accessing the CLI Through a Console Connection or Through Telnet 10

Accessing the CLI through Bluetooth 11

PART I

Interface and Hardware 13

CHAPTER 2

Configuring Interface Characteristics 15

| | |
|---|----|
| Information About Configuring Interface Characteristics | 15 |
| Interface Types | 15 |
| Port-Based VLANs | 15 |
| Switch Ports | 16 |
| Switch Virtual Interfaces | 17 |
| EtherChannel Port Groups | 18 |
| Power over Ethernet Ports | 18 |
| Using the Switch USB Ports | 18 |
| USB Mini-Type B Console Port | 18 |
| USB Type A Ports | 19 |
| Interface Connections | 20 |
| Interface Configuration Mode | 20 |
| Default Ethernet Interface Configuration | 21 |
| Interface Speed and Duplex Mode | 22 |
| Speed and Duplex Configuration Guidelines | 22 |
| IEEE 802.3x Flow Control | 23 |
| How to Configure Interface Characteristics | 24 |
| Configuring Interfaces | 24 |
| Adding a Description for an Interface | 25 |
| Configuring a Range of Interfaces | 26 |
| Configuring and Using Interface Range Macros | 27 |
| Configuring Ethernet Interfaces | 29 |
| Setting the Interface Speed and Duplex Parameters | 29 |
| Configuring IEEE 802.3x Flow Control | 30 |
| Configuring SVI Autostate Exclude | 31 |
| Shutting Down and Restarting the Interface | 32 |
| Configuring the Console Media Type | 33 |
| Configuring the USB Inactivity Timeout | 34 |
| Monitoring Interface Characteristics | 35 |
| Monitoring Interface Status | 35 |
| Clearing and Resetting Interfaces and Counters | 36 |
| Configuration Examples for Interface Characteristics | 37 |
| Configuring a Range of Interfaces: Examples | 37 |
| Configuring and Using Interface Range Macros: Examples | 37 |

| | |
|---|----|
| Setting Interface Speed and Duplex Mode: Example | 38 |
| Configuring the Console Media Type: Example | 38 |
| Configuring the USB Inactivity Timeout: Example | 38 |
| Additional References for the Interface Characteristics Feature | 39 |
| Feature History and Information for Configuring Interface Characteristics | 40 |

CHAPTER 3**Configuring Auto-MDIX 41**

| | |
|---|----|
| Prerequisites for Auto-MDIX | 41 |
| Restrictions for Auto-MDIX | 41 |
| Information About Configuring Auto-MDIX | 41 |
| Auto-MDIX on an Interface | 41 |
| How to Configure Auto-MDIX | 42 |
| Configuring Auto-MDIX on an Interface | 42 |
| Example for Configuring Auto-MDIX | 43 |
| Additional References | 43 |
| Feature History and Information for Auto-MDIX | 44 |

CHAPTER 4**Configuring Ethernet Management Port 45**

| | |
|--|----|
| Finding Feature Information | 45 |
| Prerequisites for Ethernet Management Ports | 45 |
| Information About the Ethernet Management Port | 45 |
| Ethernet Management Port Direct Connection to a Device | 46 |
| Ethernet Management Port Connection to Stack Devices using a Hub | 46 |
| Supported Features on the Ethernet Management Port | 46 |
| How to Configure the Ethernet Management Port | 47 |
| Disabling and Enabling the Ethernet Management Port | 47 |
| Additional References for Ethernet Management Ports | 48 |
| Feature History and Information for Ethernet Management Ports | 49 |

CHAPTER 5**Configuring LLDP, LLDP-MED, and Wired Location Service 51**

| | |
|--|----|
| Information About LLDP, LLDP-MED, and Wired Location Service | 51 |
| LLDP | 51 |
| LLDP Supported TLVs | 51 |
| LLDP and Cisco Device Stacks | 52 |

- LLDP and Cisco Medianet 52
- LLDP-MED 52
 - LLDP-MED Supported TLVs 52
 - Wired Location Service 53
 - Default LLDP Configuration 54
 - Restrictions for LLDP 55
- How to Configure LLDP, LLDP-MED, and Wired Location Service 55
 - Enabling LLDP 55
 - Configuring LLDP Characteristics 56
 - Configuring LLDP-MED TLVs 58
 - Configuring Network-Policy TLV 59
 - Configuring Location TLV and Wired Location Service 62
 - Enabling Wired Location Service on the Device 64
- Configuration Examples for LLDP, LLDP-MED, and Wired Location Service 65
 - Configuring Network-Policy TLV: Examples 65
- Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service 66
- Additional References for LLDP, LLDP-MED, and Wired Location Service 67
- Feature Information for LLDP, LLDP-MED, and Wired Location Service 67

CHAPTER 6

- Configuring System MTU 69**
 - Information About the MTU 69
 - System MTU Guidelines 69
 - How to Configure MTU 70
 - Configuring the System MTU 70
 - Configuration Examples for System MTU 70
 - Additional References for System MTU 71
 - Feature Information for System MTU 71

CHAPTER 7

- Configuring Boot Fast 73**
 - Configuring Boot Fast on the switch 73
 - Enabling Boot Fast 73
 - Disabling Boot Fast 74

CHAPTER 8

- Configuring PoE 75**

| | |
|---|----|
| Restrictions for PoE | 75 |
| Information About PoE | 75 |
| Power over Ethernet Ports | 75 |
| Supported Protocols and Standards | 75 |
| Powered-Device Detection and Initial Power Allocation | 76 |
| Power Management Modes | 77 |
| How to Configure PoE | 80 |
| Configuring a Power Management Mode on a PoE Port | 80 |
| Fast POE | 82 |
| Configuring Fast PoE | 82 |
| Budgeting Power for Devices Connected to a PoE Port | 83 |
| Budgeting Power to All PoE ports | 84 |
| Budgeting Power to a Specific PoE Port | 85 |
| Configuring Power Policing | 86 |
| Monitoring Power Status | 88 |
| Configuration Examples for Configuring PoE | 88 |
| Budgeting Power: Example | 88 |
| Additional References | 89 |

CHAPTER 9

| | |
|---|-----------|
| Configuring 2-event Classification | 91 |
| Information about 2-event Classification | 91 |
| Configuring 2-event Classification | 91 |
| Example: Configuring 2-Event Classification | 92 |

CHAPTER 10

| | |
|--|-----------|
| Configuring EEE | 93 |
| Restrictions for EEE | 93 |
| Information About EEE | 93 |
| EEE Overview | 93 |
| Default EEE Configuration | 93 |
| How to Configure EEE | 94 |
| Enabling or Disabling EEE | 94 |
| Monitoring EEE | 95 |
| Configuration Examples for Configuring EEE | 95 |
| Additional References | 96 |

Feature Information for Configuring EEE 96

PART II

IP Multicast Routing 97

CHAPTER 11

Configuring IGMP Snooping and Multicast VLAN Registration 99

Prerequisites for Configuring IGMP Snooping and MVR 99

Prerequisites for IGMP Snooping 99

Prerequisites for MVR 100

Restrictions for Configuring IGMP Snooping and MVR 100

Restrictions for IGMP Snooping 100

Restrictions for MVR 100

Information About IGMP Snooping and MVR 101

IGMP Snooping 101

IGMP Versions 102

Joining a Multicast Group 102

Leaving a Multicast Group 104

Immediate Leave 105

IGMP Configurable-Leave Timer 105

IGMP Report Suppression 105

IGMP Snooping and Device Stacks 106

Default IGMP Snooping Configuration 106

Multicast VLAN Registration 106

MVR and IGMP 107

Modes of Operation 107

MVR and Switch Stacks 107

MVR in a Multicast Television Application 107

Default MVR Configuration 109

IGMP Filtering and Throttling 109

Default IGMP Filtering and Throttling Configuration 110

How to Configure IGMP Snooping and MVR 110

Enabling or Disabling IGMP Snooping on a Device 110

Enabling or Disabling IGMP Snooping on a VLAN Interface 111

Setting the Snooping Method 112

Configuring a Multicast Router Port 114

| | |
|--|-----|
| Configuring a Host Statically to Join a Group | 115 |
| Enabling IGMP Immediate Leave | 116 |
| Configuring the IGMP Leave Timer | 117 |
| Configuring TCN-Related Commands | 119 |
| Controlling the Multicast Flooding Time After a TCN Event | 119 |
| Recovering from Flood Mode | 120 |
| Disabling Multicast Flooding During a TCN Event | 121 |
| Configuring the IGMP Snooping Querier | 122 |
| Disabling IGMP Report Suppression | 124 |
| Configuring MVR Global Parameters | 125 |
| Configuring MVR Interfaces | 127 |
| Configuring IGMP Profiles | 129 |
| Applying IGMP Profiles | 131 |
| Setting the Maximum Number of IGMP Groups | 133 |
| Configuring the IGMP Throttling Action | 134 |
| Monitoring IGMP Snooping and MVR | 136 |
| Monitoring IGMP Snooping Information | 136 |
| Monitoring MVR | 137 |
| Monitoring IGMP Filtering and Throttling Configuration | 138 |
| Configuration Examples for IGMP Snooping and MVR | 138 |
| Example: Configuring IGMP Snooping Using CGMP Packets | 138 |
| Example: Enabling a Static Connection to a Multicast Router | 138 |
| Example: Configuring a Host Statically to Join a Group | 138 |
| Example: Enabling IGMP Immediate Leave | 138 |
| Example: Setting the IGMP Snooping Querier Source Address | 139 |
| Example: Setting the IGMP Snooping Querier Maximum Response Time | 139 |
| Example: Setting the IGMP Snooping Querier Timeout | 139 |
| Example: Setting the IGMP Snooping Querier Feature | 139 |
| Example: Configuring IGMP Profiles | 139 |
| Example: Applying IGMP Profile | 140 |
| Example: Setting the Maximum Number of IGMP Groups | 140 |
| Example: Configuring MVR Global Parameters | 140 |
| Example: Configuring MVR Interfaces | 140 |
| Additional References | 141 |

Feature History and Information for IGMP Snooping 141

CHAPTER 12**Configuring Protocol Independent Multicast (PIM) 143**

Prerequisites for PIM 143

Restrictions for PIM 144

PIMv1 and PIMv2 Interoperability 144

Restrictions for Configuring PIM Stub Routing 144

Restrictions for Configuring Auto-RP and BSR 145

Information About PIM 146

Protocol Independent Multicast 146

PIM Dense Mode 146

PIM Sparse Mode 147

Sparse-Dense Mode 147

PIM Versions 148

PIM Stub Routing 148

IGMP Helper 149

Rendezvous Points 150

Auto-RP 150

Sparse-Dense Mode for Auto-RP 151

Bootstrap Router 151

PIM Domain Border 151

Multicast Forwarding 152

Multicast Distribution Source Tree 152

Multicast Distribution Shared Tree 153

Source Tree Advantage 153

Shared Tree Advantage 154

PIM Shared Tree and Source Tree 154

Reverse Path Forwarding 156

RPF Check 157

Default PIM Routing Configuration 158

How to Configure PIM 158

Enabling PIM Stub Routing 158

Configuring a Rendezvous Point 159

Manually Assigning an RP to Multicast Groups 160

| | |
|---|--|
| Setting Up Auto-RP in a New Internetwork | 162 |
| Adding Auto-RP to an Existing Sparse-Mode Cloud | 165 |
| Configuring Sparse Mode with a Single Static RP(CLI) | 167 |
| Preventing Join Messages to False RPs | 169 |
| Filtering Incoming RP Announcement Messages | 170 |
| Configuring PIMv2 BSR | 171 |
| Defining the PIM Domain Border | 172 |
| Defining the IP Multicast Boundary | 173 |
| Configuring Candidate BSRs | 174 |
| Configuring the Candidate RPs | 176 |
| Delaying the Use of PIM Shortest-Path Tree | 177 |
| Modifying the PIM Router-Query Message Interval | 179 |
| Verifying PIM Operations | 180 |
| Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network | 180 |
| Using PIM-Enabled Routers to Test IP Multicast Reachability | 187 |
| Monitoring and Troubleshooting PIM | 188 |
| Monitoring PIM Information | 188 |
| Monitoring the RP Mapping and BSR Information | 189 |
| Troubleshooting PIMv1 and PIMv2 Interoperability Problems | 189 |
| Configuration Examples for PIM | 190 |
| Example: Enabling PIM Stub Routing | 190 |
| Example: Verifying PIM Stub Routing | 190 |
| Example: Manually Assigning an RP to Multicast Groups | 190 |
| Example: Configuring Auto-RP | 191 |
| Example: Defining the IP Multicast Boundary to Deny Auto-RP Information | 191 |
| Example: Filtering Incoming RP Announcement Messages | 191 |
| Example: Preventing Join Messages to False RPs | 191 |
| Example: Configuring Candidate BSRs | 192 |
| Example: Configuring Candidate RPs | 192 |
| Additional References | 192 |
| | |
| CHAPTER 13 | IPv6 Protocol Independent Multicast 195 |
| | Protocol Independent Multicast 195 |
| | PIM-Sparse Mode 195 |

IPv6 BSR: Configure RP Mapping 196
 PIM-Source Specific Multicast 196
 Routable Address Hello Option 197
 PIM IPv6 Stub Routing 197

PART III **IPv6 199**

CHAPTER 14 **Configuring MLD Snooping 201**

- Finding Feature Information 201
- Information About Configuring IPv6 MLD Snooping 201
 - Understanding MLD Snooping 202
 - MLD Messages 202
 - MLD Queries 203
 - Multicast Client Aging Robustness 203
 - Multicast Router Discovery 203
 - MLD Reports 204
 - MLD Done Messages and Immediate-Leave 204
 - Topology Change Notification Processing 204
 - MLD Snooping in Switch Stacks 205
- How to Configure IPv6 MLD Snooping 205
 - Default MLD Snooping Configuration 205
 - MLD Snooping Configuration Guidelines 206
 - Enabling or Disabling MLD Snooping on the Switch 206
 - Enabling or Disabling MLD Snooping on a VLAN 207
 - Configuring a Static Multicast Group 208
 - Configuring a Multicast Router Port 209
 - Enabling MLD Immediate Leave 210
 - Configuring MLD Snooping Queries 211
 - Disabling MLD Listener Message Suppression 212
- Displaying MLD Snooping Information 213
- Configuration Examples for Configuring MLD Snooping 214
 - Configuring a Static Multicast Group: Example 214
 - Configuring a Multicast Router Port: Example 214
 - Enabling MLD Immediate Leave: Example 215

Configuring MLD Snooping Queries: Example 215

CHAPTER 15

Configuring IPv6 Unicast Routing 217

- Finding Feature Information 217
- Information About Configuring IPv6 Host Functions 217
 - Understanding IPv6 218
 - IPv6 Addresses 218
 - Supported IPv6 Unicast Routing Features 218
 - IPv6 and Switch Stacks 222
 - Default IPv6 Configuration 222
 - Configuring IPv6 Addressing and Enabling IPv6 Routing 222
 - Configuring IPv6 ICMP Rate Limiting 224
 - Configuring Static Routing for IPv6 225
 - Displaying IPv6 228
- Configuration Examples for IPv6 Unicast Routing 228
 - Configuring IPv6 Addressing and Enabling IPv6 Routing: Example 228
 - Configuring IPv6 ICMP Rate Limiting: Example 229
 - Configuring Static Routing for IPv6: Example 229
 - Displaying IPv6: Example 229

CHAPTER 16

Configuring IPv6 ACL 231

- Finding Feature Information 231
- Information About Configuring IPv6 ACLs 231
 - Understanding IPv6 ACLs 231
 - Supported ACL Features 232
 - IPv6 ACL Limitations 232
- Configuring IPv6 ACLs 233
 - Default IPv6 ACL Configuration 234
 - Interaction with Other Features and Switches 234
 - Creating IPv6 ACL 234
 - Applying an IPv6 ACL to an Interface 238
 - Displaying IPv6 ACLs 239
- Configuration Examples for IPv6 ACL 240
 - Example: Creating an IPv6 ACL 240

- Example: Applying IPv6 ACLs 240
- Example: Displaying IPv6 ACLs 240

PART IV**Layer 2 241****CHAPTER 17****Configuring Spanning Tree Protocol 243**

- Finding Feature Information 243
- Restrictions for STP 243
- Information About Spanning Tree Protocol 244
 - Spanning Tree Protocol 244
 - Spanning-Tree Topology and BPDUs 244
 - Bridge ID, Device Priority, and Extended System ID 246
 - Port Priority Versus Path Cost 247
 - Spanning-Tree Interface States 247
 - How a Device or Port Becomes the Root Device or Root Port 250
 - Spanning Tree and Redundant Connectivity 251
 - Spanning-Tree Address Management 251
 - Accelerated Aging to Retain Connectivity 251
 - Spanning-Tree Modes and Protocols 251
 - Supported Spanning-Tree Instances 252
 - Spanning-Tree Interoperability and Backward Compatibility 252
 - STP and IEEE 802.1Q Trunks 253
 - VLAN-Bridge Spanning Tree 253
 - Spanning Tree and Device Stacks 253
 - Default Spanning-Tree Configuration 254
- How to Configure Spanning-Tree Features 255
 - Changing the Spanning-Tree Mode 255
 - Disabling Spanning Tree 256
 - Configuring the Root Device 257
 - Configuring a Secondary Root Device 258
 - Configuring Port Priority 259
 - Configuring Path Cost 260
 - Configuring the Device Priority of a VLAN 261
 - Configuring the Hello Time 262

| | |
|--|-----|
| Configuring the Forwarding-Delay Time for a VLAN | 263 |
| Configuring the Maximum-Aging Time for a VLAN | 264 |
| Configuring the Transmit Hold-Count | 265 |
| Monitoring Spanning-Tree Status | 266 |
| Feature Information for STP | 266 |

CHAPTER 18**Configuring Multiple Spanning-Tree Protocol 267**

| | |
|--|-----|
| Finding Feature Information | 267 |
| Prerequisites for MSTP | 267 |
| Restrictions for MSTP | 268 |
| Information About MSTP | 268 |
| MSTP Configuration | 268 |
| MSTP Configuration Guidelines | 269 |
| Root Switch | 269 |
| Multiple Spanning-Tree Regions | 270 |
| IST, CIST, and CST | 270 |
| Operations Within an MST Region | 271 |
| Operations Between MST Regions | 271 |
| IEEE 802.1s Terminology | 272 |
| Illustration of MST Regions | 272 |
| Hop Count | 273 |
| Boundary Ports | 273 |
| IEEE 802.1s Implementation | 274 |
| Port Role Naming Change | 274 |
| Interoperation Between Legacy and Standard Devices | 275 |
| Detecting Unidirectional Link Failure | 275 |
| MSTP and Device Stacks | 276 |
| Interoperability with IEEE 802.1D STP | 276 |
| RSTP Overview | 277 |
| Port Roles and the Active Topology | 277 |
| Rapid Convergence | 278 |
| Synchronization of Port Roles | 279 |
| Bridge Protocol Data Unit Format and Processing | 280 |
| Topology Changes | 281 |

| | |
|---|-----|
| Protocol Migration Process | 282 |
| Default MSTP Configuration | 282 |
| About MST-to-PVST+ Interoperability (PVST+ Simulation) | 283 |
| About Detecting Unidirectional Link Failure | 284 |
| How to Configure MSTP Features | 285 |
| Specifying the MST Region Configuration and Enabling MSTP | 285 |
| Configuring the Root Device | 287 |
| Configuring a Secondary Root Device | 288 |
| Configuring Port Priority | 289 |
| Configuring Path Cost | 290 |
| Configuring the Device Priority | 292 |
| Configuring the Hello Time | 293 |
| Configuring the Forwarding-Delay Time | 294 |
| Configuring the Maximum-Aging Time | 295 |
| Configuring the Maximum-Hop Count | 295 |
| Specifying the Link Type to Ensure Rapid Transitions | 296 |
| Designating the Neighbor Type | 297 |
| Restarting the Protocol Migration Process | 298 |
| Configuring PVST+ Simulation | 299 |
| Enabling PVST+ Simulation on a Port | 300 |
| Examples | 301 |
| Examples: PVST+ Simulation | 301 |
| Examples: Detecting Unidirectional Link Failure | 304 |
| Monitoring MST Configuration and Status | 305 |
| Feature Information for MSTP | 305 |

CHAPTER 19
Configuring Optional Spanning-Tree Features 307

| | |
|---|-----|
| Finding Feature Information | 307 |
| Restriction for Optional Spanning-Tree Features | 307 |
| Information About Optional Spanning-Tree Features | 307 |
| PortFast | 307 |
| BPDU Guard | 308 |
| BPDU Filtering | 308 |
| UplinkFast | 309 |

| | |
|--|--|
| Cross-Stack UplinkFast | 310 |
| How Cross-Stack UplinkFast Works | 311 |
| Events That Cause Fast Convergence | 312 |
| BackboneFast | 312 |
| EtherChannel Guard | 314 |
| Root Guard | 315 |
| Loop Guard | 316 |
| STP PortFast Port Types | 316 |
| Bridge Assurance | 317 |
| How to Configure Optional Spanning-Tree Features | 319 |
| Enabling PortFast | 319 |
| Enabling BPDU Guard | 320 |
| Enabling BPDU Filtering | 322 |
| Enabling UplinkFast for Use with Redundant Links | 323 |
| Disabling UplinkFast | 324 |
| Enabling BackboneFast | 325 |
| Enabling EtherChannel Guard | 326 |
| Enabling Root Guard | 327 |
| Enabling Loop Guard | 328 |
| Enabling PortFast Port Types | 329 |
| Configuring the Default Port State Globally | 329 |
| Configuring PortFast Edge on a Specified Interface | 330 |
| Configuring a PortFast Network Port on a Specified Interface | 331 |
| Enabling Bridge Assurance | 332 |
| Examples | 333 |
| Examples: Configuring PortFast Edge on a Specified Interface | 333 |
| Examples: Configuring a PortFast Network Port on a Specified Interface | 334 |
| Example: Configuring Bridge Assurance | 335 |
| Monitoring the Spanning-Tree Status | 336 |
| Feature Information for Optional Spanning-Tree Features | 336 |
| | |
| CHAPTER 20 | Configuring Resilient Ethernet Protocol |
| | 337 |
| | Finding Feature Information |
| | 337 |
| | Overview of Resilient Ethernet Protocol |
| | 337 |

| | |
|--|-----|
| Link Integrity | 339 |
| Fast Convergence | 340 |
| VLAN Load Balancing | 340 |
| Spanning Tree Interaction | 341 |
| REP Ports | 342 |
| How to Configure Resilient Ethernet Protocol | 342 |
| Default REP Configuration | 342 |
| REP Configuration Guidelines | 342 |
| Configuring REP Administrative VLAN | 344 |
| Configuring a REP Interface | 345 |
| Setting Manual Preemption for VLAN Load Balancing | 349 |
| Configuring SNMP Traps for REP | 349 |
| Monitoring Resilient Ethernet Protocol Configuration | 350 |
| Configuration Examples for Resilient Ethernet Protocol | 351 |
| Example: Configuring the REP Administrative VLAN | 352 |
| Example: Configuring a REP Interface | 352 |
| Additional References for REP | 353 |
| Feature Information for Resilient Ethernet Protocol | 354 |

CHAPTER 21

| | |
|--|------------|
| Configuring EtherChannels | 355 |
| Finding Feature Information | 355 |
| Restrictions for EtherChannels | 355 |
| Information About EtherChannels | 356 |
| EtherChannel Overview | 356 |
| EtherChannel Modes | 356 |
| EtherChannel on Devices | 357 |
| EtherChannel Link Failover | 357 |
| Channel Groups and Port-Channel Interfaces | 358 |
| Port Aggregation Protocol | 358 |
| PAgP Modes | 359 |
| PAgP Learn Method and Priority | 359 |
| PAgP Interaction with Virtual Switches and Dual-Active Detection | 360 |
| PAgP Interaction with Other Features | 360 |
| Link Aggregation Control Protocol | 361 |

| | |
|--|-----|
| LACP Modes | 361 |
| LACP Interaction with Other Features | 361 |
| EtherChannel On Mode | 362 |
| Load-Balancing and Forwarding Methods | 362 |
| MAC Address Forwarding | 362 |
| IP Address Forwarding | 363 |
| Load-Balancing Advantages | 363 |
| EtherChannel Load Deferral Overview | 364 |
| EtherChannel and Device Stacks | 365 |
| Device Stack and PAgP | 365 |
| Switch Stacks and LACP | 365 |
| Default EtherChannel Configuration | 366 |
| EtherChannel Configuration Guidelines | 366 |
| Layer 2 EtherChannel Configuration Guidelines | 367 |
| Auto-LAG | 367 |
| Auto-LAG Configuration Guidelines | 368 |
| How to Configure EtherChannels | 369 |
| Configuring Layer 2 EtherChannels | 369 |
| Configuring EtherChannel Load-Balancing | 371 |
| Configuring Port Channel Load Deferral | 372 |
| Configuring the PAgP Learn Method and Priority | 374 |
| Configuring LACP Hot-Standby Ports | 375 |
| Configuring the LACP System Priority | 375 |
| Configuring the LACP Port Priority | 376 |
| Configuring the LACP Port Channel Min-Links Feature | 377 |
| Configuring LACP Fast Rate Timer | 378 |
| Configuring Auto-LAG Globally | 379 |
| Configuring Auto-LAG on a Port Interface | 380 |
| Configuring Persistence with Auto-LAG | 381 |
| Monitoring EtherChannel, PAgP, and LACP Status | 381 |
| Configuration Examples for Configuring EtherChannels | 382 |
| Configuring Layer 2 EtherChannels: Examples | 382 |
| Example: Configuring Port Channel Load Deferral | 383 |
| Configuring Auto LAG: Examples | 383 |

| | |
|---|-----|
| Configuring LACP Port Channel Min-Links: Examples | 384 |
| Example: Configuring LACP Fast Rate Timer | 385 |
| Additional References for EtherChannels | 385 |
| Feature Information for EtherChannels | 386 |

CHAPTER 22

| | |
|--|------------|
| Configuring Link-State Tracking | 387 |
| Finding Feature Information | 387 |
| Restrictions for Configuring Link-State Tracking | 387 |
| Understanding Link-State Tracking | 388 |
| How to Configure Link-State Tracking | 390 |
| Monitoring Link-State Tracking | 391 |
| Configuring Link-State Tracking: Example | 391 |
| Additional References for Link-State Tracking | 391 |
| Feature Information for Link-State Tracking | 392 |

CHAPTER 23

| | |
|---|------------|
| Configuring Flex Links and the MAC Address-Table Move Update Feature | 393 |
| Finding Feature Information | 393 |
| Restrictions for Configuring Flex Links and MAC Address-Table Move Update | 393 |
| Information About Flex Links and MAC Address-Table Move Update | 394 |
| Flex Links | 394 |
| Flex Links Configuration | 394 |
| VLAN Flex Links Load Balancing and Support | 395 |
| Multicast Fast Convergence with Flex Links Failover | 395 |
| Learning the Other Flex Links Port as the mrouter Port | 395 |
| Generating IGMP Reports | 396 |
| Leaking IGMP Reports | 396 |
| MAC Address-Table Move Update | 396 |
| Flex Links VLAN Load Balancing Configuration Guidelines | 398 |
| MAC Address-Table Move Update Configuration Guidelines | 398 |
| Default Flex Links and MAC Address-Table Move Update Configuration | 398 |
| How to Configure Flex Links and the MAC Address-Table Move Update Feature | 398 |
| Configuring Flex Links | 398 |
| Configuring a Preemption Scheme for a Pair of Flex Links | 399 |
| Configuring VLAN Load Balancing on Flex Links | 400 |

| | |
|--|-----|
| Configuring MAC Address-Table Move Update | 401 |
| Configuring a Device to Obtain and Process MAC Address-Table Move Update Messages | 402 |
| Monitoring Flex Links, Multicast Fast Convergence, and MAC Address-Table Move Update | 403 |
| Configuration Examples for Flex Links | 403 |
| Configuring Flex Links: Examples | 403 |
| Configuring VLAN Load Balancing on Flex Links: Examples | 403 |
| Configuring the MAC Address-Table Move Update: Examples | 405 |
| Configuring Multicast Fast Convergence with Flex Links Failover: Examples | 405 |
| Additional References for Flex Links and MAC Address-Table Move Update | 407 |
| Feature Information for Flex Links and MAC Address-Table Move Update | 409 |

CHAPTER 24**Configuring UniDirectional Link Detection 411**

| | |
|--|-----|
| Finding Feature Information | 411 |
| Restrictions for Configuring UDLD | 411 |
| Information About UDLD | 412 |
| Modes of Operation | 412 |
| Normal Mode | 412 |
| Aggressive Mode | 412 |
| Methods to Detect Unidirectional Links | 413 |
| Neighbor Database Maintenance | 413 |
| Event-Driven Detection and Echoing | 413 |
| UDLD Reset Options | 413 |
| Default UDLD Configuration | 414 |
| How to Configure UDLD | 414 |
| Enabling UDLD Globally | 414 |
| Enabling UDLD on an Interface | 415 |
| Monitoring and Maintaining UDLD | 416 |
| Additional References for UDLD | 416 |
| Feature Information for UDLD | 417 |

CHAPTER 25**Configuring the PPPoE Intermediate Agent 419**

| | |
|--|-----|
| Restrictions for PPPoE Intermediate Agent | 419 |
| Information about PPPoE Intermediate Agent | 419 |
| How to Configure PPPoE IA | 420 |

- Enabling PPPoE IA on a Switch 420
- Configuring the Access Node Identifier for PPPoE IA on a Switch 420
- Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch 421
- Configuring the Generic Error Message for PPPoE IA on a Switch 421
- Enabling PPPoE IA on an Interface 422
- Configuring the PPPoE IA Trust Setting on an Interface 423
- Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface 424
- Configuring PPPoE IA Vendor-tag Stripping on an Interface 424
- Configuring PPPoE Intermediate Agent Circuit-ID and Remote-ID on an Interface 425
- Enabling PPPoE IA for a Specific VLAN on an Interface 426
- Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface 427
- Configuration Examples for PPPoE IA 428
 - Example: Enabling PPPoE Intermediate Agent on a Switch 428
 - Example: Configuring the Access Node Identifier for PPPoE IA on a Switch 428
 - Example: Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch 428
 - Example: Configuring the Generic Error Message for PPPoE IA on a Switch 428
 - Example: Enabling PPPoE IA on an Interface 428
 - Example: Configuring the PPPoE Intermediate Agent Trust Setting on an Interface 429
 - Example: Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface 429
 - Example: Configuring PPPoE IA Vendor-tag Stripping on an Interface 429
 - Example: Configuring PPPoE IA Circuit-ID and Remote-ID on an Interface 429
 - Example: Enabling PPPoE IA for a Specific VLAN on an Interface 429
 - Example: Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface 430
- Displaying Configuration Parameters 430
- Clearing Packet Counters 432
- Debugging PPPoE Intermediate Agent 432
- Troubleshooting Tips 433
- Feature Information for Configuring the PPPoE Intermediate Agent 433

PART V

Cisco Flexible NetFlow 435

CHAPTER 26

Configuring Flexible NetFlow 437

- Prerequisites for Flexible NetFlow 437
- Restrictions for Flexible NetFlow 438

| | |
|---|-----|
| Information About Flexible Netflow | 440 |
| Flexible NetFlow Overview | 440 |
| Original NetFlow and Benefits of Flexible NetFlow | 440 |
| Flexible NetFlow Components | 441 |
| Flow Records | 441 |
| Flow Exporters | 442 |
| Flow Monitors | 443 |
| Flow Samplers | 445 |
| Supported Flexible NetFlow Fields | 445 |
| Default Settings | 446 |
| How to Configure Flexible Netflow | 447 |
| Creating a Flow Record | 447 |
| Creating a Flow Exporter | 449 |
| Creating a Flow Monitor | 451 |
| Creating a Sampler | 453 |
| Applying a Flow to an Interface | 454 |
| Configuring NetFlow on SVI | 456 |
| Configuring Layer 2 NetFlow | 456 |
| Monitoring Flexible NetFlow | 458 |
| Configuration Examples for Flexible NetFlow | 458 |
| Example: Configuring a Flow | 458 |
| Additional References for NetFlow | 459 |
| Feature Information for Flexible NetFlow | 460 |

PART VI
Openflow 461

CHAPTER 27
OpenFlow 463

| | |
|--------------------------------|-----|
| Finding Feature Information | 463 |
| Prerequisites for OpenFlow | 463 |
| Restrictions for OpenFlow | 464 |
| Information About Open Flow | 465 |
| Overview of OpenFlow | 465 |
| OpenFlow Controller Operation | 465 |
| Cisco OpenFlow Feature Support | 466 |

| | |
|---|-----|
| Supported Match and Actions and Pipelines | 468 |
| Configuring OpenFlow | 471 |
| Monitoring OpenFlow | 475 |
| Configuration Examples for OpenFlow | 475 |

PART VII
QoS 481

CHAPTER 28
Configuring QoS 483

| | |
|--|-----|
| Finding Feature Information | 483 |
| Prerequisites for QoS | 483 |
| QoS ACL Guidelines | 484 |
| Policing Guidelines | 484 |
| General QoS Guidelines | 484 |
| Restrictions for QoS | 485 |
| Information About QoS | 486 |
| QoS Implementation | 486 |
| Layer 2 Frame Prioritization Bits | 487 |
| Layer 3 Packet Prioritization Bits | 487 |
| End-to-End QoS Solution Using Classification | 488 |
| QoS Basic Model | 488 |
| Actions at Ingress Port | 488 |
| Actions at Egress Port | 489 |
| Classification Overview | 489 |
| Policing and Marking Overview | 494 |
| Mapping Tables Overview | 495 |
| Queueing and Scheduling Overview | 496 |
| Queueing and Scheduling on Ingress Queues | 498 |
| Queueing and Scheduling on Egress Queues | 501 |
| Packet Modification | 505 |
| Standard QoS Default Configuration | 505 |
| Default Ingress Queue Configuration | 506 |
| Default Egress Queue Configuration | 507 |
| Default Mapping Table Configuration | 509 |
| DSCP Maps | 510 |

| | |
|---|-----|
| Default CoS-to-DSCP Map | 510 |
| Default IP-Precedence-to-DSCP Map | 510 |
| Default DSCP-to-CoS Map | 511 |
| How to Configure QoS | 511 |
| Enabling QoS Globally | 511 |
| Enabling VLAN-Based QoS on Physical Ports | 512 |
| Configuring Classification Using Port Trust States | 513 |
| Configuring the Trust State on Ports Within the QoS Domain | 513 |
| Configuring the CoS Value for an Interface | 515 |
| Configuring a Trusted Boundary to Ensure Port Security | 517 |
| Enabling DSCP Transparency Mode | 519 |
| Configuring the DSCP Trust State on a Port Bordering Another QoS Domain | 520 |
| Configuring a QoS Policy | 523 |
| Classifying Traffic by Using ACLs | 523 |
| Classifying Traffic by Using Class Maps | 530 |
| Classifying Traffic by Using Class Maps and Filtering IPv6 Traffic | 532 |
| Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps | 534 |
| Classifying, Policing, and Marking Traffic by Using Aggregate Policers | 539 |
| Configuring DSCP Maps | 541 |
| Configuring the CoS-to-DSCP Map | 541 |
| Configuring the IP-Precedence-to-DSCP Map | 542 |
| Configuring the Policed-DSCP Map | 543 |
| Configuring the DSCP-to-CoS Map | 544 |
| Configuring the DSCP-to-DSCP-Mutation Map | 545 |
| Configuring Ingress Queue Characteristics | 547 |
| Configuration Guidelines | 547 |
| Mapping DSCP or CoS Values to an Ingress Queue and Setting WTD Thresholds | 547 |
| Allocating Buffer Space Between the Ingress Queues | 549 |
| Allocating Bandwidth Between the Ingress Queues | 550 |
| Configuring Egress Queue Characteristics | 552 |
| Configuration Guidelines | 552 |
| Allocating Buffer Space to and Setting WTD Thresholds for an Egress Queue-Set | 552 |
| Mapping DSCP or CoS Values to an Egress Queue and to a Threshold ID | 556 |
| Configuring SRR Shaped Weights on Egress Queues | 558 |

| | |
|---|-----|
| Configuring SRR Shared Weights on Egress Queues | 560 |
| Configuring the Egress Expedite Queue | 561 |
| Limiting the Bandwidth on an Egress Interface | 563 |
| Monitoring Standard QoS | 564 |
| Configuration Examples for QoS | 565 |
| Example: Configuring Port to the DSCP-Trusted State and Modifying the DSCP-to-DSCP-Mutation Map | 565 |
| Examples: Classifying Traffic by Using ACLs | 565 |
| Examples: Classifying Traffic by Using Class Maps | 566 |
| Examples: Classifying, Policing, and Marking Traffic on Physical Ports Using Policy Maps | 567 |
| Examples: Classifying, Policing, and Marking Traffic by Using Aggregate Policers | 569 |
| Examples: Configuring DSCP Maps | 570 |
| Examples: Configuring Ingress Queue Characteristics | 571 |
| Examples: Configuring Egress Queue Characteristics | 572 |
| Where to Go Next | 573 |
| Additional References | 573 |
| Feature History and Information for QoS | 574 |

CHAPTER 29**Configuring Auto-QoS 575**

| | |
|--|-----|
| Finding Feature Information | 575 |
| Prerequisites for Auto-QoS | 575 |
| Restrictions for Auto-QoS | 576 |
| Information about Configuring Auto-QoS | 576 |
| Auto-QoS Overview | 576 |
| Auto-QoS Compact Overview | 576 |
| Generated Auto-QoS Configuration | 576 |
| VoIP Device Specifics | 577 |
| Enhanced Auto-QoS for Video, Trust, and Classification | 578 |
| Auto-QoS Configuration Migration | 578 |
| Auto-QoS Configuration Guidelines | 579 |
| Auto-QoS VoIP Considerations | 579 |
| Auto-QoS Enhanced Considerations | 580 |
| Effects of Auto-QoS on Running Configuration | 580 |
| Effects of Auto-QoS Compact on Running Configuration | 580 |

| | |
|--|-----|
| How to Configure Auto-QoS | 581 |
| Configuring Auto-QoS | 581 |
| Enabling Auto-QoS | 581 |
| Enabling Auto-QoS Compact | 583 |
| Troubleshooting Auto-QoS | 584 |
| Monitoring Auto-QoS | 584 |
| Configuration Examples for Auto-QoS | 585 |
| Examples: Global Auto-QoS Configuration | 585 |
| Examples: Auto-QoS Generated Configuration for VoIP Devices | 587 |
| Examples: Auto-QoS Generated Configuration for VoIP Devices | 589 |
| Examples: Auto-QoS Generated Configuration For Enhanced Video, Trust, and Classify Devices | 590 |
| auto qos global compact | 593 |
| Where to Go Next for Auto-QoS | 593 |
| Additional References for Auto-QoS | 593 |
| Feature History and Information for Auto-QoS | 594 |

PART VIII
Network Management 595

CHAPTER 30
Configuring Cisco IOS Configuration Engine 597

| | |
|--|-----|
| Prerequisites for Configuring the Configuration Engine | 597 |
| Restrictions for Configuring the Configuration Engine | 597 |
| Information About Configuring the Configuration Engine | 598 |
| Cisco Configuration Engine Software | 598 |
| Configuration Service | 599 |
| Event Service | 599 |
| NameSpace Mapper | 600 |
| Cisco Networking Services IDs and Device Hostnames | 600 |
| ConfigID | 600 |
| DeviceID | 600 |
| Hostname and DeviceID | 601 |
| Hostname, DeviceID, and ConfigID | 601 |
| Cisco IOS CNS Agents | 601 |
| Initial Configuration | 601 |
| Incremental (Partial) Configuration | 602 |

| | |
|--|-----|
| Synchronized Configuration | 602 |
| Automated CNS Configuration | 602 |
| How to Configure the Configuration Engine | 603 |
| Enabling the CNS Event Agent | 603 |
| Enabling the Cisco IOS CNS Agent | 605 |
| Enabling an Initial Configuration for Cisco IOS CNS Agent | 606 |
| Refreshing DeviceIDs | 611 |
| Enabling a Partial Configuration for Cisco IOS CNS Agent | 613 |
| Monitoring CNS Configurations | 614 |
| Additional References | 615 |
| Feature History and Information for the Configuration Engine | 616 |

CHAPTER 31**Configuring the Cisco Discovery Protocol 617**

| | |
|--|-----|
| Information About CDP | 617 |
| Cisco Discovery Protocol Overview | 617 |
| CDP and Stacks | 618 |
| Default Cisco Discovery Protocol Configuration | 618 |
| How to Configure CDP | 618 |
| Configuring Cisco Discovery Protocol Characteristics | 618 |
| Disabling Cisco Discovery Protocol | 620 |
| Enabling Cisco Discovery Protocol | 621 |
| Disabling Cisco Discovery Protocol on an Interface | 622 |
| Enabling Cisco Discovery Protocol on an Interface | 623 |
| Monitoring and Maintaining Cisco Discovery Protocol | 625 |
| Additional References | 625 |
| Feature History and Information for Cisco Discovery Protocol | 626 |

CHAPTER 32**Configuring Simple Network Management Protocol 627**

| | |
|------------------------|-----|
| Prerequisites for SNMP | 627 |
| Restrictions for SNMP | 629 |
| Information About SNMP | 629 |
| SNMP Overview | 629 |
| SNMP Manager Functions | 630 |
| SNMP Agent Functions | 630 |

| | |
|--|-----|
| SNMP Community Strings | 631 |
| SNMP MIB Variables Access | 631 |
| SNMP Notifications | 631 |
| SNMP ifIndex MIB Object Values | 632 |
| Default SNMP Configuration | 632 |
| SNMP Configuration Guidelines | 633 |
| How to Configure SNMP | 634 |
| Disabling the SNMP Agent | 634 |
| Configuring Community Strings | 635 |
| Configuring SNMP Groups and Users | 637 |
| Configuring SNMP Notifications | 640 |
| Setting the Agent Contact and Location Information | 645 |
| Limiting TFTP Servers Used Through SNMP | 646 |
| Monitoring SNMP Status | 647 |
| SNMP Examples | 648 |
| Additional References | 649 |
| Feature History and Information for Simple Network Management Protocol | 650 |

CHAPTER 33
Configuring SPAN and RSPAN 651

| | |
|--|-----|
| Prerequisites for SPAN and RSPAN | 651 |
| Restrictions for SPAN and RSPAN | 651 |
| Information About SPAN and RSPAN | 653 |
| SPAN and RSPAN | 653 |
| Local SPAN | 653 |
| Remote SPAN | 654 |
| SPAN and RSPAN Concepts and Terminology | 655 |
| SPAN and RSPAN Interaction with Other Features | 660 |
| SPAN and RSPAN and Device Stacks | 661 |
| Default SPAN and RSPAN Configuration | 661 |
| Configuration Guidelines | 662 |
| SPAN Configuration Guidelines | 662 |
| RSPAN Configuration Guidelines | 662 |
| How to Configure SPAN and RSPAN | 662 |
| Creating a Local SPAN Session | 662 |

| | |
|--|-----|
| Creating a Local SPAN Session and Configuring Incoming Traffic | 665 |
| Specifying VLANs to Filter | 667 |
| Configuring a VLAN as an RSPAN VLAN | 669 |
| Creating an RSPAN Source Session | 670 |
| Specifying VLANs to Filter | 672 |
| Creating an RSPAN Destination Session | 674 |
| Creating an RSPAN Destination Session and Configuring Incoming Traffic | 676 |
| Monitoring SPAN and RSPAN Operations | 678 |
| SPAN and RSPAN Configuration Examples | 679 |
| Example: Configuring Local SPAN | 679 |
| Examples: Creating an RSPAN VLAN | 680 |
| Additional References | 681 |
| Feature History and Information for SPAN and RSPAN | 682 |

PART IX
Routing 683

CHAPTER 34
Configuring IP Unicast Routing 685

| | |
|--|-----|
| Finding Feature Information | 685 |
| Information About Configuring IP Unicast Routing | 685 |
| Information About IP Routing | 686 |
| Types of Routing | 686 |
| IP Routing and Switch Stacks | 686 |
| Configuring IP Unicast Routing | 687 |
| Enabling IP Unicast Routing | 688 |
| Assigning IP Addresses to SVIs | 689 |
| Configuring Static Unicast Routes | 691 |
| Monitoring and Maintaining the IP Network | 692 |

CHAPTER 35
Configuring IPv6 First Hop Security 693

| | |
|--|-----|
| Finding Feature Information | 693 |
| Prerequisites for First Hop Security in IPv6 | 693 |
| Restrictions for First Hop Security in IPv6 | 694 |
| Information about First Hop Security in IPv6 | 694 |
| How to Configure an IPv6 Snooping Policy | 697 |

| | |
|--|-----|
| How to Attach an IPv6 Snooping Policy to an Interface | 698 |
| How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface | 700 |
| How to Configure the IPv6 Binding Table Content | 701 |
| How to Configure an IPv6 Neighbor Discovery Inspection Policy | 702 |
| How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface | 703 |
| How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface | 704 |
| How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on a Device | 705 |
| How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on an Interface | 706 |
| How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy to a Layer 2 EtherChannel Interface | 707 |
| How to Configure an IPv6 Router Advertisement Guard Policy | 708 |
| How to Attach an IPv6 Router Advertisement Guard Policy to an Interface | 710 |
| How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface | 711 |
| How to Configure an IPv6 DHCP Guard Policy | 712 |
| How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface | 714 |
| How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface | 715 |
| How to Configure IPv6 Source Guard | 716 |
| How to Attach an IPv6 Source Guard Policy to an Interface | 717 |
| How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface | 718 |
| How to Configure IPv6 Prefix Guard | 718 |
| How to Attach an IPv6 Prefix Guard Policy to an Interface | 719 |
| How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface | 720 |
| Configuration Examples for IPv6 First Hop Security | 721 |
| Examples: How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface | 721 |
| Examples: How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface | 721 |
| Additional References | 721 |

CHAPTER 36**Routing Information Protocol 723**

| | |
|--|-----|
| Prerequisites for RIP | 723 |
| Restrictions for RIP | 723 |
| Information About Routing Information Protocol | 723 |
| RIP Overview | 723 |
| RIP Routing Updates | 724 |

| | |
|---|-----|
| Authentication in RIP | 724 |
| RIP Routing Metric | 725 |
| RIP Versions | 725 |
| Exchange of Routing Information | 725 |
| Neighbor Router Authentication | 726 |
| How to Configure Routing Information Protocol | 727 |
| Enabling RIP and Configuring RIP Parameters | 727 |
| Specifying a RIP Version and Enabling Authentication | 728 |
| Configuration Examples for Routing Information Protocol | 730 |
| Example: Enabling RIP and Configuring RIP Parameters | 730 |
| Example: Specifying a RIP Version and Enabling Authentication | 730 |
| Additional References for RIP | 730 |
| Feature Information for RIP | 731 |

CHAPTER 37**Open Shortest Path First (OSPF) 733**

| | |
|--|-----|
| Information About OSPF | 733 |
| OSPF for Routed Access | 734 |
| OSPF Area Parameters | 734 |
| Other OSPF Parameters | 734 |
| LSA Group Pacing | 735 |
| Loopback Interfaces | 735 |
| How to Configure OSPF | 736 |
| Default OSPF Configuration | 736 |
| Configuring Basic OSPF Parameters | 737 |
| Configuring OSPF Interfaces | 738 |
| Configuring OSPF Area Parameters | 740 |
| Configuring Other OSPF Parameters | 742 |
| Changing LSA Group Pacing | 744 |
| Configuring a Loopback Interface | 745 |
| Monitoring OSPF | 746 |
| Configuration Examples for OSPF | 747 |
| Example: Configuring Basic OSPF Parameters | 747 |

CHAPTER 38**IPv6 Open Shortest Path First version 3 749**

| | |
|---|-----|
| IPv6 Routing: OSPFv3 | 749 |
| Prerequisites for IPv6 Routing: OSPFv3 | 749 |
| Restrictions for IPv6 Routing: OSPFv3 | 749 |
| Information About IPv6 Routing: OSPFv3 | 749 |
| How OSPFv3 Works | 749 |
| Comparison of OSPFv3 and OSPF Version 2 | 750 |
| LSA Types for OSPFv3 | 750 |
| NBMA in OSPFv3 | 751 |
| Load Balancing in OSPFv3 | 752 |
| Addresses Imported into OSPFv3 | 752 |
| OSPFv3 Customization | 752 |
| Force SPF in OSPFv3 | 754 |
| How to Configure Load Balancing in OSPFv3 | 754 |
| Configuring the OSPFv3 Device Process | 754 |
| Configuring NBMA Interfaces in OSPFv3 | 756 |
| Forcing an SPF Calculation | 757 |
| Verifying OSPFv3 Configuration and Operation | 758 |
| Configuration Examples for Load Balancing in OSPFv3 | 761 |
| Example: Configuring the OSPFv3 Device Process | 761 |
| Example: Configuring NBMA Interfaces | 761 |
| Example: Forcing SPF Configuration | 762 |
| Additional References | 762 |
| Feature Information for IPv6 Routing: OSPFv3 | 763 |

CHAPTER 39 **Configuring Policy-Based Routing (PBR)** 765

| | |
|---|-----|
| Policy-Based Routing | 765 |
| Information About Policy-Based Routing | 765 |
| Policy-Based Routing Using Object Tracking | 766 |
| How to Configure PBR | 766 |
| Verifying Next-Hop IP Using Object Tracking | 769 |
| Feature Information for Configuring PBR | 771 |

PART X **Security** 773

| | | |
|-------------------|-----------------------------------|------------|
| CHAPTER 40 | Security Features Overview | 775 |
| | Security Features Overview | 775 |

| | | |
|-------------------|---------------------------------------|------------|
| CHAPTER 41 | Preventing Unauthorized Access | 779 |
| | Preventing Unauthorized Access | 779 |

| | | |
|-------------------|--|------------|
| CHAPTER 42 | Controlling Switch Access with Passwords and Privilege Levels | 781 |
| | Restrictions for Controlling Switch Access with Passwords and Privileges | 781 |
| | Information About Passwords and Privilege Levels | 781 |
| | Default Password and Privilege Level Configuration | 781 |
| | Additional Password Security | 782 |
| | Password Recovery | 782 |
| | Terminal Line Telnet Configuration | 783 |
| | Username and Password Pairs | 783 |
| | Privilege Levels | 783 |
| | How to Control Switch Access with Passwords and Privilege Levels | 784 |
| | Setting or Changing a Static Enable Password | 784 |
| | Protecting Enable and Enable Secret Passwords with Encryption | 785 |
| | Disabling Password Recovery | 787 |
| | Setting a Telnet Password for a Terminal Line | 788 |
| | Configuring Username and Password Pairs | 789 |
| | Setting the Privilege Level for a Command | 791 |
| | Changing the Default Privilege Level for Lines | 792 |
| | Logging into and Exiting a Privilege Level | 793 |
| | Monitoring Switch Access | 793 |
| | Configuration Examples for Setting Passwords and Privilege Levels | 794 |
| | Example: Setting or Changing a Static Enable Password | 794 |
| | Example: Protecting Enable and Enable Secret Passwords with Encryption | 794 |
| | Example: Setting a Telnet Password for a Terminal Line | 794 |
| | Example: Setting the Privilege Level for a Command | 794 |
| | Additional References | 794 |

| CHAPTER 43 | Configuring TACACS+ | 797 |
|-------------------|----------------------------|------------|

| | |
|---|-----|
| Finding Feature Information | 797 |
| Prerequisites for TACACS+ | 797 |
| Restrictions for TACACS+ | 798 |
| Information About TACACS+ | 799 |
| TACACS+ and Switch Access | 799 |
| TACACS+ Overview | 799 |
| TACACS+ Operation | 800 |
| Method List | 801 |
| TACACS AV Pairs | 801 |
| TACACS Authentication and Authorization AV Pairs | 801 |
| TACACS Accounting AV Pairs | 809 |
| Configuring AAA Server Group Selection Based on DNIS | 820 |
| TACACS+ Configuration Options | 822 |
| TACACS+ Login Authentication | 822 |
| TACACS+ Authorization for Privileged EXEC Access and Network Services | 822 |
| TACACS+ Authentication | 822 |
| TACACS+ Authorization | 822 |
| TACACS+ Accounting | 823 |
| Default TACACS+ Configuration | 823 |
| Per VRF for TACACS Servers | 823 |
| How to Configure TACACS+ | 823 |
| Identifying the TACACS+ Server Host and Setting the Authentication Key | 823 |
| Configuring TACACS+ Login Authentication | 825 |
| Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services | 827 |
| Starting TACACS+ Accounting | 828 |
| Establishing a Session with a Router if the AAA Server is Unreachable | 830 |
| Establishing a Session with a Router if the AAA Server is Unreachable | 830 |
| Configuring Per VRF on a TACACS Server | 830 |
| Verifying Per VRF for TACACS Servers | 832 |
| Monitoring TACACS+ | 833 |
| Configuration Examples for TACACS+ | 833 |
| Example: TACACS Authorization | 833 |
| Example: TACACS Accounting | 834 |
| Example: TACACS Authentication | 834 |

| | |
|---|-----|
| Example: Configuring Per VRF for TACACS Servers | 836 |
| Additional References for TACACS+ | 837 |
| Feature Information for TACACS+ | 837 |

CHAPTER 44
Configuring RADIUS 839

| | |
|--|-----|
| Prerequisites for Configuring RADIUS | 839 |
| Restrictions for Configuring RADIUS | 840 |
| Information about RADIUS | 840 |
| RADIUS and Switch Access | 840 |
| RADIUS Overview | 840 |
| RADIUS Operation | 841 |
| Default RADIUS Configuration | 842 |
| RADIUS Server Host | 842 |
| RADIUS Login Authentication | 842 |
| AAA Server Groups | 843 |
| AAA Authorization | 843 |
| RADIUS Accounting | 843 |
| Vendor-Specific RADIUS Attributes | 843 |
| RADIUS Disconnect-Cause Attribute Values | 855 |
| RADIUS Progress Codes | 859 |
| Vendor-Proprietary RADIUS Server Communication | 859 |
| Enhanced Test Command | 860 |
| How to Configure RADIUS | 860 |
| Identifying the RADIUS Server Host | 860 |
| Configuring Settings for All RADIUS Servers | 862 |
| Configuring RADIUS Login Authentication | 863 |
| Defining AAA Server Groups | 866 |
| Configuring RADIUS Authorization for User Privileged Access and Network Services | 867 |
| Starting RADIUS Accounting | 869 |
| Verifying Attribute 196 | 870 |
| Configuring the Device to Use Vendor-Specific RADIUS Attributes | 870 |
| Configuring the Device for Vendor-Proprietary RADIUS Server Communication | 871 |
| Configuring a User Profile and Associating it with the RADIUS Record | 873 |
| Verifying the Enhanced Test Command Configuration | 873 |

| | |
|--|---|
| Configuration Examples for RADIUS | 874 |
| Examples: Identifying the RADIUS Server Host | 874 |
| Example: Using Two Different RADIUS Group Servers | 874 |
| Examples: AAA Server Groups | 874 |
| Troubleshooting Tips for RADIUS Progress Codes | 875 |
| Examples: Configuring the Switch to Use Vendor-Specific RADIUS Attributes | 875 |
| Example: Configuring the Switch for Vendor-Proprietary RADIUS Server Communication | 876 |
| Example: User Profile Associated With the test aaa group Command | 876 |
| Additional References for RADIUS | 877 |
| Feature Information for RADIUS | 878 |
| <hr/> | |
| CHAPTER 45 | RADIUS Server Load Balancing 879 |
| Finding Feature Information | 879 |
| Prerequisites for RADIUS Server Load Balancing | 879 |
| Restrictions for RADIUS Server Load Balancing | 880 |
| Information About RADIUS Server Load Balancing | 880 |
| RADIUS Server Load Balancing Overview | 880 |
| Transaction Load Balancing Across RADIUS Server Groups | 880 |
| RADIUS Server Status and Automated Testing | 881 |
| How to Configure RADIUS Server Load Balancing | 882 |
| Enabling Load Balancing for a Named RADIUS Server Group | 882 |
| Enabling Load Balancing for a Global RADIUS Server Group | 883 |
| Troubleshooting RADIUS Server Load Balancing | 883 |
| Configuration Examples for RADIUS Server Load Balancing | 885 |
| Example: Enabling Load Balancing for a Named RADIUS Server Group | 885 |
| Example: Enabling Load Balancing for a Global RADIUS Server Group | 887 |
| Example: Monitoring Idle Timer | 889 |
| Example: Configuring the Preferred Server with the Same Authentication and Authorization Server | 890 |
| Example: Configuring the Preferred Server with Different Authentication and Authorization Servers | 890 |
| Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers | 891 |
| Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorization Servers | 891 |

Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorization Servers **892**

Additional References for RADIUS Server Load Balancing **892**

Feature Information for RADIUS Server Load Balancing **893**

CHAPTER 46

RADIUS Change of Authorization Support **895**

Information About RADIUS Change-of-Authorization **895**

RADIUS Change of Authorization **895**

Change-of-Authorization Requests **897**

RFC 5176 Compliance **897**

Preconditions **898**

CoA Request Response Code **898**

Session Identification **898**

Session Identification **899**

CoA ACK Response Code **900**

CoA NAK Response Code **900**

Session Reauthentication **900**

Session Reauthentication in a Switch Stack **900**

Session Termination **901**

CoA Activate Service Command **901**

CoA Deactivate Service Command **902**

CoA Request: Disable Host Port **903**

CoA Request: Bounce-Port **903**

CoA Session Query Command **904**

CoA Session Reauthenticate Command **904**

CoA Session Terminate Command **905**

Stacking Guidelines for Session Termination **905**

Stacking Guidelines for CoA-Request Bounce-Port **905**

Stacking Guidelines for CoA-Request Disable-Port **906**

How to Configure RADIUS Change-of-Authorization **906**

Configuring CoA on the Device **906**

Monitoring and Troubleshooting CoA Functionality **908**

Additional References for RADIUS Change-of-Authorization **909**

Feature Information for RADIUS Change-of-Authorization Support **909**

CHAPTER 47**Configuring Kerberos 911**

- Finding Feature Information 911
- Prerequisites for Controlling Switch Access with Kerberos 911
- Information About Kerberos 912
 - Kerberos and Switch Access 912
 - Kerberos Overview 912
 - Kerberos Operation 914
 - Kerberos Operation 914
 - Authenticating to a Boundary Switch 914
 - Obtaining a TGT from a KDC 915
 - Authenticating to Network Services 915
- How to Configure Kerberos 916
 - Configuring the KDC Using Kerberos Commands 916
 - Adding Users to the KDC Database 917
 - Creating and Extracting a SRVTAB on the KDC 917
 - Configuring the Device to Use the Kerberos Protocol 918
- Configuration Examples for Kerberos 922
 - Example: Defining a Kerberos Realm 922
 - Example: Copying a SRVTAB File 923
 - Example: Configuring Kerberos 923
 - Example: Encrypting a Telnet Session 932
- Additional References 932
- Feature Information for Kerberos 933

CHAPTER 48**Configuring Accounting 935**

- Prerequisites for Configuring Accounting 935
- Restrictions for Configuring Accounting 935
- Information About Configuring Accounting 936
 - Named Method Lists for Accounting 936
 - Method Lists and Server Groups 937
 - AAA Accounting Methods 937
 - Accounting Record Types 938
 - AAA Accounting Methods 938

| | |
|---|-----|
| AAA Accounting Types | 938 |
| Network Accounting | 938 |
| EXEC Accounting | 941 |
| Command Accounting | 942 |
| Connection Accounting | 943 |
| System Accounting | 944 |
| Resource Accounting | 945 |
| VRRS Accounting | 947 |
| AAA Accounting Enhancements | 948 |
| AAA Broadcast Accounting | 948 |
| AAA Session MIB | 948 |
| Accounting Attribute-Value Pairs | 949 |
| How to Configure Accounting | 949 |
| Configuring AAA Accounting Using Named Method Lists | 949 |
| Configuring RADIUS System Accounting | 950 |
| Suppressing Generation of Accounting Records for Null Username Sessions | 952 |
| Generating Interim Accounting Records | 952 |
| Generating Accounting Records for Failed Login or Session | 952 |
| Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records | 953 |
| Configuring AAA Resource Failure Stop Accounting | 953 |
| Configuring AAA Resource Accounting for Start-Stop Records | 953 |
| Configuring AAA Broadcast Accounting | 954 |
| Configuring Per-DNIS AAA Broadcast Accounting | 954 |
| Configuring AAA Session MIB | 954 |
| Configuring VRRS Accounting | 955 |
| Establishing a Session with a Device if the AAA Server is Unreachable | 956 |
| Monitoring Accounting | 957 |
| Troubleshooting Accounting | 957 |
| Configuration Examples for Accounting | 957 |
| Example Configuring Named Method List | 957 |
| Example Configuring AAA Resource Accounting | 959 |
| Example Configuring AAA Broadcast Accounting | 960 |
| Example Configuring Per-DNIS AAA Broadcast Accounting | 960 |
| Example AAA Session MIB | 961 |

| | |
|--|-----|
| Example Configuring VRRS Accounting | 961 |
| Additional References for Configuring Accounting | 961 |
| Feature Information for Configuring Accounting | 962 |

CHAPTER 49
Configuring Local Authentication and Authorization 965

| | |
|---|-----|
| How to Configure Local Authentication and Authorization | 965 |
| Configuring the Switch for Local Authentication and Authorization | 965 |
| Monitoring Local Authentication and Authorization | 967 |
| Additional References | 967 |
| Feature Information for Local Authentication and Authorization | 968 |

CHAPTER 50
MAC Authentication Bypass 969

| | |
|--|-----|
| Prerequisites for Configuring MAC Authentication Bypass | 969 |
| Information About MAC Authentication Bypass | 970 |
| Overview of the Cisco IOS Auth Manager | 970 |
| Overview of the Configurable MAB Username and Password | 970 |
| How to Configure MAC Authentication Bypass | 971 |
| Enabling MAC Authentication Bypass | 971 |
| Enabling Reauthentication on a Port | 972 |
| Specifying the Security Violation Mode | 974 |
| Enabling Configurable MAB Username and Password | 975 |
| Configuration Examples for MAC Authentication Bypass | 976 |
| Example: MAC Authentication Bypass Configuration | 976 |
| Example: Enabling Configurable MAB Username and Password | 976 |
| Additional References for MAC Authentication Bypass | 976 |
| Feature Information for MAC Authentication Bypass | 977 |

CHAPTER 51
Password Strength and Management for Common Criteria 979

| | |
|--|-----|
| Restrictions for Password Strength and Management for Common Criteria | 979 |
| Information About Password Strength and Management for Common Criteria | 979 |
| Password Composition Policy | 979 |
| Password Length Policy | 980 |
| Password Lifetime Policy | 980 |
| Password Expiry Policy | 980 |

| | |
|---|-----|
| Password Change Policy | 980 |
| User Reauthentication Policy | 981 |
| Support for Framed (Noninteractive) Session | 981 |
| How to Configure Password Strength and Management for Common Criteria | 981 |
| Configuring the Password Security Policy | 981 |
| Verifying the Common Criteria Policy | 983 |
| Configuration Examples for Password Strength and Management for Common Criteria | 984 |
| Example: Password Strength and Management for Common Criteria | 984 |
| Additional References for Password Strength and Management for Common Criteria | 984 |
| Feature Information for Password Strength and Management for Common Criteria | 985 |

CHAPTER 52**AAA-SERVER-MIB Set Operation 987**

| | |
|---|-----|
| Prerequisites for AAA-SERVER-MIB Set Operation | 987 |
| Restrictions for AAA-SERVER-MIB Set Operation | 987 |
| Information About AAA-SERVER-MIB Set Operation | 987 |
| CISCO-AAA-SERVER-MIB | 987 |
| CISCO-AAA-SERVER-MIB Set Operation | 988 |
| How to Configure AAA-SERVER-MIB Set Operation | 988 |
| Configuring AAA-SERVER-MIB Set Operations | 988 |
| Verifying SNMP Values | 988 |
| Configuration Examples for AAA-SERVER-MIB Set Operation | 989 |
| RADIUS Server Configuration and Server Statistics Example | 989 |
| Additional References for AAA-SERVER-MIB Set Operation | 991 |
| Feature Information for AAA-SERVER-MIB Set Operation | 991 |

CHAPTER 53**Configuring Secure Shell 993**

| | |
|---|-----|
| Prerequisites for Configuring Secure Shell | 993 |
| Restrictions for Configuring Secure Shell | 994 |
| Information About Configuring Secure Shell | 994 |
| SSH and Switch Access | 994 |
| SSH Servers, Integrated Clients, and Supported Versions | 994 |
| RSA Authentication Support | 995 |
| SSL Configuration Guidelines | 995 |
| Secure Copy Protocol Overview | 995 |

| | |
|---|------|
| Secure Copy Protocol | 996 |
| How Secure Copy Works | 996 |
| Reverse Telnet | 996 |
| Reverse SSH | 996 |
| How to Configure Secure Shell | 997 |
| Setting Up the Device to Run SSH | 997 |
| Configuring the SSH Server | 998 |
| Invoking an SSH Client | 1000 |
| Troubleshooting Tips | 1000 |
| Configuring Reverse SSH for Console Access | 1001 |
| Configuring Reverse SSH for Modem Access | 1002 |
| Troubleshooting Reverse SSH on the Client | 1004 |
| Troubleshooting Reverse SSH on the Server | 1004 |
| Monitoring the SSH Configuration and Status | 1005 |
| Configuring Secure Copy | 1005 |
| Configuration Examples for Secure Shell | 1007 |
| Example: Secure Copy Configuration Using Local Authentication | 1007 |
| Example: SCP Server-Side Configuration Using Network-Based Authentication | 1007 |
| Example Reverse SSH Console Access | 1007 |
| Example Reverse SSH Modem Access | 1008 |
| Example: Monitoring the SSH Configuration and Status | 1008 |
| Additional References for Secure Shell | 1009 |
| Feature Information for Configuring Secure Shell | 1009 |

CHAPTER 54
Secure Shell Version 2 Support 1011

| | |
|---|------|
| Information About Secure Shell Version 2 Support | 1011 |
| Secure Shell Version 2 | 1011 |
| Secure Shell Version 2 Enhancements | 1012 |
| Secure Shell Version 2 Enhancements for RSA Keys | 1012 |
| SNMP Trap Generation | 1013 |
| SSH Keyboard Interactive Authentication | 1014 |
| How to Configure Secure Shell Version 2 Support | 1014 |
| Configuring a Device for SSH Version 2 Using a Hostname and Domain Name | 1014 |
| Configuring a Device for SSH Version 2 Using RSA Key Pairs | 1015 |

| | |
|---|------|
| Configuring the Cisco SSH Server to Perform RSA-Based User Authentication | 1016 |
| Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication | 1018 |
| Starting an Encrypted Session with a Remote Device | 1020 |
| Enabling Secure Copy Protocol on the SSH Server | 1021 |
| Verifying the Status of the Secure Shell Connection | 1022 |
| Verifying the Secure Shell Status | 1023 |
| Monitoring and Maintaining Secure Shell Version 2 | 1024 |
| Configuration Examples for Secure Shell Version 2 Support | 1027 |
| Example: Configuring Secure Shell Version 2 | 1027 |
| Example: Starting an Encrypted Session with a Remote Device | 1028 |
| Example: Configuring Server-Side SCP | 1028 |
| Example: Setting an SNMP Trap | 1028 |
| Examples: SSH Keyboard Interactive Authentication | 1029 |
| Example: Enabling Client-Side Debugs | 1029 |
| Example: Enabling ChPass with a Blank Password Change | 1029 |
| Example: Enabling ChPass and Changing the Password on First Login | 1030 |
| Example: Enabling ChPass and Expiring the Password After Three Logins | 1030 |
| Example: SNMP Debugging | 1031 |
| Examples: SSH Debugging Enhancements | 1031 |
| Additional References for Secure Shell Version 2 Support | 1032 |
| Feature Information for Secure Shell Version 2 Support | 1033 |

CHAPTER 55**X.509v3 Certificates for SSH Authentication 1035**

| | |
|---|------|
| Prerequisites for X.509v3 Certificates for SSH Authentication | 1035 |
| Restrictions for X.509v3 Certificates for SSH Authentication | 1035 |
| Information About X.509v3 Certificates for SSH Authentication | 1036 |
| X.509v3 Certificates for SSH Authentication Overview | 1036 |
| Server and User Authentication Using X.509v3 | 1036 |
| OCSP Response Stapling | 1036 |
| How to Configure X.509v3 Certificates for SSH Authentication | 1037 |
| Configuring Digital Certificates for Server Authentication | 1037 |
| Configuring Digital Certificates for User Authentication | 1038 |
| Verifying the Server and User Authentication Using Digital Certificates | 1040 |
| Configuration Examples for X.509v3 Certificates for SSH Authentication | 1044 |

| | |
|---|------|
| Example: Configuring Digital Certificates for Server Authentication | 1044 |
| Example: Configuring Digital Certificate for User Authentication | 1044 |
| Additional References for X.509v3 Certificates for SSH Authentication | 1045 |
| Feature Information for X.509v3 Certificates for SSH Authentication | 1045 |

CHAPTER 56**Configuring Secure Socket Layer HTTP 1047**

| | |
|---|------|
| Information About Secure Socket Layer HTTP | 1047 |
| Secure HTTP Servers and Clients Overview | 1047 |
| Certificate Authority Trustpoints | 1048 |
| CipherSuites | 1049 |
| Default SSL Configuration | 1050 |
| SSL Configuration Guidelines | 1050 |
| How to Configure Secure Socket Layer HTTP | 1050 |
| Configuring the Secure HTTP Server | 1050 |
| Configuring the Secure HTTP Client | 1054 |
| Configuring a CA Trustpoint | 1055 |
| Monitoring Secure HTTP Server and Client Status | 1057 |
| Configuration Examples for Secure Socket Layer HTTP | 1057 |
| Example: Configuring Secure Socket Layer HTTP | 1057 |
| Additional References for Secure Socket Layer HTTP | 1058 |
| Feature Information for Secure Socket Layer HTTP | 1059 |
| Glossary | 1059 |

CHAPTER 57**Certification Authority Interoperability 1061**

| | |
|---|------|
| Prerequisites For Certification Authority | 1061 |
| Restrictions for Certification Authority | 1061 |
| Information About Certification Authority | 1061 |
| CA Supported Standards | 1061 |
| Purpose of CAs | 1062 |
| Implementing IPsec Without CAs | 1063 |
| Implementing IPsec With CAs | 1063 |
| Implementing IPsec with Multiple Root CAs | 1063 |
| How CA Certificates Are Used by IPsec Devices | 1064 |
| Registration Authorities | 1064 |

| | |
|---|------|
| How to Configure Certification Authority | 1064 |
| Managing NVRAM Memory Usage | 1064 |
| Configuring the Device Host Name and IP Domain Name | 1065 |
| Generating an RSA Key Pair | 1066 |
| Declaring a Certification Authority | 1067 |
| Configuring a Root CA (Trusted Root) | 1068 |
| Authenticating the CA | 1069 |
| Requesting Signed Certificates | 1070 |
| Monitoring and Maintaining Certification Authority | 1071 |
| Requesting a Certificate Revocation List | 1071 |
| Querying a Certification Revocation List | 1071 |
| Deleting RSA Keys from a Device | 1072 |
| Deleting Public Keys for a Peer | 1073 |
| Deleting Certificates from the Configuration | 1074 |
| Viewing Keys and Certificates | 1075 |

CHAPTER 58**Access Control List Overview 1077**

| | |
|---|------|
| Information About Access Control Lists | 1077 |
| Definition of an Access List | 1077 |
| Functions of an Access Control List | 1078 |
| Purpose of IP Access Lists | 1078 |
| Reasons to Configure ACLs | 1078 |
| Software Processing of an Access List | 1079 |
| Access List Rules | 1079 |
| Helpful Hints for Creating IP Access Lists | 1080 |
| IP Packet Fields You Can Filter to Control Access | 1081 |
| Source and Destination Addresses | 1081 |
| Wildcard Mask for Addresses in an Access List | 1081 |
| Access List Sequence Numbers | 1082 |
| ACL Supported Types | 1082 |
| Supported ACLs | 1083 |
| ACL Precedence | 1083 |
| Port ACLs | 1083 |
| Router ACLs | 1084 |

| | |
|---|------|
| Access Control Entries | 1085 |
| ACEs and Fragmented and Unfragmented Traffic | 1085 |
| ACEs and Fragmented and Unfragmented Traffic Examples | 1085 |

CHAPTER 59**Configuring IPv4 Access Control Lists 1087**

| | |
|---|------|
| Prerequisites for Configuring IPv4 Access Control Lists | 1087 |
| Restrictions for Configuring IPv4 Access Control Lists | 1087 |
| Information About Configuring IPv4 Access Control Lists | 1088 |
| ACL Overview | 1088 |
| Standard and Extended IPv4 ACLs | 1089 |
| IPv4 ACL Switch Unsupported Features | 1089 |
| Access List Numbers | 1089 |
| Numbered Standard IPv4 ACLs | 1090 |
| Numbered Extended IPv4 ACLs | 1090 |
| Named IPv4 ACLs | 1091 |
| Benefits of IP Access List Entry Sequence Numbering | 1092 |
| Sequence Numbering Behavior | 1092 |
| Including comments in ACLs | 1093 |
| Hardware and Software Treatment of IP ACLs | 1093 |
| Time Ranges for ACLs | 1094 |
| IPv4 ACL Interface Considerations | 1094 |
| Apply an Access Control List to an Interface | 1095 |
| ACL Logging | 1096 |
| How to Configure ACLs | 1096 |
| Configuring IPv4 ACLs | 1096 |
| Creating a Numbered Standard ACL | 1096 |
| Creating a Numbered Extended ACL | 1098 |
| Creating Named Standard ACLs | 1101 |
| Creating Extended Named ACLs | 1103 |
| Configuring an Access Control Entry with Noncontiguous Ports | 1104 |
| Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry | 1106 |
| Sequencing Access-List Entries and Revising the Access List | 1107 |
| Configuring Commented IP ACL Entries | 1110 |
| Configuring Time Ranges for ACLs | 1111 |

| | |
|--|------|
| Applying an IPv4 ACL to a Terminal Line | 1112 |
| Applying an IPv4 ACL to an Interface (CLI) | 1114 |
| Monitoring IPv4 ACLs | 1115 |
| Configuration Examples for ACLs | 1115 |
| ACLs in a Small Networked Office | 1115 |
| Example: Numbered ACLs | 1116 |
| Examples: Extended ACLs | 1116 |
| Examples: Named ACLs | 1117 |
| Example: Configuring an Access Control Entry with Noncontiguous Ports | 1118 |
| Example: Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry | 1118 |
| Example Resequencing Entries in an Access List | 1119 |
| Example Adding an Entry with a Sequence Number | 1119 |
| Example Adding an Entry with No Sequence Number | 1120 |
| Examples: Configuring Commented IP ACL Entries | 1120 |
| Examples: Using Time Ranges with ACLs | 1121 |
| Examples: Time Range Applied to an IP ACL | 1122 |
| Examples: ACL Logging | 1122 |
| Examples: Troubleshooting ACLs | 1123 |
| Additional References | 1124 |
| Feature Information for IPv4 Access Control Lists | 1125 |

CHAPTER 60

| | |
|---|-------------|
| IPv6 Access Control Lists | 1127 |
| Prerequisites for IPv6 ACLs | 1127 |
| Restrictions for IPv6 ACLs | 1127 |
| Information About Configuring IPv6 ACLs | 1128 |
| ACL Overview | 1128 |
| IPv6 ACLs Overview | 1129 |
| Understanding IPv6 ACLs | 1129 |
| Interactions with Other Features and Switches | 1130 |
| Default Configuration for IPv6 ACLs | 1130 |
| Supported ACL Features | 1131 |
| IPv6 Port-Based Access Control List Support | 1131 |
| ACLs and Traffic Forwarding | 1131 |

| | |
|---|------|
| How to Configure IPv6 ACLs | 1132 |
| Configuring IPv6 ACLs | 1132 |
| Attaching an IPv6 ACL to an Interface | 1135 |
| Monitoring IPv6 ACLs | 1137 |
| Configuring PACL Mode and Applying IPv6 PACL on an Interface | 1137 |
| Configuring IPv6 ACL Extensions for Hop by Hop Filtering | 1138 |
| Configuration Examples for IPv6 ACLs | 1140 |
| Example: Configuring IPv6 ACLs | 1140 |
| Example: Applying IPv6 ACLs | 1140 |
| Example: Configuring PACL Mode and Applying IPv6 PACL on an Interface | 1140 |
| Example: IPv6 ACL Extensions for Hop by Hop Filtering | 1140 |
| Additional References | 1141 |
| Feature Information for IPv6 Access Control Lists | 1142 |

CHAPTER 61**ACL Support for Filtering IP Options 1145**

| | |
|---|------|
| Prerequisites for ACL Support for Filtering IP Options | 1145 |
| Information About ACL Support for Filtering IP Options | 1145 |
| IP Options | 1145 |
| Benefits of Filtering IP Options | 1146 |
| Benefits of Filtering on TCP Flags | 1146 |
| TCP Flags | 1146 |
| How to Configure ACL Support for Filtering IP Options | 1147 |
| Filtering Packets That Contain IP Options | 1147 |
| Filtering Packets That Contain TCP Flags | 1148 |
| Configuration Examples for ACL Support for Filtering IP Options | 1150 |
| Example: Filtering Packets That Contain IP Options | 1150 |
| Example: Filtering Packets That Contain TCP Flags | 1151 |
| Additional References for ACL Support for Filtering IP Options | 1151 |
| Feature Information for Creating an IP Access List to Filter | 1152 |

CHAPTER 62**VLAN Access Control Lists 1153**

| | |
|---|------|
| Information About VLAN Access Control Lists | 1153 |
| VLAN Maps | 1153 |
| VLAN Map Configuration Guidelines | 1154 |

| | |
|---|------|
| VLAN Maps with Router ACLs | 1154 |
| VLAN Maps and Router ACL Configuration Guidelines | 1155 |
| How to Configure VLAN Access Control Lists | 1155 |
| Creating Named MAC Extended ACLs | 1155 |
| Applying a MAC ACL to a Layer 2 Interface | 1157 |
| Configuring VLAN Maps | 1158 |
| Creating a VLAN Map | 1160 |
| Applying a VLAN Map to a VLAN | 1161 |
| Configuration Examples for ACLs and VLAN Maps | 1162 |
| Example: Creating an ACL and a VLAN Map to Deny a Packet | 1162 |
| Example: Creating an ACL and a VLAN Map to Permit a Packet | 1163 |
| Example: Default Action of Dropping IP Packets and Forwarding MAC Packets | 1163 |
| Example: Default Action of Dropping MAC Packets and Forwarding IP Packets | 1163 |
| Example: Default Action of Dropping All Packets | 1164 |
| Configuration Examples for Using VLAN Maps in Your Network | 1164 |
| Example: Wiring Closet Configuration | 1164 |
| Example: Restricting Access to a Server on Another VLAN | 1166 |
| Example: Denying Access to a Server on Another VLAN | 1166 |
| Configuration Examples of Router ACLs and VLAN Maps Applied to VLANs | 1167 |
| Example: ACLs and Switched Packets | 1167 |
| Example: ACLs and Bridged Packets | 1167 |
| Example: ACLs and Routed Packets | 1168 |
| Example: ACLs and Multicast Packets | 1169 |

CHAPTER 63
Configuring DHCP 1171

| | |
|---------------------------------|------|
| Restrictions for DHCP | 1171 |
| Information About DHCP | 1171 |
| DHCP Server | 1171 |
| DHCP Relay Agent | 1171 |
| DHCP Snooping | 1172 |
| Option-82 Data Insertion | 1173 |
| Cisco IOS DHCP Server Database | 1176 |
| DHCP Snooping Binding Database | 1176 |
| DHCP Snooping and Switch Stacks | 1177 |

| | |
|---|------|
| How to Configure DHCP Features | 1178 |
| Default DHCP Snooping Configuration | 1178 |
| DHCP Snooping Configuration Guidelines | 1179 |
| Configuring the DHCP Server | 1179 |
| DHCP Server and Switch Stacks | 1179 |
| Configuring the DHCP Relay Agent | 1179 |
| Specifying the Packet Forwarding Address | 1180 |
| Prerequisites for Configuring DHCP Snooping and Option 82 | 1182 |
| Enabling DHCP Snooping and Option 82 | 1183 |
| Enabling the Cisco IOS DHCP Server Database | 1186 |
| Monitoring DHCP Snooping Information | 1186 |
| Configuring DHCP Server Port-Based Address Allocation | 1187 |
| Information About Configuring DHCP Server Port-Based Address Allocation | 1187 |
| Default Port-Based Address Allocation Configuration | 1187 |
| Port-Based Address Allocation Configuration Guidelines | 1187 |
| Enabling the DHCP Snooping Binding Database Agent | 1187 |
| Enabling DHCP Server Port-Based Address Allocation | 1189 |
| Monitoring DHCP Server Port-Based Address Allocation | 1191 |
| Additional References | 1191 |
| Feature Information for DHCP Snooping and Option 82 | 1191 |

CHAPTER 64**Configuring IP Source Guard 1193**

| | |
|---|------|
| Information About IP Source Guard | 1193 |
| IP Source Guard | 1193 |
| IP Source Guard for Static Hosts | 1193 |
| IP Source Guard Configuration Guidelines | 1194 |
| How to Configure IP Source Guard | 1195 |
| Enabling IP Source Guard | 1195 |
| Configuring IP Source Guard for Static Hosts on a Layer 2 Access Port | 1196 |
| Monitoring IP Source Guard | 1198 |
| Additional References | 1199 |

CHAPTER 65**Configuring Dynamic ARP Inspection 1201**

| | |
|---|------|
| Restrictions for Dynamic ARP Inspection | 1201 |
|---|------|

| | |
|---|------|
| Understanding Dynamic ARP Inspection | 1202 |
| Interface Trust States and Network Security | 1204 |
| Rate Limiting of ARP Packets | 1205 |
| Relative Priority of ARP ACLs and DHCP Snooping Entries | 1205 |
| Logging of Dropped Packets | 1205 |
| Default Dynamic ARP Inspection Configuration | 1206 |
| Relative Priority of ARP ACLs and DHCP Snooping Entries | 1206 |
| Configuring ARP ACLs for Non-DHCP Environments | 1206 |
| Configuring Dynamic ARP Inspection in DHCP Environments | 1209 |
| Limiting the Rate of Incoming ARP Packets | 1211 |
| Performing Dynamic ARP Inspection Validation Checks | 1213 |
| Monitoring DAI | 1215 |
| Verifying the DAI Configuration | 1215 |
| Additional References | 1216 |

CHAPTER 66

| | |
|---|-------------|
| Configuring IEEE 802.1x Port-Based Authentication | 1217 |
| Information About 802.1x Port-Based Authentication | 1217 |
| Port-Based Authentication Process | 1218 |
| Port-Based Authentication Initiation and Message Exchange | 1220 |
| Authentication Manager for Port-Based Authentication | 1222 |
| Port-Based Authentication Methods | 1222 |
| Per-User ACLs and Filter-Ids | 1222 |
| Port-Based Authentication Manager CLI Commands | 1223 |
| Ports in Authorized and Unauthorized States | 1224 |
| Port-Based Authentication and Switch Stacks | 1225 |
| 802.1x Host Mode | 1226 |
| 802.1x Multiple Authentication Mode | 1226 |
| Multi-auth Per User VLAN assignment | 1227 |
| MAC Move | 1228 |
| MAC Replace | 1229 |
| 802.1x Accounting | 1229 |
| 802.1x Accounting Attribute-Value Pairs | 1230 |
| 802.1x Readiness Check | 1231 |
| Switch-to-RADIUS-Server Communication | 1231 |

| | |
|---|------|
| 802.1x Authentication with VLAN Assignment | 1231 |
| 802.1x Authentication with Per-User ACLs | 1233 |
| 802.1x Authentication with Downloadable ACLs and Redirect URLs | 1234 |
| Cisco Secure ACS and Attribute-Value Pairs for the Redirect URL | 1235 |
| Cisco Secure ACS and Attribute-Value Pairs for Downloadable ACLs | 1236 |
| VLAN ID-Based MAC Authentication | 1236 |
| 802.1x Authentication with Guest VLAN | 1236 |
| 802.1x Authentication with Restricted VLAN | 1237 |
| 802.1x Authentication with Inaccessible Authentication Bypass | 1238 |
| Inaccessible Authentication Bypass Support on Multiple-Authentication Ports | 1239 |
| Inaccessible Authentication Bypass Authentication Results | 1239 |
| Inaccessible Authentication Bypass Feature Interactions | 1239 |
| 802.1x Critical Voice VLAN | 1240 |
| 802.1x User Distribution | 1241 |
| 802.1x User Distribution Configuration Guidelines | 1241 |
| IEEE 802.1x Authentication with Voice VLAN Ports | 1241 |
| IEEE 802.1x Authentication with Port Security | 1242 |
| IEEE 802.1x Authentication with Wake-on-LAN | 1242 |
| IEEE 802.1x Authentication with MAC Authentication Bypass | 1243 |
| Network Admission Control Layer 2 IEEE 802.1x Validation | 1244 |
| Flexible Authentication Ordering | 1244 |
| Open1x Authentication | 1245 |
| Multidomain Authentication | 1245 |
| Limiting Login for Users | 1246 |
| 802.1x Supplicant and Authenticator Switches with Network Edge Access Topology (NEAT) | 1247 |
| Voice Aware 802.1x Security | 1248 |
| Common Session ID | 1249 |
| How to Configure 802.1x Port-Based Authentication | 1249 |
| Default 802.1x Authentication Configuration | 1249 |
| 802.1x Authentication Configuration Guidelines | 1251 |
| 802.1x Authentication | 1251 |
| VLAN Assignment, Guest VLAN, Restricted VLAN, and Inaccessible Authentication Bypass | 1251 |
| MAC Authentication Bypass | 1252 |
| Maximum Number of Allowed Devices Per Port | 1253 |

| | |
|--|------|
| Configuring 802.1x Readiness Check | 1253 |
| Configuring Voice Aware 802.1x Security | 1254 |
| Configuring 802.1x Violation Modes | 1256 |
| Configuring 802.1x Authentication | 1257 |
| Configuring 802.1x Port-Based Authentication | 1258 |
| Configuring the Switch-to-RADIUS-Server Communication | 1260 |
| Configuring the Host Mode | 1262 |
| Configuring Periodic Re-Authentication | 1263 |
| Changing the Quiet Period | 1264 |
| Changing the Switch-to-Client Retransmission Time | 1265 |
| Setting the Switch-to-Client Frame-Retransmission Number | 1266 |
| Setting the Re-Authentication Number | 1267 |
| Enabling MAC Move | 1268 |
| Disabling MAC Move | 1269 |
| Enabling MAC Replace | 1270 |
| Configuring 802.1x Accounting | 1271 |
| Configuring a Guest VLAN | 1273 |
| Configuring a Restricted VLAN | 1274 |
| Configuring Number of Authentication Attempts on a Restricted VLAN | 1275 |
| Configuring 802.1x Inaccessible Authentication Bypass with Critical Voice VLAN | 1276 |
| Example of Configuring Inaccessible Authentication Bypass | 1280 |
| Configuring 802.1x Authentication with WoL | 1280 |
| Configuring MAC Authentication Bypass | 1281 |
| Formatting a MAC Authentication Bypass Username and Password | 1282 |
| Configuring 802.1x User Distribution | 1283 |
| Example of Configuring VLAN Groups | 1284 |
| Configuring NAC Layer 2 802.1x Validation | 1285 |
| Configuring Limiting Login for Users | 1286 |
| Configuring an Authenticator Switch with NEAT | 1288 |
| Configuring a Supplicant Switch with NEAT | 1290 |
| Configuring 802.1x Authentication with Downloadable ACLs and Redirect URLs | 1292 |
| Configuring Downloadable ACLs | 1292 |
| Configuring a Downloadable Policy | 1293 |
| Configuring VLAN ID-based MAC Authentication | 1296 |

| | |
|---|------|
| Configuring Flexible Authentication Ordering | 1296 |
| Configuring OpenIx | 1297 |
| Disabling 802.1x Authentication on the Port | 1299 |
| Resetting the 802.1x Authentication Configuration to the Default Values | 1300 |
| Monitoring 802.1x Statistics and Status | 1301 |
| Additional References for IEEE 802.1x Port-Based Authentication | 1301 |
| Feature Information for 802.1x Port-Based Authentication | 1302 |

CHAPTER 67
Configuring Web-Based Authentication 1305

| | |
|--|------|
| Information About Web-Based Authentication | 1305 |
| Web-Based Authentication Overview | 1305 |
| Device Roles | 1306 |
| Host Detection | 1307 |
| Session Creation | 1307 |
| Authentication Process | 1308 |
| Using Authentication Proxy | 1308 |
| When to Use the Authentication Proxy | 1309 |
| Applying Authentication Proxy | 1309 |
| Local Web Authentication Banner | 1310 |
| Web Authentication Customizable Web Pages | 1313 |
| Web Authentication Redirection to Original URL Overview | 1315 |
| Web-based Authentication Interactions with Other Features | 1317 |
| Default Web-Based Authentication Configuration | 1319 |
| Web-Based Authentication Configuration Guidelines and Restrictions | 1319 |
| How to Configure Web-Based Authentication | 1320 |
| Configuring the Authentication Rule and Interfaces | 1320 |
| Configuring AAA Authentication | 1322 |
| Configuring Switch-to-RADIUS-Server Communication | 1323 |
| Configuring the HTTP Server | 1324 |
| Customizing the Authentication Proxy Web Pages | 1325 |
| Specifying a Redirection URL for Successful Login | 1327 |
| Configuring the Web-Based Authentication Parameters | 1327 |
| Configuring a Web Authentication Local Banner | 1328 |
| Configuring Web-Based Authentication without SVI | 1329 |

| | |
|---|------|
| Configuring Web-Based Authentication with VRF Aware | 1330 |
| Removing Web-Based Authentication Cache Entries | 1331 |
| Monitoring Web-Based Authentication Status | 1332 |
| Displaying Web-Based Authentication Status | 1332 |
| Monitoring HTTP Authentication Proxy | 1333 |
| Verifying HTTPS Authentication Proxy | 1333 |
| Configuration Examples for Web-Based Authentication | 1334 |
| Example: Configuring the Authentication Rule and Interfaces | 1334 |
| Example: AAA Configuration | 1334 |
| Example: HTTP Server Configuration | 1335 |
| Example: Customizing the Authentication Proxy Web Pages | 1335 |
| Example: Specifying a Redirection URL for Successful Login | 1335 |
| Additional References for Web-Based Authentication | 1336 |
| Feature Information for Web-Based Authentication | 1336 |

CHAPTER 68**Auto Identity 1337**

| | |
|--|------|
| Auto Identity | 1337 |
| Information About Auto Identity | 1337 |
| Auto Identity Overview | 1337 |
| Auto Identity Global Template | 1338 |
| Auto Identity Interface Templates | 1338 |
| Auto Identity Built-in Policies | 1339 |
| Auto Identity Class Maps Templates | 1339 |
| Auto Identity Parameter Maps | 1340 |
| Auto Identity Service Templates | 1340 |
| How to Configure Auto Identity | 1340 |
| Configuring Auto Identity Globally | 1340 |
| Configuring Auto Identity at an Interface Level | 1341 |
| Configuration Examples for Auto Identity | 1343 |
| Example: Configuring Auto Identity Globally | 1343 |
| Example: Configuring Auto Identity at an Interface Level | 1343 |
| Verifying Auto Identity | 1343 |
| Feature Information for Auto Identity | 1346 |

CHAPTER 69

| | |
|--|-------------|
| Configuring Port-Based Traffic Control | 1349 |
| Overview of Port-Based Traffic Control | 1350 |
| Finding Feature Information | 1350 |
| Information About Storm Control | 1350 |
| Storm Control | 1350 |
| How Traffic Activity is Measured | 1350 |
| Traffic Patterns | 1351 |
| How to Configure Storm Control | 1352 |
| Configuring Storm Control and Threshold Levels | 1352 |
| Configuring Small-Frame Arrival Rate | 1354 |
| Finding Feature Information | 1356 |
| Information About Protected Ports | 1357 |
| Protected Ports | 1357 |
| Default Protected Port Configuration | 1357 |
| Protected Ports Guidelines | 1357 |
| How to Configure Protected Ports | 1357 |
| Configuring a Protected Port | 1357 |
| Monitoring Protected Ports | 1359 |
| Where to Go Next | 1359 |
| Additional References | 1359 |
| Feature Information | 1360 |
| Finding Feature Information | 1360 |
| Information About Port Blocking | 1360 |
| Port Blocking | 1360 |
| How to Configure Port Blocking | 1360 |
| Blocking Flooded Traffic on an Interface | 1360 |
| Monitoring Port Blocking | 1362 |
| Where to Go Next | 1362 |
| Additional References | 1362 |
| Feature Information | 1363 |
| Prerequisites for Port Security | 1363 |
| Restrictions for Port Security | 1363 |
| Information About Port Security | 1364 |

| | |
|---|------|
| Port Security | 1364 |
| Types of Secure MAC Addresses | 1364 |
| Sticky Secure MAC Addresses | 1364 |
| Security Violations | 1365 |
| Port Security Aging | 1366 |
| Port Security and Switch Stacks | 1366 |
| Default Port Security Configuration | 1366 |
| Port Security Configuration Guidelines | 1367 |
| Overview of Port-Based Traffic Control | 1368 |
| How to Configure Port Security | 1369 |
| Enabling and Configuring Port Security | 1369 |
| Enabling and Configuring Port Security Aging | 1374 |
| Configuration Examples for Port Security | 1376 |
| Additional References | 1377 |
| Finding Feature Information | 1377 |
| Information About Protocol Storm Protection | 1378 |
| Protocol Storm Protection | 1378 |
| Default Protocol Storm Protection Configuration | 1378 |
| How to Configure Protocol Storm Protection | 1378 |
| Enabling Protocol Storm Protection | 1378 |
| Monitoring Protocol Storm Protection | 1380 |
| Additional References | 1380 |

CHAPTER 70
Configuring FIPS 1381

| | |
|--|------|
| Information About FIPS and Common Criteria | 1381 |
|--|------|

CHAPTER 71
Configuring Control Plane Policing 1383

| | |
|---|------|
| Restrictions for Control Plane Policing | 1383 |
| Control Plane Policing | 1383 |
| Configuring Control Plane Policing | 1384 |
| Examples: Configuring CoPP | 1385 |

PART XI
Configuring Cisco IOS IP SLAs 1387

| | | |
|-------------------|--|-------------|
| CHAPTER 72 | Configuring Cisco IP SLAs | 1389 |
| | Restrictions on SLAs | 1389 |
| | Information About SLAs | 1389 |
| | Cisco IOS IP Service Level Agreements (SLAs) | 1389 |
| | Network Performance Measurement with Cisco IOS IP SLAs | 1390 |
| | IP SLA Responder and IP SLA Control Protocol | 1391 |
| | Response Time Computation for IP SLAs | 1392 |
| | How to Configure IP SLAs Operations | 1393 |
| | Default Configuration | 1393 |
| | Configuration Guidelines | 1393 |
| | Configuring the IP SLA Responder | 1393 |
| | Monitoring IP SLA Operations | 1394 |
| | Additional References | 1395 |
| | Feature History and Information for Service Level Agreements | 1396 |
| <hr/> | | |
| PART XII | Stacking | 1397 |
| <hr/> | | |
| CHAPTER 73 | Managing Switch Stacks | 1399 |
| | Prerequisites for Switch Stacks | 1399 |
| | Restrictions for Switch Stacks | 1399 |
| | Information About Switch Stacks | 1400 |
| | Switch Stack Overview | 1400 |
| | Supported Features in a Switch Stack | 1400 |
| | Switch Stack Membership | 1401 |
| | Changes to Switch Stack Membership | 1402 |
| | Stack Member Numbers | 1402 |
| | Stack Member Priority Values | 1404 |
| | Switch Stack Bridge ID and MAC Address | 1404 |
| | Persistent MAC Address on the Switch Stack | 1404 |
| | Active and Standby Switch Election and Reelection | 1405 |
| | Switch Stack Configuration Files | 1406 |
| | Offline Configuration to Provision a Stack Member | 1407 |
| | Effects of Adding a Provisioned Switch to a Switch Stack | 1408 |

| | |
|---|--------------------------------|
| Effects of Replacing a Provisioned Switch in a Switch Stack | 1409 |
| Effects of Removing a Provisioned Switch from a Switch Stack | 1409 |
| Stack Protocol Version | 1409 |
| Major Stack Protocol Version Number Incompatibility Among Stack-Capable Switches | 1409 |
| Minor Stack Protocol Version Number Incompatibility Among Stack-Capable Switches | 1409 |
| Auto-Upgrade | 1410 |
| Auto-Advise | 1410 |
| SDM Template Mismatch in Switch Stacks | 1413 |
| Switch Stack Management Connectivity | 1413 |
| Connectivity to Specific Stack Members | 1413 |
| Connectivity to the Switch Stack Through an IP Address | 1414 |
| Connectivity to the Switch Stack Through Console Ports or Ethernet Management Ports | 1414 |
| How to Configure a Switch Stack | 1415 |
| Enabling the Persistent MAC Address Feature | 1415 |
| Assigning a Stack Member Number | 1416 |
| Setting the Stack Member Priority Value | 1417 |
| Setting the Stack Port Speed to 10 Gbps | 1418 |
| Provisioning a New Member for a Switch Stack | 1419 |
| Removing Provisioned Switch Information | 1420 |
| Troubleshooting the Switch Stack | 1421 |
| Accessing the CLI of a Specific Member | 1421 |
| Temporarily Disabling a Stack Port | 1421 |
| Reenabling a Stack Port While Another Member Starts | 1422 |
| Monitoring the Device Stack | 1423 |
| Configuration Examples for Switch Stacks | 1423 |
| Switch Stack Configuration Scenarios | 1423 |
| Enabling the Persistent MAC Address Feature: Example | 1425 |
| Provisioning a New Member for a Switch Stack: Example | 1425 |
| Additional References for Switch Stacks | 1426 |
| | |
| CHAPTER 74 | FlexStack-Extended 1427 |
| Restrictions for FlexStack-Extended | 1427 |
| Information About FlexStack-Extended | 1427 |
| FlexStack-Extended | 1427 |

| | |
|--|------|
| FlexStack-Extended on Catalyst 2960-X and 2960-XR Switches | 1428 |
| Default Port Configurations | 1429 |
| FlexStack-Extended LED | 1430 |
| How to Configure FlexStack-Extended | 1430 |
| Configuring a Stack Port as a Network Port | 1430 |
| Configuring a Network Port as a Stack Port | 1431 |
| Configuring the Stack Speed | 1433 |
| Configuration Examples for FlexStack-Extended | 1433 |
| Examples: Configuring FlexStack-Extended | 1433 |
| Feature Information for FlexStack-Extended | 1434 |

PART XIII
System Management 1435

CHAPTER 75
Administering the System 1437

| | |
|--|------|
| Information About Administering the Device | 1437 |
| System Time and Date Management | 1437 |
| System Clock | 1437 |
| Real Time Clock | 1438 |
| Network Time Protocol | 1438 |
| NTP Stratum | 1439 |
| NTP Associations | 1440 |
| NTP Security | 1440 |
| NTP Implementation | 1440 |
| NTP Version 4 | 1441 |
| System Name and Prompt | 1441 |
| Stack System Name and Prompt | 1441 |
| Default System Name and Prompt Configuration | 1441 |
| DNS | 1442 |
| Default DNS Settings | 1442 |
| Login Banners | 1442 |
| Default Banner Configuration | 1442 |
| MAC Address Table | 1442 |
| MAC Address Table Creation | 1443 |
| MAC Addresses and VLANs | 1443 |

| | |
|---|---|
| Default MAC Address Table Settings | 1443 |
| ARP Table Management | 1444 |
| How to Administer the Device | 1444 |
| Configuring the Time and Date Manually | 1444 |
| Setting the System Clock | 1444 |
| Configuring the Time Zone | 1445 |
| Configuring Summer Time (Daylight Saving Time) | 1446 |
| Configuring a System Name | 1449 |
| Setting Up DNS | 1450 |
| Configuring a Message-of-the-Day Login Banner | 1451 |
| Configuring a Login Banner | 1452 |
| Managing the MAC Address Table | 1454 |
| Changing the Address Aging Time | 1454 |
| Configuring MAC Address Change Notification Traps | 1455 |
| Configuring MAC Address Move Notification Traps | 1457 |
| Configuring MAC Threshold Notification Traps | 1459 |
| Adding and Removing Static Address Entries | 1461 |
| Configuring Unicast MAC Address Filtering | 1462 |
| Monitoring and Maintaining Administration of the Device | 1463 |
| Configuration Examples for Device Administration | 1464 |
| Example: Setting the System Clock | 1464 |
| Examples: Configuring Summer Time | 1464 |
| Example: Configuring a MOTD Banner | 1464 |
| Example: Configuring a Login Banner | 1465 |
| Example: Configuring MAC Address Change Notification Traps | 1465 |
| Example: Configuring MAC Threshold Notification Traps | 1465 |
| Example: Adding the Static Address to the MAC Address Table | 1466 |
| Example: Configuring Unicast MAC Address Filtering | 1466 |
| Additional References for Switch Administration | 1466 |
| Feature History and Information for Device Administration | 1467 |
| | |
| CHAPTER 76 | Performing Device Setup Configuration 1469 |
| Information About Performing Device Setup Configuration | 1469 |
| Boot Process | 1469 |

| | |
|---|------|
| Devices Information Assignment | 1470 |
| Default Switch Information | 1470 |
| DHCP-Based Autoconfiguration Overview | 1471 |
| DHCP Client Request Process | 1471 |
| DHCP-based Autoconfiguration and Image Update | 1472 |
| Restrictions for DHCP-based Autoconfiguration | 1472 |
| DHCP Autoconfiguration | 1473 |
| DHCP Auto-Image Update | 1473 |
| DHCP Server Configuration Guidelines | 1473 |
| Purpose of the TFTP Server | 1474 |
| Purpose of the DNS Server | 1475 |
| How to Obtain Configuration Files | 1475 |
| How to Control Environment Variables | 1476 |
| Common Environment Variables | 1477 |
| Environment Variables for TFTP | 1479 |
| Scheduled Reload of the Software Image | 1479 |
| How to Perform Device Setup Configuration | 1480 |
| Configuring DHCP Autoconfiguration (Only Configuration File) | 1480 |
| Configuring DHCP Auto-Image Update (Configuration File and Image) | 1482 |
| Configuring the Client to Download Files from DHCP Server | 1484 |
| Manually Assigning IP Information to Multiple SVIs | 1485 |
| Configuring the NVRAM Buffer Size | 1487 |
| Modifying the Device Startup Configuration | 1488 |
| Specifying the Filename to Read and Write the System Configuration | 1488 |
| Manually Booting the Switch | 1489 |
| Configuring a Scheduled Software Image Reload | 1490 |
| Monitoring Device Setup Configuration | 1491 |
| Example: Verifying the Device Running Configuration | 1491 |
| Examples: Displaying Software Install | 1492 |
| Configuration Examples for Performing Device Setup | 1492 |

- Uploading an Image File using RCP 1630

Copying an Image File from One Stack Member to Another 1631

PART XV

Embedded Event Manager 1633

CHAPTER 84

Embedded Event Manager Overview 1635

Information About Embedded Event Manager 1635

- Embedded Event Manager 1635
- Embedded Event Manager 1.0 1636
- Embedded Event Manager 2.0 1637
- Embedded Event Manager 2.1 1637
- Embedded Event Manager 2.1 (Software Modularity) 1638
- Embedded Event Manager 2.2 1638
- Embedded Event Manager 2.3 1639
- Embedded Event Manager 2.4 1639
- Embedded Event Manager 3.0 1640
- Embedded Event Manager 3.1 1641
- Embedded Event Manager 3.2 1641
- Embedded Event Manager 4.0 1642
- EEM Event Detectors Available by Cisco IOS Release 1643
- Event Detectors 1645
- EEM Actions Available by Cisco IOS Release 1649
- Embedded Event Manager Actions 1650
- Embedded Event Manager Environment Variables 1650
- Embedded Event Manager Policy Creation 1652

Where to Go Next 1653

Feature Information for Embedded Event Manager 4.0 Overview 1653

Additional References 1653

CHAPTER 85

Information About Writing EEM Policies Using the Cisco IOS CLI 1657

Prerequisites for Writing EEM Policies Using the Cisco IOS CLI 1657

Information About Writing EEM Policies Using the Cisco IOS CLI 1657

Embedded Event Manager Policies 1657

EEM Applet 1658

EEM Script 1658

Embedded Event Manager Built-In Environment Variables Used in EEM Applets 1658

How to Write EEM Policies Using the Cisco IOS CLI 1669

Registering and Defining an Embedded Event Manager Applet 1669

EEM Environment Variables 1669

Alphabetical Order of EEM Action Labels 1670

Troubleshooting Tips 1673

Registering and Defining an EEM Tcl Script 1673

Unregistering Embedded Event Manager Policies 1674

Suspending All Embedded Event Manager Policy Execution 1676

Displaying Embedded Event Manager History Data 1677

Displaying Embedded Event Manager Registered Policies 1678

Configuring Event SNMP Notification 1679

Configuring Multiple Event Support 1680

Setting the Event Configuration Parameters 1680

Configuring EEM Class-Based Scheduling 1682

Holding a Scheduled EEM Policy Event or Event Queue 1683

Resuming Execution of EEM Policy Events or Event Queues 1684

Clearing Pending EEM Policy Events or Event Queues 1685

Modifying the Scheduling Parameters of EEM Policy Events or Event Queues 1686

Verifying Class-Based Active EEM Policies 1688

Verifying Class-Based Active EEM Policies 1688

Verifying Pending EEM Policies 1689

Configuring EEM Applet (Interactive CLI) Support 1689

Reading and Writing Input from the Active Console for Synchronous EEM Applets 1689

Configuring SNMP Library Extensions 1692

Prerequisites 1692

| | |
|---|------|
| SNMP Get and Set Operations | 1693 |
| SNMP Traps and Inform Requests | 1695 |
| Configuring EEM Applet for SNMP Get and Set Operations | 1695 |
| Configuring EEM Applet for SNMP OID Notifications | 1697 |
| Configuring Variable Logic for EEM Applets | 1699 |
| Prerequisites | 1700 |
| Configuring Variable Logic for EEM Applets | 1700 |
| Specifying a Loop of Conditional Blocks | 1700 |
| Specifying if else Conditional Blocks | 1701 |
| Specifying foreach Iterating Statements | 1703 |
| Using Regular Expressions | 1704 |
| Incrementing the Values of Variables | 1705 |
| Configuring Event SNMP Object | 1705 |
| Disabling AAA Authorization | 1707 |
| Configuring Description of an Embedded Event Manager Applet | 1708 |
| Configuration Examples for Writing Embedded Event Manager Policies Using Tcl | 1709 |
| Embedded Event Manager Applet Configuration Examples | 1709 |
| Configuration Examples for Embedded Event Manager Applet | 1714 |
| Example Identity Event Detector | 1714 |
| Example MAT Event Detector | 1714 |
| Example Neighbor-Discovery Event Detector | 1714 |
| Embedded Event Manager Manual Policy Execution Examples | 1714 |
| Embedded Event Manager Watchdog System Monitor (Cisco IOS) Event Detector Configuration Example | 1715 |
| Configuration SNMP Library Extensions Examples | 1716 |
| SNMP Get Operations Examples | 1716 |
| SNMP GetID Operations Examples | 1717 |
| Set Operations Examples | 1718 |
| Generating SNMP Notifications Examples | 1718 |
| Configuring Variable Logic for EEM Applets Examples | 1720 |
| Configuring Event SNMP-Object Examples | 1723 |
| Configuring Description of an EEM Applet Examples | 1724 |
| Additional References | 1724 |
| Feature Information for Writing EEM 4.0 Policies Using the Cisco IOS CLI | 1725 |

CHAPTER

1

Using the Command-Line Interface

- [Information About Using the Command-Line Interface, on page 1](#)
- [How to Use the CLI to Configure Features, on page 5](#)

Information About Using the Command-Line Interface

Note Search options on the GUI and CLI are case sensitive.

Command Modes

The Cisco IOS user interface is divided into many different modes. The commands available to you depend on which mode you are currently in. Enter a question mark (?) at the system prompt to obtain a list of commands available for each command mode.

You can start a CLI session through a console connection, through Telnet, an SSH, or by using the browser.

When you start a session, you begin in user mode, often called user EXEC mode. Only a limited subset of the commands are available in user EXEC mode. For example, most of the user EXEC commands are one-time commands, such as **show** commands, which show the current configuration status, and **clear** commands, which clear counters or interfaces. The user EXEC commands are not saved when the device reboots.

To have access to all commands, you must enter privileged EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. From this mode, you can enter any privileged EXEC command or enter global configuration mode.

Using the configuration modes (global, interface, and line), you can make changes to the running configuration. If you save the configuration, these commands are stored and used when the device reboots. To access the various configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and line configuration mode .

This table describes the main command modes, how to access each one, the prompt you see in that mode, and how to exit the mode.

Table 1: Command Mode Summary

| Mode | Access Method | Prompt | Exit Method | About This Mode |
|----------------------|---|----------------------|--|--|
| User EXEC | Begin a session using Telnet, SSH, or console. | Device> | Enter logout or quit . | Use this mode to <ul style="list-style-type: none"> • Change terminal settings. • Perform basic tests. • Display system information. |
| Privileged EXEC | While in user EXEC mode, enter the enable command. | Device# | Enter disable to exit. | Use this mode to verify commands that you have entered. Use a password to protect access to this mode. |
| Global configuration | While in privileged EXEC mode, enter the configure command. | Device(config)# | To exit to privileged EXEC mode, enter exit or end , or press Ctrl-Z . | Use this mode to configure parameters that apply to the entire device. |
| VLAN configuration | While in global configuration mode, enter the vlan <i>vlan-id</i> command. | Device(config-vlan)# | To exit to global configuration mode, enter the exit command. To return to privileged EXEC mode, press Ctrl-Z or enter end . | Use this mode to configure VLAN parameters. When VTP mode is transparent, you can create extended-range VLANs (VLAN IDs greater than 1005) and save configurations in the device startup configuration file. |

| Mode | Access Method | Prompt | Exit Method | About This Mode |
|-------------------------|---|------------------------|---|---|
| Interface configuration | While in global configuration mode, enter the interface command (with a specific interface). | Device (config-if) # | To exit to global configuration mode, enter exit . To return to privileged EXEC mode, press Ctrl-Z or enter end . | Use this mode to configure parameters for the Ethernet ports. |
| Line configuration | While in global configuration mode, specify a line with the line vty or line console command. | Device (config-line) # | To exit to global configuration mode, enter exit . To return to privileged EXEC mode, press Ctrl-Z or enter end . | Use this mode to configure parameters for the terminal line. |

Understanding Abbreviated Commands

You need to enter only enough characters for the device to recognize the command as unique.

This example shows how to enter the **show configuration** privileged EXEC command in an abbreviated form:

```
Device# show conf
```

No and Default Forms of Commands

Almost every configuration command also has a **no** form. In general, use the **no** form to disable a feature or function or reverse the action of a command. For example, the **no shutdown** interface configuration command reverses the shutdown of an interface. Use the command without the keyword **no** to reenab a disabled feature or to enable a feature that is disabled by default.

Configuration commands can also have a **default** form. The **default** form of a command returns the command setting to its default. Most commands are disabled by default, so the **default** form is the same as the **no** form. However, some commands are enabled by default and have variables set to certain default values. In these cases, the **default** command enables the command and sets variables to their default values.

CLI Error Messages

This table lists some error messages that you might encounter while using the CLI to configure your device.

Table 2: Common CLI Error Messages

| Error Message | Meaning | How to Get Help |
|---|--|---|
| % Ambiguous command: "show con" | You did not enter enough characters for your device to recognize the command. | Reenter the command followed by a question mark (?) without any space between the command and the question mark. The possible keywords that you can enter with the command appear. |
| % Incomplete command. | You did not enter all of the keywords or values required by this command. | Reenter the command followed by a question mark (?) with a space between the command and the question mark. The possible keywords that you can enter with the command appear. |
| % Invalid input detected at '^' marker. | You entered the command incorrectly. The caret (^) marks the point of the error. | Enter a question mark (?) to display all of the commands that are available in this command mode. The possible keywords that you can enter with the command appear. |

Configuration Logging

You can log and view changes to the device configuration. You can use the Configuration Change Logging and Notification feature to track changes on a per-session and per-user basis. The logger tracks each configuration command that is applied, the user who entered the command, the time that the command was entered, and the parser return code for the command. This feature includes a mechanism for asynchronous notification to registered applications whenever the configuration changes. You can choose to have the notifications sent to the syslog.

Note Only CLI or HTTP changes are logged.

Using the Help System

You can enter a question mark (?) at the system prompt to display a list of commands available for each command mode. You can also obtain a list of associated keywords and arguments for any command.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | help Example: Device# help | Obtains a brief description of the help system in any command mode. |

| | Command or Action | Purpose |
|--------|--|---|
| Step 2 | <i>abbreviated-command-entry</i> ? Example: Device# di ? dir disable disconnect | Obtains a list of commands that begin with a particular character string. |
| Step 3 | <i>abbreviated-command-entry</i> <Tab> Example: Device# sh conf <tab> Device# show configuration | Completes a partial command name. |
| Step 4 | ? Example: Device> ? | Lists all commands available for a particular command mode. |
| Step 5 | <i>command</i> ? Example: Device> show ? | Lists the associated keywords for a command. |
| Step 6 | <i>command keyword</i> ? Example: Device(config)# cdp holdtime ? <10-255> Length of time (in sec) that receiver must keep this packet | Lists the associated arguments for a keyword. |

How to Use the CLI to Configure Features

Configuring the Command History

The software provides a history or record of commands that you have entered. The command history feature is particularly useful for recalling long or complex commands or entries, including access lists. You can customize this feature to suit your needs.

Changing the Command History Buffer Size

By default, the device records ten command lines in its history buffer. You can alter this number for a current terminal session or for all sessions on a particular line. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | terminal history [<i>size number-of-lines</i>] Example: Device# terminal history size 200 | Changes the number of command lines that the device records during the current terminal session in privileged EXEC mode. You can configure the size from 0 to 256. |

Recalling Commands

To recall commands from the history buffer, perform one of the actions listed in this table. These actions are optional.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | Ctrl-P or use the up arrow key | Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall successively older commands. |
| Step 2 | Ctrl-N or use the down arrow key | Returns to more recent commands in the history buffer after recalling commands with Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands. |
| Step 3 | show history Example: Device# show history | Lists the last several commands that you just entered in privileged EXEC mode. The number of commands that appear is controlled by the setting of the terminal history global configuration command and the history line configuration command. |

Disabling the Command History Feature

The command history feature is automatically enabled. You can disable it for the current terminal session or for the command line. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | terminal no history Example: Device# terminal no history | Disables the feature during the current terminal session in privileged EXEC mode. |

Enabling and Disabling Editing Features

Although enhanced editing mode is automatically enabled, you can disable it and reenble it.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | terminal editing Example: Device# <code>terminal editing</code> | Reenables the enhanced editing mode for the current terminal session in privileged EXEC mode. |
| Step 2 | terminal no editing Example: Device# <code>terminal no editing</code> | Disables the enhanced editing mode for the current terminal session in privileged EXEC mode. |

Editing Commands Through Keystrokes

The keystrokes help you to edit the command lines. These keystrokes are optional.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

Table 3: Editing Commands

| Editing Commands | Description |
|---|--|
| Ctrl-B or use the left arrow key | Moves the cursor back one character. |
| Ctrl-F or use the right arrow key | Moves the cursor forward one character. |
| Ctrl-A | Moves the cursor to the beginning of the command line. |
| Ctrl-E | Moves the cursor to the end of the command line. |
| Esc B | Moves the cursor back one word. |
| Esc F | Moves the cursor forward one word. |
| Ctrl-T | Transposes the character to the left of the cursor with the character located at the cursor. |
| Delete or Backspace key | Erases the character to the left of the cursor. |
| Ctrl-D | Deletes the character at the cursor. |
| Ctrl-K | Deletes all characters from the cursor to the end of the command line. |
| Ctrl-U or Ctrl-X | Deletes all characters from the cursor to the beginning of the command line. |

| | |
|-------------------------|---|
| Ctrl-W | Deletes the word to the left of the cursor. |
| Esc D | Deletes from the cursor to the end of the word. |
| Esc C | Capitalizes at the cursor. |
| Esc L | Changes the word at the cursor to lowercase. |
| Esc U | Capitalizes letters from the cursor to the end of the word. |
| Ctrl-V or Esc Q | Designates a particular keystroke as an executable command, perhaps as a shortcut. |
| Return key | Scrolls down a line or screen on displays that are longer than the terminal screen can display. Note The More prompt is used for any output that has more lines than can be displayed on the terminal screen, including show command output. You can use the Return and Space bar keystrokes whenever you see the More prompt. |
| Space bar | Scrolls down one screen. |
| Ctrl-L or Ctrl-R | Redisplays the current command line if the device suddenly sends a message to your screen. |

Editing Command Lines That Wrap

You can use a wraparound feature for commands that extend beyond a single line on the screen. When the cursor reaches the right margin, the command line shifts ten spaces to the left. You cannot see the first ten characters of the line, but you can scroll back and check the syntax at the beginning of the command. The keystroke actions are optional.

To scroll back to the beginning of the command entry, press **Ctrl-B** or the left arrow key repeatedly. You can also press **Ctrl-A** to immediately move to the beginning of the line.

Note The arrow keys function only on ANSI-compatible terminals such as VT100s.

The following example shows how to wrap a command line that extends beyond a single line on the screen.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | access-list Example: <pre>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35 Device(config)# \$ 101 permit tcp 10.15.22.25 255.255.255.0 10.15.22.35</pre> | Displays the global configuration command entry that extends beyond one line. When the cursor first reaches the end of the line, the line is shifted ten spaces to the left and redisplayed. The dollar sign (\$) shows that the line has been scrolled to the left. Each time the |

| | Command or Action | Purpose |
|---------------|--|--|
| | <pre>255.25 Device(config)# \$t tcp 10.15.22.25 255.255.255.0 131.108.1.20 255.255.255.0 eq Device(config)# \$15.22.25 255.255.255.0 10.15.22.35 255.255.255.0 eq 45</pre> | <p>cursor reaches the end of the line, the line is again shifted ten spaces to the left.</p> |
| Step 2 | <p>Ctrl-A</p> <p>Example:</p> <pre>Device(config)# access-list 101 permit tcp 10.15.22.25 255.255.255.0 10.15.2\$</pre> | <p>Checks the complete syntax.</p> <p>The dollar sign (\$) appears at the end of the line to show that the line has been scrolled to the right.</p> |
| Step 3 | Return key | <p>Execute the commands.</p> <p>The software assumes that you have a terminal screen that is 80 columns wide. If you have a different width, use the terminal width privileged EXEC command to set the width of your terminal.</p> <p>Use line wrapping with the command history feature to recall and modify previous complex command entries.</p> |

Searching and Filtering Output of show and more Commands

You can search and filter the output for **show** and **more** commands. This is useful when you need to sort through large amounts of output or if you want to exclude output that you do not need to see. Using these commands is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | <pre>{show more} command {begin include exclude} regular-expression</pre> <p>Example:</p> <pre>Device# show interfaces include protocol Vlan1 is up, line protocol is up Vlan10 is up, line protocol is down GigabitEthernet1/0/1 is up, line protocol is down GigabitEthernet1/0/2 is up, line protocol is up</pre> | <p>Searches and filters the output.</p> <p>Expressions are case sensitive. For example, if you enter exclude output, the lines that contain output are not displayed, but the lines that contain output appear.</p> |

Accessing the CLI

You can access the CLI through a console connection, through Telnet, a SSH, or by using the browser.

You manage the switch stack and the stack member interfaces through the stack's active switch. You cannot manage stack members on an individual switch basis. You can connect to the stack's active switch through the console port or the Ethernet management port of one or more stack members. Be careful with using multiple CLI sessions on the stack's active switch. Commands that you enter in one session are not displayed in the other sessions. Therefore, it is possible to lose track of the session from which you entered commands.

Note We recommend using one CLI session when managing the switch stack.

If you want to configure a specific stack member port, you must include the stack member number in the CLI command interface notation.

To debug the standby switch, use the **session standby ios** privileged EXEC command from the active switch to access the IOS console of the standby switch. To debug a specific stack member, use the **session switch stack-member-number** privileged EXEC command from the active switch to access the diagnostic shell of the stack member. For more information about these commands, see the switch command reference.

To debug a specific stack member, you can start a CLI session from the stack master by using the **session stack-member-number** privileged EXEC command. The stack member number is appended to the system prompt. For example, *Switch-2#* is the prompt for stack member 2 where the system prompt for the stack master is *Switch*. Only the **show** and **debug** commands are available in a CLI session to a specific stack member. You can also use the **remote command stack-member-number LINE** privileged EXEC command on the stack master to enable debugging on a member switch without first starting a session.

Accessing the CLI Through a Console Connection or Through Telnet

Before you can access the CLI, you must connect a terminal or a PC to the device console or connect a PC to the Ethernet management port and then power on the device, as described in the hardware installation guide that shipped with your device.

If your device is already configured, you can access the CLI through a local console connection or through a remote Telnet session, but your device must first be configured for this type of access.

You can use one of these methods to establish a connection with the device:

Procedure

- Connect the device console port to a management station or dial-up modem, or connect the Ethernet management port to a PC. For information about connecting to the console or Ethernet management port, see the device hardware installation guide.
- Use any Telnet TCP/IP or encrypted Secure Shell (SSH) package from a remote management station. The device must have network connectivity with the Telnet or SSH client, and the device must have an enable secret password configured.
 - The device supports up to 16 simultaneous Telnet sessions. Changes made by one Telnet user are reflected in all other Telnet sessions.
 - The device supports up to five simultaneous secure SSH sessions.

After you connect through the console port, through the Ethernet management port, through a Telnet session or through an SSH session, the user EXEC prompt appears on the management station.

Accessing the CLI through Bluetooth

You can access the CLI through Bluetooth connectivity by pairing the switch to a computer.

Note This feature is available on Cisco IOS Release 15.2(5)E2 and higher.

1. Connect a Bluetooth dongle to the USB port on your switch and power on the switch.
2. Turn on Bluetooth on your computer and discover the switch.
3. Pair the computer to the switch.
4. Connect to the switch as an access point.
 - If you are connecting from a Windows computer: Go to *Devices & Printers*, select the switch, click on the *Connect Using* tab and select *Access point*.
 - If you are connecting from a Mac computer: On the menu bar, click the Bluetooth icon, hover over the switch name, and click *Connect to Network*.

Once a connection is established, you can open a management window and configure the switch.

Information About Configuring Interface Characteristics

Interface Types

This section describes the different types of interfaces supported by the device. The rest of the chapter describes configuration procedures for physical interface characteristics.

Note The stack ports on the rear of the stacking-capable devices are not Ethernet ports and cannot be configured.

Port-Based VLANs

A VLAN is a switched network that is logically segmented by function, team, or application, without regard to the physical location of the users. Packets received on a port are forwarded only to ports that belong to the same VLAN as the receiving port. Network devices in different VLANs cannot communicate with one another without a Layer 3 device to route traffic between the VLANs.

VLAN partitions provide hard firewalls for traffic in the VLAN, and each VLAN has its own MAC address table. A VLAN comes into existence when a local port is configured to be associated with the VLAN, when the VLAN Trunking Protocol (VTP) learns of its existence from a neighbor on a trunk, or when a user creates a VLAN. VLANs can be formed with ports across the stack.

To configure VLANs, use the **vlan *vlan-id*** global configuration command to enter VLAN configuration mode. The VLAN configurations for normal-range VLANs (VLAN IDs 1 to 1005) are saved in the VLAN database. If VTP is version 1 or 2, to configure extended-range VLANs (VLAN IDs 1006 to 4094), you must first set VTP mode to transparent. Extended-range VLANs created in transparent mode are not added to the VLAN

database but are saved in the device running configuration. With VTP version 3, you can create extended-range VLANs in client or server mode. These VLANs are saved in the VLAN database.

In a switch stack, the VLAN database is downloaded to all switches in a stack, and all switches in the stack build the same VLAN database. The running configuration and the saved configuration are the same for all switches in a stack.

Add ports to a VLAN by using the **switchport** interface configuration commands:

- Identify the interface.
- For a trunk port, set trunk characteristics, and, if desired, define the VLANs to which it can belong.
- For an access port, set and define the VLAN to which it belongs.

Switch Ports

Switch ports are Layer 2-only interfaces associated with a physical port. Switch ports belong to one or more VLANs. A switch port can be an access port or a trunk port. You can configure a port as an access port or trunk port or let the Dynamic Trunking Protocol (DTP) operate on a per-port basis to set the switchport mode by negotiating with the port on the other end of the link. switch ports are used for managing the physical interface and associated Layer 2 protocols and do not handle routing or bridging.

Configure switch ports by using the **switchport** interface configuration commands.

Access Ports

An access port belongs to and carries the traffic of only one VLAN (unless it is configured as a voice VLAN port). Traffic is received and sent in native formats with no VLAN tagging. Traffic arriving on an access port is assumed to belong to the VLAN assigned to the port. If an access port receives a tagged packet (Inter-Switch Link [ISL] or IEEE 802.1Q tagged), the packet is dropped, and the source address is not learned.

The types of access ports supported are:

- Static access ports are manually assigned to a VLAN (or through a RADIUS server for use with IEEE 802.1x).
- VLAN membership of dynamic access ports is learned through incoming packets. By default, a dynamic access port is not a member of any VLAN, and forwarding to and from the port is enabled only when the VLAN membership of the port is discovered. Dynamic access ports on the device are assigned to a VLAN by a VLAN Membership Policy Server (VMPS). The VMPS can be a Catalyst 6500 series switch; the device cannot be a VMPS server.

You can also configure an access port with an attached Cisco IP Phone to use one VLAN for voice traffic and another VLAN for data traffic from a device attached to the phone.

Trunk Ports

A trunk port carries the traffic of multiple VLANs and by default is a member of all VLANs in the VLAN database.

The device supports only IEEE 802.1Q trunk ports. An IEEE 802.1Q trunk port supports simultaneous tagged and untagged traffic. An IEEE 802.1Q trunk port is assigned a default port VLAN ID (PVID), and all untagged traffic travels on the port default PVID. All untagged traffic and tagged traffic with a NULL VLAN ID are assumed to belong to the port default PVID. A packet with a VLAN ID equal to the outgoing port default PVID is sent untagged. All other traffic is sent with a VLAN tag.

Although by default, a trunk port is a member of every VLAN known to the VTP, you can limit VLAN membership by configuring an allowed list of VLANs for each trunk port. The list of allowed VLANs does not affect any other port but the associated trunk port. By default, all possible VLANs (VLAN ID 1 to 4094) are in the allowed list. A trunk port can become a member of a VLAN only if VTP knows of the VLAN and if the VLAN is in the enabled state. If VTP learns of a new, enabled VLAN and the VLAN is in the allowed list for a trunk port, the trunk port automatically becomes a member of that VLAN and traffic is forwarded to and from the trunk port for that VLAN. If VTP learns of a new, enabled VLAN that is not in the allowed list for a trunk port, the port does not become a member of the VLAN, and no traffic for the VLAN is forwarded to or from the port.

Switch Virtual Interfaces

A switch virtual interface (SVI) represents a VLAN of switch ports as one interface to the routing or bridging function in the system. You can associate only one SVI with a VLAN. You configure an SVI for a VLAN only to route between VLANs or to provide IP host connectivity to the device. By default, an SVI is created for the default VLAN (VLAN 1) to permit remote device administration. Additional SVIs must be explicitly configured.

Note You cannot delete interface VLAN 1.

SVIs provide IP host connectivity only to the system. SVIs are created the first time that you enter the **vlan** interface configuration command for a VLAN interface. The VLAN corresponds to the VLAN tag associated with data frames on an ISL or IEEE 802.1Q encapsulated trunk or the VLAN ID configured for an access port. Configure a VLAN interface for each VLAN for which you want to route traffic, and assign it an IP address.

You can also use the interface range command to configure existing VLAN SVIs within the range. The commands entered under the interface range command are applied to all existing VLAN SVIs within the range. You can enter the command **interface range create vlan x - y** to create all VLANs in the specified range that do not already exist. When the VLAN interface is created, **interface range vlan id** can be used to configure the VLAN interface.

Although the switch stack or device supports a total of 1005 VLANs and SVIs, the interrelationship between the number of SVIs and routed ports and the number of other features being configured might impact CPU performance because of hardware limitations.

When you create an SVI, it does not become active until it is associated with a physical port.

SVI Autostate Exclude

The line state of an SVI with multiple ports on a VLAN is in the *up* state when it meets these conditions:

- The VLAN exists and is active in the VLAN database on the device
- The VLAN interface exists and is not administratively down.
- At least one Layer 2 (access or trunk) port exists, has a link in the *up* state on this VLAN, and is in the spanning-tree forwarding state on the VLAN.

Note The protocol link state for VLAN interfaces come up when the first switchport belonging to the corresponding VLAN link comes up and is in STP forwarding state.

The default action, when a VLAN has multiple ports, is that the SVI goes down when all ports in the VLAN go down. You can use the SVI `autostate exclude` feature to configure a port so that it is not included in the SVI line-state up-or-down calculation. For example, if the only active port on the VLAN is a monitoring port, you might configure `autostate exclude` on that port so that the VLAN goes down when all other ports go down. When enabled on a port, **autostate exclude** applies to all VLANs that are enabled on that port.

The VLAN interface is brought up when one Layer 2 port in the VLAN has had time to converge (transition from STP listening-learning state to forwarding state). This prevents features such as routing protocols from using the VLAN interface as if it were fully operational and minimizes other problems.

EtherChannel Port Groups

EtherChannel port groups treat multiple switch ports as one switch port. These port groups act as a single logical port for high-bandwidth connections between devices or between devices and servers. An EtherChannel balances the traffic load across the links in the channel. If a link within the EtherChannel fails, traffic previously carried over the failed link changes to the remaining links. You can group multiple trunk ports into one logical trunk port or multiple access ports into one logical access port. Most protocols operate over either single ports or aggregated switch ports and do not recognize the physical ports within the port group. Exceptions are the DTP, the Cisco Discovery Protocol (CDP), and the Port Aggregation Protocol (PAgP), which operate only on physical ports.

When you configure an EtherChannel, you create a port-channel logical interface and assign an interface to the EtherChannel. For Layer 2 interfaces, use the **channel-group** interface configuration command to dynamically create the port-channel logical interface. This command binds the physical and logical ports together.

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Using the Switch USB Ports

The device has three USB ports on the front panel — a USB mini-Type B console port and two USB Type A ports.

USB Mini-Type B Console Port

The device has the following console ports:

- USB mini-Type B console connection

- RJ-45 console port

Console output appears on devices connected to both ports, but console input is active on only one port at a time. By default, the USB connector takes precedence over the RJ-45 connector.

Note Windows PCs require a driver for the USB port. See the hardware installation guide for driver installation instructions.

Use the supplied USB Type A-to-USB mini-Type B cable to connect a PC or other device to the device. The connected device must include a terminal emulation application. When the device detects a valid USB connection to a powered-on device that supports host functionality (such as a PC), input from the RJ-45 console is immediately disabled, and input from the USB console is enabled. Removing the USB connection immediately reenables input from the RJ-45 console connection. An LED on the device shows which console connection is in use.

Console Port Change Logs

At software startup, a log shows whether the USB or the RJ-45 console is active. Each device in a stack issues this log. Every device always first displays the RJ-45 media type.

In the sample output, Device 1 has a connected USB console cable. Because the bootloader did not change to the USB console, the first log from Device 1 shows the RJ-45 console. A short time later, the console changes and the USB console log appears. Device 2 and Device 3 have connected RJ-45 console cables.

```
switch-stack-1
*Mar 1 00:01:00.171: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
*Mar 1 00:01:00.431: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

```
switch-stack-2
*Mar 1 00:01:09.835: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

```
switch-stack-3
*Mar 1 00:01:10.523: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

When the USB cable is removed or the PC de-activates the USB connection, the hardware automatically changes to the RJ-45 console interface:

```
switch-stack-1
Mar 1 00:20:48.635: %USB_CONSOLE-6-MEDIA_RJ45: Console media-type is RJ45.
```

You can configure the console type to always be RJ-45, and you can configure an inactivity timeout for the USB connector.

USB Type A Ports

The USB Type A ports provide access to external USB flash devices, also known as thumb drives or USB keys. The switch supports Cisco 64 MB, 256 MB, 512 MB, 1 GB, 4 GB, and 8 GB flash drives. You can use standard Cisco IOS command-line interface (CLI) commands to read, write, erase, and copy to or from the flash device. You can also configure the switch to boot from the USB flash drive.

For information about configuring the switch to boot from a USB flash drive, refer to the *Catalyst 2960-X Switch System Management Configuration Guide*.

For information about reading, writing, erasing, and copying files to or from the flash device, refer to the *Catalyst 2960-X Switch Managing Cisco IOS Image Files Configuration Guide*.

Interface Connections

Devices within a single VLAN can communicate directly through any switch. Ports in different VLANs cannot exchange data without going through a routing device.

In the following configuration example, when Host A in VLAN 20 sends data to Host B in VLAN 30, the data must go from Host A to the device, to the router, back to the device, and then to Host B.

Figure 1: Connecting VLANs with the Switch

With a standard Layer 2 switch, ports in different VLANs have to exchange information through a router.

Note The Catalyst 3560-CX and 2960-CX switches do not support stacking. Ignore all references to stacking throughout this book.

Interface Configuration Mode

The device supports these interface types:

- Physical ports—device ports and routed ports
- VLANs—switch virtual interfaces
- Port channels—EtherChannel interfaces

You can also configure a range of interfaces.

To configure a physical interface (port), specify the interface type, module number, and device port number, and enter interface configuration mode.

- **Type**—Gigabit Ethernet (gigabitethernet or gi) for 10/100/1000 Mb/s Ethernet ports, or small form-factor pluggable (SFP) module Gigabit Ethernet interfaces (gigabitethernet or gi).
- **Stack member number**—The number that identifies the switch within the stack. The range is 1 to 8 for a stack of Catalyst 2960-X switches, and 1 to 4 for a mixed stack of Catalyst 2960-X and Catalyst 2960-S switches. The switch number is assigned the first time the switch initializes. The default switch number, before it is integrated into a switch stack, is 1. When a switch has been assigned a stack member number, it keeps that number until another is assigned to it.

You can use the switch port LEDs in Stack mode to identify the stack member number of a switch.

- **Module number**—The module or slot number on the switch (always 0).
- **Port number**—The interface number on the switch. The 10/100/1000 port numbers always begin at 1, starting with the far left port when facing the front of the switch, for example, gigabitethernet1/0/1 or gigabitethernet1/0/8. For a switch with 10/100/1000 ports and SFP module ports, SFP module ports are numbered consecutively following the 10/100/1000 ports.

You can identify physical interfaces by physically checking the interface location on the switch. You can also use the **show** privileged EXEC commands to display information about a specific interface or all the interfaces on the switch. The remainder of this chapter primarily provides physical interface configuration procedures.

These are examples of how to identify interfaces on a stacking-capable switch:

- To configure 10/100/1000 port 4 on a standalone device, enter this command:

```
Device(config)# interface gigabitethernet1/0/4
```

- To configure 10/100/1000 port 4 on stack member 3, enter this command:

```
Device(config)# interface gigabitethernet1/0/4
```

Default Ethernet Interface Configuration

This table shows the Ethernet interface default configuration, including some features that apply only to Layer 2 interfaces.

Table 4: Default Layer 2 Ethernet Interface Configuration

| Feature | Default Setting |
|--------------------------------------|---|
| Operating mode | Layer 2 or switching mode (switchport command). |
| Allowed VLAN range | VLANs 1– 4094. |
| Default VLAN (for access ports) | VLAN 1. |
| Native VLAN (for IEEE 802.1Q trunks) | VLAN 1. |
| 802.1p priority-tagged traffic | Drop all packets tagged with VLAN 0. |
| VLAN trunking | Switchport mode dynamic auto (supports DTP). |

| Feature | Default Setting |
|---|---|
| Port enable state | All ports are enabled. |
| Port description | None defined. |
| Speed | Autonegotiate. (Not supported on the 10-Gigabit interfaces.) |
| Duplex mode | Autonegotiate. (Not supported on the 10-Gigabit interfaces.) |
| Flow control | Flow control is set to receive: off . It is always off for sent packets. |
| EtherChannel (PAgP) | Disabled on all Ethernet ports. |
| Port blocking (unknown multicast and unknown unicast traffic) | Disabled (not blocked). |
| Broadcast, multicast, and unicast storm control | Disabled. |
| Protected port | Disabled. |
| Port security | Disabled. |
| Port Fast | Disabled. |
| Auto-MDIX | Enabled. Note The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port. |
| Power over Ethernet (PoE) | Enabled (auto). |
| Keepalive messages | Disabled on SFP module ports; enabled on all other ports. |

Interface Speed and Duplex Mode

Ethernet interfaces on the switch operate at 10, 100, or 1000 Mb/s and in either full- or half-duplex mode. In full-duplex mode, two stations can send and receive traffic at the same time. Normally, 10-Mb/s ports operate in half-duplex mode, which means that stations can either receive or send traffic.

Switch modules include Gigabit Ethernet (10/100/1000-Mb/s) ports and small form-factor pluggable (SFP) module slots supporting SFP modules.

Speed and Duplex Configuration Guidelines

When configuring an interface speed and duplex mode, note these guidelines:

- Do not disable Auto-Negotiation on PoE switches.
- Gigabit Ethernet (10/100/1000-Mb/s) ports support all speed options and all duplex options (auto, half, and full). However, Gigabit Ethernet ports operating at 1000 Mb/s do not support half-duplex mode.
- For SFP module ports, the speed and duplex CLI options change depending on the SFP module type:
 - The 1000BASE-x (where -x is -BX, -CWDM, -LX, -SX, and -ZX) SFP module ports support the **nonegotiate** keyword in the **speed** interface configuration command. Duplex options are not supported.
 - The 1000BASE-T SFP module ports support the same speed and duplex options as the 10/100/1000-Mb/s ports.
 -
- If both ends of the line support autonegotiation, we highly recommend the default setting of **auto** negotiation.
- If one interface supports autonegotiation and the other end does not, configure duplex and speed on both interfaces; do not use the **auto** setting on the supported side.
- When STP is enabled and a port is reconfigured, the device can take up to 30 seconds to check for loops. The port LED is amber while STP reconfigures.
- As best practice, we suggest configuring the speed and duplex options on a link to auto or to fixed on both the ends. If one side of the link is configured to auto and the other side is configured to fixed, the link will not be up and this is expected.

**Caution**

Changing the interface speed and duplex mode configuration might shut down and re-enable the interface during the reconfiguration.

IEEE 802.3x Flow Control

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If one port experiences congestion and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

**Note**

The switch ports can receive, but not send, pause frames.

You use the **flowcontrol** interface configuration command to set the interface's ability to **receive** pause frames to **on**, **off**, or **desired**. The default state is **off**.

When set to **desired**, an interface can operate with an attached device that is required to send flow-control packets or with an attached device that is not required to but can send flow-control packets.

These rules apply to flow control settings on the device:

- **receive on** (or **desired**): The port cannot send pause frames but can operate with an attached device that is required to or can send pause frames; the port can receive pause frames.
- **receive off**: Flow control does not operate in either direction. In case of congestion, no indication is given to the link partner, and no pause frames are sent or received by either device.

Note For details on the command settings and the resulting flow control resolution on local and remote ports, see the **flowcontrol** interface configuration command in the command reference for this release.

How to Configure Interface Characteristics

Configuring Interfaces

These general instructions apply to all interface configuration processes.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface Example: Device(config)# interface gigabitethernet 1/0/1 Device(config-if)# | Identifies the interface type, the device number (only on stacking-capable switches), and the number of the connector. Note You do not need to add a space between the interface type and the interface number. For example, in the preceding line, you can specify either gigabitethernet 1/0/1 , gigabitethernet1/0/1 , gi 1/0/1 , or gi1/0/1 . |
| Step 4 | Follow each interface command with the interface configuration commands that the interface requires. | Defines the protocols and applications that will run on the interface. The commands are collected and applied to the interface when you |

| | Command or Action | Purpose |
|---------------|--|--|
| | | enter another interface command or enter end to return to privileged EXEC mode. |
| Step 5 | interface range or interface range macro | (Optional) Configures a range of interfaces. Note Interfaces configured in a range must be the same type and must be configured with the same feature options. |
| Step 6 | show interfaces | Displays a list of all interfaces on or configured for the switch. A report is provided for each interface that the device supports or for the specified interface. |

Adding a Description for an Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the interface for which you are adding a description, and enter interface configuration mode. |
| Step 4 | description <i>string</i> Example: Device(config-if)# description Connects to Marketing | Adds a description (up to 240 characters) for an interface. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |
| Step 6 | show interfaces <i>interface-id</i> description | Verifies your entry. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring a Range of Interfaces

To configure multiple interfaces with the same configuration parameters, use the **interface range** global configuration command. When you enter the interface-range configuration mode, all command parameters that you enter are attributed to all interfaces within that range until you exit this mode.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface range { <i>port-range</i> macro <i>macro_name</i> } Example: Device (config) # interface range macro | Specifies the range of interfaces (VLANs or physical ports) to be configured, and enter interface-range configuration mode. <ul style="list-style-type: none"> • You can use the interface range command to configure up to five port ranges or a previously defined macro. • The macro variable is explained in the section on <i>Configuring and Using Interface Range Macros</i>. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> In a comma-separated <i>port-range</i>, you must enter the interface type for each entry and enter spaces before and after the comma. In a hyphen-separated <i>port-range</i>, you do not need to re-enter the interface type, but you must enter a space before the hyphen. <p>Note Use the normal configuration commands to apply the configuration parameters to all interfaces in the range. Each command is executed as it is entered.</p> |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show interfaces [<i>interface-id</i>] Example: <pre>Device# show interfaces</pre> | Verifies the configuration of the interfaces in the range. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring and Using Interface Range Macros

You can create an interface range macro to automatically select a range of interfaces for configuration. Before you can use the **macro** keyword in the **interface range macro** global configuration command string, you must use the **define interface-range** global configuration command to define the macro.

Procedure

| | Command or Action | Purpose |
|---------------|----------------------------------|--|
| Step 1 | enable Example: | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device> enable | |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | define interface-range <i>macro_name</i> <i>interface-range</i> Example: Device(config)# define interface-range enet_list gigabitethernet 1/0/1 - 2 | Defines the interface-range macro, and save it in NVRAM. <ul style="list-style-type: none"> • The <i>macro_name</i> is a 32-character maximum character string. • A macro can contain up to five comma-separated interface ranges. • Each <i>interface-range</i> must consist of the same port type. <p>Note Before you can use the macro keyword in the interface range macro global configuration command string, you must use the define interface-range global configuration command to define the macro.</p> |
| Step 4 | interface range macro <i>macro_name</i> Example: Device(config)# interface range macro enet_list | Selects the interface range to be configured using the values saved in the interface-range macro called <i>macro_name</i> . You can now use the normal configuration commands to apply the configuration to all interfaces in the defined macro. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config include define Example: Device# show running-config include define | Shows the defined interface range macro configuration. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring Ethernet Interfaces

Setting the Interface Speed and Duplex Parameters

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: <pre>Device(config)# interface gigabitethernet 1/0/3</pre> | Specifies the physical interface to be configured, and enter interface configuration mode. |
| Step 4 | speed {10 100 1000 2500 5000 10000 auto [10 100 1000 2500 5000 10000] nonegotiate} Example: <pre>Device(config-if)# speed 10</pre> | Enter the appropriate speed parameter for the interface: <ul style="list-style-type: none"> • Enter 10, 100, 1000, 2500, 5000, or 10000 to set a specific speed for the interface. • Enter auto to enable the interface to autonegotiate speed with the connected device. If you specify a speed and also set the auto keyword, the port autonegotiates only at the specified speeds. • The nonegotiate keyword is available only for SFP module ports. SFP module ports operate only at 1000 Mb/s but can be |

| | Command or Action | Purpose |
|---------------|---|--|
| | | configured to not negotiate if connected to a device that does not support autonegotiation. |
| Step 5 | duplex {auto full half} Example: <pre>Device(config-if)# duplex half</pre> | <p>This command is not available on a 10-Gigabit Ethernet interface.</p> <p>Enter the duplex parameter for the interface.</p> <p>Enable half-duplex mode (for interfaces operating only at 10 or 100 Mb/s). You cannot configure half-duplex mode for interfaces operating at 1000 Mb/s.</p> <p>You can configure the duplex setting when the speed is set to auto.</p> |
| Step 6 | end Example: <pre>Device(config-if)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | show interfaces <i>interface-id</i> Example: <pre>Device# show interfaces gigabitethernet 1/0/3</pre> | Displays the interface speed and duplex mode configuration. |
| Step 8 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring IEEE 802.3x Flow Control

Procedure

| | Command or Action | Purpose |
|---------------|---|----------------------------------|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 2 | interface <i>interface-id</i> Example: <pre>Device(config)# interface gigabitethernet 1/0/1</pre> | Specifies the physical interface to be configured, and enter interface configuration mode. |
| Step 3 | flowcontrol {receive} {on off desired} Example: <pre>Device(config-if)# flowcontrol receive on</pre> | Configures the flow control mode for the port. |
| Step 4 | end Example: <pre>Device(config-if)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show interfaces <i>interface-id</i> Example: <pre>Device# show interfaces gigabitethernet 1/0/1</pre> | Verifies the interface flow control settings. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring SVI Autostate Exclude

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>configure terminal</code> | |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2 | Specifies a Layer 2 interface (physical port or port channel), and enter interface configuration mode. |
| Step 4 | switchport autostate exclude Example: Device(config-if)# switchport autostate exclude | Excludes the access or trunk port when defining the status of an SVI line state (up or down) |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | show running config interface <i>interface-id</i> | (Optional) Shows the running configuration. Verifies the configuration. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Shutting Down and Restarting the Interface

Shutting down an interface disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface {vlan vlan-id} {gigabitethernetinterface-id} {port-channel port-channel-number} Example: Device(config)# interface gigabitethernet 1/0/2 | Selects the interface to be configured. |
| Step 4 | shutdown Example: Device(config-if)# shutdown | Shuts down an interface. |
| Step 5 | no shutdown Example: Device(config-if)# no shutdown | Restarts an interface. |
| Step 6 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |

Configuring the Console Media Type

Follow these steps to set the console media type to RJ-45. If you configure the console as RJ-45, USB console operation is disabled, and input comes only through the RJ-45 connector.

This configuration applies to all switches in a stack.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line console 0 Example: Device(config)# line console 0 | Configures the console and enters line configuration mode. |
| Step 4 | media-type rj45 Example: Device(config-line)# media-type rj45 | Configures the console media type to be only RJ-45 port. If you do not enter this command and both types are connected, the USB port is used by default. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring the USB Inactivity Timeout

The configurable inactivity timeout reactivates the RJ-45 console port if the USB console port is activated but no input activity occurs on it for a specified time period. When the USB console port is deactivated due to a timeout, you can restore its operation by disconnecting and reconnecting the USB cable.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line console 0 Example: Device(config)# line console 0 | Configures the console and enters line configuration mode. |
| Step 4 | usb-inactivity-timeout <i>timeout-minutes</i> Example: Device(config-line)# usb-inactivity-timeout 30 | Specify an inactivity timeout for the console port. The range is 1 to 240 minutes. The default is to have no timeout configured. |
| Step 5 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring Interface Characteristics

Monitoring Interface Status

Commands entered at the privileged EXEC prompt display information about the interface, including the versions of the software and the hardware, the configuration, and statistics about the interfaces.

Table 5: Show Commands for Interfaces

| Command | Purpose |
|---|--|
| show interfaces <i>interface-id</i> status [err-disabled] | Displays interface status or a list of interfaces in the error-disabled state. |

| Command | Purpose |
|---|--|
| show interfaces [<i>interface-id</i>] switchport | Displays administrative and operational status of switching (nonrouting) ports. You can use this command to find out if a port is in routing or in switching mode. |
| show interfaces [<i>interface-id</i>] description | Displays the description configured on an interface or all interfaces and the interface status. |
| show ip interface [<i>interface-id</i>] | Displays the usability status of all interfaces configured for IP routing or the specified interface. |
| show interface [<i>interface-id</i>] stats | Displays the input and output packets by the switching path for the interface. |
| show interfaces <i>interface-id</i> | (Optional) Displays speed and duplex on the interface. |
| show interfaces transceiver dom-supported-list | (Optional) Displays Digital Optical Monitoring (DOM) status on the connect SFP modules. |
| show interfaces transceiver properties | (Optional) Displays temperature, voltage, or amount of current on the interface. |
| show interfaces [<i>interface-id</i>] [{ transceiver properties detail }] <i>module number</i> | Displays physical and operational status about an SFP module. |
| show running-config interface [<i>interface-id</i>] | Displays the running configuration in RAM for the interface. |
| show version | Displays the hardware configuration, software version, the names and sources of configuration files, and the boot images. |
| show controllers ethernet-controller <i>interface-id</i> phy | Displays the operational state of the auto-MDIX feature on the interface. |

Clearing and Resetting Interfaces and Counters

Table 6: Clear Commands for Interfaces

| Command | Purpose |
|--|---|
| clear counters [<i>interface-id</i>] | Clears interface counters. |
| clear interface <i>interface-id</i> | Resets the hardware logic on an interface. |
| clear line [<i>number</i> console 0 <i>vty number</i>] | Resets the hardware logic on an asynchronous serial line. |

Note The **clear counters** privileged EXEC command does not clear counters retrieved by using Simple Network Management Protocol (SNMP), but only those seen with the **show interface** privileged EXEC command.

Configuration Examples for Interface Characteristics

Configuring a Range of Interfaces: Examples

This example shows how to use the **interface range** global configuration command to set the speed to 100 Mb/s on ports 1 to 4 on switch 1:

```
Device# configure terminal
Device(config)# interface range gigabitethernet 1/0/1 - 4
Device(config-if-range)# speed 100
```

This example shows how to use a comma to add different interface type strings to the range to enable Gigabit Ethernet ports 1 to 3 and 10-Gigabit Ethernet ports 1 and 2 to receive flow-control pause frames:

```
Device# configure terminal
Device(config)# interface range gigabitethernet1/0/1 - 3 , tengigabitethernet1/1/1 - 2
Device(config-if-range)# flowcontrol receive on
```

If you enter multiple configuration commands while you are in interface-range mode, each command is executed as it is entered. The commands are not batched and executed after you exit interface-range mode. If you exit interface-range configuration mode while the commands are being executed, some commands might not be executed on all interfaces in the range. Wait until the command prompt reappears before exiting interface-range configuration mode.

Configuring and Using Interface Range Macros: Examples

This example shows how to define an interface-range named *enet_list* to include ports 1 and 2 on switch 1 and to verify the macro configuration:

```
Device# configure terminal
Device(config)# define interface-range enet_list gigabitethernet 1/1/1 - 2
Device(config)# end
Device# show running-config | include define
define interface-range enet_list gigabitethernet 1/1/1 - 2
```

This example shows how to create a multiple-interface macro named *macro1*:

```
Device# configure terminal
Device(config)# define interface-range macro1 gigabitethernet1/1/1 - 2, gigabitethernet1/1/5
- 7, tengigabitethernet1/1/1 -2
Device(config)# end
```

This example shows how to enter interface-range configuration mode for the interface-range macro *enet_list*:

```
Device# configure terminal
Device(config)# interface range macro enet_list
Device(config-if-range)#
```

This example shows how to delete the interface-range macro *enet_list* and to verify that it was deleted.

```
Device# configure terminal
Device(config)# no define interface-range enet_list
Device(config)# end
Device# show run | include define
Device#
```

Setting Interface Speed and Duplex Mode: Example

This example shows how to set the interface speed to 100 Mb/s and the duplex mode to half on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/3
Device(config-if)# speed 10
Device(config-if)# duplex half
```

This example shows how to set the interface speed to 100 Mb/s on a 10/100/1000 Mb/s port:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/2
Device(config-if)# speed 100
```

Configuring the Console Media Type: Example

This example disables the USB console media type and enables the RJ-45 console media type.

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# media-type rj45
```

This example reverses the previous configuration and immediately activates any USB console that is connected.

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# no media-type rj45
```

Configuring the USB Inactivity Timeout: Example

This example configures the inactivity timeout to 30 minutes:

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# usb-inactivity-timeout 30
```

To disable the configuration, use these commands:

```
Device# configure terminal
Device(config)# line console 0
```

```
Device(config-line)# no usb-inactivity-timeout
```

If there is no (input) activity on a USB console port for the configured number of minutes, the inactivity timeout setting applies to the RJ-45 port, and a log shows this occurrence:

```
*Mar 1 00:47:25.625: %USB_CONSOLE-6-INACTIVITY_DISABLE: Console media-type USB disabled
due to inactivity, media-type reverted to RJ45.
```

At this point, the only way to reactivate the USB console port is to disconnect and reconnect the cable.

When the USB cable on the switch has been disconnected and reconnected, a log similar to this appears:

```
*Mar 1 00:48:28.640: %USB_CONSOLE-6-MEDIA_USB: Console media-type is USB.
```

CHAPTER 3

Configuring Auto-MDIX

- [Prerequisites for Auto-MDIX, on page 41](#)
- [Restrictions for Auto-MDIX, on page 41](#)
- [Information About Configuring Auto-MDIX, on page 41](#)
- [How to Configure Auto-MDIX, on page 42](#)
- [Example for Configuring Auto-MDIX, on page 43](#)
- [Additional References, on page 43](#)
- [Feature History and Information for Auto-MDIX, on page 44](#)

Prerequisites for Auto-MDIX

Automatic medium-dependent interface crossover (auto-MDIX) is enabled by default.

Auto-MDIX is supported on all 10/100/1000-Mb/s and on 10/100/1000BASE-TX small form-factor pluggable (SFP)-module interfaces. It is not supported on 1000BASE-SX or -LX SFP module interfaces.

Restrictions for Auto-MDIX

The device might not support a pre-standard powered device—such as Cisco IP phones and access points that do not fully support IEEE 802.3af—if that powered device is connected to the device through a crossover cable. This is regardless of whether auto-MIDX is enabled on the switch port.

Information About Configuring Auto-MDIX

Auto-MDIX on an Interface

When automatic medium-dependent interface crossover (auto-MDIX) is enabled on an interface, the interface automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting devices without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other devices or repeaters. With auto-MDIX enabled, you can use either type of cable to connect to other devices, and the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

This table shows the link states that result from auto-MDIX settings and correct and incorrect cabling.

Table 7: Link Conditions and Auto-MDIX Settings

| Local Side Auto-MDIX | Remote Side Auto-MDIX | With Correct Cabling | With Incorrect Cabling |
|----------------------|-----------------------|----------------------|------------------------|
| On | On | Link up | Link up |
| On | Off | Link up | Link up |
| Off | On | Link up | Link up |
| Off | Off | Link up | Link down |

How to Configure Auto-MDIX

Configuring Auto-MDIX on an Interface

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the physical interface to be configured, and enter interface configuration mode. |
| Step 4 | speed auto Example: Device(config-if)# speed auto | Configures the interface to autonegotiate speed with the connected device. |
| Step 5 | duplex auto Example: | Configures the interface to autonegotiate duplex mode with the connected device. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <code>Device(config-if)# duplex auto</code> | |
| Step 6 | end Example: <code>Device(config-if)# end</code> | Returns to privileged EXEC mode. |
| Step 7 | copy running-config startup-config Example: <code>Device# copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Example for Configuring Auto-MDIX

This example shows how to enable auto-MDIX on a port:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# speed auto
Device(config-if)# duplex auto
Device(config-if)# mdix auto
Device(config-if)# end
```

CHAPTER 4

Configuring Ethernet Management Port

- [Finding Feature Information, on page 45](#)
- [Prerequisites for Ethernet Management Ports, on page 45](#)
- [Information About the Ethernet Management Port, on page 45](#)
- [How to Configure the Ethernet Management Port, on page 47](#)
- [Additional References for Ethernet Management Ports, on page 48](#)
- [Feature History and Information for Ethernet Management Ports, on page 49](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Ethernet Management Ports

When connecting a PC to the Ethernet management port, you must first assign an IP address.

Information About the Ethernet Management Port

The Ethernet management port, also referred to as the *Fa0* or *fastethernet0* port, is a Layer 3 host port to which you can connect a PC. You can use the Ethernet management port instead of the device console port for network management. When managing a device stack, connect the PC to the Ethernet management port on a stack member.

Ethernet Management Port Direct Connection to a Device

Figure 2: Connecting a Switch to a PC

This figure displays how to connect the Ethernet management port to the PC for a device or a standalone

Ethernet Management Port Connection to Stack Devices using a Hub

In a stack with only stack devices, all the Ethernet management ports on the stack members are connected to a hub to which the PC is connected. The active link is from the Ethernet management port on the stack's active switch through the hub, to the PC. If the active device fails and a new active device is elected, the active link is now from the Ethernet management port on the new active device to the PC.

Figure 3: Connecting a Device Stack to a PC

This figure displays how a PC uses a hub to connect to a device stack.

Supported Features on the Ethernet Management Port

The Ethernet management port supports these features:

- Express Setup (only in switch stacks)
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SNMP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features

- Speed—10 Mb/s, 100 Mb/s, and autonegotiation
- Duplex mode—Full, half, and autonegotiation
- Loopback detection
- Cisco Discovery Protocol (CDP)
- DHCP relay agent
- IPv4 and IPv6 access control lists (ACLs)

Caution Before enabling a feature on the Ethernet management port, make sure that the feature is supported. If you try to configure an unsupported feature on the Ethernet Management port, the feature might not work properly, and the device might fail.

How to Configure the Ethernet Management Port

Disabling and Enabling the Ethernet Management Port

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | interface fastethernet0 Example: Device(config)# <code>interface fastethernet0</code> | Specifies the Ethernet management port in the CLI. |
| Step 3 | shutdown Example: Device(config-if)# <code>shutdown</code> | Disables the Ethernet management port. |
| Step 4 | no shutdown Example: Device(config-if)# <code>no shutdown</code> | Enables the Ethernet management port. |
| Step 5 | exit Example: Device(config-if)# <code>exit</code> | Exits interface configuration mode. |
| Step 6 | show interfaces fastethernet0 | Displays the link status. |

| | Command or Action | Purpose |
|--|---|--|
| | Example: Device# <code>show interfaces fastethernet0</code> | To find out the link status to the PC, you can monitor the LED for the Ethernet management port. The LED is green (on) when the link is active, and the LED is off when the link is down. The LED is amber when there is a POST failure. |

What to do next

Proceed to manage or configure your switch using the Ethernet management port. Refer to the *Catalyst 2960-X Switch Network Management Configuration Guide*.

CHAPTER 5

Configuring LLDP, LLDP-MED, and Wired Location Service

- [Information About LLDP, LLDP-MED, and Wired Location Service, on page 51](#)
- [How to Configure LLDP, LLDP-MED, and Wired Location Service, on page 55](#)
- [Configuration Examples for LLDP, LLDP-MED, and Wired Location Service, on page 65](#)
- [Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service, on page 66](#)
- [Additional References for LLDP, LLDP-MED, and Wired Location Service, on page 67](#)
- [Feature Information for LLDP, LLDP-MED, and Wired Location Service, on page 67](#)

Information About LLDP, LLDP-MED, and Wired Location Service

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, switches, and controllers). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the device supports the IEEE 802.1AB Link Layer Discovery Protocol (LLDP). LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

LLDP Supported TLVs

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as TLVs. LLDP supported devices can use TLVs to receive and send information to their neighbors. This protocol can advertise details such as configuration information, device capabilities, and device identity.

The switch supports these basic management TLVs. These are mandatory LLDP TLVs.

- Port description TLV
- System name TLV

- System description TLV
- System capabilities TLV
- Management address TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED.

- Port VLAN ID TLV (IEEE 802.1 organizationally specific TLVs)
- MAC/PHY configuration/status TLV (IEEE 802.3 organizationally specific TLVs)

LLDP and Cisco Device Stacks

A device stack appears as a single device in the network. Therefore, LLDP discovers the device stack, not the individual stack members.

LLDP and Cisco Medianet

When you configure LLDP or CDP location information on a per-port basis, remote devices can send Cisco Medianet location information to the device.

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, Power over Ethernet, inventory management and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED Supported TLVs

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV

Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and has enabled.

- Network policy TLV

Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect to any device, obtain its VLAN number, and then start communicating with the call control.

By defining a network-policy profile TLV, you can create a profile for voice and voice-signaling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

- Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows devices and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

LLDP-MED also supports an extended power TLV to advertise fine-grained power requirements, end-point power priority, and end-point and network connectivity-device power status. LLDP is enabled and power is applied to a port, the power TLV determines the actual power requirement of the endpoint device so that the system power budget can be adjusted accordingly. The device processes the requests and either grants or denies power based on the current power budget. If the request is granted, the switch updates the power budget. If the request is denied, the device turns off power to the port, generates a syslog message, and updates the power budget. If LLDP-MED is disabled or if the endpoint does not support the LLDP-MED power TLV, the initial allocation value is used throughout the duration of the connection.

You can change power settings by entering the **power inline** {**auto** [**max** *max-wattage*] | **never** | **static** [**max** *max-wattage*]} interface configuration command. By default the PoE interface is in **auto** mode; If no value is specified, the maximum is allowed (30 W).

- Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the device, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

- Location TLV

Provides location information from the device to the endpoint device. The location TLV can send this information:

- Civic location information

Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

- ELIN location information

Provides the location information of a caller. The location is determined by the Emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

Wired Location Service

The device uses the location service feature to send location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired device or controller. The device notifies the MSE of device link up and link down events through the Network Mobility Services Protocol (NMSP) location and attachment notifications.

The MSE starts the NMSP connection to the device, which opens a server port. When the MSE connects to the device there are a set of message exchanges to establish version compatibility and service exchange information followed by location information synchronization. After connection, the device periodically sends location and attachment notifications to the MSE. Any link up or link down events detected during an interval are aggregated and sent at the end of the interval.

When the device determines the presence or absence of a device on a link-up or link-down event, it obtains the client-specific information such as the MAC address, IP address, and username. If the client is LLDP-MED- or CDP-capable, the device obtains the serial number and UDI through the LLDP-MED location TLV or CDP.

Depending on the device capabilities, the device obtains this client information at link up:

- Slot and port specified in port connection

- MAC address specified in the client MAC address
- IP address specified in port connection
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *new*
- Serial number, UDI
- Model number
- Time in seconds since the device detected the association

Depending on the device capabilities, the device obtains this client information at link down:

- Slot and port that was disconnected
- MAC address
- IP address
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *delete*
- Serial number, UDI
- Time in seconds since the device detected the disassociation

When the device shuts down, it sends an attachment notification with the state *delete* and the IP address before closing the NMSF connection to the MSE. The MSE interprets this notification as disassociation for all the wired clients associated with the device.

If you change a location address on the device, the device sends an NMSF location notification message that identifies the affected ports and the changed address information.

Default LLDP Configuration

Table 8: Default LLDP Configuration

| Feature | Default Setting |
|--------------------------------------|---------------------------------------|
| LLDP global state | Disabled |
| LLDP holdtime (before discarding) | 120 seconds |
| LLDP timer (packet update frequency) | 30 seconds |
| LLDP reinitialization delay | 2 seconds |
| LLDP tlv-select | Disabled to send and receive all TLVs |
| LLDP interface state | Disabled |

| Feature | Default Setting |
|---------------------|--|
| LLDP receive | Disabled |
| LLDP transmit | Disabled |
| LLDP med-tlv-select | Disabled to send all LLDP-MED TLVs. When LLDP is glob LLDP-MED-TLV is also enabled. |

Restrictions for LLDP

- If the interface is configured as a tunnel port, LLDP is automatically disabled.
- If you first configure a network-policy profile on an interface, you cannot apply the **switchport voice vlan** command on the interface. If the **switchport voice vlan *vlan-id*** is already configured on an interface, you can apply a network-policy profile on the interface. This way the interface has the voice or voice-signaling VLAN network-policy profile applied on the interface.
- You cannot configure static secure MAC addresses on an interface that has a network-policy profile.
- When Cisco Discovery Protocol and LLDP are both in use within the same switch, it is necessary to disable LLDP on interfaces where Cisco Discovery Protocol is in use for power negotiation. LLDP can be disabled at interface level with the commands **no lldp tlv-select power-management** or **no lldp transmit / no lldp receive**.

How to Configure LLDP, LLDP-MED, and Wired Location Service

Enabling LLDP

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | lldp run Example: | Enables LLDP globally on the device. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device (config)# lldp run | |
| Step 4 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 2/0/1 | Specifies the interface on which you are enabling LLDP, and enter interface configuration mode. |
| Step 5 | lldp transmit Example: Device(config-if)# lldp transmit | Enables the interface to send LLDP packets. |
| Step 6 | lldp receive Example: Device(config-if)# lldp receive | Enables the interface to receive LLDP packets. |
| Step 7 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 8 | show lldp Example: Device# show lldp | Verifies the configuration. |
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, and the initialization delay time. You can also select the LLDP and LLDP-MED TLVs to send and receive.

Note Steps 3 through 6 are optional and can be performed in any order.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | lldp holdtime <i>seconds</i> Example: Device (config)# lldp holdtime 120 | (Optional) Specifies the amount of time a receiving device should hold the information from your device before discarding it. The range is 0 to 65535 seconds; the default is 120 seconds. |
| Step 4 | lldp reinit <i>delay</i> Example: Device (config)# lldp reinit 2 | (Optional) Specifies the delay time in seconds for LLDP to initialize on an interface. The range is 2 to 5 seconds; the default is 2 seconds. |
| Step 5 | lldp timer <i>rate</i> Example: Device (config)# lldp timer 30 | (Optional) Sets the sending frequency of LLDP updates in seconds. The range is 5 to 65534 seconds; the default is 30 seconds. |
| Step 6 | lldp tlv-select Example: Device (config)# tlv-select | (Optional) Specifies the LLDP TLVs to send or receive. |
| Step 7 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 2/0/1 | Specifies the interface on which you are enabling LLDP, and enter interface configuration mode. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 8 | lldp med-tlv-select Example: Device (config-if)# lldp med-tlv-select inventory management | (Optional) Specifies the LLDP-MED TLVs to send or receive. |
| Step 9 | end Example: Device (config-if)# end | Returns to privileged EXEC mode. |
| Step 10 | show lldp Example: Device# show lldp | Verifies the configuration. |
| Step 11 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring LLDP-MED TLVs

By default, the device only sends LLDP packets until it receives LLDP-MED packets from the end device. It then sends LLDP packets with MED TLVs, as well. When the LLDP-MED entry has been aged out, it again only sends LLDP packets.

By using the **lldp** interface configuration command, you can configure the interface not to send the TLVs listed in the following table.

Table 9: LLDP-MED TLVs

| LLDP-MED TLV | Description |
|----------------------|-----------------------------------|
| inventory-management | LLDP-MED inventory management TLV |
| location | LLDP-MED location TLV |
| network-policy | LLDP-MED network policy TLV |
| power-management | LLDP-MED power management TLV |

Follow these steps to enable a TLV on an interface:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 2/0/1 | Specifies the interface on which you are enabling LLDP, and enter interface configuration mode. |
| Step 4 | lldp med-tlv-select Example: Device(config-if)# lldp med-tlv-select inventory management | Specifies the TLV to enable. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Network-Policy TLV

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Example: Device> enable | <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | network-policy profile <i>profile number</i> Example: Device (config)# network-policy profile 1 | Specifies the network-policy profile number, and enter network-policy configuration mode. The range is 1 to 4294967295. |
| Step 4 | {voice voice-signaling} vlan [<i>vlan-id</i> {cos <i>cvalue</i> dscp <i>dvalue</i>}] [[dot1p {cos <i>cvalue</i> dscp <i>dvalue</i>}] none untagged] Example: Device (config-network-policy)# voice vlan 100 cos 4 | Configures the policy attributes: <ul style="list-style-type: none"> • voice—Specifies the voice application type. • voice-signaling—Specifies the voice-signaling application type. • vlan—Specifies the native VLAN for voice traffic. • vlan-id—(Optional) Specifies the VLAN for voice traffic. The range is 1 to 4094. • cos <i>cvalue</i>—(Optional) Specifies the Layer 2 priority class of service (CoS) for the configured VLAN. The range is 0 to 7; the default is 5. • dscp <i>dvalue</i>—(Optional) Specifies the differentiated services code point (DSCP) value for the configured VLAN. The range is 0 to 63; the default is 46. • dot1p—(Optional) Configures the telephone to use IEEE 802.1p priority tagging and use VLAN 0 (the native VLAN). • none—(Optional) Do not instruct the IP telephone about the voice VLAN. The telephone uses the configuration from the telephone key pad. |

| | Command or Action | Purpose |
|----------------|--|--|
| | | <ul style="list-style-type: none"> • untagged—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone. • untagged—(Optional) Configures the telephone to send untagged voice traffic. This is the default for the telephone. |
| Step 5 | exit Example: <pre>Device (config) # exit</pre> | Returns to global configuration mode. |
| Step 6 | interface <i>interface-id</i> Example: <pre>Device (config) # interface gigabitethernet 2/0/1</pre> | Specifies the interface on which you are configuring a network-policy profile, and enter interface configuration mode. |
| Step 7 | network-policy <i>profile number</i> Example: <pre>Device (config-if) # network-policy 1</pre> | Specifies the network-policy profile number. |
| Step 8 | lldp med-tlv-select network-policy Example: <pre>Device (config-if) # lldp med-tlv-select network-policy</pre> | Specifies the network-policy TLV. |
| Step 9 | end Example: <pre>Device (config) # end</pre> | Returns to privileged EXEC mode. |
| Step 10 | show network-policy profile Example: <pre>Device# show network-policy profile</pre> | Verifies the configuration. |
| Step 11 | copy running-config startup-config Example: | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

Configuring Location TLV and Wired Location Service

Beginning in privileged EXEC mode, follow these steps to configure location information for an endpoint and to apply it to an interface.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | location { admin-tag <i>string</i> civic-location identifier { <i>id</i> <i>host</i> } elin-location string identifier <i>id</i> custom-location identifier { <i>id</i> <i>host</i> } geo-location identifier { <i>id</i> <i>host</i> }} Example: Device(config)# <code>location civic-location identifier 1</code> Device(config-civic)# <code>number 3550</code> Device(config-civic)# <code>primary-road-name "Cisco Way"</code> Device(config-civic)# <code>city "San Jose"</code> Device(config-civic)# <code>state CA</code> Device(config-civic)# <code>building 19</code> Device(config-civic)# <code>room C6</code> Device(config-civic)# <code>county "Santa Clara"</code> Device(config-civic)# <code>country US</code> | Specifies the location information for an endpoint. <ul style="list-style-type: none"> • admin-tag—Specifies an administrative tag or site information. • civic-location—Specifies civic location information. • elin-location—Specifies emergency location information (ELIN). • custom-location—Specifies custom location information. • geo-location—Specifies geo-spatial location information. • identifier <i>id</i>—Specifies the ID for the civic, ELIN, custom, or geo location. • host—Specifies the host civic, custom, or geo location. • <i>string</i>—Specifies the site or location information in alphanumeric format. |
| Step 3 | exit Example: Device(config-civic)# <code>exit</code> | Returns to global configuration mode. |

| | Command or Action | Purpose |
|--------|--|---|
| Step 4 | <p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device (config)# interface gigabitethernet2/0/1</pre> | Specifies the interface on which you are configuring the location information, and enter interface configuration mode. |
| Step 5 | <p>location {additional-location-information <i>word</i> civic-location-id {<i>id</i> host} elin-location-id <i>id</i> custom-location-id {<i>id</i> host} geo-location-id {<i>id</i> host} }</p> <p>Example:</p> <pre>Device (config-if)# location elin-location-id 1</pre> | <p>Enters location information for an interface:</p> <ul style="list-style-type: none"> • additional-location-information—Specifies additional information for a location or place. • civic-location-id—Specifies global civic location information for an interface. • elin-location-id—Specifies emergency location information for an interface. • custom-location-id—Specifies custom location information for an interface. • geo-location-id—Specifies geo-spatial location information for an interface. • host—Specifies the host location identifier. • <i>word</i>—Specifies a word or phrase with additional location information. • <i>id</i>—Specifies the ID for the civic, ELIN, custom, or geo location. The ID range is 1 to 4095. |
| Step 6 | <p>end</p> <p>Example:</p> <pre>Device (config-if)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | <p>Use one of the following:</p> <ul style="list-style-type: none"> • show location admin-tag <i>string</i> • show location civic-location identifier <i>id</i> • show location elin-location identifier <i>id</i> <p>Example:</p> <pre>Device# show location admin-tag</pre> <p>or</p> | Verifies the configuration. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <pre>Device# show location civic-location identifier OR Device# show location elin-location identifier</pre> | |
| Step 8 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Enabling Wired Location Service on the Device

Before you begin

For wired location to function, you must first enter the **ip device tracking** global configuration command.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | <p>nmsp notification interval {attachment location} interval-seconds</p> <p>Example:</p> <pre>Device(config)# nmsp notification interval location 10</pre> | <p>Specifies the Nmsp notification interval.</p> <p>attachment—Specifies the attachment notification interval.</p> <p>location—Specifies the location notification interval.</p> <p><i>interval-seconds</i>—Duration in seconds before the device sends the MSE the location or attachment updates. The range is 1 to 30; the default is 30.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show network-policy profile Example: Device# show network-policy profile | Verifies the configuration. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuration Examples for LLDP, LLDP-MED, and Wired Location Service

Configuring Network-Policy TLV: Examples

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
# configure terminal
(config)# network-policy 1
(config-network-policy)# voice vlan 100 cos 4
(config-network-policy)# exit
(config)# interface gigabitethernet 1/0/1
(config-if)# network-policy profile 1
(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
config-network-policy)# voice vlan dot1p cos 4
config-network-policy)# voice vlan dot1p dscp 34
```

Monitoring and Maintaining LLDP, LLDP-MED, and Wired Location Service

Commands for monitoring and maintaining LLDP, LLDP-MED, and wired location service.

| Command | Description |
|--|--|
| clear lldp counters | Resets the traffic counters to zero. |
| clear lldp table | Deletes the LLDP neighbor information table. |
| clear nmsp statistics | Clears the Nmsp statistic counters. |
| show lldp | Displays global information, such as frequency of transmissions, the holdtime for packets being sent, and the delay time before LLDP initializes on an interface. |
| show lldp entry <i>entry-name</i> | Displays information about a specific neighbor. You can enter an asterisk (*) to display all neighbors, or you can enter the neighbor name. |
| show lldp interface [<i>interface-id</i>] | Displays information about interfaces with LLDP enabled. You can limit the display to a specific interface. |
| show lldp neighbors [<i>interface-id</i>] [detail] | Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID. You can limit the display to neighbors of a specific interface or expand the display for more detailed information. |
| show lldp traffic | Displays LLDP counters, including the number of packets sent and received, number of packets discarded, and number of unrecognized TLVs. |
| show location admin-tag <i>string</i> | Displays the location information for the specified administrative tag or site. |
| show location civic-location identifier <i>id</i> | Displays the location information for a specific global civic location. |
| show location elin-location identifier <i>id</i> | Displays the location information for an emergency location |
| show network-policy profile | Displays the configured network-policy profiles. |
| show nmsp | Displays the Nmsp information |

CHAPTER 6

Configuring System MTU

- [Information About the MTU](#), on page 69
- [How to Configure MTU](#), on page 70
- [Configuration Examples for System MTU](#), on page 70
- [Additional References for System MTU](#), on page 71
- [Feature Information for System MTU](#), on page 71

Information About the MTU

The default maximum transmission unit (MTU) size for frames received and transmitted on all interfaces is 1500 bytes. You can increase the MTU size for all interfaces operating at 10 or 100 Mb/s by using the **system mtu** global configuration command. You can increase the MTU size to support jumbo frames on all Gigabit Ethernet interfaces by using the **system mtu jumbo** global configuration command.

Note The switch supports jumbo frames at CPU.

System MTU Guidelines

When configuring the system MTU values, follow these guidelines:

- The default maximum transmission unit (MTU) size for frames received and transmitted on all interfaces is 1500 bytes. You can increase the MTU size for all interfaces operating at 10 or 100 Mb/s by using the **system mtu** global configuration command. You can increase the MTU size to support jumbo frames on all Gigabit Ethernet interfaces by using the **system mtu jumbo** global configuration command.
- Gigabit Ethernet ports are not affected by the **system mtu** command; 10/100 ports are not affected by the **system mtu jumbo** command. If you do not configure the **system mtu jumbo** command, the setting of the **system mtu** command applies to all Gigabit Ethernet interfaces.

How to Configure MTU

Configuring the System MTU

Beginning in privileged EXEC mode, follow these steps to change the MTU size for all 10/100 or Gigabit Ethernet interfaces:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | system mtu <i>bytes</i> Example: Device(config)# <code>system mtu 2500</code> | (Optional) Change the MTU size for all interfaces on the switch stack that are operating at 10 or 100 Mb/s. The range is 1500 to 1998 bytes; the default is 1500 bytes. |
| Step 3 | system mtu jumbo <i>bytes</i> Example: Device(config)# <code>system mtu jumbo7500</code> | (Optional) Changes the MTU size for all Gigabit Ethernet interfaces on the switch or the switch stack. The range is 1500 to 9198 bytes; the default is 1500 bytes. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 5 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | Saves your entries in the configuration file. |
| Step 6 | show system mtu Example: Device# <code>show system mtu</code> | Verifies your settings. |

Configuration Examples for System MTU

This example shows how to set the maximum packet size for a Gigabit Ethernet port to 7500 bytes:

```
Device(config)# system mtu 7500
Device(config)# exit
```

This example shows how to set the jumbo packet size for a Gigabit Ethernet port to 7500 bytes:

```
Device(config)# system mtu jumbo 7500
Device(config)# exit
```

If you enter a value that is outside the allowed range for the specific type of interface, the value is not accepted. This example shows the response when you try to set Gigabit Ethernet interfaces to an out-of-range number:

```
Device(config)# system mtu jumbo 25000
                        ^
% Invalid input detected at '^' marker.
```

| Cisco IOS Release 15.0(2)EX | This feature was introduced. |

CHAPTER 7

Configuring Boot Fast

- [Configuring Boot Fast on the switch, on page 73](#)

Configuring Boot Fast on the switch

This feature, when enabled, helps the switch to boot up fast. The Memory test is performed for a limited range, the switch skips File system check (FSCK) and Skips Post test.

Note When Fast boot is enabled, you can still run the POST tests manually from the command line interface, once the switch has booted up, using **diagnostic start** command.

Enabling Boot Fast

To enable the boot fast feature, perform the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | boot fast Example: | Enables fast boot feature Performs Memory test for a limited range, Skips File system check (FSCK) and Skips Post test. |

| | Command or Action | Purpose |
|---------------|---|----------------------------------|
| | Device(config)# boot fast | |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Disabling Boot Fast

To disable the boot fast feature, perform the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no boot fast Example: Device(config)# no boot fast | Disables the boot fast feature. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

CHAPTER 8

Configuring PoE

- [Restrictions for PoE, on page 75](#)
- [Information About PoE, on page 75](#)
- [How to Configure PoE, on page 80](#)
- [Monitoring Power Status, on page 88](#)
- [Configuration Examples for Configuring PoE, on page 88](#)
- [Additional References, on page 89](#)

Restrictions for PoE

Note This feature is supported only on the LAN Base image.

Information About PoE

Power over Ethernet Ports

A PoE-capable switch port automatically supplies power to one of these connected devices if the device senses that there is no power on the circuit:

- a Cisco pre-standard powered device (such as a Cisco IP Phone or a Cisco Aironet Access Point)
- an IEEE 802.3af-compliant powered device

A powered device can receive redundant power when it is connected to a PoE switch port and to an AC power source. The device does not receive redundant power when it is only connected to the PoE port.

Supported Protocols and Standards

The device uses these protocols and standards to support PoE:

- CDP with power consumption—The powered device notifies the device of the amount of power it is consuming. The device does not reply to the power-consumption messages. The device can only supply power to or remove power from the PoE port.

- Cisco intelligent power management—The powered device and the device negotiate through power-negotiation CDP messages for an agreed-upon power-consumption level. The negotiation allows a high-power Cisco powered device, which consumes more than 7 W, to operate at its highest power mode. The powered device first boots up in low-power mode, consumes less than 7 W, and negotiates to obtain enough power to operate in high-power mode. The device changes to high-power mode only when it receives confirmation from the device.

High-power devices can operate in low-power mode on devices that do not support power-negotiation CDP.

Cisco intelligent power management is backward-compatible with CDP with power consumption; the device responds according to the CDP message that it receives. CDP is not supported on third-party powered devices; therefore, the device uses the IEEE classification to determine the power usage of the device.

- IEEE 802.3af—The major features of this standard are powered-device discovery, power administration, disconnect detection, and optional powered-device power classification. For more information, see the standard.

Powered-Device Detection and Initial Power Allocation

The device detects a Cisco pre-standard or an IEEE-compliant powered device when the PoE-capable port is in the no-shutdown state, PoE is enabled (the default), and the connected device is not being powered by an AC adaptor.

After device detection, the device determines the device power requirements based on its type:

- The initial power allocation is the maximum amount of power that a powered device requires. The device initially allocates this amount of power when it detects and powers the powered device. As the device receives CDP messages from the powered device and as the powered device negotiates power levels with the device through CDP power-negotiation messages, the initial power allocation might be adjusted.
- The device classifies the detected IEEE device within a power consumption class. Based on the available power in the power budget, the device determines if a port can be powered. [Table 10: IEEE Power Classifications, on page 76](#) lists these levels.

Table 10: IEEE Power Classifications

| Class | Maximum Power Level Required from the Device |
|--------------------------|--|
| 0 (class status unknown) | 15.4 W |
| 1 | 4 W |
| 2 | 7 W |
| 3 | 15.4 W |
| 4 | 30 W (For IEEE 802.3at Type 2 powered devices) |

The device monitors and tracks requests for power and grants power only when it is available. The device tracks its power budget (the amount of power available on the device for PoE). The device performs power-accounting calculations when a port is granted or denied power to keep the power budget up to date.

After power is applied to the port, the device uses CDP to determine the *CDP-specific* power consumption requirement of the connected Cisco powered devices, which is the amount of power to allocate based on the CDP messages. The device adjusts the power budget accordingly. This does not apply to third-party PoE devices. The device processes a request and either grants or denies power. If the request is granted, the device updates the power budget. If the request is denied, the device ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. Powered devices can also negotiate with the device for more power.

With PoE+, powered devices use IEEE 802.3at and LLDP power with media dependent interface (MDI) type, length, and value descriptions (TLVs), Power-via-MDI TLVs, for negotiating power up to 30 W. Cisco pre-standard devices and Cisco IEEE powered devices can use CDP or the IEEE 802.3at power-via-MDI power negotiation mechanism to request power levels up to 30 W.

Note The initial allocation for Class 0, Class 3, and Class 4 powered devices is 15.4 W. When a device starts up and uses CDP or LLDP to send a request for more than 15.4 W, it can be allocated up to the maximum of 30 W.

Note The CDP-specific power consumption requirement is referred to as the *actual* power consumption requirement in the software configuration guides and command references.

If the device detects a fault caused by an undervoltage, overvoltage, overtemperature, oscillator-fault, or short-circuit condition, it turns off power to the port, generates a syslog message, and updates the power budget and LEDs.

The PoE feature operates the same whether or not the device is a stack member. The power budget is per device and independent of any other device in the stack. Election of a new active device does not affect PoE operation. The active device keeps track of the PoE status for all devices and ports in the stack and includes the status in output displays.

Power Management Modes

The device supports these PoE modes:

- **auto**—The device automatically detects if the connected device requires power. If the device discovers a powered device connected to the port and if the device has enough power, it grants power, updates the power budget, turns on power to the port on a first-come, first-served basis, and updates the LEDs. For LED information, see the hardware installation guide.

If the device has enough power for all the powered devices, they all come up. If enough power is available for all powered devices connected to the device, power is turned on to all devices. If there is not enough available PoE, or if a device is disconnected and reconnected while other devices are waiting for power, it cannot be determined which devices are granted or are denied power.

If granting power would exceed the system power budget, the device denies power, ensures that power to the port is turned off, generates a syslog message, and updates the LEDs. After power has been denied, the device periodically rechecks the power budget and continues to attempt to grant the request for power.

If a device being powered by the device is then connected to wall power, the device might continue to power the device. The device might continue to report that it is still powering the device whether the device is being powered by the device or receiving power from an AC power source.

If a powered device is removed, the device automatically detects the disconnect and removes power from the port. You can connect a nonpowered device without damaging it.

You can specify the maximum wattage that is allowed on the port. If the IEEE class maximum wattage of the powered device is greater than the configured maximum value, the device does not provide power to the port. If the device powers a powered device, but the powered device later requests through CDP messages more than the configured maximum value, the device removes power to the port. The power that was allocated to the powered device is reclaimed into the global power budget. If you do not specify a wattage, the device delivers the maximum value. Use the **auto** setting on any PoE port. The auto mode is the default setting.

- **static**—The device pre-allocates power to the port (even when no powered device is connected) and guarantees that power will be available for the port. The device allocates the port configured maximum wattage, and the amount is never adjusted through the IEEE class or by CDP messages from the powered device. Because power is pre-allocated, any powered device that uses less than or equal to the maximum wattage is guaranteed to be powered when it is connected to the static port. The port no longer participates in the first-come, first-served model.

However, if the powered-device IEEE class is greater than the maximum wattage, the device does not supply power to it. If the device learns through CDP messages that the powered device is consuming more than the maximum wattage, the device shuts down the powered device.

If you do not specify a wattage, the device pre-allocates the maximum value. The device powers the port only if it discovers a powered device. Use the **static** setting on a high-priority interface.

- **never**—The device disables powered-device detection and never powers the PoE port even if an unpowered device is connected. Use this mode only when you want to make sure that power is never applied to a PoE-capable port, making the port a data-only port.

For most situations, the default configuration (auto mode) works well, providing plug-and-play operation. No further configuration is required. However, perform this task to configure a PoE port for a higher priority, to make it data only, or to specify a maximum wattage to disallow high-power powered devices on a port.

Power Monitoring and Power Policing

When policing of the real-time power consumption is enabled, the device takes action when a powered device consumes more power than the maximum amount allocated, also referred to as the *cutoff-power value*.

When PoE is enabled, the device senses the real-time power consumption of the powered device. The device monitors the real-time power consumption of the connected powered device; this is called *power monitoring* or *power sensing*. The device also polices the power usage with the *power policing* feature.

Power monitoring is backward-compatible with Cisco intelligent power management and CDP-based power consumption. It works with these features to ensure that the PoE port can supply power to the powered device.

The device senses the real-time power consumption of the connected device as follows:

1. The device monitors the real-time power consumption on individual ports.
2. The device records the power consumption, including peak power usage. The device reports the information through the CISCO-POWER-ETHERNET-EXT-MIB.
3. If power policing is enabled, the device polices power usage by comparing the real-time power consumption to the maximum power allocated to the device. The maximum power consumption is also referred to as the *cutoff power* on a PoE port.

If the device uses more than the maximum power allocation on the port, the device can either turn off power to the port, or the device can generate a syslog message and update the LEDs (the port LED is now blinking amber) while still providing power to the device based on the device configuration. By default, power-usage policing is disabled on all PoE ports.

If error recovery from the PoE error-disabled state is enabled, the device automatically takes the PoE port out of the error-disabled state after the specified amount of time.

If error recovery is disabled, you can manually re-enable the PoE port by using the **shutdown** and **no shutdown** interface configuration commands.

4. If policing is disabled, no action occurs when the powered device consumes more than the maximum power allocation on the PoE port, which could adversely affect the device.

Maximum Power Allocation (Cutoff Power) on a PoE Port

When power policing is enabled, the device determines one of these values as the cutoff power on the PoE port in this order:

1. Manually when you set the user-defined power level that the device budgets for the port by using the **power inline consumption default** *wattage* global or interface configuration command
2. Manually when you set the user-defined power level that limits the power allowed on the port by using the **power inline auto max** *max-wattage* or the **power inline static max** *max-wattage* interface configuration command
3. Automatically when the device sets the power usage of the device by using CDP power negotiation or by the IEEE classification and LLDP power negotiation.

Use the first or second method in the previous list to manually configure the cutoff-power value by entering the **power inline consumption default** *wattage* or the **power inline [auto | static max]** *max-wattage* command.

You should use **power inline consumption default** *wattage* command to manually set the power level for a port only in situations where CDP/LLDP power negotiations are not supported.

If you do not manually configure the cutoff-power value, the device automatically determines it by using CDP power negotiation or the device IEEE classification and LLDP power negotiation. If CDP or LLDP are not enabled, the default value of 30 W is applied. However without CDP or LLDP, the device does not allow devices to consume more than 15.4 W of power because values from 15400 to 30000 mW are only allocated based on CDP or LLDP requests. If a powered device consumes more than 15.4 W without CDP or LLDP negotiation, the device might be in violation of the maximum current (*I_{max}*) limitation and might experience an *I_{cut}* fault for drawing more current than the maximum. The port remains in the fault state for a time before attempting to power on again. If the port continuously draws more than 15.4 W, the cycle repeats.

Note When a powered device connected to a PoE+ port restarts and sends a CDP or LLDP packet with a power TLV, the device locks to the power-negotiation protocol of that first packet and does not respond to power requests from the other protocol. For example, if the device is locked to CDP, it does not provide power to devices that send LLDP requests. If CDP is disabled after the device has locked on it, the device does not respond to LLDP power requests and can no longer power on any accessories. In this case, you should restart the powered device.

Power Consumption Values

You can configure the initial power allocation and the maximum power allocation on a port. However, these values are only the configured values that determine when the device should turn on or turn off power on the PoE port. The maximum power allocation is not the same as the actual power consumption of the powered device. The actual cutoff power value that the device uses for power policing is not equal to the configured power value.

When power policing is enabled, the device polices the power usage *at the switch port*, which is greater than the power consumption of the device. When you manually set the maximum power allocation, you must consider the power loss over the cable from the switch port to the powered device. The cutoff power is the sum of the rated power consumption of the powered device and the worst-case power loss over the cable.

We recommend that you enable power policing when PoE is enabled on your device. For example, if policing is disabled and you set the cutoff-power value by using the **power inline auto max 6300** interface configuration command, the configured maximum power allocation on the PoE port is 6.3 W (6300 mW). The device provides power to the connected devices on the port if the device needs up to 6.3 W. If the CDP-power negotiated value or the IEEE classification value exceeds the configured cutoff value, the device does not provide power to the connected device. After the device turns on power on the PoE port, the device does not police the real-time power consumption of the device, and the device can consume more power than the maximum allocated amount, which could adversely affect the device and the devices connected to the other PoE ports.

Because the device supports internal power supplies and the Cisco Redundant Power System 2300 (also referred to as the RPS 2300), the total amount of power available for the powered devices varies depending on the power supply configuration.

How to Configure PoE

Configuring a Power Management Mode on a PoE Port

Note When you make PoE configuration changes, the port being configured drops power. Depending on the new configuration, the state of the other PoE ports, and the state of the power budget, the port might not be powered up again. For example, port 1 is in the auto and on state, and you configure it for static mode. The device removes power from port 1, detects the powered device, and repowers the port. If port 1 is in the auto and on state and you configure it with a maximum wattage of 10 W, the device removes power from the port and then redetects the powered device. The device repowers the port only if the powered device is a class 1, class 2, or a Cisco-only powered device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|--------|---|---|
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface interface-id Example: Device(config)# interface gigabitethernet 2/0/1 | Specifies the physical port to be configured, and enters interface configuration mode. |
| Step 4 | power inline {auto [max max-wattage] never static [max max-wattage]} Example: Device(config-if)# power inline auto | <p>Configures the PoE mode on the port. The keywords have these meanings:</p> <ul style="list-style-type: none"> • auto—Enables powered-device detection. If enough power is available, automatically allocates power to the PoE port after device detection. This is the default setting. • max max-wattage—Limits the power allowed on the port. The range is 4000 to 30000 mW. If no value is specified, the maximum is allowed. • never—Disables device detection, and disable power to the port. <p>Note If a port has a Cisco powered device connected to it, do not use the power inline never command to configure the port. A false link-up can occur, placing the port into the error-disabled state.</p> <ul style="list-style-type: none"> • static—Enables powered-device detection. Pre-allocate (reserve) power for a port before the device discovers the powered device. The device reserves power for this port even when no device is connected and guarantees that power will be provided upon device detection. <p>The device allocates power to a port configured in static mode before it allocates power to a port configured in auto mode.</p> |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 6 | show power inline [<i>interface-id</i> module <i>switch-number</i>] Example: Device# show power inline | Displays PoE status for a device or a device stack, for the specified interface, or for a specified stack member. The module <i>switch-number</i> keywords are supported only on stacking-capable devices. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Fast POE

This feature remembers the last power drawn from a particular PSE port and switches on power the moment AC power is plugged in (within 15 to 20 seconds of switching on power) without waiting for IOS to boot up. When **poe-ha** is enabled on a particular port, the switch on a recovery after power failure, provides power to the connected endpoint devices within short duration before even the IOS forwarding starts up.

This feature can be configured by the same command as **poe-ha** which is already implemented. If the user replaces the power device connected to a port when the switch is powered off, then this new device will get the power which the previous device was drawing.

Note Fast POE is supported on Catalyst 3850 only.

Note In case of UPOE, even though Fast POE is available on the switch side, the PD endpoints may not be able to take advantage of the same, due to the reliance on LLDP to signal the UPOE power availability. This reliance on LLDP requires that the PD endpoint still needs to wait till the IOS comes up and LLDP packet exchanges can happen, signaling the availability of UPOE power.

Configuring Fast PoE

To configure Fast PoE, perform the following steps:

Note You will need to configure the **poe-ha** command before connecting the PD, or you will need to manually shut/unshut the port after configuring **poe-ha**.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface interface-id Example: Device(config)# interface gigabitethernet2/0/1 | Specifies the physical port to be configured, and enters interface configuration mode. |
| Step 4 | power inline port poe-ha Example: Device(config-if)# power inline port poe-ha | Configures POE High Availability. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Budgeting Power for Devices Connected to a PoE Port

When Cisco powered devices are connected to PoE ports, the device uses Cisco Discovery Protocol (CDP) to determine the *protocol-specific* power consumption of the devices, and the device adjusts the power budget accordingly. This does not apply to IEEE third-party powered devices. For these devices, when the device grants a power request, the device adjusts the power budget according to the powered-device IEEE classification. If the powered device is a class 0 (class status unknown) or a class 3, the device budgets 15,400 mW for the device, regardless of the CDP-specific amount of power needed. If the powered device reports a higher class than its CDP-specific consumption or does not support power classification (defaults to class 0), the device can power fewer devices because it uses the IEEE class information to track the global power budget.

By using the **power inline consumption wattage** interface configuration command or the **power inline consumption default wattage** global configuration command, you can override the default power requirement specified by the IEEE classification. The difference between what is mandated by the IEEE classification and what is actually needed by the device is reclaimed into the global power budget for use by additional devices. You can then extend the device power budget and use it more effectively.

Caution You should carefully plan your device power budget, enable the power monitoring feature, and make certain not to oversubscribe the power supply.

Note When you manually configure the power budget, you must also consider the power loss over the cable between the device and the powered device.

Budgeting Power to All PoE ports

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no cdp run Example: Device (config)# no cdp run | (Optional) Disables CDP. |
| Step 4 | power inline consumption default <i>wattage</i> Example: Device (config)# power inline consumption default 5000 | Configures the power consumption of powered devices connected to each PoE port. The range for each device is 4000 to 30000 mW (PoE+). The default is 30000 mW. |
| Step 5 | end Example: Device (config)# end | Returns to privileged EXEC mode. |
| Step 6 | show power inline consumption default Example: Device# show power inline consumption default | Displays the power consumption status. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|-----------------------------|---------|
| | <code>startup-config</code> | |

Budgeting Power to a Specific PoE Port

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | no cdp run Example: Device(config)# <code>no cdp run</code> | (Optional) Disables CDP. |
| Step 4 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 1/0/1</code> | Specifies the physical port to be configured, and enter interface configuration mode. |
| Step 5 | power inline consumption <i>wattage</i> Example: Device(config-if)# <code>power inline consumption 5000</code> | Configures the power consumption of a powered device connected to a PoE port on the device. The range for each device is 4000 to 30000 mW (PoE+). The default is 30000 mW (PoE+). |
| Step 6 | end Example: Device(config-if)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 7 | show power inline consumption Example: Device# <code>show power inline consumption</code> | Displays the power consumption data. |
| Step 8 | copy running-config startup-config Example: | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

Configuring Power Policing

By default, the device monitors the real-time power consumption of connected powered devices. You can configure the device to police the power usage. By default, policing is disabled.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 2/0/1</code> | Specifies the physical port to be configured, and enter interface configuration mode. |
| Step 4 | power inline police [action{log errdisable}] Example: Device(config-if)# <code>power inline police</code> | If the real-time power consumption exceeds the maximum power allocation on the port, configures the device to take one of these actions: <ul style="list-style-type: none"> • power inline police—Shuts down the PoE port, turns off power to it, and puts it in the error-disabled state. <p>Note You can enable error detection for the PoE error-disabled cause by using the errdisable detect cause inline-power global configuration command. You can also enable the timer to recover from the PoE error-disabled state by using the errdisable recovery cause inline-power interval <i>interval</i> global configuration command.</p> |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> • power inline police action errdisable—Turns off power to the port if the real-time power consumption exceeds the maximum power allocation on the port. • power inline police action log—Generates a syslog message while still providing power to the port. <p>If you do not enter the action log keywords, the default action shuts down the port and puts the port in the error-disabled state.</p> |
| Step 5 | exit Example: <pre>Device(config-if)# exit</pre> | Returns to global configuration mode. |
| Step 6 | Use one of the following: <ul style="list-style-type: none"> • errdisable detect cause inline-power • errdisable recovery cause inline-power • errdisable recovery interval interval Example: <pre>Device(config)# errdisable detect cause inline-power</pre> <pre>Device(config)# errdisable recovery cause inline-power</pre> <pre>Device(config)# errdisable recovery interval 100</pre> | (Optional) Enables error recovery from the PoE error-disabled state, and configures the PoE recover mechanism variables. By default, the recovery interval is 300 seconds. For interval interval , specifies the time in seconds to recover from the error-disabled state. The range is 30 to 86400. |
| Step 7 | exit Example: <pre>Device(config)# exit</pre> | Returns to privileged EXEC mode. |
| Step 8 | Use one of the following: <ul style="list-style-type: none"> • show power inline police • show errdisable recovery Example: <pre>Device# show power inline police</pre> <pre>Device# show errdisable recovery</pre> | Displays the power monitoring status, and verify the error recovery settings. |

| | Command or Action | Purpose |
|--------|---|--|
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring Power Status

Table 11: Show Commands for Power Status

| Command | Purpose |
|---|---|
| show env power switch <i>[switch-number]</i> | (Optional) Displays the status of the internal power supplies for each switch in the stack or for the specified switch. The range is 1 to , depending on the switch member numbers in the stack. These keywords are available only on stacking-capable switches. |
| show power inline <i>[interface-id module switch-number]</i> | Displays PoE status for a switch or switch stack, for an interface, or for a specific switch in the stack. |
| show power inline police | Displays the power policing data. |

Configuration Examples for Configuring PoE

Budgeting Power: Example

When you enter one of the following commands,

- **[no] power inline consumption default** *wattage* global configuration command
- **[no] power inline consumption** *wattage* interface configuration command

this caution message appears:

```
%CAUTION: Interface Gi1/0/1: Misconfiguring the 'power inline consumption/allocation'
command may cause damage to the
switch and void your warranty. Take precaution not to oversubscribe the power supply. It
is recommended to enable power
policing if the switch supports it. Refer to documentation.
```

CHAPTER 9

Configuring 2-event Classification

- [Information about 2-event Classification, on page 91](#)
- [Configuring 2-event Classification, on page 91](#)
- [Example: Configuring 2-Event Classification, on page 92](#)

Information about 2-event Classification

When a class 4 device gets detected, IOS allocates 30W without any CDP or LLDP negotiation. This means that even before the link comes up the class 4 power device gets 30W.

Also, on the hardware level the PSE does a 2-event classification which allows a class 4 PD to detect PSE capability of providing 30W from hardware, register itself and it can move up to PoE+ level without waiting for any CDP/LLDP packet exchange.

Once 2-event is enabled on a port, you need to manually shut/un-shut the port or connect the PD again to start the IEEE detection again. Power budget allocation for a class-4 device will be 30W if 2-event classification is enabled on the port, else it will be 15.4W.

Configuring 2-event Classification

To configure the switch for a 2-event Classification, perform the steps given below:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1 | Specifies the physical port to be configured, and enters interface configuration mode. |
| Step 4 | power inline port 2-event Example: Device(config-if)# power inline port 2-event | Configures 2-event classification on the switch. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Example: Configuring 2-Event Classification

This example shows how you can configure 2-event classification.

```
Device> enable
Device# configure terminal
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# power inline port 2-event
Device(config-if)# end
```

CHAPTER 10

Configuring EEE

- [Restrictions for EEE, on page 93](#)
- [Information About EEE, on page 93](#)
- [How to Configure EEE, on page 94](#)
- [Monitoring EEE, on page 95](#)
- [Configuration Examples for Configuring EEE, on page 95](#)
- [Additional References, on page 96](#)
- [Feature Information for Configuring EEE, on page 96](#)

Restrictions for EEE

EEE has the following restrictions:

- Changing the EEE configuration resets the interface because the device has to restart Layer 1 autonegotiation.
- You might want to enable the Link Layer Discovery Protocol (LLDP) for devices that require longer wakeup times before they are able to accept data on their receive paths. Doing so enables the device to negotiate for extended system wakeup times from the transmitting link partner.

Information About EEE

EEE Overview

Energy Efficient Ethernet (EEE) is an IEEE 802.3az standard that is designed to reduce power consumption in Ethernet networks during idle periods.

Default EEE Configuration

EEE is enabled by default.

How to Configure EEE

You can enable or disable EEE on an interface that is connected to an EEE-capable link partner.

Enabling or Disabling EEE

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enter interface configuration mode. |
| Step 3 | power efficient-ethernet auto Example: Device (config-if)# power efficient-ethernet auto | Enables EEE on the specified interface. When EEE is enabled, the device advertises and autonegotiates EEE to its link partner. |
| Step 4 | no power efficient-ethernet auto Example: Device (config-if)# no power efficient-ethernet auto | Disables EEE on the specified interface. |
| Step 5 | end Example: Device (config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring EEE

Table 12: Commands for Displaying EEE Settings

| Command | Purpose |
|--|--|
| show eee capabilities interface <i>interface-id</i> | Displays EEE capabilities for the specified interface. |
| show eee status interface <i>interface-id</i> | Displays EEE status information for the specified interface. |
| show eee counters interface <i>interface-id</i> | Displays EEE counters for the specified interface. |

Following are examples of the **show eee** commands

```
Switch#show eee capabilities interface gigabitEthernet2/0/1
Gi2/0/1
EEE(efficient-ethernet): yes (100-Tx and 1000T auto)
Link Partner : yes (100-Tx and 1000T auto)

ASIC/Interface : EEE Capable/EEE Enabled

Switch#show eee status interface gigabitEthernet2/0/1
Gi2/0/1 is up
EEE(efficient-ethernet): Operational
Rx LPI Status : Low Power
Tx LPI Status : Low Power
Wake Error Count : 0

ASIC EEE STATUS
Rx LPI Status : Receiving LPI
Tx LPI Status : Transmitting LPI
Link Fault Status : Link Up
Sync Status : Code group synchronization with data stream intact

Switch#show eee counters interface gigabitEthernet2/0/1

LP Active Tx Time (10us) : 66649648
LP Transitioning Tx : 462
LP Active Rx Time (10us) : 64911682
LP Transitioning Rx : 153
```

Examples for Catalyst Digital Building Series Switches

```
Switch#show eee capabilities interface gig1/0/1
Gi1/0/1
EEE(efficient-ethernet): yes (100-Tx and 1000T auto)
Link Partner : no

Switch#show eee status int gig1/0/1
Gi1/0/1 is up
EEE(efficient-ethernet): Disagreed
Rx LPI Status : None
Tx LPI Status : None
Wake Error Count : 0
```

Configuration Examples for Configuring EEE

This example shows how to enable EEE for an interface:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# power efficient-ethernet auto
```

This example shows how to disable EEE for an interface:

```
Device# configure terminal
Device(config)# interface gigabitethernet 1/0/1
Device(config-if)# no power efficient-ethernet auto
```

- [Configuration Examples for IGMP Snooping and MVR, on page 138](#)
- [Additional References, on page 141](#)
- [Feature History and Information for IGMP Snooping, on page 141](#)

Prerequisites for Configuring IGMP Snooping and MVR

Prerequisites for IGMP Snooping

Observe these guidelines when configuring the IGMP snooping querier:

- Configure the VLAN in global configuration mode.
- Configure an IP address on the VLAN interface. When enabled, the IGMP snooping querier uses the IP address as the query source address.
- If there is no IP address configured on the VLAN interface, the IGMP snooping querier tries to use the configured global IP address for the IGMP querier. If there is no global IP address specified, the IGMP querier tries to use the VLAN device virtual interface (SVI) IP address (if one exists). If there is no SVI IP address, the device uses the first available IP address configured on the device. The first IP address available appears in the output of the **show ip interface** privileged EXEC command. The IGMP snooping querier does not generate an IGMP general query if it cannot find an available IP address on the device.
- The IGMP snooping querier supports IGMP Versions 1 and 2.
- When administratively enabled, the IGMP snooping querier moves to the nonquerier state if it detects the presence of a multicast router in the network.
- When it is administratively enabled, the IGMP snooping querier moves to the operationally disabled state under these conditions:

- IGMP snooping is disabled in the VLAN.
- PIM is enabled on the SVI of the corresponding VLAN.

-
-

Prerequisites for MVR

The following are the prerequisites for Multicast VLAN Registration (MVR):

- To use MVR, the device must be running the LAN Base image.

Restrictions for Configuring IGMP Snooping and MVR

Restrictions for IGMP Snooping

The following are the restrictions for IGMP snooping:

- The switch supports homogeneous stacking and mixed stacking. Mixed stacking is supported only with the Catalyst 2960-S switches. A homogenous stack can have up to eight stack members, while a mixed stack can have up to four stack members. All switches in a switch stack must be running the LAN Base image.
- IGMPv3 join and leave messages are not supported on devices running IGMP filtering or Multicast VLAN registration (MVR).
- IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.
- The IGMP configurable leave time is only supported on hosts running IGMP Version 2. IGMP version 2 is the default version for the device.

The actual leave latency in the network is usually the configured leave time. However, the leave time might vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

- The IGMP throttling action restriction can be applied only to Layer 2 ports. You can use **ip igmp max-groups action replace** interface configuration command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

When the maximum group limitation is set to the default (no maximum), entering the **ip igmp max-groups action {deny | replace}** command has no effect.

If you configure the throttling action and set the maximum group limitation after an interface has added multicast entries to the forwarding table, the forwarding-table entries are either aged out or removed, depending on the throttling action.

Restrictions for MVR

The following are restrictions for MVR:

- Only Layer 2 ports participate in MVR. You must configure ports as MVR receiver ports.
- Only one MVR multicast VLAN per device or device stack is supported.
- Receiver ports can only be access ports; they cannot be trunk ports. Receiver ports on a device can be in different VLANs, but should not belong to the multicast VLAN.
- The maximum number of multicast entries (MVR group addresses) that can be configured on a device (that is, the maximum number of television channels that can be received) is 256.
- MVR multicast data received in the source VLAN and leaving from receiver ports has its time-to-live (TTL) decremented by 1 in the device.
- Because MVR on the device uses IP multicast addresses instead of MAC multicast addresses, alias IP multicast addresses are allowed on the device. However, if the device is interoperating with Catalyst 3550 or Catalyst 3500 XL devices, you should not configure IP addresses that alias between themselves or with the reserved IP multicast addresses (in the range 224.0.0.xxx).
- Do not configure MVR on private VLAN ports.
- MVR is not supported when multicast routing is enabled on a device. If you enable multicast routing and a multicast routing protocol while MVR is enabled, MVR is disabled, and you receive a warning message. If you try to enable MVR while multicast routing and a multicast routing protocol are enabled, the operation to enable MVR is cancelled, and you receive an error message.
- MVR data received on an MVR receiver port is not forwarded to MVR source ports.
- MVR does not support IGMPv3 messages.
- The switch supports homogeneous stacking and mixed stacking. Mixed stacking is supported only with the Catalyst 2960-S switches. A homogenous stack can have up to eight stack members, while a mixed stack can have up to four stack members. All switches in a switch stack must be running the LAN Base image.

Information About IGMP Snooping and MVR

IGMP Snooping

Layer 2 devices can use IGMP snooping to constrain the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. As the name implies, IGMP snooping requires the LAN device to snoop on the IGMP transmissions between the host and the router and to keep track of multicast groups and member ports. When the device receives an IGMP report from a host for a particular multicast group, the device adds the host port number to the forwarding table entry; when it receives an IGMP Leave Group message from a host, it removes the host port from the table entry. It also periodically deletes entries if it does not receive IGMP membership reports from the multicast clients.

Note For more information on IP multicast and IGMP, see RFC 1112 and RFC 2236.

The multicast router sends out periodic general queries to all VLANs. All hosts interested in this multicast traffic send join requests and are added to the forwarding table entry. The device creates one entry per VLAN in the IGMP snooping IP multicast forwarding table for each group from which it receives an IGMP join request.

The device supports IP multicast group-based bridging, instead of MAC-addressed based groups. With multicast MAC address-based groups, if an IP address being configured translates (aliases) to a previously configured MAC address or to any reserved multicast MAC addresses (in the range 224.0.0.xxx), the command fails. Because the device uses IP multicast groups, there are no address aliasing issues.

The IP multicast groups learned through IGMP snooping are dynamic. However, you can statically configure multicast groups by using the **ip igmp snooping vlan *vlan-id* static *ip_address* interface *interface-id*** global configuration command. If you specify group membership for a multicast group address statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can consist of both user-defined and IGMP snooping-learned settings.

You can configure an IGMP snooping querier to support IGMP snooping in subnets without multicast interfaces because the multicast traffic does not need to be routed.

If a port spanning-tree, a port group, or a VLAN ID change occurs, the IGMP snooping-learned multicast groups from this port on the VLAN are deleted.

These sections describe IGMP snooping characteristics:

IGMP Versions

The device supports IGMP version 1, IGMP version 2, and IGMP version 3. These versions are interoperable on the device. For example, if IGMP snooping is enabled and the querier's version is IGMPv2, and the device receives an IGMPv3 report from a host, then the device can forward the IGMPv3 report to the multicast router.

An IGMPv3 device can receive messages from and forward messages to a device running the Source Specific Multicast (SSM) feature.

Joining a Multicast Group

Figure 4: Initial IGMP Join Message

When a host connected to the device wants to join an IP multicast group and it is an IGMP version 2 client, it sends an unsolicited IGMP join message, specifying the IP multicast group to join. Alternatively, when the device receives a general query from the router, it forwards the query to all ports in the VLAN. IGMP version 1 or version 2 hosts wanting to join the multicast group respond by sending a join message to the device. The device CPU creates a multicast forwarding-table entry for the group if it is not already present. The CPU also adds the interface where the join message was received to the forwarding-table entry. The host associated with that interface receives multicast traffic for that multicast group.

Router A sends a general query to the device, which forwards the query to ports 2 through 5, all of which are members of the same VLAN. Host 1 wants to join multicast group 224.1.2.3 and multicasts an IGMP membership report (IGMP join message) to the group. The device CPU uses the information in the IGMP report to set up a forwarding-table entry that includes the port numbers connected to Host 1 and to the router.

Table 13: IGMP Snooping Forwarding Table

| Destination Address | Type of Packet | Ports |
|---------------------|----------------|-------|
| 224.1.2.3 | IGMP | 1, 2 |

The device hardware can distinguish IGMP information packets from other packets for the multicast group. The information in the table tells the switching engine to send frames addressed to the 224.1.2.3 multicast IP address that are not IGMP packets to the router and to the host that has joined the group.

Figure 5: Second Host Joining a Multicast Group

If another host (for example, Host 4) sends an unsolicited IGMP join message for the same group, the CPU receives that message and adds the port number of Host 4 to the forwarding table. Because the forwarding table directs IGMP messages only to the CPU, the message is not flooded to other ports on the device. Any

known multicast traffic is forwarded to the group and not to the CPU.

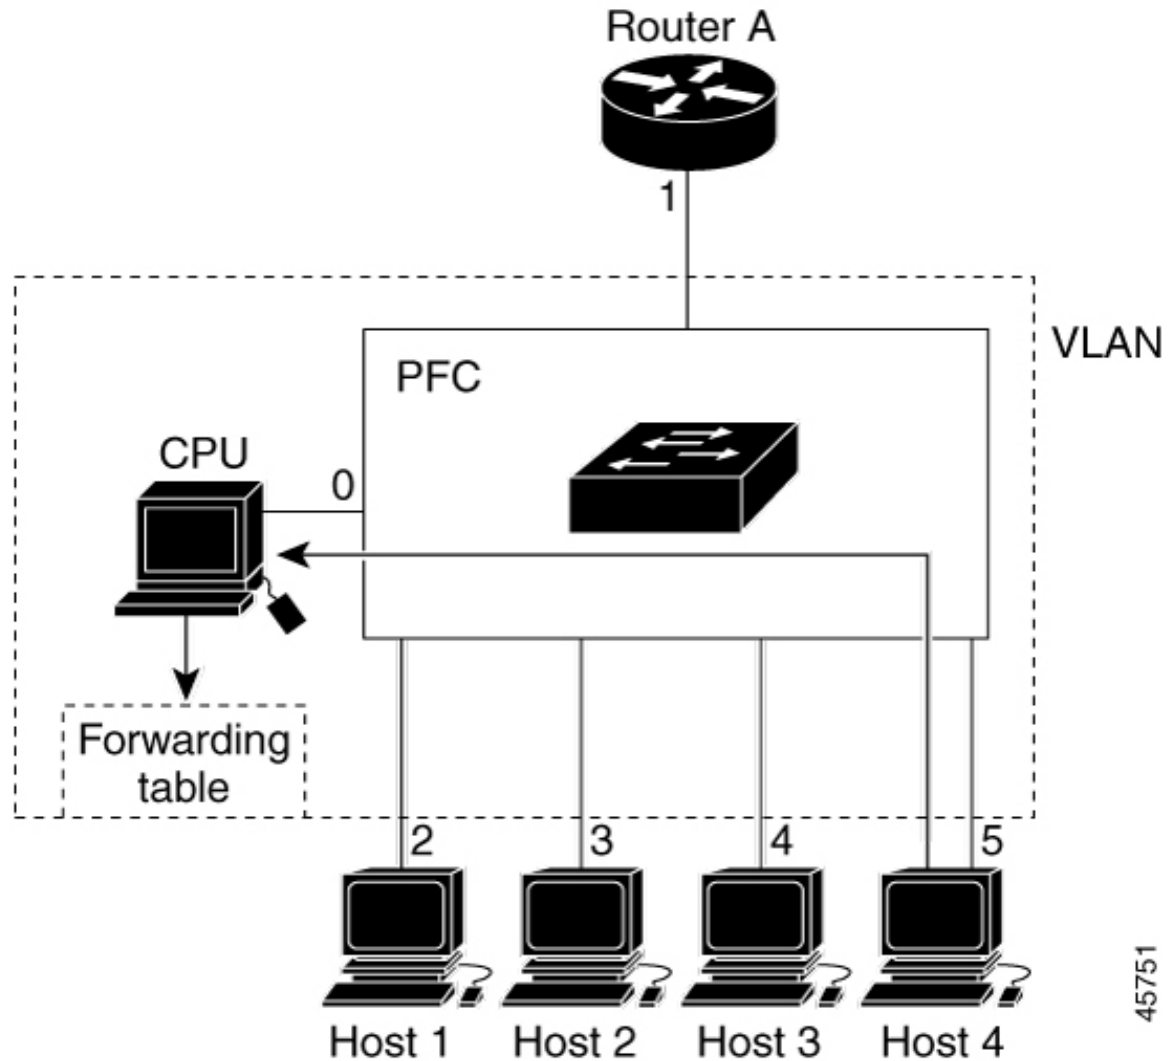

Table 14: Updated IGMP Snooping Forwarding Table

| Destination Address | Type of Packet | Ports |
|---------------------|----------------|---------|
| 224.1.2.3 | IGMP | 1, 2, 5 |

Leaving a Multicast Group

The router sends periodic multicast general queries, and the device forwards these queries through all ports in the VLAN. Interested hosts respond to the queries. If at least one host in the VLAN wants to receive multicast traffic, the router continues forwarding the multicast traffic to the VLAN. The device forwards multicast group traffic only to those hosts listed in the forwarding table for that IP multicast group maintained by IGMP snooping.

When hosts want to leave a multicast group, they can silently leave, or they can send a leave message. When the device receives a leave message from a host, it sends a group-specific query to learn if any other devices

connected to that interface are interested in traffic for the specific multicast group. The device then updates the forwarding table for that MAC group so that only those hosts interested in receiving multicast traffic for the group are listed in the forwarding table. If the router receives no reports from a VLAN, it removes the group for the VLAN from its IGMP cache.

Immediate Leave

The device uses IGMP snooping Immediate Leave to remove from the forwarding table an interface that sends a leave message without the device sending group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original leave message. Immediate Leave ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are simultaneously in use.

Immediate Leave is only supported on IGMP version 2 hosts. IGMP version 2 is the default version for the device.

Note You should use the Immediate Leave feature only on VLANs where a single host is connected to each port. If Immediate Leave is enabled on VLANs where more than one host is connected to a port, some hosts may be dropped inadvertently.

IGMP Configurable-Leave Timer

You can configure the time that the device waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 32767 milliseconds.

IGMP Report Suppression

Note IGMP report suppression is supported only when the multicast query has IGMPv1 and IGMPv2 reports. This feature is not supported when the query includes IGMPv3 reports.

The device uses IGMP report suppression to forward only one IGMP report per multicast router query to multicast devices. When IGMP report suppression is enabled (the default), the device sends the first IGMP report from all hosts for a group to all the multicast routers. The device does not send the remaining IGMP reports for the group to the multicast routers. This feature prevents duplicate reports from being sent to the multicast devices.

If the multicast router query includes requests only for IGMPv1 and IGMPv2 reports, the device forwards only the first IGMPv1 or IGMPv2 report from all hosts for a group to all the multicast routers.

If the multicast router query also includes requests for IGMPv3 reports, the device forwards all IGMPv1, IGMPv2, and IGMPv3 reports for a group to the multicast devices.

If you disable IGMP report suppression, all IGMP reports are forwarded to the multicast routers.

IGMP Snooping and Device Stacks

IGMP snooping functions across the device stack; that is, IGMP control information from one device is distributed to all devices in the stack. Regardless of the stack member through which IGMP multicast data enters the stack, the data reaches the hosts that have registered for that group.

If a device in the stack fails or is removed from the stack, only the members of the multicast group that are on that device will not receive the multicast data. All other members of a multicast group on other devices in the stack continue to receive multicast data streams. However, multicast groups that are common for both Layer 2 and Layer 3 (IP multicast routing) might take longer to converge if the active device is removed.

Default IGMP Snooping Configuration

This table displays the default IGMP snooping configuration for the device.

Table 15: Default IGMP Snooping Configuration

| Feature | Default Setting |
|------------------------------------|-------------------------------|
| IGMP snooping | Enabled globally and per VLAN |
| Multicast routers | None configured |
| IGMP snooping Immediate Leave | Disabled |
| Static groups | None configured |
| TCN ¹ flood query count | 2 |
| TCN query solicitation | Disabled |
| IGMP snooping querier | Disabled |
| IGMP report suppression | Enabled |

¹ (1) TCN = Topology Change Notification

Multicast VLAN Registration

Multicast VLAN Registration (MVR) is designed for applications using wide-scale deployment of multicast traffic across an Ethernet ring-based service-provider network (for example, the broadcast of multiple television channels over a service-provider network). MVR allows a subscriber on a port to subscribe and unsubscribe to a multicast stream on the network-wide multicast VLAN. It allows the single multicast VLAN to be shared in the network while subscribers remain in separate VLANs. MVR provides the ability to continuously send multicast streams in the multicast VLAN, but to isolate the streams from the subscriber VLANs for bandwidth and security reasons.

These sections describe MVR:

MVR and IGMP

Note MVR can coexist with IGMP snooping on a device.

MVR assumes that subscriber ports subscribe and unsubscribe (join and leave) these multicast streams by sending out IGMP join and leave messages. These messages can originate from an IGMP version-2-compatible host with an Ethernet connection. Although MVR operates on the underlying method of IGMP snooping, the two features operate independently of each other. One can be enabled or disabled without affecting the behavior of the other feature. However, if IGMP snooping and MVR are both enabled, MVR reacts only to join and leave messages from multicast groups configured under MVR. Join and leave messages from all other multicast groups are managed by IGMP snooping.

The device CPU identifies the MVR IP multicast streams and their associated IP multicast group in the device forwarding table, intercepts the IGMP messages, and modifies the forwarding table to include or remove the subscriber as a receiver of the multicast stream, even though the receivers might be in a different VLAN from the source. This forwarding behavior selectively allows traffic to cross between different VLANs.

Modes of Operation

You can set the device for compatible or dynamic mode of MVR operation:

- In compatible mode, multicast data received by MVR hosts is forwarded to all MVR data ports, regardless of MVR host membership on those ports. The multicast data is forwarded only to those receiver ports that MVR hosts have joined, either by IGMP reports or by MVR static configuration. IGMP reports received from MVR hosts are never forwarded from MVR data ports that were configured in the device.
- In dynamic mode, multicast data received by MVR hosts on the device is forwarded from only those MVR data and client ports that the MVR hosts have joined, either by IGMP reports or by MVR static configuration. Any IGMP reports received from MVR hosts are also forwarded from all the MVR data ports in the host. This eliminates using unnecessary bandwidth on MVR data port links, which occurs when the device runs in compatible mode.

MVR and Switch Stacks

Only one MVR multicast VLAN per device or device stack is supported.

Receiver ports and source ports can be on different devices in a device stack. Multicast data sent on the multicast VLAN is forwarded to all MVR receiver ports across the stack. When a new device is added to a stack, by default it has no receiver ports.

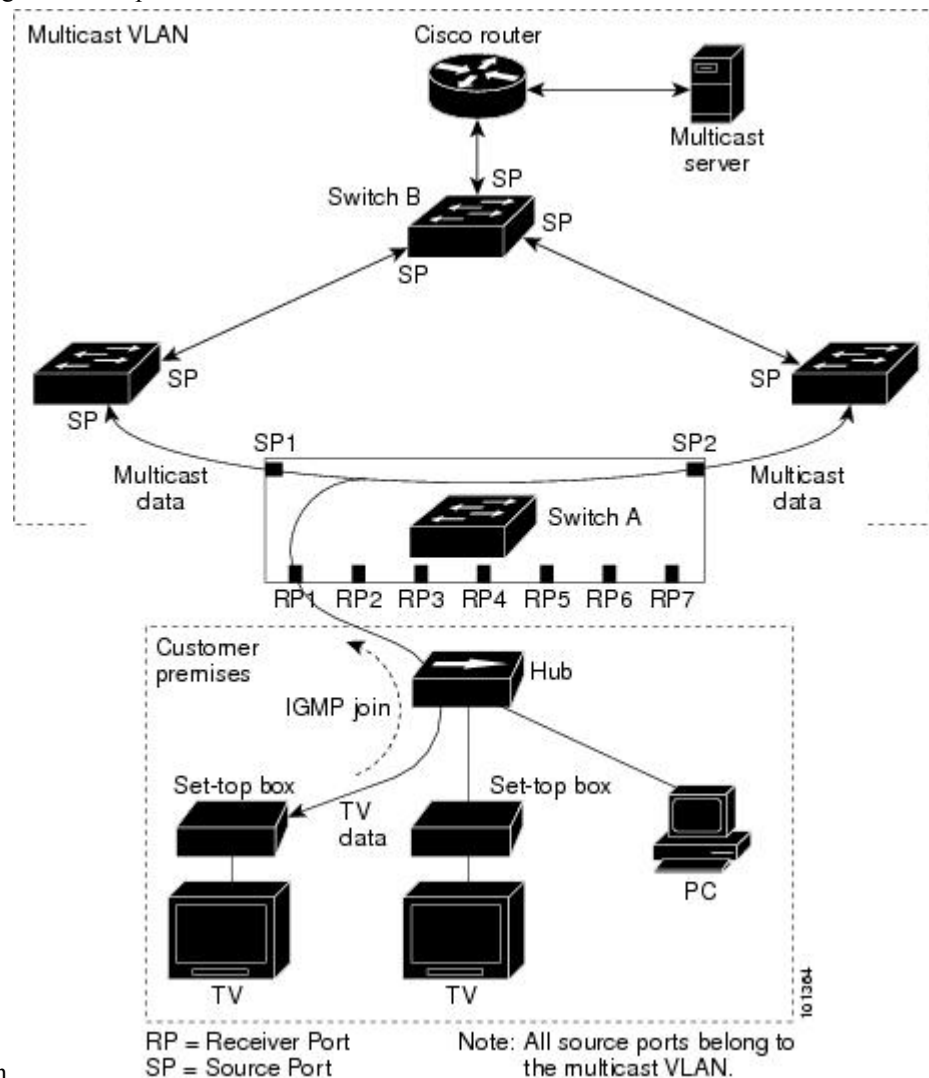

If a device fails or is removed from the stack, only those receiver ports belonging to that device will not receive the multicast data. All other receiver ports on other devices continue to receive the multicast data.

MVR in a Multicast Television Application

In a multicast television application, a PC or a television with a set-top box can receive the multicast stream. Multiple set-top boxes or PCs can be connected to one subscriber port, which is a device port configured as an MVR receiver port.

Figure 6: Multicast VLAN Registration Example

The following is an example

configuration.

In this example configuration, DHCP assigns an IP address to the set-top box or the PC. When a subscriber selects a channel, the set-top box or PC sends an IGMP report to Switch A to join the appropriate multicast. If the IGMP report matches one of the configured IP multicast group addresses, the device CPU modifies the hardware address table to include this receiver port and VLAN as a forwarding destination of the specified multicast stream when it is received from the multicast VLAN. Uplink ports that send and receive multicast data to and from the multicast VLAN are called MVR source ports.

When a subscriber changes channels or turns off the television, the set-top box sends an IGMP leave message for the multicast stream. The device CPU sends a MAC-based general query through the receiver port VLAN. If there is another set-top box in the VLAN still subscribing to this group, that set-top box must respond within the maximum response time specified in the query. If the CPU does not receive a response, it eliminates the receiver port as a forwarding destination for this group.

Without Immediate Leave, when the device receives an IGMP leave message from a subscriber on a receiver port, it sends out an IGMP query on that port and waits for IGMP group membership reports. If no reports

are received in a configured time period, the receiver port is removed from multicast group membership. With Immediate Leave, an IGMP query is not sent from the receiver port on which the IGMP leave was received. As soon as the leave message is received, the receiver port is removed from multicast group membership, which speeds up leave latency. Enable the Immediate-Leave feature only on receiver ports to which a single receiver device is connected.

MVR eliminates the need to duplicate television-channel multicast traffic for subscribers in each VLAN. Multicast traffic for all channels is only sent around the VLAN trunk once—only on the multicast VLAN. The IGMP leave and join messages are in the VLAN to which the subscriber port is assigned. These messages dynamically register for streams of multicast traffic in the multicast VLAN on the Layer 3 device. The access layer device, Switch A, modifies the forwarding behavior to allow the traffic to be forwarded from the multicast VLAN to the subscriber port in a different VLAN, selectively allowing traffic to cross between two VLANs.

IGMP reports are sent to the same IP multicast group address as the multicast data. The Switch A CPU must capture all IGMP join and leave messages from receiver ports and forward them to the multicast VLAN of the source (uplink) port, based on the MVR mode.

Default MVR Configuration

Table 16: Default MVR Configuration

| Feature | Default Setting |
|------------------------------|--------------------------------------|
| MVR | Disabled globally and per interface |
| Multicast addresses | None configured |
| Query response time | 0.5 second |
| Multicast VLAN | VLAN 1 |
| Mode | Compatible |
| Interface (per port) default | Neither a receiver nor a source port |
| Immediate Leave | Disabled on all ports |

IGMP Filtering and Throttling

In some environments, for example, metropolitan or multiple-dwelling unit (MDU) installations, you might want to control the set of multicast groups to which a user on a device port can belong. You can control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan. You might also want to limit the number of multicast groups to which a user on a device port can belong.

With the IGMP filtering feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual device ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a device port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing. You can also set the maximum number of IGMP groups that a Layer 2 interface can join.

IGMP filtering controls only group-specific query and membership reports, including join and leave reports. It does not control general IGMP queries. IGMP filtering has no relationship with the function that directs

the forwarding of IP multicast traffic. The filtering feature operates in the same manner whether CGMP or MVR is used to forward the multicast traffic.

IGMP filtering applies only to the dynamic learning of IP multicast group addresses, not static configuration.

With the IGMP throttling feature, you can set the maximum number of IGMP groups that a Layer 2 interface can join. If the maximum number of IGMP groups is set, the IGMP snooping forwarding table contains the maximum number of entries, and the interface receives an IGMP join report, you can configure an interface to drop the IGMP report or to replace the randomly selected multicast entry with the received IGMP report.

Note IGMPv3 join and leave messages are not supported on devices running IGMP filtering.

Default IGMP Filtering and Throttling Configuration

This table displays the default IGMP filtering and throttling configuration for the device.

Table 17: Default IGMP Filtering Configuration

| Feature | Default Setting |
|------------------------------------|--|
| IGMP filters | None applied. |
| IGMP maximum number of IGMP groups | No maximum set. Note When the maximum number of groups is in the forwarding table, the default IGMP throttling action is to deny the report. |
| IGMP profiles | None defined. |
| IGMP profile action | Deny the range addresses. |

How to Configure IGMP Snooping and MVR

Enabling or Disabling IGMP Snooping on a Device

When IGMP snooping is globally enabled or disabled, it is also enabled or disabled in all existing VLAN interfaces. IGMP snooping is enabled on all VLANs by default, but can be enabled and disabled on a per-VLAN basis.

Global IGMP snooping overrides the VLAN IGMP snooping. If global snooping is disabled, you cannot enable VLAN snooping. If global snooping is enabled, you can enable or disable VLAN snooping.

Follow these steps to globally enable IGMP snooping on the device:

Procedure

| | Command or Action | Purpose |
|---------------|---------------------|-------------------------------|
| Step 1 | <code>enable</code> | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Example: Device> enable | <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp snooping Example: Device(config)# ip igmp snooping | Globally enables IGMP snooping in all existing VLAN interfaces. Note To globally disable IGMP snooping on all VLAN interfaces, use the no ip igmp snooping global configuration command. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Enabling or Disabling IGMP Snooping on a VLAN Interface

Follow these steps to enable IGMP snooping on a VLAN interface:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# <code>configure terminal</code> | |
| Step 3 | <p>ip igmp snooping vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping vlan 7</pre> | <p>Enables IGMP snooping on the VLAN interface. The VLAN ID range is 1 to 1001 and 1006 to 4094.</p> <p>IGMP snooping must be globally enabled before you can enable VLAN snooping.</p> <p>Note To disable IGMP snooping on a VLAN interface, use the no ip igmp snooping vlan <i>vlan-id</i> global configuration command for the specified VLAN number.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Setting the Snooping Method

Multicast-capable router ports are added to the forwarding table for every Layer 2 multicast entry. The switch learns of the ports through one of these methods:

- Snooping on IGMP queries, Protocol-Independent Multicast (PIM) packets, and Distance Vector Multicast Routing Protocol (DVMRP) packets.
- Listening to Cisco Group Management Protocol (CGMP) packets from other routers.
- Statically connecting to a multicast router port using the **ip igmp snooping mrouter** global configuration command.

You can configure the switch either to snoop on IGMP queries and PIM/DVMRP packets or to listen to CGMP self-join or proxy-join packets. By default, the switch snoops on PIM/DVMRP packets on all VLANs. To learn of multicast router ports through only CGMP packets, use the **ip igmp snooping vlan *vlan-id* mrouter learn cgmp** global configuration command. When this command is entered, the router listens to only CGMP self-join and CGMP proxy-join packets and to no other CGMP packets. To learn of multicast router ports through only PIM-DVMRP packets, use the **ip igmp snooping vlan *vlan-id* mrouter learn pim-dvmrp** global configuration command.

If you want to use CGMP as the learning method and no multicast routers in the VLAN are CGMP proxy-enabled, you must enter the **ip cgmp router-only** command to dynamically access the router.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp snooping vlan <i>vlan-id</i> mrouter learn {cgmp pim-dvmrp } Example: Device(config)# ip igmp snooping vlan 1 mrouter learn cgmp | Specifies the multicast router learning method: <ul style="list-style-type: none"> • cgmp—Listens for CGMP packets. This method is useful for reducing control traffic. • pim-dvmrp—Snoops on IGMP queries and PIM-DVMRP packets. This is the default. <p>Note To return to the default learning method, use the no ip igmp snooping vlan <i>vlan-id</i> mrouter learn cgmp global configuration command.</p> |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip igmp snooping Example: Device# show ip igmp snooping | Verifies the configuration. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|-----------------------------|---------|
| | <code>startup-config</code> | |

Configuring a Multicast Router Port

Perform these steps to add a multicast router port (enable a static connection to a multicast router) on the device.

Note Static connections to multicast routers are supported only on device ports.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | <p>Enters global configuration mode.</p> |
| Step 3 | <p>ip igmp snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping vlan 5 mrouter interface gigabitethernet1/0/1</pre> | <p>Specifies the multicast router VLAN ID and the interface to the multicast router.</p> <ul style="list-style-type: none"> • The VLAN ID range is 1 to 1001 and 1006 to 4094. • The interface can be a physical interface or a port channel. The port-channel range is 1 to 128. <p>Note To remove a multicast router port from the VLAN, use the no ip igmp snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i> global configuration command.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | <p>Returns to privileged EXEC mode.</p> |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 5 | show ip igmp snooping mrouter [vlan <i>vlan-id</i>] Example: <pre>Device# show ip igmp snooping mrouter vlan 5</pre> | Verifies that IGMP snooping is enabled on the VLAN interface. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring a Host Statically to Join a Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure a host on an interface.

Follow these steps to add a Layer 2 port as a member of a multicast group:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | ip igmp snooping vlan <i>vlan-id</i> static <i>ip_address</i> interface <i>interface-id</i> Example: <pre>Device(config)# ip igmp snooping vlan 105 static 230.0.0.1 interface gigabitethernet1/0/1</pre> | Statically configures a Layer 2 port as a member of a multicast group: <ul style="list-style-type: none"> • <i>vlan-id</i> is the multicast group VLAN ID. The range is 1 to 1001 and 1006 to 4094. • <i>ip-address</i> is the group IP address. • <i>interface-id</i> is the member port. It can be a physical interface or a port channel (1 to 128). |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note To remove the Layer 2 port from the multicast group, use the no ip igmp snooping vlan <i>vlan-id</i> static <i>mac-address</i> interface <i>interface-id</i> global configuration command. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip igmp snooping groups Example: Device# show ip igmp snooping groups | Verifies the member port and the IP address. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Enabling IGMP Immediate Leave

When you enable IGMP Immediate Leave, the device immediately removes a port when it detects an IGMP Version 2 leave message on that port. You should use the Immediate-Leave feature only when there is a single receiver present on every port in the VLAN.

Note Immediate Leave is supported only on IGMP Version 2 hosts. IGMP Version 2 is the default version for the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | ip igmp snooping vlan <i>vlan-id</i> immediate-leave Example: Device(config)# <code>ip igmp snooping vlan 21 immediate-leave</code> | Enables IGMP Immediate Leave on the VLAN interface. Note To disable IGMP Immediate Leave on a VLAN, use the no ip igmp snooping vlan <i>vlan-id</i> immediate-leave global configuration command. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 5 | show ip igmp snooping vlan <i>vlan-id</i> Example: Device# <code>show ip igmp snooping vlan 21</code> | Verifies that Immediate Leave is enabled on the VLAN interface. |
| Step 6 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

Configuring the IGMP Leave Timer

You can configure the leave time globally or on a per-VLAN basis. Follow these steps to enable the IGMP configurable-leave timer:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | ip igmp snooping last-member-query-interval time Example: <pre>Device(config)# ip igmp snooping last-member-query-interval 1000</pre> | Configures the IGMP leave timer globally. The range is 100 to 32767 milliseconds. The default leave time is 1000 milliseconds. Note To globally reset the IGMP leave timer to the default setting, use the no ip igmp snooping last-member-query-interval global configuration command. |
| Step 4 | ip igmp snooping vlan <i>vlan-id</i> last-member-query-interval time Example: <pre>Device(config)# ip igmp snooping vlan 210 last-member-query-interval 1000</pre> | (Optional) Configures the IGMP leave time on the VLAN interface. The range is 100 to 32767 milliseconds. Note Configuring the leave time on a VLAN overrides the globally configured timer. Note To remove the configured IGMP leave-time setting from the specified VLAN, use the no ip igmp snooping vlan <i>vlan-id</i> last-member-query-interval global configuration command. |
| Step 5 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show ip igmp snooping Example: <pre>Device# show ip igmp snooping</pre> | (Optional) Displays the configured IGMP leave time. |
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring TCN-Related Commands

Controlling the Multicast Flooding Time After a TCN Event

You can configure the number of general queries by which multicast data traffic is flooded after a topology change notification (TCN) event. If you set the TCN flood query count to 1 the flooding stops after receiving 1 general query. If you set the count to 7, the flooding continues until 7 general queries are received. Groups are relearned based on the general queries received during the TCN event.

Some examples of TCN events are when the client location is changed and the receiver is on same port that was blocked but is now forwarding, and when a port goes down without sending a leave message.

Follow these steps to configure the TCN flood query count:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp snooping tcn flood query count count Example: Device(config)# ip igmp snooping tcn flood query count 3 | Specifies the number of IGMP general queries for which the multicast traffic is flooded. The range is 1 to 10. The default, the flooding query count is 2. Note To return to the default flooding query count, use the no ip igmp snooping tcn flood query count global configuration command. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip igmp snooping Example: Device# show ip igmp snooping | Verifies the TCN settings. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Recovering from Flood Mode

When a topology change occurs, the spanning-tree root sends a special IGMP leave message (also known as global leave) with the group multicast address 0.0.0.0. However, you can enable the device to send the global leave message whether it is the spanning-tree root or not. When the router receives this special leave, it immediately sends general queries, which expedite the process of recovering from the flood mode during the TCN event. Leaves are always sent if the device is the spanning-tree root regardless of this configuration.

Follow these steps to enable sending of leave messages:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp snooping tcn query solicit Example: Device(config)# ip igmp snooping tcn query solicit | Sends an IGMP leave message (global leave) to speed the process of recovering from the flood mode caused during a TCN event. By default, query solicitation is disabled. <p>Note To return to the default query solicitation, use the no ip igmp snooping tcn query solicit global configuration command.</p> |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | show ip igmp snooping Example: Device# <code>show ip igmp snooping</code> | Verifies the TCN settings. |
| Step 6 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Disabling Multicast Flooding During a TCN Event

When the device receives a TCN, multicast traffic is flooded to all the ports until 2 general queries are received. If the device has many ports with attached hosts that are subscribed to different multicast groups, this flooding might exceed the capacity of the link and cause packet loss. Follow these steps to control TCN flooding:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 1/0/1</code> | Specifies the interface to be configured, and enters interface configuration mode. |
| Step 4 | no ip igmp snooping tcn flood Example: Device(config-if)# <code>no ip igmp snooping tcn flood</code> | Disables the flooding of multicast traffic during a spanning-tree TCN event. By default, multicast flooding is enabled on an interface. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note To re-enable multicast flooding on an interface, use the ip igmp snooping tcn flood interface configuration command. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show ip igmp snooping Example: Device# show ip igmp snooping | Verifies the TCN settings. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring the IGMP Snooping Querier

Follow these steps to enable the IGMP snooping querier feature in a VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp snooping querier Example: Device(config)# ip igmp snooping querier | Enables the IGMP snooping querier. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 4 | <p>ip igmp snooping querier address <i>ip_address</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping querier address 172.16.24.1</pre> | <p>(Optional) Specifies an IP address for the IGMP snooping querier. If you do not specify an IP address, the querier tries to use the global IP address configured for the IGMP querier.</p> <p>Note The IGMP snooping querier does not generate an IGMP general query if it cannot find an IP address on the device.</p> |
| Step 5 | <p>ip igmp snooping querier query-interval <i>interval-count</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping querier query-interval 30</pre> | <p>(Optional) Sets the interval between IGMP queriers. The range is 1 to 18000 seconds.</p> |
| Step 6 | <p>ip igmp snooping querier tcn query [<i>count count</i> <i>interval interval</i>]</p> <p>Example:</p> <pre>Device(config)# ip igmp snooping querier tcn query interval 20</pre> | <p>(Optional) Sets the time between Topology Change Notification (TCN) queries. The count range is 1 to 10. The interval range is 1 to 255 seconds.</p> |
| Step 7 | <p>ip igmp snooping querier timer expiry <i>timeout</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping querier timer expiry 180</pre> | <p>(Optional) Sets the length of time until the IGMP querier expires. The range is 60 to 300 seconds.</p> |
| Step 8 | <p>ip igmp snooping querier version <i>version</i></p> <p>Example:</p> <pre>Device(config)# ip igmp snooping querier version 2</pre> | <p>(Optional) Selects the IGMP version number that the querier feature uses. Select 1 or 2.</p> |
| Step 9 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | <p>Returns to privileged EXEC mode.</p> |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 10 | show ip igmp snooping vlan <i>vlan-id</i> Example: <pre>Device# show ip igmp snooping vlan 30</pre> | (Optional) Verifies that the IGMP snooping querier is enabled on the VLAN interface. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| Step 11 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Disabling IGMP Report Suppression

Follow these steps to disable IGMP report suppression:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | no ip igmp snooping report-suppression Example: <pre>Device(config)# no ip igmp snooping report-suppression</pre> | Disables IGMP report suppression. When report suppression is disabled, all IGMP reports are forwarded to the multicast routers. IGMP report suppression is enabled by default. When IGMP report suppression is enabled, the device forwards only one IGMP report per multicast router query. Note To re-enable IGMP report suppression, use the ip igmp snooping report-suppression global configuration command. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip igmp snooping Example: Device# show ip igmp snooping | Verifies that IGMP report suppression is disabled. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring MVR Global Parameters

You do not need to set the optional MVR parameters if you choose to use the default settings. If you want to change the default parameters (except for the MVR VLAN), you must first enable MVR.

Note For complete syntax and usage information for the commands used in this section, see the command reference for this release.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | mvr Example: | Enables MVR on the device. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Device (config)# mvr | |
| Step 4 | mvr group <i>ip-address</i> [<i>count</i>] Example: Device (config)# mvr group 228.1.23.4 | Configures an IP multicast address on the device or use the <i>count</i> parameter to configure a contiguous series of MVR group addresses (the range for <i>count</i> is 1 to 256; the default is 1). Any multicast data sent to this address is sent to all source ports on the device and all receiver ports that have elected to receive data on that multicast address. Each multicast address would correspond to one television channel. Note To return the switch to its default settings, use the no mvr [mode group ip-address querytime vlan] global configuration commands. |
| Step 5 | mvr querytime <i>value</i> Example: Device (config)# mvr querytime 10 | (Optional) Defines the maximum time to wait for IGMP report memberships on a receiver port before removing the port from multicast group membership. The value is in units of tenths of a second. The range is 1 to 100, and the default is 5 tenths or one-half second. |
| Step 6 | mvr vlan <i>vlan-id</i> Example: Device (config)# mvr vlan 22 | (Optional) Specifies the VLAN in which multicast data is received; all source ports must belong to this VLAN. The VLAN range is 1 to 1001 and 1006 to 4094. The default is VLAN 1. |
| Step 7 | mvr mode { dynamic compatible } Example: Device (config)# mvr mode dynamic | (Optional) Specifies the MVR mode of operation: <ul style="list-style-type: none"> • dynamic—Allows dynamic MVR membership on source ports. • compatible—Is compatible with Catalyst 3500 XL and Catalyst 2900 XL devices and does not support IGMP dynamic joins on source ports. The default is compatible mode. Note To return the switch to its default settings, use the no mvr [mode group ip-address querytime vlan] global configuration commands. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 8 | end Example: Device (config) # end | Returns to privileged EXEC mode. |
| Step 9 | Use one of the following: <ul style="list-style-type: none"> • show mvr • show mvr members Example: Device# show mvr OR Device# show mvr members | Verifies the configuration. |
| Step 10 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring MVR Interfaces

Follow these steps to configure Layer 2 MVR interfaces:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | mvr Example: | Enables MVR on the device. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device (config)# mvr | |
| Step 4 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet1/0/2 | Specifies the Layer 2 port to configure, and enter interface configuration mode. |
| Step 5 | mvr type {source receiver} Example: Device (config-if)# mvr type receiver | Configures an MVR port as one of these: <ul style="list-style-type: none"> • source—Configures uplink ports that receive and send multicast data as source ports. Subscribers cannot be directly connected to source ports. All source ports on a device belong to the single multicast VLAN. • receiver—Configures a port as a receiver port if it is a subscriber port and should only receive multicast data. It does not receive data unless it becomes a member of the multicast group, either statically or by using IGMP leave and join messages. Receiver ports cannot belong to the multicast VLAN. <p>The default configuration is as a non-MVR port. If you attempt to configure a non-MVR port with MVR characteristics, the operation fails.</p> <p>Note To return the interface to its default settings, use the no mvr [type immediate vlan <i>vlan-id</i> group] interface configuration commands.</p> |
| Step 6 | mvr vlan <i>vlan-id</i> group [<i>ip-address</i>] Example: Device (config-if)# mvr vlan 22 group 228.1.1.23.4 | (Optional) Statically configures a port to receive multicast traffic sent to the multicast VLAN and the IP multicast address. A port statically configured as a member of a group remains a member of the group until statically removed. <p>Note In compatible mode, this command applies to only receiver ports. In dynamic mode, it applies to receiver ports and source ports.</p> |

| | Command or Action | Purpose |
|----------------|--|--|
| | | Receiver ports can also dynamically join multicast groups by using IGMP join and leave messages. |
| Step 7 | mvr immediate Example: <pre>Device(config-if)# mvr immediate</pre> | (Optional) Enables the Immediate-Learn feature of MVR on the port. Note This command applies to only receiver ports and should only be enabled on receiver ports to which a single receiver device is connected. |
| Step 8 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 9 | Use one of the following: <ul style="list-style-type: none"> • show mvr • show mvr interface • show mvr members Example: <pre>Device# show mvr interface Port Type Status ----- Immediate Leave ----- ----- Gi1/0/2 RECEIVER ACTIVE/DOWN ENABLED</pre> | Verifies the configuration. |
| Step 10 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring IGMP Profiles

Follow these steps to create an IGMP profile:

This task is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip igmp profile <i>profile number</i> Example: Device(config)# ip igmp profile 3 | Assigns a number to the profile you are configuring, and enters IGMP profile configuration mode. The profile number range is 1 to 4294967295. When you are in IGMP profile configuration mode, you can create the profile by using these commands: <ul style="list-style-type: none"> • deny—Specifies that matching addresses are denied; this is the default. • exit—Exits from igmp-profile configuration mode. • no—Negates a command or returns to its defaults. • permit—Specifies that matching addresses are permitted. • range—Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with a start and an end address. The default is for the device to have no IGMP profiles configured. Note To delete a profile, use the no ip igmp profile <i>profile number</i> global configuration command. |
| Step 4 | permit deny Example: Device(config-igmp-profile)# permit | (Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | <p>range <i>ip multicast address</i></p> <p>Example:</p> <pre>Device(config-igmp-profile)# range 229.9.9.0</pre> | <p>Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address.</p> <p>You can use the range command multiple times to enter multiple addresses or ranges of addresses.</p> <p>Note To delete an IP multicast address or range of IP multicast addresses, use the no range ip multicast address IGMP profile configuration command.</p> |
| Step 6 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | <p>show ip igmp profile <i>profile number</i></p> <p>Example:</p> <pre>Device# show ip igmp profile 3</pre> | Verifies the profile configuration. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 9 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Applying IGMP Profiles

To control access as defined in an IGMP profile, you have to apply the profile to the appropriate interfaces. You can apply IGMP profiles only to Layer 2 access ports; you cannot apply IGMP profiles to routed ports or SVIs. You cannot apply profiles to ports that belong to an EtherChannel port group. You can apply a profile to multiple interfaces, but each interface can have only one profile applied to it.

Follow these steps to apply an IGMP profile to a switch port:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1 | Specifies the physical interface, and enters interface configuration mode. The interface must be a Layer 2 port that does not belong to an EtherChannel port group. |
| Step 4 | ip igmp filter <i>profile number</i> Example: Device(config-if)# ip igmp filter 321 | Applies the specified IGMP profile to the interface. The range is 1 to 4294967295. Note To remove a profile from an interface, use the no ip igmp filter <i>profile number</i> interface configuration command. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Setting the Maximum Number of IGMP Groups

Follow these steps to set the maximum number of IGMP groups that a Layer 2 interface can join:

Before you begin

This restriction can be applied to Layer 2 ports only; you cannot set a maximum number of IGMP groups on routed ports or SVIs. You also can use this command on a logical EtherChannel interface but cannot use it on ports that belong to an EtherChannel port group.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/2 | Specifies the interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or a EtherChannel interface. |
| Step 4 | ip igmp max-groups <i>number</i> Example: Device(config-if)# ip igmp max-groups 20 | Sets the maximum number of IGMP groups that the interface can join. The range is 0 to 4294967294. The default is to have no maximum set. <p>Note To remove the maximum group limitation and return to the default of no maximum, use the no ip igmp max-groups interface configuration command.</p> |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 6 | show running-config interface <i>interface-id</i> Example: Device# <code>interface gigabitethernet1/0/1</code> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Configuring the IGMP Throttling Action

After you set the maximum number of IGMP groups that a Layer 2 interface can join, you can configure an interface to replace the existing group with the new group for which the IGMP report was received.

Follow these steps to configure the throttling action when the maximum number of entries is in the forwarding table:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet1/0/1</code> | Specifies the physical interface to be configured, and enters interface configuration mode. The interface can be a Layer 2 port that does not belong to an EtherChannel group or an EtherChannel interface. The interface cannot be a trunk port. |
| Step 4 | ip igmp max-groups action {deny replace} Example: Device(config-if)# <code>ip igmp max-groups</code> | When an interface receives an IGMP report and the maximum number of entries is in the forwarding table, specifies the action that the interface takes: |

| | Command or Action | Purpose |
|---------------|--|---|
| | <pre>action replace</pre> | <ul style="list-style-type: none"> • deny—Drops the report. If you configure this throttling action, the entries that were previously in the forwarding table are not removed but are aged out. After these entries are aged out and the maximum number of entries is in the forwarding table, the device drops the next IGMP report received on the interface. • replace—Replaces the existing group with the new group for which the IGMP report was received. If you configure this throttling action, the entries that were previously in the forwarding table are removed. When the maximum number of entries is in the forwarding table, the device replaces a randomly selected entry with the received IGMP report. <p>To prevent the device from removing the forwarding-table entries, you can configure the IGMP throttling action before an interface adds entries to the forwarding table.</p> <p>Note To return to the default action of dropping the report, use the no ip igmp max-groups action interface configuration command.</p> |
| Step 5 | <pre>end</pre> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <pre>show running-config interface interface-id</pre> <p>Example:</p> <pre>Device# show running-config interface gigabitethernet1/0/1</pre> | Verifies your entries. |
| Step 7 | <pre>copy running-config startup-config</pre> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Monitoring IGMP Snooping and MVR

Monitoring IGMP Snooping Information

You can display IGMP snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for IGMP snooping.

Table 18: Commands for Displaying IGMP Snooping Information

| Command | Purpose |
|--|---|
| show ip igmp snooping [vlan <i>vlan-id</i> [detail]] | Displays the snooping configuration information for all VLANs on the device or for a specified VLAN. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| show ip igmp snooping groups [count dynamic [count] user [count]] | Displays multicast table information for the device or about a specific parameter: <ul style="list-style-type: none"> • count—Displays the total number of entries for the specified command options instead of the actual entries. • dynamic—Displays entries learned through IGMP snooping. • user—Displays only the user-configured multicast entries. |
| show ip igmp snooping groups vlan <i>vlan-id</i> [<i>ip_address</i> count dynamic [count] user[count]] | Displays multicast table information for a multicast VLAN or about a specific parameter for the VLAN: <ul style="list-style-type: none"> • <i>vlan-id</i>—The VLAN ID range is 1 to 1001 and 1006 to 4094. • count—Displays the total number of entries for the specified command options instead of the actual entries. • dynamic—Displays entries learned through IGMP snooping. • <i>ip_address</i>—Displays characteristics of the multicast group with the specified group IP address. • user—Displays only the user-configured multicast entries. |

| Command | Purpose |
|---|--|
| show ip igmp snooping mrouter [vlan <i>vlan-id</i>] | <p>Displays information on dynamically learned and manually configured multicast router interfaces.</p> <p>Note When you enable IGMP snooping, the device automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces.</p> <p>(Optional) Enter the vlan <i>vlan-id</i> to display information for a particular VLAN.</p> |
| show ip igmp snooping querier [vlan <i>vlan-id</i>] detail | Displays information about the IP address and receiving port of the most-recently received IGMP query message in the VLAN and the configuration and operational state of the IGMP snooping querier in the VLAN. |

Monitoring MVR

You can monitor MVR for the switch or for a specified interface by displaying the following MVR information.

Table 19: Commands for Displaying MVR Information

| Command | Purpose |
|--|--|
| show mvr | Displays MVR status and values for the switch—whether MVR is enabled, the maximum number of multicast VLANs, the maximum (256) and current (0 through 255) number of multicast VLANs, the query response time, and the MVR mode. |
| show mvr interface [<i>interface-id</i>] [members [vlan <i>vlan-id</i>]] | <p>Displays all MVR interfaces and their MVR configurations.</p> <p>When a specific interface is entered, displays this information:</p> <ul style="list-style-type: none"> • Type—Receiver or Source • Status—One of these: <ul style="list-style-type: none"> • Active means the port is part of a VLAN. • Up/Down means that the port is forwarding or not forwarding. • Inactive means that the port is not part of any VLAN. • Immediate Leave—Enabled or Disabled <p>If the members keyword is entered, displays all multicast group members. If the vlan identification is entered, all multicast group member IP addresses in the range 1 to 1001 and 1006 to 4094.</p> |
| show mvr members [<i>ip-address</i>] | Displays all receiver and source ports that are members of any multicast group with the specified IP multicast group IP address. |

Monitoring IGMP Filtering and Throttling Configuration

You can display IGMP profile characteristics, and you can display the IGMP profile and maximum group configuration for all interfaces on the device or for a specified interface. You can also display the IGMP throttling configuration for all interfaces on the device or for a specified interface.

Table 20: Commands for Displaying IGMP Filtering and Throttling Configuration

| Command | Purpose |
|---|--|
| <code>show ip igmp profile [profile number]</code> | Displays the specified IGMP profile or all the IGMP profiles defined on the device. |
| <code>show running-config [interface interface-id]</code> | Displays the configuration of the specified interface or the configuration of all interfaces on the device, including (if configured) the maximum number of IGMP groups an interface can belong and the IGMP profile applied to the interface. |

Configuration Examples for IGMP Snooping and MVR

Example: Configuring IGMP Snooping Using CGMP Packets

This example shows how to configure IGMP snooping to use CGMP packets as the learning method:

```
Device# configure terminal
Device(config)# ip igmp snooping vlan 1 mrouter learn cgmp
Device(config)# end
```

Example: Enabling a Static Connection to a Multicast Router

This example shows how to enable a static connection to a multicast router:

```
Device configure terminal
Device ip igmp snooping vlan 200 mrouter interface gigabitethernet1/0/2
Device end
```

Example: Configuring a Host Statically to Join a Group

This example shows how to statically configure a host on a port:

```
Device# configure terminal
Device# ip igmp snooping vlan 105 static 0100.1212.0000 interface gigabitethernet1/0/1
Device# end
```

Example: Enabling IGMP Immediate Leave

This example shows how to enable IGMP Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ip igmp snooping vlan 130 immediate-leave
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Source Address

This example shows how to set the IGMP snooping querier source address to 10.0.0.64:

```
Device# configure terminal
Device(config)# ip igmp snooping querier 10.0.0.64
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Maximum Response Time

This example shows how to set the IGMP snooping querier maximum response time to 25 seconds:

```
Device# configure terminal
Device(config)# ip igmp snooping querier query-interval 25
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Timeout

This example shows how to set the IGMP snooping querier timeout to 60 seconds:

```
Device# configure terminal
Device(config)# ip igmp snooping querier timeout expiry 60
Device(config)# end
```

Example: Setting the IGMP Snooping Querier Feature

This example shows how to set the IGMP snooping querier feature to Version 2:

```
Device# configure terminal
Device(config)# no ip igmp snooping querier version 2
Device(config)# end
```

Example: Configuring IGMP Profiles

This example shows how to create IGMP profile 4 allowing access to the single IP multicast address and how to verify the configuration. If the action was to deny (the default), it would not appear in the **show ip igmp profile** output display.

```
Device(config)# ip igmp profile 4
Device(config-igmp-profile)# permit
Device(config-igmp-profile)# range 229.9.9.0
Device(config-igmp-profile)# end
Device# show ip igmp profile 4
IGMP Profile 4
  permit
  range 229.9.9.0 229.9.9.0
```

Example: Applying IGMP Profile

This example shows how to apply IGMP profile 4 to a port:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp filter 4
Device(config-if)# end
```

Example: Setting the Maximum Number of IGMP Groups

This example shows how to limit to 25 the number of IGMP groups that a port can join:

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip igmp max-groups 25
Device(config-if)# end
```

Example: Configuring MVR Global Parameters

This example shows how to enable MVR, configure the group address, set the query time to 1 second (10 tenths), specify the MVR multicast VLAN as VLAN 22, and set the MVR mode as dynamic:

```
Device(config)# mvr
Device(config)# mvr group 228.1.23.4
Device(config)# mvr querytime 10
Device(config)# mvr vlan 22
Device(config)# mvr mode dynamic
Device(config)# end
```

Example: Configuring MVR Interfaces

This example shows how to configure a port as a receiver port, statically configure the port to receive multicast traffic sent to the multicast group address, configure Immediate Leave on the port, and verify the results:

```
Device(config)# mvr
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# mvr type receiver
Device(config-if)# mvr vlan 22 group 228.1.23.4
Device(config-if)# mvr immediate
Device(config)# end
Device# show mvr interface

Port Type Status Immediate Leave
-----
Gi1/0/2 RECEIVER ACTIVE/DOWN ENABLED
```

Configuring Protocol Independent Multicast (PIM)

- [Prerequisites for PIM, on page 143](#)
- [Restrictions for PIM, on page 144](#)
- [Information About PIM, on page 146](#)
- [How to Configure PIM, on page 158](#)
- [Monitoring and Troubleshooting PIM, on page 188](#)
- [Configuration Examples for PIM, on page 190](#)
- [Additional References, on page 192](#)

Prerequisites for PIM

- Before you begin the PIM configuration process, decide which PIM mode to use. This is based on the applications you intend to support on your network. Use the following guidelines:
 - In general, if the application is one-to-many or many-to-many in nature, then PIM-SM can be used successfully.
 - For optimal one-to-many application performance, SSM is appropriate but requires IGMP version 3 support.
- Before you configure PIM stub routing, check that you have met these conditions:
 - You must have IP multicast routing configured on both the stub router and the central router. You must also have PIM mode (dense-mode, sparse-mode, or sparse-dense-mode) configured on the uplink interface of the stub router.
 - You must also configure Enhanced Interior Gateway Routing Protocol (EIGRP) stub routing on the device.
 - The PIM stub router does not route the transit traffic between the distribution routers. Unicast (EIGRP) stub routing enforces this behavior. You must configure unicast stub routing to assist the PIM stub router behavior.

Restrictions for PIM

PIMv1 and PIMv2 Interoperability

To avoid misconfiguring multicast routing on your device, review the information in this section.

The Cisco PIMv2 implementation provides interoperability and transition between Version 1 and Version 2, although there might be some minor problems.

You can upgrade to PIMv2 incrementally. PIM Versions 1 and 2 can be configured on different routers and multilayer devices within one network. Internally, all routers and multilayer devices on a shared media network must run the same PIM version. Therefore, if a PIMv2 device detects a PIMv1 device, the Version 2 device downgrades itself to Version 1 until all Version 1 devices have been shut down or upgraded.

PIMv2 uses the BSR to discover and announce RP-set information for each group prefix to all the routers and multilayer devices in a PIM domain. PIMv1, together with the Auto-RP feature, can perform the same tasks as the PIMv2 BSR. However, Auto-RP is a standalone protocol, separate from PIMv1, and is a proprietary Cisco protocol. PIMv2 is a standards track protocol in the IETF.

Note We recommend that you use PIMv2. The BSR function interoperates with Auto-RP on Cisco routers and multilayer devices.

When PIMv2 devices interoperate with PIMv1 devices, Auto-RP should have already been deployed. A PIMv2 BSR that is also an Auto-RP mapping agent automatically advertises the RP elected by Auto-RP. That is, Auto-RP sets its single RP on every router or multilayer device in the group. Not all routers and devices in the domain use the PIMv2 hash function to select multiple RPs.

Sparse-mode groups in a mixed PIMv1 and PIMv2 region are possible because the Auto-RP feature in PIMv1 interoperates with the PIMv2 RP feature. Although all PIMv2 devices can also use PIMv1, we recommend that the RPs be upgraded to PIMv2. To ease the transition to PIMv2, we recommend:

- Using Auto-RP throughout the region.
- Configuring sparse-dense mode throughout the region.

If Auto-RP is not already configured in the PIMv1 regions, configure Auto-RP.

Restrictions for Configuring PIM Stub Routing

- The IP services image contains complete multicast routing.
- Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM protocol is not supported in access domains.
- In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing.
- The redundant PIM stub router topology is not supported. Only the nonredundant access router topology is supported by the PIM stub feature.

Restrictions for Configuring Auto-RP and BSR

Take into consideration your network configuration, and the following restrictions when configuring Auto-RP and BSR:

Restrictions for Configuring Auto-RP

The following are restrictions for configuring Auto-RP (if used in your network configuration):

- If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must manually configure an RP.
- If routed interfaces are configured in sparse mode, Auto-RP can still be used if all devices are configured with a manual RP address for the Auto-RP groups.
- If routed interfaces are configured in sparse mode and you enter the **ip pim autorp listener** global configuration command, Auto-RP can still be used even if all devices are not configured with a manual RP address for the Auto-RP groups.

Restrictions for Configuring BSR

The following are the restrictions for configuring BSR (if used in your network configuration):

- Configure the candidate BSRs as the RP-mapping agents for Auto-RP.
- For group prefixes advertised through Auto-RP, the PIMv2 BSR mechanism should not advertise a subrange of these group prefixes served by a different set of RPs. In a mixed PIMv1 and PIMv2 domain, have backup RPs serve the same group prefixes. This prevents the PIMv2 DRs from selecting a different RP from those PIMv1 DRs, due to the longest match lookup in the RP-mapping database.

Restrictions and Guidelines for Configuring Auto-RP and BSR

The following are restrictions for configuring Auto-RP and BSR (if used in your network configuration):

- If your network is all Cisco routers and multilayer devices, you can use either Auto-RP or BSR.
- If you have non-Cisco routers in your network, you must use BSR.
- If you have Cisco PIMv1 and PIMv2 routers and multilayer devices and non-Cisco routers, you must use both Auto-RP and BSR. If your network includes routers from other vendors, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 device. Ensure that no PIMv1 device is located in the path a between the BSR and a non-Cisco PIMv2 device.

Note There are two approaches to using PIMv2. You can use Version 2 exclusively in your network or migrate to Version 2 by employing a mixed PIM version environment.

- Because bootstrap messages are sent hop-by-hop, a PIMv1 device prevents these messages from reaching all routers and multilayer devices in your network. Therefore, if your network has a PIMv1 device in it and only Cisco routers and multilayer devices, it is best to use Auto-RP.

- If you have a network that includes non-Cisco routers, configure the Auto-RP mapping agent and the BSR on a Cisco PIMv2 router or multilayer device. Ensure that no PIMv1 device is on the path between the BSR and a non-Cisco PIMv2 router.
- If you have non-Cisco PIMv2 routers that need to interoperate with Cisco PIMv1 routers and multilayer devices, both Auto-RP and a BSR are required. We recommend that a Cisco PIMv2 device be both the Auto-RP mapping agent and the BSR.

Information About PIM

Protocol Independent Multicast

The Protocol Independent Multicast (PIM) protocol maintains the current IP multicast service mode of receiver-initiated membership. PIM is not dependent on a specific unicast routing protocol; it is IP routing protocol independent and can leverage whichever unicast routing protocols are used to populate the unicast routing table, including Enhanced Interior Gateway Routing Protocol (EIGRP), Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and static routes. PIM uses unicast routing information to perform the multicast forwarding function.

Although PIM is called a multicast routing protocol, it actually uses the unicast routing table to perform the reverse path forwarding (RPF) check function instead of building up a completely independent multicast routing table. Unlike other routing protocols, PIM does not send and receive routing updates between routers.

PIM can operate in dense mode or sparse mode. The router can also handle both sparse groups and dense groups at the same time. The mode determines how the router populates its multicast routing table and how the router forwards multicast packets it receives from its directly connected LANs.

For information about PIM forwarding (interface) modes, see the following sections:

PIM Dense Mode

PIM dense mode (PIM-DM) uses a push model to flood multicast traffic to every corner of the network. This push model is a method for delivering data to the receivers without the receivers requesting the data. This method is efficient in certain deployments in which there are active receivers on every subnet in the network.

In dense mode, a router assumes that all other routers want to forward multicast packets for a group. If a router receives a multicast packet and has no directly connected members or PIM neighbors present, a prune message is sent back to the source. Subsequent multicast packets are not flooded to this router on this pruned branch. PIM builds source-based multicast distribution trees.

PIM-DM initially floods multicast traffic throughout the network. Routers that have no downstream neighbors prune back the unwanted traffic. This process repeats every 3 minutes.

Routers accumulate state information by receiving data streams through the flood and prune mechanism. These data streams contain the source and group information so that downstream routers can build up their multicast forwarding table. PIM-DM supports only source trees--that is, (S,G) entries--and cannot be used to build a shared distribution tree.

Note Dense mode is not often used and its use is not recommended. For this reason it is not specified in the configuration tasks in related modules.

PIM Sparse Mode

PIM sparse mode (PIM-SM) uses a pull model to deliver multicast traffic. Only network segments with active receivers that have explicitly requested the data will receive the traffic.

Sparse mode interfaces are added to the multicast routing table only when periodic Join messages are received from downstream routers, or when a directly connected member is on the interface. When forwarding from a LAN, sparse mode operation occurs if an RP is known for the group. If so, the packets are encapsulated and sent toward the RP. When no RP is known, the packet is flooded in a dense mode fashion. If the multicast traffic from a specific source is sufficient, the first hop router of the receiver may send Join messages toward the source to build a source-based distribution tree.

PIM-SM distributes information about active sources by forwarding data packets on the shared tree. Because PIM-SM uses shared trees (at least, initially), it requires the use of a rendezvous point (RP). The RP must be administratively configured in the network. See the [Rendezvous Points, on page 150](#) section for more information.

In sparse mode, a router assumes that other routers do not want to forward multicast packets for a group, unless there is an explicit request for the traffic. When hosts join a multicast group, the directly connected routers send PIM Join messages toward the RP. The RP keeps track of multicast groups. Hosts that send multicast packets are registered with the RP by the first hop router of that host. The RP then sends Join messages toward the source. At this point, packets are forwarded on a shared distribution tree. If the multicast traffic from a specific source is sufficient, the first hop router of the host may send Join messages toward the source to build a source-based distribution tree.

Sources register with the RP and then data is forwarded down the shared tree to the receivers. The edge routers learn about a particular source when they receive data packets on the shared tree from that source through the RP. The edge router then sends PIM (S,G) Join messages toward that source. Each router along the reverse path compares the unicast routing metric of the RP address to the metric of the source address. If the metric for the source address is better, it will forward a PIM (S,G) Join message toward the source. If the metric for the RP is the same or better, then the PIM (S,G) Join message will be sent in the same direction as the RP. In this case, the shared tree and the source tree would be considered congruent.

If the shared tree is not an optimal path between the source and the receiver, the routers dynamically create a source tree and stop traffic from flowing down the shared tree. This behavior is the default behavior in software. Network administrators can force traffic to stay on the shared tree by using the **ip pim spt-threshold infinity** command.

PIM-SM scales well to a network of any size, including those with WAN links. The explicit join mechanism prevents unwanted traffic from flooding the WAN links.

Sparse-Dense Mode

If you configure either sparse mode or dense mode on an interface, then sparseness or denseness is applied to the interface as a whole. However, some environments might require PIM to run in a single region in sparse mode for some groups and in dense mode for other groups.

An alternative to enabling only dense mode or only sparse mode is to enable sparse-dense mode. In this case, the interface is treated as dense mode if the group is in dense mode; the interface is treated in sparse mode if the group is in sparse mode. You must have an RP if the interface is in sparse-dense mode and you want to treat the group as a sparse group.

If you configure sparse-dense mode, the idea of sparseness or denseness is applied to the groups for which the router is a member.

Another benefit of sparse-dense mode is that Auto-RP information can be distributed in a dense mode; yet, multicast groups for user groups can be used in a sparse mode manner. Therefore there is no need to configure a default RP at the leaf routers.

When an interface is treated in dense mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- There are PIM neighbors and the group has not been pruned.

When an interface is treated in sparse mode, it is populated in the outgoing interface list of a multicast routing table when either of the following conditions is true:

- Members or DVMRP neighbors are on the interface.
- An explicit Join message has been received by a PIM neighbor on the interface.

PIM Versions

PIMv2 includes these improvements over PIMv1:

- A single, active rendezvous point (RP) exists per multicast group, with multiple backup RPs. This single RP compares to multiple active RPs for the same group in PIMv1.
- A bootstrap router (BSR) provides a fault-tolerant, automated RP discovery and distribution function that enables routers and multilayer devices to dynamically learn the group-to-RP mappings.
- Sparse mode and dense mode are properties of a group, as opposed to an interface.

Note We strongly recommend using sparse-dense mode as opposed to either sparse mode or dense mode only.

- PIM join and prune messages have more flexible encoding for multiple address families.
- A more flexible hello packet format replaces the query packet to encode current and future capability options.
- Register messages sent to an RP specify whether they are sent by a border router or a designated router.
- PIM packets are no longer inside IGMP packets; they are standalone packets.

PIM Stub Routing

The PIM stub routing feature, available in all of the device software images, reduces resource usage by moving routed traffic closer to the end user.

The PIM stub routing feature supports multicast routing between the distribution layer and the access layer. It supports two types of PIM interfaces, uplink PIM interfaces, and PIM passive interfaces. A routed interface configured with the PIM passive mode does not pass or forward PIM control traffic, it only passes and forwards IGMP traffic.

In a network using PIM stub routing, the only allowable route for IP traffic to the user is through a device that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast (IGMP) receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IP multicast routing and configure only the device as a PIM stub router. The device does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the device. The device uplink port cannot be used with SVIs. If you need PIM for an SVI uplink port, you should upgrade to the IP Services feature set.

Note You must also configure EIGRP stub routing when configuring PIM stub routing on the device

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM asset and designated router election mechanisms are not supported on the PIM passive interfaces. Only the nonredundant access router topology is supported by the PIM stub feature. By using a nonredundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

Figure 7: PIM Stub Router Configuration

In the following figure, the Device A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source 200.1.1.3.

IGMP Helper

PIM stub routing moves routed traffic closer to the end user and reduces network traffic. You can also reduce traffic by configuring a stub router (switch) with the IGMP helper feature.

You can configure a stub router (switch) with the **ip igmp helper-address** *ip-address* interface configuration command to enable the switch to send reports to the next-hop interface. Hosts that are not directly connected to a downstream router can then join a multicast group sourced from an upstream network. The IGMP packets from a host wanting to join a multicast stream are forwarded upstream to the next-hop device when this feature

is configured. When the upstream central router receives the helper IGMP reports or leaves, it adds or removes the interfaces from its outgoing interface list for that group.

Rendezvous Points

A rendezvous point (RP) is a role that a device performs when operating in Protocol Independent Multicast (PIM) Sparse Mode (SM). An RP is required only in networks running PIM SM. In the PIM-SM model, only network segments with active receivers that have explicitly requested multicast data will be forwarded the traffic.

This method of delivering multicast data is in contrast to PIM Dense Mode (PIM DM). In PIM DM, multicast traffic is initially flooded to all segments of the network. Routers that have no downstream neighbors or directly connected receivers prune back the unwanted traffic.

An RP acts as the meeting place for sources and receivers of multicast data. In a PIM-SM network, sources must send their traffic to the RP. This traffic is then forwarded to receivers down a shared distribution tree. By default, when the first hop device of the receiver learns about the source, it will send a Join message directly to the source, creating a source-based distribution tree from the source to the receiver. This source tree does not include the RP unless the RP is located within the shortest path between the source and receiver.

In most cases, the placement of the RP in the network is not a complex decision. By default, the RP is needed only to start new sessions with sources and receivers. Consequently, the RP experiences little overhead from traffic flow or processing. In PIM version 2, the RP performs less processing than in PIM version 1 because sources must only periodically register with the RP to create state.

Auto-RP

In the first version of PIM-SM, all leaf routers (routers directly connected to sources or receivers) were required to be manually configured with the IP address of the RP. This type of configuration is also known as static RP configuration. Configuring static RPs is relatively easy in a small network, but it can be laborious in a large, complex network.

Following the introduction of PIM-SM version 1, Cisco implemented a version of PIM-SM with the Auto-RP feature. Auto-RP automates the distribution of group-to-RP mappings in a PIM network. Auto-RP has the following benefits:

- Configuring the use of multiple RPs within a network to serve different groups is easy.
- Auto-RP allows load splitting among different RPs and arrangement of RPs according to the location of group participants.
- Auto-RP avoids inconsistent, manual RP configurations that can cause connectivity problems.

Multiple RPs can be used to serve different group ranges or serve as backups to each other. For Auto-RP to work, a router must be designated as an RP-mapping agent, which receives the RP-announcement messages from the RPs and arbitrates conflicts. The RP-mapping agent then sends the consistent group-to-RP mappings to all other routers. Thus, all routers automatically discover which RP to use for the groups they support.

Note If you configure PIM in sparse mode or sparse-dense mode and do not configure Auto-RP, you must statically configure an RP.

Note If router interfaces are configured in sparse mode, Auto-RP can still be used if all routers are configured with a static RP address for the Auto-RP groups.

To make Auto-RP work, a router must be designated as an RP mapping agent, which receives the RP announcement messages from the RPs and arbitrates conflicts. The RP mapping agent then sends the consistent group-to-RP mappings to all other routers by dense mode flooding. Thus, all routers automatically discover which RP to use for the groups they support. The Internet Assigned Numbers Authority (IANA) has assigned two group addresses, 224.0.1.39 and 224.0.1.40, for Auto-RP. One advantage of Auto-RP is that any change to the RP designation must be configured only on the routers that are RPs and not on the leaf routers. Another advantage of Auto-RP is that it offers the ability to scope the RP address within a domain. Scoping can be achieved by defining the time-to-live (TTL) value allowed for the Auto-RP advertisements.

Each method for configuring an RP has its own strengths, weaknesses, and level of complexity. In conventional IP multicast network scenarios, we recommend using Auto-RP to configure RPs because it is easy to configure, well-tested, and stable. The alternative ways to configure an RP are static RP, Auto-RP, and bootstrap router.

Sparse-Dense Mode for Auto-RP

A prerequisite of Auto-RP is that all interfaces must be configured in sparse-dense mode using the **ip pim sparse-dense-mode** interface configuration command. An interface configured in sparse-dense mode is treated in either sparse mode or dense mode of operation, depending on which mode the multicast group operates. If a multicast group has a known RP, the interface is treated in sparse mode. If a group has no known RP, by default the interface is treated in dense mode and data will be flooded over this interface. (You can prevent dense-mode fallback; see the module “Configuring Basic IP Multicast.”)

To successfully implement Auto-RP and prevent any groups other than 224.0.1.39 and 224.0.1.40 from operating in dense mode, we recommend configuring a “sink RP” (also known as “RP of last resort”). A sink RP is a statically configured RP that may or may not actually exist in the network. Configuring a sink RP does not interfere with Auto-RP operation because, by default, Auto-RP messages supersede static RP configurations. We recommend configuring a sink RP for all possible multicast groups in your network, because it is possible for an unknown or unexpected source to become active. If no RP is configured to limit source registration, the group may revert to dense mode operation and be flooded with data.

Bootstrap Router

Another RP selection model called bootstrap router (BSR) was introduced after Auto-RP in PIM-SM version 2. BSR performs similarly to Auto-RP in that it uses candidate routers for the RP function and for relaying the RP information for a group. RP information is distributed through BSR messages, which are carried within PIM messages. PIM messages are link-local multicast messages that travel from PIM router to PIM router. Because of this single hop method of disseminating RP information, TTL scoping cannot be used with BSR. A BSR performs similarly as an RP, except that it does not run the risk of reverting to dense mode operation, and it does not offer the ability to scope within a domain.

PIM Domain Border

As IP multicast becomes more widespread, the chance of one PIMv2 domain bordering another PIMv2 domain increases. Because two domains probably do not share the same set of RPs, BSR, candidate RPs, and candidate BSRs, you need to constrain PIMv2 BSR messages from flowing into or out of the domain. Allowing messages to leak across the domain borders could adversely affect the normal BSR election mechanism and elect a

single BSR across all bordering domains and comingle candidate RP advertisements, resulting in the election of RPs in the wrong domain.

Multicast Forwarding

Forwarding of multicast traffic is accomplished by multicast-capable routers. These routers create distribution trees that control the path that IP multicast traffic takes through the network in order to deliver traffic to all receivers.

Multicast traffic flows from the source to the multicast group over a distribution tree that connects all of the sources to all of the receivers in the group. This tree may be shared by all sources (a shared tree) or a separate distribution tree can be built for each source (a source tree). The shared tree may be one-way or bidirectional.

Before describing the structure of source and shared trees, it is helpful to explain the notations that are used in multicast routing tables. These notations include the following:

- (S,G) = (unicast source for the multicast group G, multicast group G)
- (*,G) = (any source for the multicast group G, multicast group G)

The notation of (S,G), pronounced “S comma G,” enumerates a shortest path tree where S is the IP address of the source and G is the multicast group address.

Shared trees are (*,G) and the source trees are (S,G) and always rooted at the sources.

Multicast Distribution Source Tree

The simplest form of a multicast distribution tree is a source tree. A source tree has its root at the source host and has branches forming a spanning tree through the network to the receivers. Because this tree uses the shortest path through the network, it is also referred to as a shortest path tree (SPT).

The figure shows an example of an SPT for group 224.1.1.1 rooted at the source, Host A, and connecting two receivers, Hosts B and C.

Using standard notation, the SPT for the example shown in the figure would be (192.168.1.1, 224.1.1.1).

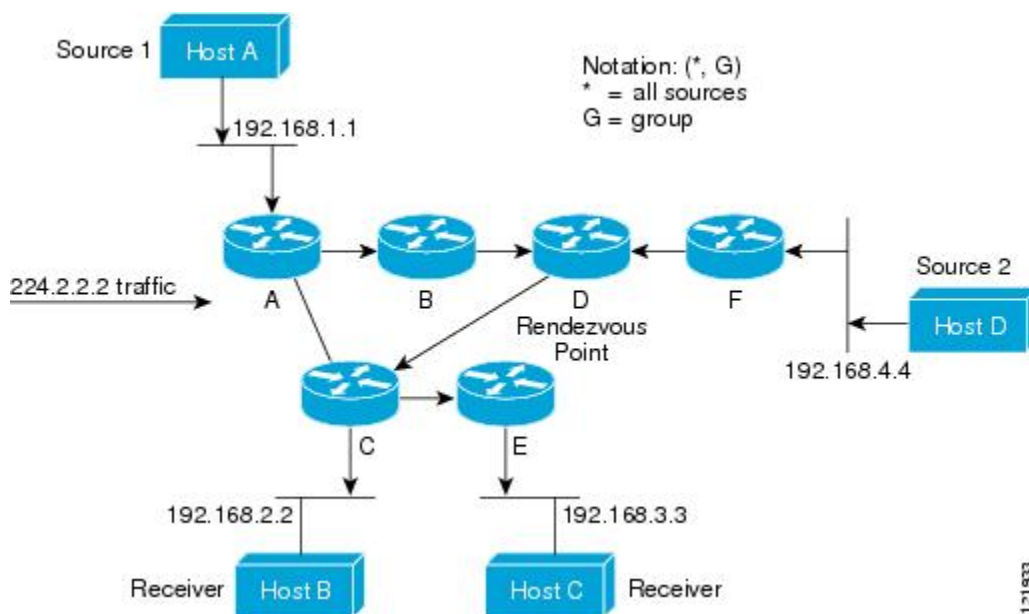

The (S,G) notation implies that a separate SPT exists for each individual source sending to each group--which is correct.

Multicast Distribution Shared Tree

Unlike source trees that have their root at the source, shared trees use a single common root placed at some chosen point in the network. This shared root is called a rendezvous point (RP).

The following figure shows a shared tree for the group 224.2.2.2 with the root located at Router D. This shared tree is unidirectional. Source traffic is sent towards the RP on a source tree. The traffic is then forwarded down the shared tree from the RP to reach all of the receivers (unless the receiver is located between the source and the RP, in which case it will be serviced directly).

Figure 8: Shared Tree

In this example, multicast traffic from the sources, Hosts A and D, travels to the root (Router D) and then down the shared tree to the two receivers, Hosts B and C. Because all sources in the multicast group use a common shared tree, a wildcard notation written as (*, G), pronounced “star comma G,” represents the tree. In this case, * means all sources, and G represents the multicast group. Therefore, the shared tree shown in the figure would be written as (*, 224.2.2.2).

Both source trees and shared trees are loop-free. Messages are replicated only where the tree branches. Members of multicast groups can join or leave at any time; therefore the distribution trees must be dynamically updated. When all the active receivers on a particular branch stop requesting the traffic for a particular multicast group, the routers prune that branch from the distribution tree and stop forwarding traffic down that branch. If one receiver on that branch becomes active and requests the multicast traffic, the router will dynamically modify the distribution tree and start forwarding traffic again.

Source Tree Advantage

Source trees have the advantage of creating the optimal path between the source and the receivers. This advantage guarantees the minimum amount of network latency for forwarding multicast traffic. However,

this optimization comes at a cost. The routers must maintain path information for each source. In a network that has thousands of sources and thousands of groups, this overhead can quickly become a resource issue on the routers. Memory consumption from the size of the multicast routing table is a factor that network designers must take into consideration.

Shared Tree Advantage

Shared trees have the advantage of requiring the minimum amount of state in each router. This advantage lowers the overall memory requirements for a network that only allows shared trees. The disadvantage of shared trees is that under certain circumstances the paths between the source and receivers might not be the optimal paths, which might introduce some latency in packet delivery. For example, in the figure above the shortest path between Host A (source 1) and Host B (a receiver) would be Router A and Router C. Because we are using Router D as the root for a shared tree, the traffic must traverse Routers A, B, D and then C. Network designers must carefully consider the placement of the rendezvous point (RP) when implementing a shared tree-only environment.

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination address and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

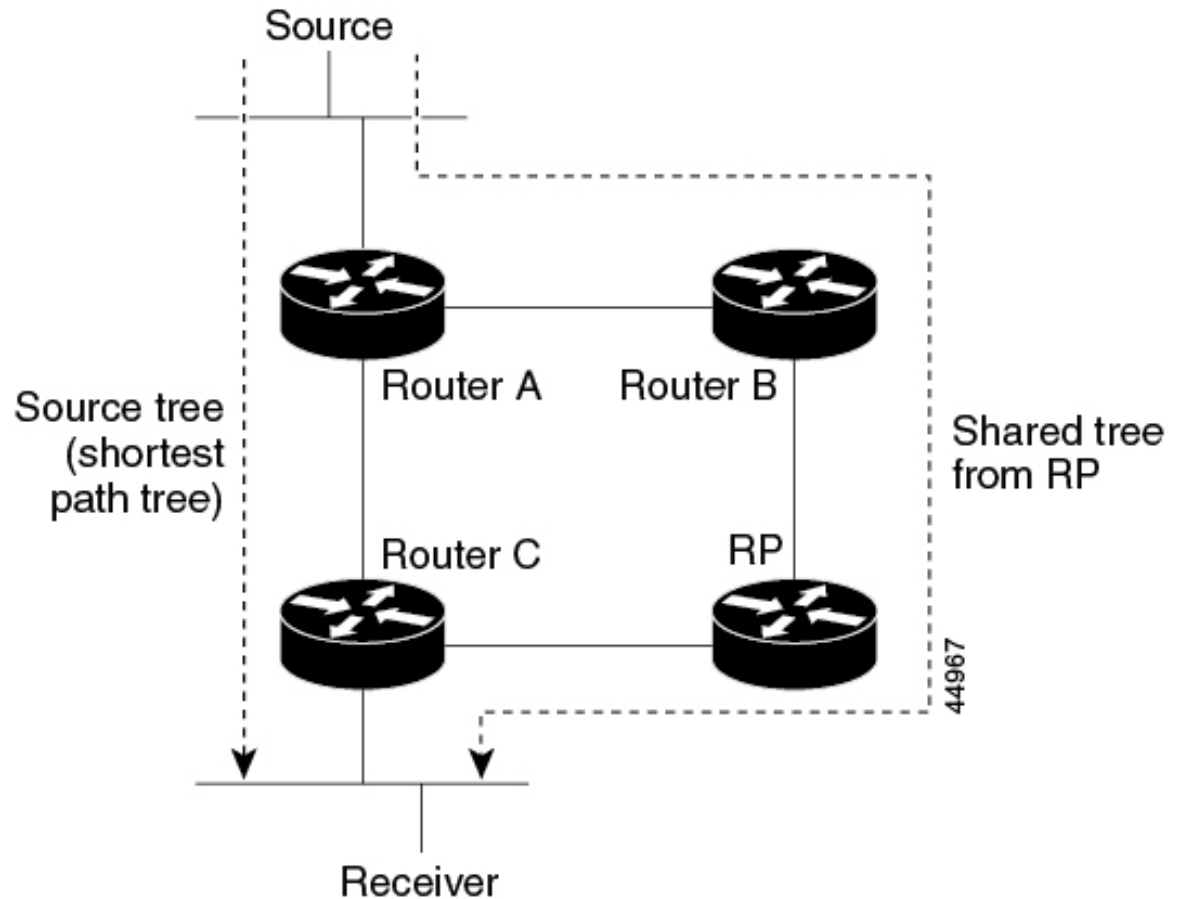

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)--which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is described in the following section.

PIM Shared Tree and Source Tree

By default, members of a group receive data from senders to the group across a single data-distribution tree rooted at the RP.

Figure 9: Shared Tree and Source Tree (Shortest-Path Tree)

The following figure shows this type of shared-distribution tree. Data from senders is delivered to the RP for distribution to group members joined to the shared tree.

If the data rate warrants, leaf routers (routers without any downstream connections) on the shared tree can use the data distribution tree rooted at the source. This type of distribution tree is called a shortest-path tree or source tree. By default, the software devices to a source tree upon receiving the first data packet from a source.

This process describes the move from a shared tree to a source tree:

1. A receiver joins a group; leaf Router C sends a join message toward the RP.
2. The RP puts a link to Router C in its outgoing interface list.
3. A source sends data; Router A encapsulates the data in a register message and sends it to the RP.
4. The RP forwards the data down the shared tree to Router C and sends a join message toward the source. At this point, data might arrive twice at Router C, once encapsulated and once natively.
5. When data arrives natively (unencapsulated) at the RP, it sends a register-stop message to Router A.
6. By default, reception of the first data packet prompts Router C to send a join message toward the source.
7. When Router C receives data on (S, G), it sends a prune message for the source up the shared tree.

8. The RP deletes the link to Router C from the outgoing interface of (S, G). The RP triggers a prune message toward the source.

Join and prune messages are sent for sources and RPs. They are sent hop-by-hop and are processed by each PIM device along the path to the source or RP. Register and register-stop messages are not sent hop-by-hop. They are sent by the designated router that is directly connected to a source and are received by the RP for the group.

Multiple sources sending to groups use the shared tree. You can configure the PIM device to stay on the shared tree.

The change from shared to source tree happens when the first data packet arrives at the last-hop router. This change depends upon the threshold that is configured by using the **ip pim spt-threshold** global configuration command.

The shortest-path tree requires more memory than the shared tree but reduces delay. You may want to postpone its use. Instead of allowing the leaf router to immediately move to the shortest-path tree, you can specify that the traffic must first reach a threshold.

You can configure when a PIM leaf router should join the shortest-path tree for a specified group. If a source sends at a rate greater than or equal to the specified kbps rate, the multilayer switch triggers a PIM join message toward the source to construct a source tree (shortest-path tree). If the traffic rate from the source drops below the threshold value, the leaf router switches back to the shared tree and sends a prune message toward the source.

You can specify to which groups the shortest-path tree threshold applies by using a group list (a standard access list). If a value of 0 is specified or if the group list is not used, the threshold applies to all groups.

Reverse Path Forwarding

In unicast routing, traffic is routed through the network along a single path from the source to the destination host. A unicast router does not consider the source address; it considers only the destination address and how to forward the traffic toward that destination. The router scans through its routing table for the destination network and then forwards a single copy of the unicast packet out the correct interface in the direction of the destination.

In multicast forwarding, the source is sending traffic to an arbitrary group of hosts that are represented by a multicast group address. The multicast router must determine which direction is the upstream direction (toward the source) and which one is the downstream direction (or directions) toward the receivers. If there are multiple downstream paths, the router replicates the packet and forwards it down the appropriate downstream paths (best unicast route metric)--which is not necessarily all paths. Forwarding multicast traffic away from the source, rather than to the receiver, is called Reverse Path Forwarding (RPF). RPF is an algorithm used for forwarding multicast datagrams.

Protocol Independent Multicast (PIM) uses the unicast routing information to create a distribution tree along the reverse path from the receivers towards the source. The multicast routers then forward packets along the distribution tree from the source to the receivers. RPF is a key concept in multicast forwarding. It enables routers to correctly forward multicast traffic down the distribution tree. RPF makes use of the existing unicast routing table to determine the upstream and downstream neighbors. A router will forward a multicast packet only if it is received on the upstream interface. This RPF check helps to guarantee that the distribution tree will be loop-free.

RPF Check

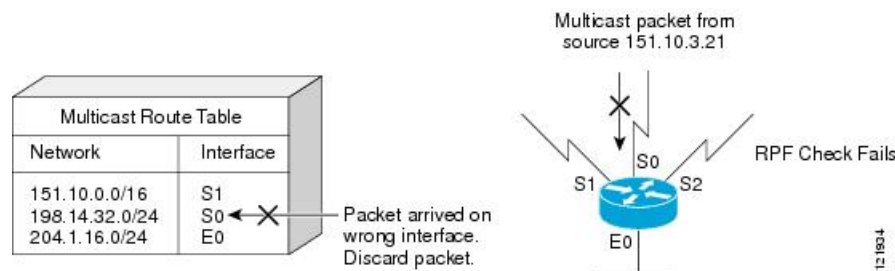

When a multicast packet arrives at a router, the router performs an RPF check on the packet. If the RPF check succeeds, the packet is forwarded. Otherwise, it is dropped.

For traffic flowing down a source tree, the RPF check procedure works as follows:

1. The router looks up the source address in the unicast routing table to determine if the packet has arrived on the interface that is on the reverse path back to the source.
2. If the packet has arrived on the interface leading back to the source, the RPF check succeeds and the packet is forwarded out the interfaces present in the outgoing interface list of a multicast routing table entry.
3. If the RPF check in Step 2 fails, the packet is dropped.

The figure shows an example of an unsuccessful RPF check.

Figure 10: RPF Check Fails

As the figure illustrates, a multicast packet from source 151.10.3.21 is received on serial interface 0 (S0). A check of the unicast route table shows that S1 is the interface this router would use to forward unicast data to 151.10.3.21. Because the packet has arrived on interface S0, the packet is discarded.

The figure shows an example of a successful RPF check.

Figure 11: RPF Check Succeeds

In this example, the multicast packet has arrived on interface S1. The router refers to the unicast routing table and finds that S1 is the correct interface. The RPF check passes, and the packet is forwarded.

Default PIM Routing Configuration

This table displays the default PIM routing configuration for the device.

Table 21: Default Multicast Routing Configuration

| Feature | Default Setting |
|-----------------------------------|-----------------------------|
| Multicast routing | Disabled on all interfaces. |
| PIM version | Version 2. |
| PIM mode | No mode is defined. |
| PIM stub routing | None configured. |
| PIM RP address | None configured. |
| PIM domain border | Disabled. |
| PIM multicast boundary | None. |
| Candidate BSRs | Disabled. |
| Candidate RPs | Disabled. |
| Shortest-path tree threshold rate | 0 kb/s. |
| PIM router query message interval | 30 seconds. |

How to Configure PIM

Enabling PIM Stub Routing

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | interface <i>interface-id</i> Example: Device(config) # interface gigabitethernet 1/0/1 | Specifies the interface on which you want to enable PIM stub routing, and enters interface configuration mode. |
| Step 4 | ip pim passive Example: Device(config-if) # ip pim passive | Configures the PIM stub feature on the interface. |
| Step 5 | end Example: Device(config) # end | Returns to privileged EXEC mode. |
| Step 6 | show ip pim interface Example: Device# show ip pim interface | (Optional) Displays the PIM stub that is enabled on each interface. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring a Rendezvous Point

You must have a rendezvous point (RP), if the interface is in sparse-dense mode and if you want to handle the group as a sparse group. You can use these methods:

- By manually assigning an RP to multicast groups.
- As a standalone, Cisco-proprietary protocol separate from PIMv1, which includes:
 - Setting up Auto-RP in a new internetwork
 - Adding Auto-RP to an existing sparse-mode cloud

- Preventing join messages to false RPs
- Filtering incoming RP announcement messages
- By using a standards track protocol in the Internet Engineering Task Force (IETF), which includes configuring PIMv2 BSR .

Note You can use Auto-RP, BSR, or a combination of both, depending on the PIM version that you are running and the types of routers in your network. For information about working with different PIM versions in your network, see the PIMv1 and PIMv2 Interoperability section.

Manually Assigning an RP to Multicast Groups

If the rendezvous point (RP) for a group is learned through a dynamic mechanism (such as Auto-RP or BSR), you need not perform this task for that RP.

Senders of multicast traffic announce their existence through register messages received from the source first-hop router (designated router) and forwarded to the RP. Receivers of multicast packets use RPs to join a multicast group by using explicit join messages.

Note RPs are not members of the multicast group; they serve as a *meeting place* for multicast sources and group members.

You can configure a single RP for multiple groups defined by an access list. If there is no RP configured for a group, the multilayer device responds to the group as dense and uses the dense-mode PIM techniques.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip pim rp-address <i>ip-address</i> [<i>access-list-number</i>] [<i>override</i>] Example: | Configures the address of a PIM RP. By default, no PIM RP address is configured. You must configure the IP address of RPs on |

| | Command or Action | Purpose |
|---------------|---|--|
| | <pre>Device(config)# ip pim rp-address 10.1.1.1 20 override</pre> | <p>all routers and multilayer devices (including the RP).</p> <p>Note If there is no RP configured for a group, the device treats the group as dense, using the dense-mode PIM techniques.</p> <p>A PIM device can be an RP for more than one group. Only one RP address can be used at a time within a PIM domain. The access list conditions specify for which groups the device is an RP.</p> <ul style="list-style-type: none"> • For <i>ip-address</i>, enter the unicast address of the RP in dotted-decimal notation. • (Optional) For <i>access-list-number</i>, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups. • (Optional) The override keyword indicates that if there is a conflict between the RP configured with this command and one learned by Auto-RP or BSR, the RP configured with this command prevails. |
| Step 4 | <p>access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>]</p> <p>Example:</p> <pre>Device(config)# access-list 25 permit 10.5.0.1 255.224.0.0</pre> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 2. • The deny keyword denies access if the conditions are matched. • The permit keyword permits access if the conditions are matched. • For <i>source</i>, enter the multicast group address for which the RP should be used. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | <p>end</p> <p>Example:</p> | <p>Returns to privileged EXEC mode.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config)# end | |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Setting Up Auto-RP in a New Internetwork

If you are setting up Auto-RP in a new internetwork, you do not need a default RP because you configure all the interfaces for sparse-dense mode.

Note Omit Step 3 in the following procedure, if you want to configure a PIM router as the RP for the local group.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show running-config Example: Device# show running-config | Verifies that a default RP is already configured on all PIM devices and the RP in the sparse-mode network. It was previously configured with the ip pim rp-address global configuration command. <p>Note This step is not required for sparse-dense-mode environments.</p> <p>The selected RP should have good connectivity and be available across the network. Use this RP for the global groups (for example, 224.x.x.x and other global groups). Do not reconfigure the group address range that this</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| | | RP serves. RPs dynamically discovered through Auto-RP take precedence over statically configured RPs. Assume that it is desirable to use a second RP for the local groups. |
| Step 3 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 4 | ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds Example: Device(config)# <code>ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120</code> | Configures another PIM device to be the candidate RP for local groups. <ul style="list-style-type: none"> • For <i>interface-id</i>, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs. • For scope ttl, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255. • For group-list access-list-number, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups. • For interval seconds, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383. |
| Step 5 | access-list access-list-number {deny permit} source [source-wildcard] Example: Device(config)# <code>access-list 10 permit 10.10.0.0</code> | Creates a standard access list, repeating the command as many times as necessary. <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 3. • The deny keyword denies access if the conditions are matched. • The permit keyword permits access if the conditions are matched. • For <i>source</i>, enter the multicast group address range for which the RP should be used. |

| | Command or Action | Purpose |
|----------------|--|--|
| | | <ul style="list-style-type: none"> (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Note Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| Step 6 | <p>ip pim send-rp-discovery scope ttl</p> <p>Example:</p> <pre>Device(config)# ip pim send-rp-discovery scope 50</pre> | <p>Finds a device whose connectivity is not likely to be interrupted, and assign it the role of RP-mapping agent.</p> <p>For scope ttl, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255.</p> |
| Step 7 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 9 | <p>show ip pim rp mapping</p> <p>Example:</p> <pre>Device# show ip pim rp mapping</pre> | Displays active RPs that are cached with associated multicast routing entries. |
| Step 10 | <p>show ip pim rp</p> <p>Example:</p> <pre>Device# show ip pim rp</pre> | Displays the information cached in the routing table. |
| Step 11 | <p>copy running-config startup-config</p> <p>Example:</p> | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

Adding Auto-RP to an Existing Sparse-Mode Cloud

This section contains suggestions for the initial deployment of Auto-RP into an existing sparse-mode cloud to minimize disruption of the existing multicast infrastructure.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show running-config Example: Device# <code>show running-config</code> | Verifies that a default RP is already configured on all PIM devices and the RP in the sparse-mode network. It was previously configured with the ip pim rp-address global configuration command. <p>Note This step is not required for sparse-dense-mode environments.</p> <p>The selected RP should have good connectivity and be available across the network. Use this RP for the global groups (for example, 224.x.x.x and other global groups). Do not reconfigure the group address range that this RP serves. RPs dynamically discovered through Auto-RP take precedence over statically configured RPs. Assume that it is desirable to use a second RP for the local groups.</p> |
| Step 3 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 4 | ip pim send-rp-announce interface-id scope ttl group-list access-list-number interval seconds | Configures another PIM device to be the candidate RP for local groups. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <p>Example:</p> <pre>Device(config)# ip pim send-rp-announce gigabitethernet 1/0/5 scope 20 group-list 10 interval 120</pre> | <ul style="list-style-type: none"> • For <i>interface-id</i>, enter the interface type and number that identifies the RP address. Valid interfaces include physical ports, port channels, and VLANs. • For scope <i>tll</i>, specify the time-to-live value in hops. Enter a hop count that is high enough so that the RP-announce messages reach all mapping agents in the network. There is no default setting. The range is 1 to 255. • For group-list <i>access-list-number</i>, enter an IP standard access list number from 1 to 99. If no access list is configured, the RP is used for all groups. • For interval <i>seconds</i>, specify how often the announcement messages must be sent. The default is 60 seconds. The range is 1 to 16383. |
| Step 5 | <p>access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>]</p> <p>Example:</p> <pre>Device(config)# access-list 10 permit 224.0.0.0 15.255.255.255</pre> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 3. • The deny keyword denies access if the conditions are matched. • The permit keyword permits access if the conditions are matched. • For <i>source</i>, enter the multicast group address range for which the RP should be used. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| Step 6 | <p>ip pim send-rp-discovery scope <i>tll</i></p> <p>Example:</p> <pre>Device(config)# ip pim send-rp-discovery scope 50</pre> | <p>Finds a device whose connectivity is not likely to be interrupted, and assigns it the role of RP-mapping agent.</p> <p>For scope <i>tll</i>, specify the time-to-live value in hops to limit the RP discovery packets. All devices within the hop count from the source</p> |

| | Command or Action | Purpose |
|----------------|---|---|
| | | <p>device receive the Auto-RP discovery messages. These messages tell other devices which group-to-RP mapping to use to avoid conflicts (such as overlapping group-to-RP ranges). There is no default setting. The range is 1 to 255.</p> <p>Note To remove the device as the RP-mapping agent, use the no ip pim send-rp-discovery global configuration command.</p> |
| Step 7 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 9 | <p>show ip pim rp mapping</p> <p>Example:</p> <pre>Device# show ip pim rp mapping</pre> | Displays active RPs that are cached with associated multicast routing entries. |
| Step 10 | <p>show ip pim rp</p> <p>Example:</p> <pre>Device# show ip pim rp</pre> | Displays the information cached in the routing table. |
| Step 11 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring Sparse Mode with a Single Static RP(CLI)

A rendezvous point (RP) is required in networks running Protocol Independent Multicast sparse mode (PIM-SM). In PIM-SM, traffic will be forwarded only to network segments with active receivers that have explicitly requested multicast data.

This section describes how to configure sparse mode with a single static RP.

Before you begin

All access lists that are needed when sparse mode is configured with a single static RP should be configured prior to beginning the configuration task.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: device# configure terminal | Enters global configuration mode. |
| Step 3 | ip multicast-routing [distributed] Example: device (config)# ip multicast-routing | Enables IP multicast routing. • Use the distributed keyword to enable Multicast Distributed Switching. |
| Step 4 | interface type number Example: device (config)# interface gigabitethernet 1/0/0 | Selects an interface that is connected to hosts on which PIM can be enabled. |
| Step 5 | ip pim sparse-mode Example: device (config-if)# ip pim sparse-mode | Enables PIM on an interface. You must use sparse mode. |
| Step 6 | Repeat Steps 1 through 5 on every interface that uses IP multicast. | -- |
| Step 7 | exit Example: device (config-if)# exit | Returns to global configuration mode. |
| Step 8 | ip pim rp-address rp-address [access-list] [override] Example: device (config)# ip pim rp-address 192.168.0.0 | Configures the address of a PIM RP for a particular group. • The optional <i>access-list</i> argument is used to specify the number or name a standard access list that defines the multicast groups to be statically mapped to the RP. |

| | Command or Action | Purpose |
|----------------|--|---|
| | | <p>Note If no access list is defined, the RP will map to all multicast groups, 224/4.</p> <ul style="list-style-type: none"> The optional override keyword is used to specify that if dynamic and static group-to-RP mappings are used together and there is an RP address conflict, the RP address configured for a static group-to-RP mapping will take precedence. <p>Note If the override keyword is not specified and there is RP address conflict, dynamic group-to-RP mappings will take precedence over static group-to-RP mappings.</p> |
| Step 9 | <p>end</p> <p>Example:</p> <pre>device(config)# end</pre> | Ends the current configuration session and returns to EXEC mode. |
| Step 10 | <p>show ip pim rp [mapping] [rp-address]</p> <p>Example:</p> <pre>device# show ip pim rp mapping</pre> | (Optional) Displays RPs known in the network and shows how the router learned about each RP. |
| Step 11 | <p>show ip igmp groups [group-name group-address interface-type interface-number] [detail]</p> <p>Example:</p> <pre>device# show ip igmp groups</pre> | <p>(Optional) Displays the multicast groups having receivers that are directly connected to the router and that were learned through IGMP.</p> <ul style="list-style-type: none"> A receiver must be active on the network at the time that this command is issued in order for receiver information to be present on the resulting display. |
| Step 12 | <p>show ip mroute</p> <p>Example:</p> <pre>device# show ip mroute</pre> | (Optional) Displays the contents of the IP mroute table. |

Preventing Join Messages to False RPs

Determine whether the **ip pim accept-rp** command was previously configured throughout the network by using the **show running-config** privileged EXEC command. If the **ip pim accept-rp** command is not configured on any device, this problem can be addressed later. In those routers or multilayer devices already configured with the **ip pim accept-rp** command, you must enter the command again to accept the newly advertised RP.

To accept all RPs advertised with Auto-RP and reject all other RPs by default, use the **ip pim accept-rp auto-rp** global configuration command.

This procedure is optional.

Filtering Incoming RP Announcement Messages

You can add configuration commands to the mapping agents to prevent a maliciously configured router from masquerading as a candidate RP and causing problems.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip pim rp-announce-filter rp-list access-list-number group-list access-list-number Example: Device(config)# ip pim rp-announce-filter rp-list 10 group-list 14 | Filters incoming RP announcement messages. Enter this command on each mapping agent in the network. Without this command, all incoming RP-announce messages are accepted by default. For rp-list access-list-number , configure an access list of candidate RP addresses that, if permitted, is accepted for the group ranges supplied in the group-list access-list-number variable. If this variable is omitted, the filter applies to all multicast groups. If more than one mapping agent is used, the filters must be consistent across all mapping agents to ensure that no conflicts occur in the group-to-RP mapping information. |
| Step 4 | access-list access-list-number {deny permit} source [source-wildcard] Example: Device(config)# access-list 10 permit 10.8.1.0 255.255.224.0 | Creates a standard access list, repeating the command as many times as necessary. <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 2. • The deny keyword denies access if the conditions are matched. |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <ul style="list-style-type: none"> • The permit keyword permits access if the conditions are matched. • Create an access list that specifies from which routers and multilayer devices the mapping agent accepts candidate RP announcements (rp-list ACL). • Create an access list that specifies the range of multicast groups from which to accept or deny (group-list ACL). • For <i>source</i>, enter the multicast group address range for which the RP should be used. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring PIMv2 BSR

The process for configuring PIMv2 BSR may involve the following optional tasks:

- Defining the PIM domain border
- Defining the IP multicast boundary

- Configuring candidate BSRs
- Configuring candidate RPs

Defining the PIM Domain Border

Perform the following steps to configure the PIM domain border. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enters interface configuration mode. |
| Step 4 | ip pim bsr-border Example: Device(config-if)# ip pim bsr-border | Defines a PIM bootstrap message boundary for the PIM domain. Enter this command on each interface that connects to other bordering PIM domains. This command instructs the device to neither send nor receive PIMv2 BSR messages on this interface. Note To remove the PIM border, use the no ip pim bsr-border interface configuration command. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>show running-config</code> | |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Defining the IP Multicast Boundary

You define a multicast boundary to prevent Auto-RP messages from entering the PIM domain. You create an access list to deny packets destined for 224.0.1.39 and 224.0.1.40, which carry Auto-RP information.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | access-list access-list-number deny source [source-wildcard] Example: Device(config)# <code>access-list 12 deny 224.0.1.39</code> <code>access-list 12 deny 224.0.1.40</code> | Creates a standard access list, repeating the command as many times as necessary. <ul style="list-style-type: none"> • For <i>access-list-number</i>, the range is 1 to 99. • The deny keyword denies access if the conditions are matched. • For <i>source</i>, enter multicast addresses 224.0.1.39 and 224.0.1.40, which carry Auto-RP information. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. |

| | Command or Action | Purpose |
|---------------|---|--|
| | | The access list is always terminated by an implicit deny statement for everything. |
| Step 4 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enters interface configuration mode. |
| Step 5 | ip multicast boundary <i>access-list-number</i> Example: Device(config-if)# ip multicast boundary 12 | Configures the boundary, specifying the access list you created in Step 2. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Candidate BSRs

You can configure one or more candidate BSRs. The devices serving as candidate BSRs should have good connectivity to other devices and be in the backbone portion of the network.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|----------------------------------|--|
| Step 1 | enable Example: | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device> enable | |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip pim bsr-candidate <i>interface-id</i> <i>hash-mask-length</i> [<i>priority</i>] Example: Device(config)# ip pim bsr-candidate gigabitethernet 1/0/3 28 100 | Configures your device to be a candidate BSR. <ul style="list-style-type: none"> • For <i>interface-id</i>, enter the interface on this device from which the BSR address is derived to make it a candidate. This interface must be enabled with PIM. Valid interfaces include physical ports, port channels, and VLANs. • For <i>hash-mask-length</i>, specify the mask length (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash correspond to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. • (Optional) For <i>priority</i>, enter a number from 0 to 255. The BSR with the larger priority is preferred. If the priority values are the same, the device with the highest IP address is selected as the BSR. The default is 0. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|-----------------------------|---------|
| | <code>startup-config</code> | |

Configuring the Candidate RPs

You can configure one or more candidate RPs. Similar to BSRs, the RPs should also have good connectivity to other devices and be in the backbone portion of the network. An RP can serve the entire IP multicast address space or a portion of it. Candidate RPs send candidate RP advertisements to the BSR.

This procedure is optional.

Before you begin

When deciding which devices should be RPs, consider these options:

- In a network of Cisco routers and multilayer devices where only Auto-RP is used, any device can be configured as an RP.
- In a network that includes only Cisco PIMv2 routers and multilayer devices and with routers from other vendors, any device can be used as an RP.
- In a network of Cisco PIMv1 routers, Cisco PIMv2 routers, and routers from other vendors, configure only Cisco PIMv2 routers and multilayer devices as RPs.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | ip pim rp-candidate <i>interface-id</i> [group-list <i>access-list-number</i>] Example: Device(config)# <code>ip pim rp-candidate gigabitethernet 1/0/5 group-list 10</code> | Configures your device to be a candidate RP. <ul style="list-style-type: none"> • For <i>interface-id</i>, specify the interface whose associated IP address is advertised as a candidate RP address. Valid interfaces include physical ports, port channels, and VLANs. • (Optional) For group-list <i>access-list-number</i>, enter an IP standard access list number from 1 to 99. If no |

| | Command or Action | Purpose |
|---------------|--|---|
| | | group-list is specified, the device is a candidate RP for all groups. |
| Step 4 | <p>access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>]</p> <p>Example:</p> <pre>Device(config)# access-list 10 permit 239.0.0.0 0.255.255.255</pre> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> For <i>access-list-number</i>, enter the access list number specified in Step 2. The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. For <i>source</i>, enter the number of the network or host from which the packet is being sent. (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Delaying the Use of PIM Shortest-Path Tree

Perform these steps to configure a traffic rate threshold that must be reached before multicast routing is switched from the source tree to the shortest-path tree.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>] Example: Device(config)# access-list 16 permit 225.0.0.0 0.255.255.255 | Creates a standard access list. <ul style="list-style-type: none"> • For <i>access-list-number</i>, the range is 1 to 99. • The deny keyword denies access if the conditions are matched. • The permit keyword permits access if the conditions are matched. • For <i>source</i>, specify the multicast group to which the threshold will apply. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 4 | ip pim spt-threshold {<i>kbps</i> infinity} [<i>group-list access-list-number</i>] Example: Device(config)# ip pim spt-threshold infinity group-list 16 | Specifies the threshold that must be reached before moving to shortest-path tree (spt). <ul style="list-style-type: none"> • For <i>kbps</i>, specify the traffic rate in kilobits per second. The default is 0 kbps. <p>Note Because of device hardware limitations, 0 kbps is the only valid entry even though the range is 0 to 4294967.</p> <ul style="list-style-type: none"> • Specify infinity if you want all sources for the specified group to use the shared tree, never switching to the source tree. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> (Optional) For group-list <i>access-list-number</i>, specify the access list created in Step 2. If the value is 0 or if the group list is not used, the threshold applies to all groups. |
| Step 5 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Modifying the PIM Router-Query Message Interval

PIM routers and multilayer devices send PIM router-query messages to find which device will be the designated router (DR) for each LAN segment (subnet). The DR is responsible for sending IGMP host-query messages to all hosts on the directly connected LAN.

With PIM DM operation, the DR has meaning only if IGMPv1 is in use. IGMPv1 does not have an IGMP querier election process, so the elected DR functions as the IGMP querier. With PIM-SM operation, the DR is the device that is directly connected to the multicast source. It sends PIM register messages to notify the RP that multicast traffic from a source needs to be forwarded down the shared tree. In this case, the DR is the device with the highest IP address.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the interface to be configured, and enters interface configuration mode. |
| Step 4 | ip pim query-interval <i>seconds</i> Example: Device(config-if)# ip pim query-interval 45 | Configures the frequency at which the device sends PIM router-query messages. The default is 30 seconds. The range is 1 to 65535. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show ip igmp interface [<i>interface-id</i>] Example: Device# show ip igmp interface | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Verifying PIM Operations

Verifying IP Multicast Operation in a PIM-SM or a PIM-SSM Network

Perform the following optional tasks to verify IP multicast operation in a PIM-SM or a PIM-SSM network. The steps in these tasks help to locate a faulty hop when sources and receivers are not operating as expected.

Note If packets are not reaching their expected destinations, you might want consider disabling IP multicast fast switching, which would place the router in process switching mode. If packets begin reaching their proper destinations after IP multicast fast switching has been disabled, then the issue most likely was related to IP multicast fast switching.

Verifying IP Multicast on the First Hop Router

Enter these commands on the first hop router to verify IP multicast operations on the first hop router:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show ip mroute [group-address] Example: Device# show ip mroute 239.1.2.3 (*, 239.1.2.3), 00:18:10/stopped, RP 172.16.0.1, flags: SPF Incoming interface: Serial1/0, RPF nbr 172.31.200.2 Outgoing interface list: Null (10.0.0.1, 239.1.2.3), 00:18:10/00:03:22, flags: FT Incoming interface: GigabitEthernet0/0/0, RPF nbr 0.0.0.0 Outgoing interface list: Serial1/0, Forward/Sparse-Dense, 00:18:10/00:03:19 | Confirms that the F flag has been set for mroutes on the first hop router. |
| Step 3 | show ip mroute active [kb/s] Example: Device# show ip mroute active Active IP Multicast Sources - sending >= 4 kbps | Displays information about active multicast sources sending to groups. The output of this command provides information about the multicast packet rate for active sources. |

| | Command or Action | Purpose |
|--|---|---|
| | <pre>Group: 239.1.2.3, (?) Source: 10.0.0.1 (?) Rate: 20 pps/4 kbps(1sec), 4 kbps(last 30 secs), 4 kbps(life avg)</pre> | <p>Note By default, the output of the show ip mroute command with the active keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the <i>kb/s</i> argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.</p> |

Verifying IP Multicast on Routers Along the SPT

Enter these commands on routers along the SPT to verify IP multicast operations on routers along the SPT in a PIM-SM or PIM-SSM network:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>show ip mroute [<i>group-address</i>]</p> <p>Example:</p> <pre>Device# show ip mroute 239.1.2.3 (*, 239.1.2.3), 00:17:56/00:03:02, RP 172.16.0.1, flags: S Incoming interface: Null, RPF nbr 0.0.0.0 Outgoing interface list: GigabitEthernet0/0/0, Forward/Sparse-Dense, 00:17:56/00:03:02 (10.0.0.1, 239.1.2.3), 00:15:34/00:03:28, flags: T Incoming interface: Serial11/0, RPF nbr 172.31.200.1 Outgoing interface list: GigabitEthernet0/0/0, Forward/Sparse-Dense, 00:15:34/00:03:02</pre> | <p>Confirms the RPF neighbor towards the source for a particular group or groups.</p> |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | <p>show ip mroute active</p> <p>Example:</p> <pre>Device# show ip mroute active Active IP Multicast Sources - sending >= 4 kbps Group: 239.1.2.3, (?) Source: 10.0.0.1 (?) Rate: 20 pps/4 kbps(1sec), 4 kbps(last 30 secs), 4 kbps(life avg)</pre> | <p>Displays information about active multicast sources sending to groups. The output of this command provides information about the multicast packet rate for active sources.</p> <p>Note By default, the output of the show ip mroute command with the active keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the <i>kb/s</i> argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.</p> |

Verifying IP Multicast Operation on the Last Hop Router

Enter these commands on the last hop router to verify IP multicast operations on the last hop router:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>show ip igmp groups</p> <p>Example:</p> <pre>Device# show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 239.1.2.3 GigabitEthernet1/0/0 00:05:14 00:02:14 10.1.0.6 224.0.1.39 GigabitEthernet0/0/0 00:09:11 00:02:08 172.31.100.1</pre> | <p>Verifies IGMP memberships on the last hop router. This information will confirm the multicast groups with receivers that are directly connected to the last hop router and that are learned through IGMP.</p> |

| | Command or Action | Purpose |
|--------|--|---|
| Step 3 | <p>show ip pim rp mapping</p> <p>Example:</p> <pre>Device# show ip pim rp mapping PIM Group-to-RP Mappings Group(s) 224.0.0.0/4 RP 172.16.0.1 (?), v2v1 Info source: 172.16.0.1 (?), elected via Auto-RP Uptime: 00:09:11, expires: 00:02:47</pre> | <p>Confirms that the group-to-RP mappings are being populated correctly on the last hop router.</p> <p>Note Ignore this step if you are verifying a last hop router in a PIM-SSM network. The show ip pim rp mapping command does not work with routers in a PIM-SSM network because PIM-SSM does not use RPs. In addition, if configured correctly, PIM-SSM groups do not appear in the output of the show ip pim rp mapping command.</p> |
| Step 4 | <p>show ip mroute</p> <p>Example:</p> <pre>Device# show ip mroute (*, 239.1.2.3), 00:05:14/00:03:04, RP 172.16.0.1, flags: SJC Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1 Outgoing interface list: GigabitEthernet1/0, Forward/Sparse-Dense, 00:05:10/00:03:04 (10.0.0.1, 239.1.2.3), 00:02:49/00:03:29, flags: T Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1 Outgoing interface list: GigabitEthernet1/0, Forward/Sparse-Dense, 00:02:49/00:03:04 (*, 224.0.1.39), 00:10:05/00:00:00, RP 0.0.0.0, flags: DC Incoming interface: Null, RPF nbr 0.0.0.0 Outgoing interface list: GigabitEthernet1/0, Forward/Sparse-Dense, 00:05:15/00:00:00 GigabitEthernet0/0, Forward/Sparse-Dense, 00:10:05/00:00:00 (172.16.0.1, 224.0.1.39), 00:02:00/00:01:33, flags: PTX Incoming interface: GigabitEthernet0/0/0, RPF nbr 172.31.100.1</pre> | <p>Verifies that the mroute table is being populated properly on the last hop router.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | <p>show ip interface [<i>type number</i>]</p> <p>Example:</p> <pre>Device# show ip interface GigabitEthernet 0/0/0 GigabitEthernet0/0 is up, line protocol is up Internet address is 172.31.100.2/24 Broadcast address is 255.255.255.255 Address determined by setup command MTU is 1500 bytes Helper address is not set Directed broadcast forwarding is disabled Multicast reserved groups joined: 224.0.0.1 224.0.0.22 224.0.0.13 224.0.0.5 224.0.0.6 Outgoing access list is not set Inbound access list is not set Proxy ARP is enabled Local Proxy ARP is disabled Security level is default Split horizon is enabled ICMP redirects are always sent ICMP unreachable are always sent ICMP mask replies are never sent IP fast switching is enabled IP fast switching on the same interface is disabled IP Flow switching is disabled IP CEF switching is disabled IP Fast switching turbo vector IP multicast fast switching is enabled IP multicast distributed fast switching is disabled IP route-cache flags are Fast Router Discovery is disabled IP output packet accounting is disabled IP access violation accounting is disabled TCP/IP header compression is disabled RTP/IP header compression is disabled Policy routing is disabled Network address translation is disabled WCCP Redirect outbound is disabled WCCP Redirect inbound is disabled WCCP Redirect exclude is disabled BGP Policy Mapping is disabled</pre> | <p>Verifies that multicast fast switching is enabled for optimal performance on the outgoing interface on the last hop router.</p> <p>Note Using the no ip mroute-cache interface command disables IP multicast fast-switching. When IP multicast fast switching is disabled, packets are forwarded through the process-switched path.</p> |
| Step 6 | <p>show ip pim interface count</p> <p>Example:</p> <pre>Device# show ip pim interface count State: * - Fast Switched, D - Distributed Fast Switched H - Hardware Switching Enabled Address Interface</pre> | <p>Confirms that multicast traffic is being forwarded on the last hop router.</p> |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre> FS Mpackets In/Out 172.31.100.2 GigabitEthernet0/0/0 * 4122/0 10.1.0.1 GigabitEthernet1/0/0 * 0/3193 </pre> | |
| Step 7 | <p>show ip mroute count</p> <p>Example:</p> <pre> Device# show ip mroute count IP Multicast Statistics 6 routes using 4008 bytes of memory 3 groups, 1.00 average sources per group Forwarding Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second Other counts: Total/RPF failed/Other drops(OIF-null, rate-limit etc) Group: 239.1.2.3, Source count: 1, Packets forwarded: 3165, Packets received: 3165 RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0 Source: 10.0.0.1/32, Forwarding: 3165/20/28/4, Other: 0/0/0 Group: 224.0.1.39, Source count: 1, Packets forwarded: 21, Packets received: 120 Source: 172.16.0.1/32, Forwarding: 21/1/48/0, Other: 120/0/99 Group: 224.0.1.40, Source count: 1, Packets forwarded: 10, Packets received: 10 Source: 172.16.0.1/32, Forwarding: 10/1/48/0, Other: 10/0/0 </pre> | Confirms that multicast traffic is being forwarded on the last hop router. |
| Step 8 | <p>show ip mroute active [kb/s]</p> <p>Example:</p> <pre> Device# show ip mroute active Active IP Multicast Sources - sending >= 4 kbps </pre> | Displays information about active multicast sources sending traffic to groups on the last hop router. The output of this command provides information about the multicast packet rate for active sources. |

| | Command or Action | Purpose |
|--|---|---|
| | <pre>Group: 239.1.2.3, (?) Source: 10.0.0.1 (?) Rate: 20 pps/4 kbps(1sec), 4 kbps(last 50 secs), 4 kbps(life avg)</pre> | <p>Note By default, the output of the show ip mroute command with the active keyword displays information about active sources sending traffic to groups at a rate greater than or equal to 4 kb/s. To display information about active sources sending low-rate traffic to groups (that is, traffic less than 4 kb/s), specify a value of 1 for the <i>kb/s</i> argument. Specifying a value of 1 for this argument displays information about active sources sending traffic to groups at a rate equal to or greater than 1 kb/s, which effectively displays information about all possible active source traffic.</p> |

Using PIM-Enabled Routers to Test IP Multicast Reachability

If all the PIM-enabled routers and access servers that you administer are members of a multicast group, pinging that group causes all routers to respond, which can be a useful administrative and debugging tool.

To use PIM-enabled routers to test IP multicast reachability, perform the following tasks:

Configuring Routers to Respond to Multicast Pings

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>type number</i> | Enters interface configuration mode. For the <i>type</i> and <i>number</i> arguments, specify an interface that is directly connected to hosts or is facing hosts. |
| Step 4 | ip igmp join-group <i>group-address</i> | (Optional) Configures an interface on the router to join the specified group. For the purpose of this task, configure the same group address for the <i>group-address</i> argument on all interfaces on the router participating in the multicast network. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note With this method, the router accepts the multicast packets in addition to forwarding them. Accepting the multicast packets prevents the router from fast switching. |
| Step 5 | Repeat Step 3 and Step 4 for each interface on the router participating in the multicast network. | -- |
| Step 6 | end | Ends the current configuration session and returns to privileged EXEC mode. |

Pinging Routers Configured to Respond to Multicast Pings

on a router to initiate a ping test to the routers configured to respond to multicast pings. This task is used to test IP multicast reachability in a network.

Procedure

| | Command or Action | Purpose |
|---------------|----------------------------------|--|
| Step 1 | enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | ping <i>group-address</i> | Pings an IP multicast group address. A successful response indicates that the group address is functioning. |

Monitoring and Troubleshooting PIM

Monitoring PIM Information

Use the privileged EXEC commands in the following table to monitor your PIM configurations.

Table 22: PIM Monitoring Commands

| Command | Purpose |
|--|--|
| show ip pim interface | Displays information about interfaces configured for Protocol Independent Multicast (PIM). |
| show ip pim neighbor | Displays the PIM neighbor information. |
| show ip pim rp [<i>group-name</i> <i>group-address</i>] | Displays RP routers associated with a sparse-mode multicast group. This command is available in all software images. |

Monitoring the RP Mapping and BSR Information

Use the privileged EXEC mode in the following table to verify the consistency of group-to-RP mappings:

Table 23: RP Mapping Monitoring Commands

| Command | Purpose |
|--|--|
| show ip pim rp [<i>hostname</i> or <i>IP address</i> mapping [<i>hostname</i> or <i>IP address</i> elected in-use] metric [<i>hostname</i> or <i>IP address</i>]] | <p>Displays all available RP mappings and metrics. This tells you how the device learns of the RP (through the BSR or the Auto-RP mechanism).</p> <ul style="list-style-type: none"> • (Optional) For the <i>hostname</i>, specify the IP name of the group about which to display RPs. • (Optional) For the <i>IP address</i>, specify the IP address of the group about which to display RPs. • (Optional) Use the mapping keyword to display all group-to-RP mappings of which the Cisco device is aware (either configured or learned from Auto-RP). • (Optional) Use the metric keyword to display the RP RPF metric. |
| show ip pim rp-hash <i>group</i> | <p>Displays the RP that was selected for the specified group. That is, on a PIMv2 router or multilayer device, confirms that the same RP is the one that a PIMv1 system chooses. For <i>group</i>, enter the group address for which to display RP information.</p> |

Use the privileged EXEC commands in the following table to monitor BSR information:

Table 24: BSR Monitoring Commands

| Command | Purpose |
|------------------------|---|
| show ip pim bsr | Displays information about the elected BSR. |

Troubleshooting PIMv1 and PIMv2 Interoperability Problems

When debugging interoperability problems between PIMv1 and PIMv2, check these in the order shown:

1. Verify RP mapping with the **show ip pim rp-hash** privileged EXEC command, making sure that all systems agree on the same RP for the same group.
2. Verify interoperability between different versions of DRs and RPs. Make sure that the RPs are interacting with the DRs properly (by responding with register-stops and forwarding decapsulated data packets from registers).

Configuration Examples for PIM

Example: Enabling PIM Stub Routing

In this example, IP multicast routing is enabled, Switch A PIM uplink port 25 is configured as a routed uplink port with **sparse-dense-mode** enabled. PIM stub routing is enabled on the VLAN 100 interfaces and on Gigabit Ethernet port 20.

```
Device(config)# ip multicast-routing distributed
Device(config)# interface GigabitEthernet3/0/25
Device(config-if)# no switchport
Device(config-if)# ip address 3.1.1.2 255.255.255.0
Device(config-if)# ip pim sparse-dense-mode
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface vlan100
Device(config-if)# ip address 100.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# exit
Device(config)# interface GigabitEthernet3/0/20
Device(config-if)# no switchport
Device(config-if)# ip address 10.1.1.1 255.255.255.0
Device(config-if)# ip pim passive
Device(config-if)# end
```

Example: Verifying PIM Stub Routing

To verify that PIM stub is enabled for each interface, use the **show ip pim interface** privileged EXEC command:

```
Device# show ip pim interface
Address Interface Ver/ Nbr Query DR DR
Mode Count Intvl Prior
3.1.1.2 GigabitEthernet3/0/25 v2/SD 1 30 1 3.1.1.2
100.1.1.1 Vlan100 v2/P 0 30 1 100.1.1.1
10.1.1.1 GigabitEthernet3/0/20 v2/P 0 30 1 10.1.1.1
```

Example: Manually Assigning an RP to Multicast Groups

This example shows how to configure the address of the RP to 147.106.6.22 for multicast group 225.2.2.2 only:

```
Device(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Device(config)# ip pim rp-address 147.106.6.22 1
```

Example: Configuring Auto-RP

This example shows how to send RP announcements out all PIM-enabled interfaces for a maximum of 31 hops. The IP address of port 1 is the RP. Access list 5 describes the group for which this device serves as RP:

```
Device(config)# ip pim send-rp-announce gigabitethernet1/0/1 scope 31 group-list 5
Device(config)# access-list 5 permit 224.0.0.0 15.255.255.255
```

Example: Defining the IP Multicast Boundary to Deny Auto-RP Information

This example shows a portion of an IP multicast boundary configuration that denies Auto-RP information:

```
Device(config)# access-list 1 deny 224.0.1.39
Device(config)# access-list 1 deny 224.0.1.40
Device(config)# access-list 1 permit all
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# ip multicast boundary 1
```

Example: Filtering Incoming RP Announcement Messages

This example shows a sample configuration on an Auto-RP mapping agent that is used to prevent candidate RP announcements from being accepted from unauthorized candidate RPs:

```
Device(config)# ip pim rp-announce-filter rp-list 10 group-list 20
Device(config)# access-list 10 permit host 172.16.5.1
Device(config)# access-list 10 permit host 172.16.2.1
Device(config)# access-list 20 deny 239.0.0.0 0.0.255.255
Device(config)# access-list 20 permit 224.0.0.0 15.255.255.255
```

The mapping agent accepts candidate RP announcements from only two devices, 172.16.5.1 and 172.16.2.1. The mapping agent accepts candidate RP announcements from these two devices only for multicast groups that fall in the group range of 224.0.0.0 to 239.255.255.255. The mapping agent does not accept candidate RP announcements from any other devices in the network. Furthermore, the mapping agent does not accept candidate RP announcements from 172.16.5.1 or 172.16.2.1 if the announcements are for any groups in the 239.0.0.0 through 239.255.255.255 range. This range is the administratively scoped address range.

Example: Preventing Join Messages to False RPs

If all interfaces are in sparse mode, use a default-configured RP to support the two well-known groups 224.0.1.39 and 224.0.1.40. Auto-RP uses these two well-known groups to collect and distribute RP-mapping information. When this is the case and the **ip pim accept-rp auto-rp** command is configured, another **ip pim accept-rp** command accepting the RP must be configured as follows:

```
Device(config)# ip pim accept-rp 172.10.20.1 1
Device(config)# access-list 1 permit 224.0.1.39
Device(config)# access-list 1 permit 224.0.1.40
```

Example: Configuring Candidate BSRs

This example shows how to configure a candidate BSR, which uses the IP address 172.21.24.18 on a port as the advertised BSR address, uses 30 bits as the hash-mask-length, and has a priority of 10.

```
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# ip address 172.21.24.18 255.255.255.0
Device(config-if)# ip pim sparse-mode
Device(config-if)# ip pim bsr-candidate gigabitethernet1/0/2 30 10
```

Example: Configuring Candidate RPs

This example shows how to configure the device to advertise itself as a candidate RP to the BSR in its PIM domain. Standard access list number 4 specifies the group prefix associated with the RP that has the address identified by a port. That RP is responsible for the groups with the prefix 239.

```
Device(config)# ip pim rp-candidate gigabitethernet1/0/2 group-list 4
Device(config)# access-list 4 permit 239.0.0.0 0.255.255.255
```

CHAPTER 13

IPv6 Protocol Independent Multicast

- [Protocol Independent Multicast](#), on page 195

Protocol Independent Multicast

Protocol Independent Multicast (PIM) is used between switches so that they can track which multicast packets to forward to each other and to their directly connected LANs. PIM works independently of the unicast routing protocol to perform send or receive multicast route updates like other protocols. Regardless of which unicast routing protocols are being used in the LAN to populate the unicast routing table, Cisco IOS PIM uses the existing unicast table content to perform the Reverse Path Forwarding (RPF) check instead of building and maintaining its own separate routing table.

You can configure IPv6 multicast to use either PIM-SM or PIM-SSM operation, or you can use both PIM-SM and PIM-SSM together in your network.

PIM-Sparse Mode

IPv6 multicast provides support for intradomain multicast routing using PIM-SM. PIM-SM uses unicast routing to provide reverse-path information for multicast tree building, but it is not dependent on any particular unicast routing protocol.

PIM-SM is used in a multicast network when relatively few switches are involved in each multicast and these switches do not forward multicast packets for a group, unless there is an explicit request for the traffic. PIM-SM distributes information about active sources by forwarding data packets on the shared tree. PIM-SM initially uses shared trees, which requires the use of an RP.

Requests are accomplished via PIM joins, which are sent hop by hop toward the root node of the tree. The root node of a tree in PIM-SM is the RP in the case of a shared tree or the first-hop switch that is directly connected to the multicast source in the case of a shortest path tree (SPT). The RP keeps track of multicast groups and the hosts that send multicast packets are registered with the RP by that host's first-hop switch.

As a PIM join travels up the tree, switches along the path set up multicast forwarding state so that the requested multicast traffic will be forwarded back down the tree. When multicast traffic is no longer needed, a switch sends a PIM prune up the tree toward the root node to prune (or remove) the unnecessary traffic. As this PIM prune travels hop by hop up the tree, each switch updates its forwarding state appropriately. Ultimately, the forwarding state associated with a multicast group or source is removed.

A multicast data sender sends data destined for a multicast group. The designated switch (DR) of the sender takes those data packets, unicast-encapsulates them, and sends them directly to the RP. The RP receives these

encapsulated data packets, de-encapsulates them, and forwards them onto the shared tree. The packets then follow the (*, G) multicast tree state in the switches on the RP tree, being replicated wherever the RP tree branches, and eventually reaching all the receivers for that multicast group. The process of encapsulating data packets to the RP is called registering, and the encapsulation packets are called PIM register packets.

IPv6 BSR: Configure RP Mapping

PIM switches in a domain must be able to map each multicast group to the correct RP address. The BSR protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

Every PIM-SM multicast group needs to be associated with the IP or IPv6 address of an RP. When a new multicast sender starts sending, its local DR will encapsulate these data packets in a PIM register message and send them to the RP for that multicast group. When a new multicast receiver joins, its local DR will send a PIM join message to the RP for that multicast group. When any PIM switch sends a (*, G) join message, the PIM switch needs to know which is the next switch toward the RP so that G (Group) can send a message to that switch. Also, when a PIM switch is forwarding data packets using (*, G) state, the PIM switch needs to know which is the correct incoming interface for packets destined for G, because it needs to reject any packets that arrive on other interfaces.

A small set of switches from a domain are configured as candidate bootstrap switches (C-BSRs) and a single BSR is selected for that domain. A set of switches within a domain are also configured as candidate RPs (C-RPs); typically, these switches are the same switches that are configured as C-BSRs. Candidate RPs periodically unicast candidate-RP-advertisement (C-RP-Adv) messages to the BSR of that domain, advertising their willingness to be an RP. A C-RP-Adv message includes the address of the advertising C-RP, and an optional list of group addresses and mask length fields, indicating the group prefixes for which the candidacy is advertised. The BSR then includes a set of these C-RPs, along with their corresponding group prefixes, in bootstrap messages (BSMs) it periodically originates. BSMs are distributed hop-by-hop throughout the domain.

Bidirectional BSR support allows bidirectional RPs to be advertised in C-RP messages and bidirectional ranges in the BSM. All switches in a system must be able to use the bidirectional range in the BSM; otherwise, the bidirectional RP feature will not function.

PIM-Source Specific Multicast

PIM-SSM is the routing protocol that supports the implementation of SSM and is derived from PIM-SM. However, unlike PIM-SM where data from all multicast sources are sent when there is a PIM join, the SSM feature forwards datagram traffic to receivers from only those multicast sources that the receivers have explicitly joined, thus optimizing bandwidth utilization and denying unwanted Internet broadcast traffic. Further, instead of the use of RP and shared trees, SSM uses information found on source addresses for a multicast group. This information is provided by receivers through the source addresses relayed to the last-hop switches by MLD membership reports, resulting in shortest-path trees directly to the sources.

In SSM, delivery of datagrams is based on (S, G) channels. Traffic for one (S, G) channel consists of datagrams with an IPv6 unicast source address S and the multicast group address G as the IPv6 destination address. Systems will receive this traffic by becoming members of the (S, G) channel. Signaling is not required, but receivers must subscribe or unsubscribe to (S, G) channels to receive or not receive traffic from specific sources.

MLD version 2 is required for SSM to operate. MLD allows the host to provide source information. Before SSM can run with MLD, SSM must be supported in the Cisco IOS IPv6 switch, the host where the application is running, and the application itself.

Routable Address Hello Option

When an IPv6 interior gateway protocol is used to build the unicast routing table, the procedure to detect the upstream switch address assumes the address of a PIM neighbor is always same as the address of the next-hop switch, as long as they refer to the same switch. However, it may not be the case when a switch has multiple addresses on a link.

Two typical situations can lead to this situation for IPv6. The first situation can occur when the unicast routing table is not built by an IPv6 interior gateway protocol such as multicast BGP. The second situation occurs when the address of an RP shares a subnet prefix with downstream switches (note that the RP switch address has to be domain-wide and therefore cannot be a link-local address).

The routable address hello option allows the PIM protocol to avoid such situations by adding a PIM hello message option that includes all the addresses on the interface on which the PIM hello message is advertised. When a PIM switch finds an upstream switch for some address, the result of RPF calculation is compared with the addresses in this option, in addition to the PIM neighbor's address itself. Because this option includes all the possible addresses of a PIM switch on that link, it always includes the RPF calculation result if it refers to the PIM switch supporting this option.

Because of size restrictions on PIM messages and the requirement that a routable address hello option fits within a single PIM hello message, a limit of 16 addresses can be configured on the interface.

PIM IPv6 Stub Routing

The PIM stub routing feature reduces resource usage by moving routed traffic closer to the end user.

In a network using PIM stub routing, the only allowable route for IPv6 traffic to the user is through a switch that is configured with PIM stub routing. PIM passive interfaces are connected to Layer 2 access domains, such as VLANs, or to interfaces that are connected to other Layer 2 devices. Only directly connected multicast receivers and sources are allowed in the Layer 2 access domains. The PIM passive interfaces do not send or process any received PIM control packets.

When using PIM stub routing, you should configure the distribution and remote routers to use IPv6 multicast routing and configure only the switch as a PIM stub router. The switch does not route transit traffic between distribution routers. You also need to configure a routed uplink port on the switch. The switch uplink port cannot be used with SVIs.

You must also configure EIGRP stub routing when configuring PIM stub routing on the switch.

The redundant PIM stub router topology is not supported. The redundant topology exists when there is more than one PIM router forwarding multicast traffic to a single access domain. PIM messages are blocked, and the PIM assert and designated router election mechanisms are not supported on the PIM passive interfaces. Only the non-redundant access router topology is supported by the PIM stub feature. By using a non-redundant topology, the PIM passive interface assumes that it is the only interface and designated router on that access domain.

In the figure shown below, Switch A routed uplink port 25 is connected to the router and PIM stub routing is enabled on the VLAN 100 interfaces and on Host 3. This configuration allows the directly connected hosts to receive traffic from multicast source.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IPv6 MLD Snooping

You can use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP Version 6 (IPv6) multicast data to clients and routers in a switched network on the switch. Unless otherwise noted, the term switch refers to a standalone switch and to a switch stack.

Note To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch.

Note For complete syntax and usage information for the commands used in this chapter, see the command reference for this release or the Cisco IOS documentation referenced in the procedures.

Understanding MLD Snooping

In IP Version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes wishing to receive IPv6 multicast packets) on the links that are directly attached to the routers and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD Version 1 (MLDv1) is equivalent to IGMPv2, and MLD Version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol Version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

Note The switch does not support MLDv2 enhanced snooping, which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

MLD Messages

MLDv1 supports three types of messages:

- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages.

Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

MLD Queries

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast group address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

Note When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the Catalyst 2960, 2960-S, 2960-C, 2960-X or 2960-CX switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

Multicast Client Aging Robustness

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

Multicast Router Discovery

Like IGMP snooping, MLD snooping performs multicast router discovery, with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If there are multiple routers on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
- IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.
- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether or not MLD snooping is enabled on the switch.

- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address is entered in the VLAN MLD database. Then all IPv6 multicast traffic to the group within the VLAN is forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (which would be the case when there are multiple clients for a group on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the **ipv6 mld snooping last-listener-query count** global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If there are no reports sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the **ipv6 mld snooping last-listener-query-interval** global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the **ipv6 mld snooping tcn query solicit** global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the **ipv6 mld snooping tcn flood query count** global configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This is same as done in IGMP snooping.

MLD Snooping in Switch Stacks

The MLD IPv6 group address databases are maintained on all switches in the stack, regardless of which switch learns of an IPv6 multicast group. Report suppression and proxy reporting are done stack-wide. During the maximum response time, only one received report for a group is forwarded to the multicast routers, regardless of which switch the report arrives on.

The election of a new active stack does not affect the learning or bridging of IPv6 multicast data; bridging of IPv6 multicast data does not stop during an active stack re-election. When a new switch is added to the stack, it synchronizes the learned IPv6 multicast information from the active stack. Until the synchronization is complete, data ingress on the newly added switch is treated as unknown multicast data.

How to Configure IPv6 MLD Snooping

Default MLD Snooping Configuration

Table 25: Default MLD Snooping Configuration

| Feature | Default Setting |
|----------------------------------|--|
| MLD snooping (Global) | Disabled. |
| MLD snooping (per VLAN) | Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place. |
| IPv6 Multicast addresses | None configured. |
| IPv6 Multicast router ports | None configured. |
| MLD snooping Immediate Leave | Disabled. |
| MLD snooping robustness variable | Global: 2; Per VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query count | Global: 2; Per VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count. |
| Last listener query interval | Global: 1000 (1 second); VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global interval. |
| TCN query solicit | Disabled. |

| Feature | Default Setting |
|--------------------------|-----------------|
| TCN query count | 2. |
| MLD listener suppression | Enabled. |

MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the **ipv6 mld snooping** global configuration command for the configuration to take effect.
- When the IPv6 multicast router is a Catalyst 6500 switch and you are using extended VLANs (in the range 1006 to 4094), IPv6 MLD snooping must be enabled on the extended VLAN on the Catalyst 6500 switch in order for the switch to receive queries on the VLAN. For normal-range VLANs (1 to 1005), it is not necessary to enable IPv6 MLD snooping on the VLAN on the Catalyst 6500 switch.
- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch.
- The maximum number of address entries allowed for the switch or switch stack is 1000.

Enabling or Disabling MLD Snooping on the Switch

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. That is, MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis or for a range of VLANs, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

To globally enable MLD snooping on the switch, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | ipv6 mld snooping Example: Device(config)# ipv6 mld snooping | Enables MLD snooping on the switch. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | copy running-config startup-config Example: Device(config)# copy running-config startup-config | (Optional) Save your entries in the configuration file. |
| Step 6 | reload Example: Device(config)# reload | Reload the operating system. |

Enabling or Disabling MLD Snooping on a VLAN

To enable MLD snooping on a VLAN, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ipv6 mld snooping Example: | Enables MLD snooping on the switch. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Device(config)# <code>ipv6 mld snooping</code> | |
| Step 4 | ipv6 mld snooping vlan <i>vlan-id</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1</code> | Enables MLD snooping on the VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. Note MLD snooping must be globally enabled for VLAN snooping to be enabled. |
| Step 5 | end Example: Device(config)# <code>ipv6 mld snooping vlan 1</code> | Returns to privileged EXEC mode. |

Configuring a Static Multicast Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

To add a Layer 2 port as a member of a multicast group, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | ipv6 mld snooping vlan <i>vlan-id</i> static <i>ipv6_multicast_address</i> interface <i>interface-id</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 static 3333.0000.1111 interface gigabitethernet 0/1</code> | Configures a multicast group with a Layer 2 port as a member of a multicast group: <ul style="list-style-type: none"> • <i>vlan-id</i> is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094. • <i>ipv6_multicast_address</i> is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> <i>interface-id</i> is the member port. It can be a physical interface or a port channel (1 to 48). |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | Use one of the following: <ul style="list-style-type: none"> show ipv6 mld snooping address show ipv6 mld snooping address vlan <i>vlan-id</i> Example: Device# show ipv6 mld snooping address or Device# show ipv6 mld snooping vlan 1 | Verifies the static member port and the IPv6 address. |

Configuring a Multicast Router Port

Note Static connections to multicast routers are supported only on switch ports.

To add a multicast router port to a VLAN, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i> | Specifies the multicast router VLAN ID, and specify the interface to the multicast router. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Example: <pre>Device(config)# ipv6 mld snooping vlan 1 mrouter interface gigabitethernet 0/2</pre> | <ul style="list-style-type: none"> The VLAN ID range is 1 to 1001 and 1006 to 4094. The interface can be a physical interface or a port channel. The port-channel range is 1 to 48. |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show ipv6 mld snooping mrouter [vlan vlan-id] Example: <pre>Device# show ipv6 mld snooping mrouter vlan 1</pre> | Verifies that IPv6 MLD snooping is enabled on the VLAN interface. |

Enabling MLD Immediate Leave

To enable MLDv1 immediate leave, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | ipv6 mld snooping vlan <i>vlan-id</i> immediate-leave Example: <pre>Device(config)# ipv6 mld snooping vlan 1 immediate-leave</pre> | Enables MLD Immediate Leave on the VLAN interface. |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 5 | show ipv6 mld snooping vlan <i>vlan-id</i> Example: Device# <code>show ipv6 mld snooping vlan 1</code> | Verifies that Immediate Leave is enabled on the VLAN interface. |

Configuring MLD Snooping Queries

To configure MLD snooping query characteristics for the switch or for a VLAN, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | ipv6 mld snooping robustness-variable <i>value</i> Example: Device(config)# <code>ipv6 mld snooping robustness-variable 3</code> | (Optional) Sets the number of queries that are sent before switch will deletes a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2. |
| Step 4 | ipv6 mld snooping vlan <i>vlan-id</i> robustness-variable <i>value</i> Example: Device(config)# <code>ipv6 mld snooping vlan 1 robustness-variable 3</code> | (Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value. |
| Step 5 | ipv6 mld snooping last-listener-query-count <i>count</i> Example: Device(config)# <code>ipv6 mld snooping last-listener-query-count 7</code> | (Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart. |
| Step 6 | ipv6 mld snooping vlan <i>vlan-id</i> last-listener-query-count <i>count</i> | (Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; |

| | Command or Action | Purpose |
|----------------|---|---|
| | Example: <pre>Device(config)# ipv6 mld snooping vlan 1 last-listener-query-count 7</pre> | the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart. |
| Step 7 | ipv6 mld snooping last-listener-query-interval interval Example: <pre>Device(config)# ipv6 mld snooping last-listener-query-interval 2000</pre> | (Optional) Sets the maximum response time that the switch waits after sending out a MASQ before deleting a port from the multicast group. The range is 100 to 32,768 thousands of a second. The default is 1000 (1 second). |
| Step 8 | ipv6 mld snooping vlan vlan-id last-listener-query-interval interval Example: <pre>Device(config)# ipv6 mld snooping vlan 1 last-listener-query-interval 2000</pre> | (Optional) Sets the last-listener query interval on a VLAN basis. This value overrides the value configured globally. The range is 0 to 32,768 thousands of a second. The default is 0. When set to 0, the global last-listener query interval is used. |
| Step 9 | ipv6 mld snooping tcn query solicit Example: <pre>Device(config)# ipv6 mld snooping tcn query solicit</pre> | (Optional) Enables topology change notification (TCN) solicitation, which means that VLANs flood all IPv6 multicast traffic for the configured number of queries before sending multicast data to only those ports requesting to receive it. The default is for TCN to be disabled. |
| Step 10 | ipv6 mld snooping tcn flood query count count Example: <pre>Device(config)# ipv6 mld snooping tcn flood query count 5</pre> | (Optional) When TCN is enabled, specifies the number of TCN queries to be sent. The range is from 1 to 10; the default is 2. |
| Step 11 | end | Returns to privileged EXEC mode. |
| Step 12 | show ipv6 mld snooping querier [vlan vlan-id] Example: <pre>Device(config)# show ipv6 mld snooping querier vlan 1</pre> | (Optional) Verifies that the MLD snooping querier information for the switch or for the VLAN. |

Disabling MLD Listener Message Suppression

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

To disable MLD listener message suppression, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enter global configuration mode. |
| Step 3 | no ipv6 mld snooping listener-message-suppression Example: Device(config)# no ipv6 mld snooping listener-message-suppression | Disable MLD message suppression. |
| Step 4 | end Example: Device(config)# end | Return to privileged EXEC mode. |
| Step 5 | show ipv6 mld snooping Example: Device# show ipv6 mld snooping | Verify that IPv6 MLD snooping report suppression is disabled. |

Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display IPv6 group address multicast entries for a VLAN configured for MLD snooping.

Table 26: Commands for Displaying MLD Snooping Information

| Command | Purpose |
|---|--|
| show ipv6 mld snooping [vlan vlan-id] | Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |

| Command | Purpose |
|---|---|
| show ipv6 mld snooping mrouter [vlan <i>vlan-id</i>] | Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enters vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| show ipv6 mld snooping querier [vlan <i>vlan-id</i>] | Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enters vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. |
| show ipv6 mld snooping address [vlan <i>vlan-id</i>] [count dynamic user] | Displays all IPv6 multicast address information or specific IPv6 multicast address information for the switch or a VLAN. <ul style="list-style-type: none"> • Enters count to show the group count on the switch or in a VLAN. • Enters dynamic to display MLD snooping learned group information for the switch or for a VLAN. • Enters user to display MLD snooping user-configured group information for the switch or for a VLAN. |
| show ipv6 mld snooping address vlan <i>vlan-id</i> [<i>ipv6-multicast-address</i>] | Displays MLD snooping for the specified VLAN and IPv6 multicast address. |

Configuration Examples for Configuring MLD Snooping

Configuring a Static Multicast Group: Example

This example shows how to statically configure an IPv6 multicast group:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 2 static 3333.0000.1111 interface gigabitethernet1/0/1
Device(config)# end
```

Configuring a Multicast Router Port: Example

This example shows how to add a multicast router port to VLAN 200:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet
```

0/2

```
Device(config)# exit
```

Enabling MLD Immediate Leave: Example

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 130 immediate-leave
Device(config)# exit
```

Configuring MLD Snooping Queries: Example

This example shows how to set the MLD snooping global robustness variable to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping robustness-variable 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```
Device# configure terminal
Device(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Device(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```
Device# configure terminal
Device(config)# ipv6 mld snooping last-listener-query-interval 2000
Device(config)# exit
```

CHAPTER 15

Configuring IPv6 Unicast Routing

- [Finding Feature Information, on page 217](#)
- [Information About Configuring IPv6 Host Functions , on page 217](#)
- [Configuration Examples for IPv6 Unicast Routing, on page 228](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IPv6 Host Functions

This chapter describes how to configure IPv6 host functions on the Catalyst 2960, 2960-S, and 2960-C.

Note To use IPv6 Host Functions, the switch must be running the LAN Base image.

For information about configuring IPv6 Multicast Listener Discovery (MLD) snooping, see *Configuring MLD Snooping*.

To enable dual stack environments (supporting both IPv4 and IPv6) on a Catalyst 2960 switch, you must configure the switch to use the a dual IPv4 and IPv6 switch database management (SDM) template. See the ["Dual IPv4 and IPv6 Protocol Stacks"](#) section. This template is not required on Catalyst 2960-S switches.

Note For complete syntax and usage information for the commands used in this chapter, see the Cisco IOS documentation referenced in the procedures.

Understanding IPv6

IPv4 users can move to IPv6 and receive services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For information about how Cisco Systems implements IPv6, go to:

http://www.cisco.com/en/US/products/ps6553/products_ios_technology_home.html

For information about IPv6 and other features in this chapter

- See the *Cisco IOS IPv6 Configuration Library*.
- Use the Search field on Cisco.com to locate the Cisco IOS software documentation. For example, if you want information about static routes, you can enter *Implementing Static Routes for IPv6* in the search field to learn about static routes.

IPv6 Addresses

The switch supports only IPv6 unicast addresses. It does not support site-local unicast addresses, or anycast addresses.

The IPv6 128-bit addresses are represented as a series of eight 16-bit hexadecimal fields separated by colons in the format: n:n:n:n:n:n:n:n. This is an example of an IPv6 address:

```
2031:0000:130F:0000:0000:09C0:080F:130B
```

For easier implementation, leading zeros in each field are optional. This is the same address without leading zeros:

```
2031:0:130F:0:0:9C0:80F:130B
```

You can also use two colons (::) to represent successive hexadecimal fields of zeros, but you can use this short version only once in each address:

```
2031:0:130F::09C0:080F:130B
```

For more information about IPv6 address formats, address types, and the IPv6 packet header, see the http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipv6_basic/configuration/xe-3e/ip6b-xe-3e-book.html of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

In the "Implementing Addressing and Basic Connectivity" chapter, these sections apply to the Catalyst 2960, 2960-S, 2960-C, 2960-X, 2960-CX and 3560-CX switches:

- IPv6 Address Formats
- IPv6 Address Type: Multicast
- IPv6 Address Output Display
- Simplified IPv6 Packet Header

Supported IPv6 Unicast Routing Features

These sections describe the IPv6 protocol features supported by the switch:

128-Bit Wide Unicast Addresses

The switch supports aggregatable global unicast addresses and link-local unicast addresses. It does not support site-local unicast addresses.

- Aggregatable global unicast addresses are IPv6 addresses from the aggregatable global unicast prefix. The address structure enables strict aggregation of routing prefixes and limits the number of routing table entries in the global routing table. These addresses are used on links that are aggregated through organizations and eventually to the Internet service provider.

These addresses are defined by a global routing prefix, a subnet ID, and an interface ID. Current global unicast address allocation uses the range of addresses that start with binary value 001 (2000::/3). Addresses with a prefix of 2000::/3(001) through E000::/3(111) must have 64-bit interface identifiers in the extended unique identifier (EUI)-64 format.

- Link local unicast addresses can be automatically configured on any interface by using the link-local prefix FE80::/10(1111 1110 10) and the interface identifier in the modified EUI format. Link-local addresses are used in the neighbor discovery protocol (NDP) and the stateless autoconfiguration process. Nodes on a local link use link-local addresses and do not require globally unique addresses to communicate. IPv6 routers do not forward packets with link-local source or destination addresses to other links.

For more information, see the section about IPv6 unicast addresses in the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

DNS for IPv6

IPv6 supports Domain Name System (DNS) record types in the DNS name-to-address and address-to-name lookup processes. The DNS AAAA resource record types support IPv6 addresses and are equivalent to an A address record in IPv4. The switch supports DNS resolution for IPv4 and IPv6.

ICMPv6

The Internet Control Message Protocol (ICMP) in IPv6 generates error messages, such as ICMP destination unreachable messages, to report errors during processing and other diagnostic functions. In IPv6, ICMP packets are also used in the neighbor discovery protocol and path MTU discovery.

Neighbor Discovery

The switch supports NDP for IPv6, a protocol running on top of ICMPv6, and static neighbor entries for IPv6 stations that do not support NDP. The IPv6 neighbor discovery process uses ICMP messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), to verify the reachability of the neighbor, and to keep track of neighboring routers.

The switch supports ICMPv6 redirect for routes with mask lengths less than 64 bits. ICMP redirect is not supported for host routes or for summarized routes with mask lengths greater than 64 bits.

Neighbor discovery throttling ensures that the switch CPU is not unnecessarily burdened while it is in the process of obtaining the next hop forwarding information to route an IPv6 packet. The switch drops any additional IPv6 packets whose next hop is the same neighbor that the switch is actively trying to resolve. This drop avoids further load on the CPU.

IPv6 Stateless Autoconfiguration and Duplicate Address Detection

The switch uses stateless autoconfiguration to manage link, subnet, and site addressing changes, such as management of host and mobile IP addresses. A host autonomously configures its own link-local address, and booting nodes send router solicitations to request router advertisements for configuring interfaces.

For more information about autoconfiguration and duplicate address detection, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

IPv6 Applications

The switch has IPv6 support for these applications:

- Ping, traceroute, and Telnet
- Secure Shell (SSH) over an IPv6 transport
- HTTP server access over IPv6 transport
- DNS resolver for AAAA over IPv4 transport
- Cisco Discovery Protocol (CDP) support for IPv6 addresses

For more information about managing these applications, see the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Dual IPv4 and IPv6 Protocol Stacks

On a Catalyst 2960-X switch, you must use the dual IPv4 and IPv6 template to allocate ternary content addressable memory (TCAM) usage to both IPv4 and IPv6 protocols.

This figure shows a router forwarding both IPv4 and IPv6 traffic through the same interface, based on the IP packet and destination addresses.

Figure 13: Dual IPv4 and IPv6 Support on an Interface

Use the dual IPv4 and IPv6 switch database management (SDM) template to enable IPv6 routing dual stack environments (supporting both IPv4 and IPv6). For more information about the dual IPv4 and IPv6 SDM template, see *Configuring SDM Templates*.

The dual IPv4 and IPv6 templates allow the switch to be used in dual stack environments.

- If you try to configure IPv6 without first selecting a dual IPv4 and IPv6 template, a warning message appears.
- In IPv4-only environments, the switch routes IPv4 packets and applies IPv4 QoS and ACLs in hardware. IPv6 packets are not supported.
- In dual IPv4 and IPv6 environments, the switch applies IPv4 QoS and ACLs in hardware .
- IPv6 QoS and ACLs are not supported.
- If you do not plan to use IPv6, do not use the dual stack template because this template results in less hardware memory capacity for each resource.

For more information about IPv4 and IPv6 protocol stacks, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter of *Cisco IOS IPv6 Configuration Library* on Cisco.com.

SNMP and Syslog Over IPv6

To support both IPv4 and IPv6, IPv6 network management requires both IPv6 and IPv4 transports. Syslog over IPv6 supports address data types for these transports.

Simple Network Management Protocol (SNMP) and syslog over IPv6 provide these features:

- Support for both IPv4 and IPv6
- IPv6 transport for SNMP and to modify the SNMP agent to support traps for an IPv6 host
- SNMP- and syslog-related MIBs to support IPv6 addressing
- Configuration of IPv6 hosts as trap receivers

For support over IPv6, SNMP modifies the existing IP transport mapping to simultaneously support IPv4 and IPv6. These SNMP actions support IPv6 transport management:

- Opens User Datagram Protocol (UDP) SNMP socket with default settings
- Provides a new transport mechanism called `SR_IPV6_TRANSPORT`
- Sends SNMP notifications over IPv6 transport
- Supports SNMP-named access lists for IPv6 transport
- Supports SNMP proxy forwarding using IPv6 transport
- Verifies SNMP Manager feature works with IPv6 transport

For information on SNMP over IPv6, including configuration procedures, see the “Managing Cisco IOS Applications over IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

For information about syslog over IPv6, including configuration procedures, see the “Implementing IPv6 Addressing and Basic Connectivity” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

HTTP(S) Over IPv6

The HTTP client sends requests to both IPv4 and IPv6 HTTP servers, which respond to requests from both IPv4 and IPv6 HTTP clients. URLs with literal IPv6 addresses must be specified in hexadecimal using 16-bit values between colons.

The accept socket call chooses an IPv4 or IPv6 address family. The accept socket is either an IPv4 or IPv6 socket. The listening socket continues to listen for both IPv4 and IPv6 signals that indicate a connection. The IPv6 listening socket is bound to an IPv6 wildcard address.

The underlying TCP/IP stack supports a dual-stack environment. HTTP relies on the TCP/IP stack and the sockets for processing network-layer interactions.

Basic network connectivity (**ping**) must exist between the client and the server hosts before HTTP connections can be made.

For more information, see the “Managing Cisco IOS Applications over IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

IPv6 and Switch Stacks

The switch supports IPv6 forwarding across the stack and IPv6 host functionality on the active stack. The active stack runs IPv6 host functionality and IPv6 applications.

While the new active stack is being elected and is resetting, the switch stack does not forward IPv6 packets. The stack MAC address changes, which also changes the IPv6 address. When you specify the stack IPv6 address with an extended unique identifier (EUI) by using the **ipv6 address** ipv6-prefix/prefix length eui-64 interface configuration command, the address is based on the interface MAC address. See the ["Configuring IPv6 Addressing and Enabling IPv6 Host" section](#).

If you configure the persistent MAC address feature on the stack and the active stack changes, the stack MAC address does not change for approximately 4 minutes. For more information, see the "Enabling Persistent MAC Address" section in "Managing Switch Stacks."

Default IPv6 Configuration

Table 27: Default IPv6 Configuration

| Feature | Default Setting |
|----------------|---|
| SDM template | Advance desktop. Default is advanced template |
| IPv6 addresses | None configured |

Configuring IPv6 Addressing and Enabling IPv6 Routing

This section describes how to assign IPv6 addresses to individual Layer 3 interfaces and to globally forward IPv6 traffic on the switch.

Before configuring IPv6 on the switch, consider these guidelines:

- Be sure to select a dual IPv4 and IPv6 SDM template.
- In the **ipv6 address** interface configuration command, you must enter the *ipv6-address* and *ipv6-prefix* variables with the address specified in hexadecimal using 16-bit values between colons. The *prefix-length* variable (preceded by a slash [/]) is a decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address).

To forward IPv6 traffic on an interface, you must configure a global IPv6 address on that interface. Configuring an IPv6 address on an interface automatically configures a link-local address and activates IPv6 for the interface. The configured interface automatically joins these required multicast groups for that link:

- solicited-node multicast group FF02:0:0:0:1:ff00::/104 for each unicast address assigned to the interface (this address is used in the neighbor discovery process.)
- all-nodes link-local multicast group FF02::1
- all-routers link-local multicast group FF02::2

For more information about configuring IPv6 routing, see the "Implementing Addressing and Basic Connectivity for IPv6" chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

Beginning in privileged EXEC mode, follow these steps to assign an IPv6 address to a Layer 3 interface and enable IPv6 forwarding:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | sdm prefer dual-ipv4-and-ipv6 {default} Example: Device(config)# <code>sdm prefer dual-ipv4-and-ipv6 default</code> | Selects an SDM template that supports IPv4 and IPv6. • default —Sets the switch to the default template to balance system resources. |
| Step 3 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 4 | reload Example: Device# <code>reload</code> | Reloads the operating system. |
| Step 5 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode after the switch reloads. |
| Step 6 | interface interface-id Example: Device(config)# <code>interface gigabitethernet 1/0/1</code> | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |
| Step 7 | Use one of the following: • ipv6 address ipv6-prefix/prefix length eui-64 • ipv6 address ipv6-address/prefix length • ipv6 address ipv6-address link-local • ipv6 enable | • Specifies a global IPv6 address with an extended unique identifier (EUI) in the low-order 64 bits of the IPv6 address. Specify only the network prefix; the last 64 bits are automatically computed from the switch MAC address. This enables IPv6 processing on the interface. |

| | Command or Action | Purpose |
|----------------|---|--|
| | <p>Example:</p> <pre>Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64</pre> <p>Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64</p> <p>Device(config-if)# ipv6 address 2001:0DB8:c18:1:: link-local</p> <p>Device(config-if)# ipv6 enable</p> | <ul style="list-style-type: none"> Manually configures an IPv6 address on the interface. Specifies a link-local address on the interface to be used instead of the link-local address that is automatically configured when IPv6 is enabled on the interface. This command enables IPv6 processing on the interface. Automatically configures an IPv6 link-local address on the interface, and enables the interface for IPv6 processing. The link-local address can only be used to communicate with nodes on the same link. |
| Step 8 | <p>exit</p> <p>Example:</p> <pre>Device(config-if)# exit</pre> | Returns to global configuration mode. |
| Step 9 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 10 | <p>show ipv6 interface <i>interface-id</i></p> <p>Example:</p> <pre>Device# show ipv6 interface gigabitethernet 1/0/1</pre> | Verifies your entries. |
| Step 11 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring IPv6 ICMP Rate Limiting

ICMP rate limiting is enabled by default with a default interval between error messages of 100 milliseconds and a bucket size (maximum number of tokens to be stored in a bucket) of 10.

To change the ICMP rate-limiting parameters, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | ipv6 icmp error-interval interval [bucketsize] Example: <pre>Device(config)# ipv6 icmp error-interval 50 20</pre> | Configures the interval and bucket size for IPv6 ICMP error messages: <ul style="list-style-type: none"> • <i>interval</i>—The interval (in milliseconds) between tokens being added to the bucket. The range is from 0 to 2147483647 milliseconds. • <i>bucketsize</i>—(Optional) The maximum number of tokens stored in the bucket. The range is from 1 to 200. |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show ipv6 interface [interface-id] Example: <pre>Device# show ipv6 interface gigabitethernet0/1</pre> | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring Static Routing for IPv6

For more information about configuring static IPv6 routing, see the “Implementing Static Routes for IPv6” chapter in the *Cisco IOS IPv6 Configuration Library* on Cisco.com.

To configure static IPv6 routing, perform this procedure:

Before you begin

You must enable routing by using the **ip routing** global configuration command, enable the forwarding of IPv6 packets by using the **ipv6 unicast-routing** global configuration command, and enable IPv6 on at least one Layer 3 interface by configuring an IPv6 address on the interface.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ipv6 route <i>ipv6-prefix/prefix length</i> <i>{ipv6-address interface-id [ipv6-address]}</i> <i>[administrative distance]</i> Example: Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet2/0/1 130 | Configures a static IPv6 route. <ul style="list-style-type: none"> • <i>ipv6-prefix</i>—The IPv6 network that is the destination of the static route. It can also be a hostname when static host routes are configured. • <i>/prefix length</i>—The length of the IPv6 prefix. A decimal value that shows how many of the high-order contiguous bits of the address comprise the prefix (the network portion of the address). A slash mark must precede the decimal value. • <i>ipv6-address</i>—The IPv6 address of the next hop that can be used to reach the specified network. The IPv6 address of the next hop need not be directly connected; recursion is done to find the IPv6 address of the directly connected next hop. The address must be in the form documented in RFC 2373, specified in hexadecimal using 16-bit values between colons. • <i>interface-id</i>—Specifies direct static routes from point-to-point and broadcast interfaces. With point-to-point interfaces, there is no need to specify the IPv6 address of the next hop. With broadcast interfaces, you should always specify the IPv6 |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <p>address of the next hop, or ensure that the specified prefix is assigned to the link, specifying a link-local address as the next hop. You can optionally specify the IPv6 address of the next hop to which packets are sent.</p> <p>Note You must specify an <i>interface-id</i> when using a link-local address as the next hop (the link-local next hop must also be an adjacent router).</p> <ul style="list-style-type: none"> • <i>administrative distance</i>—(Optional) An administrative distance. The range is 1 to 254; the default value is 1, which gives static routes precedence over any other type of route except connected routes. To configure a floating static route, use an administrative distance greater than that of the dynamic routing protocol. |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>Use one of the following:</p> <ul style="list-style-type: none"> • show ipv6 static [<i>ipv6-address</i> <i>ipv6-prefix/prefix length</i>] [interface <i>interface-id</i>] [detail][recursive] [detail] • show ipv6 route static [<i>updated</i>] <p>Example:</p> <pre>Device# show ipv6 static 2001:0DB8::/32 interface gigabitethernet2/0/1</pre> <p>or</p> <pre>Device# show ipv6 route static</pre> | <p>Verifies your entries by displaying the contents of the IPv6 routing table.</p> <ul style="list-style-type: none"> • interface <i>interface-id</i>—(Optional) Displays only those static routes with the specified interface as an egress interface. • recursive—(Optional) Displays only recursive static routes. The recursive keyword is mutually exclusive with the interface keyword, but it can be used with or without the IPv6 prefix included in the command syntax. • detail—(Optional) Displays this additional information: <ul style="list-style-type: none"> • For valid recursive routes, the output path set, and maximum resolution depth. • For invalid routes, the reason why the route is not valid. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Displaying IPv6

For complete syntax and usage information on these commands, see the Cisco IOS command reference publications.

Table 28: Command for Monitoring IPv6

| Command | Purpose |
|--|--|
| show ipv6 access-list | Displays a summary of access lists. |
| show ipv6 cef | Displays Cisco Express Forwarding for IPv6. |
| show ipv6 interface <i>interface-id</i> | Displays IPv6 interface status and configuration. |
| show ipv6 mtu | Displays IPv6 MTU per destination cache. |
| show ipv6 neighbors | Displays IPv6 neighbor cache entries. |
| show ipv6 prefix-list | Displays a list of IPv6 prefix lists. |
| show ipv6 protocols | Displays a list of IPv6 routing protocols on the switch. |
| show ipv6 rip | Displays IPv6 RIP routing protocol status. |
| show ipv6 route | Displays IPv6 route table entries. |
| show ipv6 static | Displays IPv6 static routes. |
| show ipv6 traffic | Displays IPv6 traffic statistics. |

Configuration Examples for IPv6 Unicast Routing

Configuring IPv6 Addressing and Enabling IPv6 Routing: Example

This example shows how to enable IPv6 with both a link-local address and a global address based on the IPv6 prefix 2001:0DB8:c18:1::/64. The EUI-64 interface ID is used in the low-order 64 bits of both addresses. Output from the **show ipv6 interface EXEC** command is included to show how the interface ID (20B:46FF:FE2F:D940) is appended to the link-local prefix FE80::/64 of the interface.

```

Device(config)# ipv6 unicast-routing
Device(config)# interface gigabitethernet0/11

Device(config-if)# ipv6 address 2001:0DB8:c18:1::/64 eui 64
Device(config-if)# end
Device# show ipv6 interface gigabitethernet0/11
GigabitEthernet0/11 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
  Global unicast address(es):
    2001:0DB8:c18:1:20B:46FF:FE2F:D940, subnet is 2001:0DB8:c18:1::/64 [EUI]
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF2F:D940
  MTU is 1500 bytes
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds
  ND router advertisements live for 1800 seconds
  Hosts use stateless autoconfig for addresses.

```

Configuring IPv6 ICMP Rate Limiting: Example

This example shows how to configure an IPv6 ICMP error message interval of 50 milliseconds and a bucket size of 20 tokens.

```
Device(config)#ipv6 icmp error-interval 50 20
```

Configuring Static Routing for IPv6: Example

This example shows how to configure a floating static route to an interface with an administrative distance of 130:

```
Device(config)# ipv6 route 2001:0DB8::/32 gigabitethernet 1/0/1 130
```

Displaying IPv6: Example

This is an example of the output from the **show ipv6 interface** privileged EXEC command:

```

Device# show ipv6 interface
Vlan1 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::20B:46FF:FE2F:D940
  Global unicast address(es):
    3FFE:C000:0:1:20B:46FF:FE2F:D940, subnet is 3FFE:C000:0:1::/64 [EUI]
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF2F:D940

```

```
MTU is 1500 bytes
ICMP error messages limited to one every 100 milliseconds
ICMP redirects are enabled
ND DAD is enabled, number of DAD attempts: 1
ND reachable time is 30000 milliseconds
ND advertised reachable time is 0 milliseconds
ND advertised retransmit interval is 0 milliseconds
ND router advertisements are sent every 200 seconds
ND router advertisements live for 1800 seconds
<output truncated>
```

- [Configuration Examples for IPv6 ACL, on page 240](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IPv6 ACLs

You can filter IP version 6 (IPv6) traffic by creating IPv6 access control lists (ACLs) and applying them to interfaces similarly to the way that you create and apply IP version 4 (IPv4) named ACLs. You can also create and apply input router ACLs to filter Layer 3 management traffic.

Note To use IPv6, you must configure the dual IPv4 and IPv6 Switch Database Management (SDM) template on the switch. You select the template by entering the `sdm prefer {default | dual-ipv4-and-ipv6}` global configuration command.

Understanding IPv6 ACLs

A switch image supports two types of IPv6 ACLs:

- IPv6 router ACLs - Supported on inbound or outbound traffic on Layer 3 interfaces, which can be routed ports, switch virtual interfaces (SVIs), or Layer 3 EtherChannels. Applied to only IPv6 packets that are routed.
- IPv6 port ACLs - Supported on inbound traffic on Layer 2 interfaces only. Applied to all IPv6 packets entering the interface.

Note If you configure unsupported IPv6 ACLs, an error message appears and the configuration does not take affect.

The switch does not support VLAN ACLs (VLAN maps) for IPv6 traffic.

You can apply both IPv4 and IPv6 ACLs to an interface.

As with IPv4 ACLs, IPv6 port ACLs take precedence over router ACLs:

- When an input router ACL and input port ACL exist in an SVI, packets received on ports to which a port ACL is applied are filtered by the port ACL. Routed IP packets received on other ports are filtered by the router ACL. Other packets are not filtered.
- When an output router ACL and input port ACL exist in an SVI, packets received on the ports to which a port ACL is applied are filtered by the port ACL. Outgoing routed IPv6 packets are filtered by the router ACL. Other packets are not filtered.

Note If any port ACL (IPv4, IPv6, or MAC) is applied to an interface, that port ACL is used to filter packets, and any router ACLs attached to the SVI of the port VLAN are ignored.

Supported ACL Features

IPv6 ACLs on the switch have these characteristics:

- Fragmented frames (the fragments keyword as in IPv4) are supported.
- The same statistics supported in IPv4 are supported for IPv6 ACLs.
- If the switch runs out of TCAM space, packets associated with the ACL label are forwarded to the CPU, and the ACLs are applied in software.
- Routed or bridged packets with hop-by-hop options have IPv6 ACLs applied in software.
- Logging is supported for router ACLs, but not for port ACLs.

IPv6 ACL Limitations

With IPv4, you can configure standard and extended numbered IP ACLs, named IP ACLs, and MAC ACLs. IPv6 supports only named ACLs.

The switch supports most Cisco IOS-supported IPv6 ACLs with some exceptions:

- IPv6 source and destination addresses-ACL matching is supported only on prefixes from /0 to /64 and host addresses (/128) that are in the extended universal identifier (EUI)-64 format. The switch supports only these host addresses with no loss of information:

- aggregatable global unicast addresses
- link local addresses
- The switch does not support matching on these keywords: **flowlabel**, **routing header**, and **undetermined-transport**.
- The switch does not support reflexive ACLs (the **reflect** keyword).
- This release supports only port ACLs and router ACLs for IPv6; it does not support VLAN ACLs (VLAN maps).
- The switch does not apply MAC-based ACLs on IPv6 frames.
- You cannot apply IPv6 port ACLs to Layer 2 EtherChannels.
- The switch does not support output port ACLs.
- Output router ACLs and input port ACLs for IPv6 are supported only on . Switches support only control plane (incoming) IPv6 ACLs.
- When configuring an ACL, there is no restriction on keywords entered in the ACL, regardless of whether or not they are supported on the platform. When you apply the ACL to an interface that requires hardware forwarding (physical ports or SVIs), the switch checks to determine whether or not the ACL can be supported on the interface. If not, attaching the ACL is rejected.
- If an ACL is applied to an interface and you attempt to add an access control entry (ACE) with an unsupported keyword, the switch does not allow the ACE to be added to the ACL that is currently attached to the interface.

Configuring IPv6 ACLs

To filter IPv6 traffic, you perform these steps:

Before you begin

Before configuring IPv6 ACLs, you must select one of the dual IPv4 and IPv6 SDM templates.

Procedure

| | Command or Action | Purpose |
|---------------|--|---------|
| Step 1 | Create an IPv6 ACL, and enter IPv6 access list configuration mode. | |
| Step 2 | Configure the IPv6 ACL to block (deny) or pass (permit) traffic. | |
| Step 3 | Apply the IPv6 ACL to an interface. For router ACLs, you must also configure an IPv6 address on the Layer 3 interface to which the ACL is applied. | |

Default IPv6 ACL Configuration

There are no IPv6 ACLs configured or applied.

Interaction with Other Features and Switches

- If an IPv6 router ACL is configured to deny a packet, the packet is not routed. A copy of the packet is sent to the Internet Control Message Protocol (ICMP) queue to generate an ICMP unreachable message for the frame.
- If a bridged frame is to be dropped due to a port ACL, the frame is not bridged.
- You can create both IPv4 and IPv6 ACLs on a switch or switch stack, and you can apply both IPv4 and IPv6 ACLs to the same interface. Each ACL must have a unique name; an error message appears if you try to use a name that is already configured.

You use different commands to create IPv4 and IPv6 ACLs and to attach IPv4 or IPv6 ACLs to the same Layer 2 or Layer 3 interface. If you use the wrong command to attach an ACL (for example, an IPv4 command to attach an IPv6 ACL), you receive an error message.

- You cannot use MAC ACLs to filter IPv6 frames. MAC ACLs can only filter non-IP frames.
- If the hardware memory is full, for any additional configured ACLs, packets are dropped to the CPU, and the ACLs are applied in software. When the hardware is full a message is printed to the console indicating the ACL has been unloaded and the packets will be dropped on the interface.

Note Only packets of the same type as the ACL that could not be added (ipv4, ipv6, MAC) will be dropped on the interface.

Creating IPv6 ACL

Follow these steps to create an IPv6 ACL:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 3 | ipv6access-list <i>access-list-name</i> Example: ipv6 access-list access-list-name | Define an IPv6 access list name, and enter IPv6 access-list configuration mode. |
| Step 4 | {deny permit} protocol Example: <pre>{deny permit} protocol {source-ipv6-prefix/prefix-length any host source-ipv6-address} [operator [port-number]]{destination-ipv6-prefix/prefix-length any host destination-ipv6-address} [operator [port-number]][dscp value] [fragments][log] [log-input] [routing][sequence value] [time-range name]</pre> | <p>Enter deny or permit to specify whether to deny or permit the packet if conditions are matched. These are the conditions:</p> <ul style="list-style-type: none"> For protocol, enter the name or number of an Internet protocol: ahp, esp, icmp, ipv6, pcp, stcp, tcp, or udp, or an integer in the range 0 to 255 representing an IPv6 protocol number. The source-ipv6-prefix/prefix-length or destination-ipv6-prefix/ prefix-length is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373). Enter any as an abbreviation for the IPv6 prefix ::/0. For host source-ipv6-address or destination-ipv6-address, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons. (Optional) For operator, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range. <p>If the operator follows the source-ipv6-prefix/prefix-length argument, it must match the source port. If the operator follows the destination-ipv6-prefix/prefix-length argument, it must match the destination port.</p> <ul style="list-style-type: none"> (Optional) The port-number is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP. |

| | Command or Action | Purpose |
|----------------------|---|--|
| | | <ul style="list-style-type: none"> • (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63. • (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is ipv6. • (Optional) Enter log to cause an logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in the log entry. Logging is supported only for router ACLs. • (Optional) Enter routing to specify that IPv6 packets be routed. • (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295 • (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement. |
| <p>Step 5</p> | <p>{deny permit} tcp</p> <p>Example:</p> <pre>{deny permit} tcp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]]{destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][ack] [dscp value][established] [fin] [log][log-input] [neq {port protocol}] [psh] [range{port protocol}] [rst][routing] [sequence value] [syn] [time-range name][urg]</pre> | <p>(Optional) Define a TCP access list and the access conditions.</p> <p>Enter tcp for Transmission Control Protocol. The parameters are the same as those described in Step 3, with these additional optional parameters:</p> <ul style="list-style-type: none"> • ack—Acknowledgment bit set. • established—An established connection. A match occurs if the TCP datagram has the ACK or RST bits set. • fin—Finished bit set; no more data from sender. • neq {port protocol}—Matches only packets that are not on a given port number. • psh—Push function bit set. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <ul style="list-style-type: none"> • range {port protocol}—Matches only packets in the port number range. • rst—Reset bit set. • syn—Synchronize bit set. • urg—Urgent pointer bit set. |
| Step 6 | <p>{deny permit} udp</p> <p>Example:</p> <pre>{deny permit} udp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]]{destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][dscp value] [log] [log-input] [neq {port protocol}] [range {port protocol}] [routing] [sequence value] [time-range name]</pre> | <p>(Optional) Define a UDP access list and the access conditions.</p> <p>Enter udp for the User Datagram Protocol. The UDP parameters are the same as those described for TCP, except that the operator [port] port number or name must be a UDP port number or name, and the established parameter is not valid for UDP.</p> |
| Step 7 | <p>{deny permit} icmp</p> <p>Example:</p> <pre>{deny permit} icmp {source-ipv6-prefix/prefix-length any hostsource-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/prefix-length any hostdestination-ipv6-address} [operator [port-number]][icmp-type [icmp-code] icmp-message] [dscpvalue] [log] [log-input] [routing] [sequence value] [time-range name]</pre> | <p>(Optional) Define an ICMP access list and the access conditions.</p> <p>Enter icmp for Internet Control Message Protocol. The ICMP parameters are the same as those described for most IP protocols in Step 3a, with the addition of the ICMP message type and code parameters. These optional keywords have these meanings:</p> <ul style="list-style-type: none"> • icmp-type—Enter to filter by ICMP message type, a number from 0 to 255. • icmp-code—Enter to filter ICMP packets that are filtered by the ICMP message code type, a number from 0 to 255. • icmp-message—Enter to filter ICMP packets by the ICMP message type name or the ICMP message type and code name. To see a list of ICMP message type names and code names, use the ? key or see command reference for this release. |
| Step 8 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 9 | show ipv6 access-list Example: show ipv6 access-list | Verify the access list configuration. |
| Step 10 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 11 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Applying an IPv6 ACL to an Interface

This section describes how to apply IPv6 ACLs to network interfaces. You can apply an ACL to outbound or inbound traffic on Layer 3 interfaces, or to inbound traffic on Layer 2 interfaces.

Beginning in privileged EXEC mode, follow these steps to control access to an interface:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface_id Example: Device# interface interface-id | Identify a Layer 2 interface (for port ACLs) or Layer 3 interface (for router ACLs) on which to apply an access list, and enter interface configuration mode. |
| Step 3 | no switchport Example: Device# no switchport | If applying a router ACL, change the interface from Layer 2 mode (the default) to Layer 3 mode. |
| Step 4 | ipv6 address ipv6_address Example: Device# ipv6 address ipv6-address | Configure an IPv6 address on a Layer 3 interface (for router ACLs). This command is not required on Layer 2 interfaces or if the interface has already been configured with an explicit IPv6 address. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | ipv6 traffic-filter <i>access-list-name</i> Example: Device# <code>ipv6 traffic-filter access-list-name {in out}</code> | Apply the access list to incoming or outgoing traffic on the interface. The out keyword is not supported for Layer 2 interfaces (port ACLs). |
| Step 6 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode. |
| Step 7 | show running-config | Verify the access list configuration. |
| Step 8 | copy running-config startup-config Example: <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Displaying IPv6 ACLs

To display IPv6 ACLs, perform this procedure:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | show access-list Example: Device# <code>show access-lists</code> | Displays all access lists configured on the device |
| Step 4 | show ipv6 access-list <i>acl_name</i> Example: Device# <code>show ipv6 access-list [access-list-name]</code> | Displays all configured IPv6 access list or the access list specified by name. |

Configuration Examples for IPv6 ACL

Example: Creating an IPv6 ACL

This example configures the IPv6 access list named CISCO. The first deny entry in the list denies all packets that have a destination TCP port number greater than 5000. The second deny entry denies packets that have a source UDP port number less than 5000. The second deny also logs all matches to the console. The first permit entry in the list permits all ICMP packets. The second permit entry in the list permits all other traffic. The second permit entry is necessary because an implicit deny -all condition is at the end of each IPv6 access list.

Note Logging is supported only on Layer 3 interfaces.

```
Device(config)# ipv6 access-list CISCO
Device(config-ipv6-acl)# deny tcp any any gt 5000
Device (config-ipv6-acl)# deny ::/0 lt 5000 ::/0 log
Device(config-ipv6-acl)# permit icmp any any
Device(config-ipv6-acl)# permit any any
```

Example: Applying IPv6 ACLs

This example shows how to apply the access list Cisco to outbound traffic on a Layer 3 interface.

```
Device(config-if)# no switchport
Device(config-if)# ipv6 address 2001::/64 eui-64
Device(config-if)# ipv6 traffic-filter CISCO out
```

Example: Displaying IPv6 ACLs

This is an example of the output from the **show access-lists** privileged EXEC command. The output shows all access lists that are configured on the switch or switch stack.

```
Device #show access-lists
Extended IP access list hello
10 permit ip any any
IPv6 access list ipv6
permit ipv6 any any sequence 10
```

This is an example of the output from the **show ipv6 access-lists** privileged EXEC command. The output shows only IPv6 access lists configured on the switch or switch stack.

```
Device# show ipv6 access-list
IPv6 access list inbound
permit tcp any any eq bgp (8 matches) sequence 10
permit tcp any any eq telnet (15 matches) sequence 20
permit udp any any sequence 30

IPv6 access list outbound
deny udp any any sequence 10
deny tcp any any eq telnet sequence 20
```

CHAPTER 17

Configuring Spanning Tree Protocol

This chapter describes how to configure the Spanning Tree Protocol (STP) on port-based VLANs on the Catalyst devices. The device can use either the per-VLAN spanning-tree plus (PVST+) protocol based on the IEEE 802.1D standard and Cisco proprietary extensions, or the rapid per-VLAN spanning-tree plus (rapid-PVST+) protocol based on the IEEE 802.1w standard. A switch stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for STP

- An attempt to configure a device as the root device fails if the value necessary to be the root device is less than 1.
- If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected devices running older software.
- The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Information About Spanning Tree Protocol

Spanning Tree Protocol

Spanning Tree Protocol (STP) is a Layer 2 link management protocol that provides path redundancy while preventing loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. Multiple active paths among end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages. Devices might also learn end-station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network. Spanning-tree operation is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

The STP uses a spanning-tree algorithm to select one device of a redundantly connected network as the root of the spanning tree. The algorithm calculates the best loop-free path through a switched Layer 2 network by assigning a role to each port based on the role of the port in the active topology:

- Root—A forwarding port elected for the spanning-tree topology
- Designated—A forwarding port elected for every switched LAN segment
- Alternate—A blocked port providing an alternate path to the root bridge in the spanning tree
- Backup—A blocked port in a loopback configuration

The device that has *all* of its ports as the designated role or as the backup role is the root device. The device that has at least *one* of its ports in the designated role is called the designated device.

Spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning-tree algorithm recalculates the spanning-tree topology and activates the standby path. Devices send and receive spanning-tree frames, called bridge protocol data units (BPDUs), at regular intervals. The devices do not forward these frames but use them to construct a loop-free path. BPDUs contain information about the sending device and its ports, including device and MAC addresses, device priority, port priority, and path cost. Spanning tree uses this information to elect the root device and root port for the switched network and the root port and designated port for each switched segment.

When two ports on a device are part of a loop, the spanning-tree and path cost settings control which port is put in the forwarding state and which is put in the blocking state. The spanning-tree port priority value represents the location of a port in the network topology and how well it is located to pass traffic. The path cost value represents the media speed.

Note By default, the device sends keepalive messages (to ensure the connection is up) only on interfaces that do not have small form-factor pluggable (SFP) modules. You can change the default for an interface by entering the `[no] keepalive` interface configuration command with no keywords.

Spanning-Tree Topology and BPDUs

The stable, active spanning-tree topology of a switched network is controlled by these elements:

- The unique bridge ID (device priority and MAC address) associated with each VLAN on each device. In a device stack, all devices use the same bridge ID for a given spanning-tree instance.

- The spanning-tree path cost to the root device.
- The port identifier (port priority and MAC address) associated with each Layer 2 interface.

When the devices in a network are powered up, each functions as the root device. Each device sends a configuration BPDU through all of its ports. The BPDUs communicate and compute the spanning-tree topology. Each configuration BPDU contains this information:

- The unique bridge ID of the device that the sending device identifies as the root device
- The spanning-tree path cost to the root
- The bridge ID of the sending device
- Message age
- The identifier of the sending interface
- Values for the hello, forward delay, and max-age protocol timers

When a device receives a configuration BPDU that contains *superior* information (lower bridge ID, lower path cost, and so forth), it stores the information for that port. If this BPDU is received on the root port of the device, the device also forwards it with an updated message to all attached LANs for which it is the designated device.

If a device receives a configuration BPDU that contains *inferior* information to that currently stored for that port, it discards the BPDU. If the device is a designated device for the LAN from which the inferior BPDU was received, it sends that LAN a BPDU containing the up-to-date information stored for that port. In this way, inferior information is discarded, and superior information is propagated on the network.

A BPDU exchange results in these actions:

- One device in the network is elected as the root device (the logical center of the spanning-tree topology in a switched network). See the figure following the bullets.
For each VLAN, the device with the highest device priority (the lowest numerical priority value) is elected as the root device. If all devices are configured with the default priority (32768), the device with the lowest MAC address in the VLAN becomes the root device. The device priority value occupies the most significant bits of the bridge ID, as shown in the following figure.
- A root port is selected for each device (except the root device). This port provides the best path (lowest cost) when the device forwards packets to the root device.
- Only one outgoing port on the stack root device is selected as the root port. The remaining devices in the stack become its designated devices (Device 2 and Device 3) as shown in the following figure.
- The shortest distance to the root device is calculated for each device based on the path cost.
- A designated device for each LAN segment is selected. The designated device incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.

Note If the **logging event spanning tree** command is configured on multiple interfaces and the topology changes, it may result in several logging messages and high CPU utilization. This may cause the switch to drop or delay the processing of STP BPDUs.

To prevent this behavior, remove the **logging event spanning tree** and **logging event status** commands or disable logging to the console.

Figure 14: Spanning-Tree Port States in a Device Stack

One stack member is elected as the stack root device. The stack root device contains the outgoing root port (Device 1).

All paths that are not needed to reach the root device from anywhere in the switched network are placed in the spanning-tree blocking mode.

Bridge ID, Device Priority, and Extended System ID

The IEEE 802.1D standard requires that each device has an unique bridge identifier (bridge ID), which controls the selection of the root device. Because each VLAN is considered as a different *logical bridge* with PVST+ and Rapid PVST+, the same device must have a different bridge ID for each configured VLAN. Each VLAN on the device has a unique 8-byte bridge ID. The 2 most-significant bytes are used for the device priority, and the remaining 6 bytes are derived from the device MAC address.

The device supports the IEEE 802.1t spanning-tree extensions, and some of the bits previously used for the device priority are now used as the VLAN identifier. The result is that fewer MAC addresses are reserved for the device, and a larger range of VLAN IDs can be supported, all while maintaining the uniqueness of the bridge ID.

The 2 bytes previously used for the device priority are reallocated into a 4-bit priority value and a 12-bit extended system ID value equal to the VLAN ID.

Table 29: Device Priority Value and Extended System ID

| Priority Value | | | | Extended System ID (Set Equal to the VLAN ID) | | | | | | | | | |
|----------------|--------|--------|--------|---|--------|--------|-------|-------|-------|-------|-------|-------|-------|
| Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 |
| 32768 | 16384 | 8192 | 4096 | 2048 | 1024 | 512 | 256 | 128 | 64 | 32 | 16 | 8 | 4 |

Spanning tree uses the extended system ID, the device priority, and the allocated spanning-tree MAC address to make the bridge ID unique for each VLAN. Because the device stack appears as a single device to the rest of the network, all devices in the stack use the same bridge ID for a given spanning tree. If the stack's active switch fails, the stack members recalculate their bridge IDs of all running spanning trees based on the new MAC address of the new stack's active switch.

Support for the extended system ID affects how you manually configure the root device, the secondary root device, and the device priority of a VLAN. For example, when you change the device priority value, you change the probability that the device will be elected as the root device. Configuring a higher value decreases the probability; a lower value increases the probability.

If any root device for the specified VLAN has a device priority lower than 24576, the device sets its own priority for the specified VLAN to 4096 less than the lowest device priority. 4096 is the value of the least-significant bit of a 4-bit device priority value as shown in the table.

Port Priority Versus Path Cost

If a loop occurs, spanning tree uses port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

The spanning-tree path cost default value is derived from the media speed of an interface. If a loop occurs, spanning tree uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

If your device is a member of a device stack, you must assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last instead of adjusting its port priority. For details, see Related Topics.

Spanning-Tree Interface States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When an interface transitions directly from nonparticipation in the spanning-tree topology to the forwarding state, it can create temporary data loops. Interfaces must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for forwarded frames that have used the old topology.

Each Layer 2 interface on a device using spanning tree exists in one of these states:

- Blocking—The interface does not participate in frame forwarding.
- Listening—The first transitional state after the blocking state when the spanning tree decides that the interface should participate in frame forwarding.
- Learning—The interface prepares to participate in frame forwarding.
- Forwarding—The interface forwards frames.
- Disabled—The interface is not participating in spanning tree because of a shutdown port, no link on the port, or no spanning-tree instance running on the port.

An interface moves through these states:

- From initialization to blocking
- From blocking to listening or to disabled
- From listening to learning or to disabled
- From learning to forwarding or to disabled
- From forwarding to disabled

Figure 15: Spanning-Tree Interface States

An interface moves through the states.

When you power up the device, spanning tree is enabled by default, and every interface in the device, VLAN, or network goes through the blocking state and the transitory states of listening and learning. Spanning tree stabilizes each interface at the forwarding or blocking state.

When the spanning-tree algorithm places a Layer 2 interface in the forwarding state, this process occurs:

1. The interface is in the listening state while spanning tree waits for protocol information to move the interface to the blocking state.
2. While spanning tree waits for the forward-delay timer to expire, it moves the interface to the learning state and resets the forward-delay timer.
3. In the learning state, the interface continues to block frame forwarding as the device learns end-station location information for the forwarding database.

4. When the forward-delay timer expires, spanning tree moves the interface to the forwarding state, where both learning and frame forwarding are enabled.

Blocking State

A Layer 2 interface in the blocking state does not participate in frame forwarding. After initialization, a BPDU is sent to each device interface. A device initially functions as the root until it exchanges BPDUs with other devices. This exchange establishes which device in the network is the root or root device. If there is only one device in the network, no exchange occurs, the forward-delay timer expires, and the interface moves to the listening state. An interface always enters the blocking state after device initialization.

An interface in the blocking state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

Listening State

The listening state is the first state a Layer 2 interface enters after the blocking state. The interface enters this state when the spanning tree decides that the interface should participate in frame forwarding.

An interface in the listening state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Receives BPDUs

Learning State

A Layer 2 interface in the learning state prepares to participate in frame forwarding. The interface enters the learning state from the listening state.

An interface in the learning state performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Learns addresses
- Receives BPDUs

Forwarding State

A Layer 2 interface in the forwarding state forwards frames. The interface enters the forwarding state from the learning state.

An interface in the forwarding state performs these functions:

- Receives and forwards frames received on the interface

- Forwards frames switched from another interface
- Learns addresses
- Receives BPDUs

Disabled State

A Layer 2 interface in the disabled state does not participate in frame forwarding or in the spanning tree. An interface in the disabled state is nonoperational.

A disabled interface performs these functions:

- Discards frames received on the interface
- Discards frames switched from another interface for forwarding
- Does not learn addresses
- Does not receive BPDUs

How a Device or Port Becomes the Root Device or Root Port

If all devices in a network are enabled with default spanning-tree settings, the device with the lowest MAC address becomes the root device.

Figure 16: Spanning-Tree Topology

Device A is elected as the root device because the device priority of all the devices is set to the default (32768) and Device A has the lowest MAC address. However, because of traffic patterns, number of forwarding interfaces, or link types, Device A might not be the ideal root device. By increasing the priority (lowering the numerical value) of the ideal device so that it becomes the root device, you force a spanning-tree recalculation

RP = Root Port
DP = Designated Port

to form a new topology with the ideal device as the root.

When the spanning-tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be ideal. For instance, connecting higher-speed links to an interface that has a higher number than the root port can cause a root-port change. The goal is to make the fastest link the root port.

For example, assume that one port on Device B is a Gigabit Ethernet link and that another port on Device B (a 10/100 link) is the root port. Network traffic might be more efficient over the Gigabit Ethernet link. By changing the spanning-tree port priority on the Gigabit Ethernet port to a higher priority (lower numerical value) than the root port, the Gigabit Ethernet port becomes the new root port.

Spanning Tree and Redundant Connectivity

Figure 17: Spanning Tree and Redundant Connectivity

You can create a redundant backbone with spanning tree by connecting two device interfaces to another device or to two different devices. Spanning tree automatically disables one interface but enables it if the other one fails. If one link is high-speed and the other is low-speed, the low-speed link is always disabled. If the speeds are the same, the port priority and port ID are added together, and spanning tree disables the link with the

highest value.

You can also create redundant links between devices by using EtherChannel groups.

Spanning-Tree Address Management

IEEE 802.1D specifies 17 multicast addresses, ranging from 0x00180C2000000 to 0x0180C2000010, to be used by different bridge protocols. These addresses are static addresses that cannot be removed.

Regardless of the spanning-tree state, each device in the stack receives but does not forward packets destined for addresses between 0x0180C2000000 and 0x0180C200000F.

If spanning tree is enabled, the CPU on the device or on each device in the stack receives packets destined for 0x0180C2000000 and 0x0180C2000010. If spanning tree is disabled, the device or each device in the stack forwards those packets as unknown multicast addresses.

Accelerated Aging to Retain Connectivity

The default for aging dynamic addresses is 5 minutes, the default setting of the **mac address-table aging-time** global configuration command. However, a spanning-tree reconfiguration can cause many station locations to change. Because these stations could be unreachable for 5 minutes or more during a reconfiguration, the address-aging time is accelerated so that station addresses can be dropped from the address table and then relearned. The accelerated aging is the same as the forward-delay parameter value (**spanning-tree vlan vlan-id forward-time seconds** global configuration command) when the spanning tree reconfigures.

Because each VLAN is a separate spanning-tree instance, the device accelerates aging on a per-VLAN basis. A spanning-tree reconfiguration on one VLAN can cause the dynamic addresses learned on that VLAN to be subject to accelerated aging. Dynamic addresses on other VLANs can be unaffected and remain subject to the aging interval entered for the device.

Spanning-Tree Modes and Protocols

The device supports these spanning-tree modes and protocols:

- **PVST+**—This spanning-tree mode is based on the IEEE 802.1D standard and Cisco proprietary extensions. The PVST+ runs on each VLAN on the device up to the maximum supported, ensuring that each has a loop-free path through the network.

The PVST+ provides Layer 2 load-balancing for the VLAN on which it runs. You can create different logical topologies by using the VLANs on your network to ensure that all of your links are used but that no one link is oversubscribed. Each instance of PVST+ on a VLAN has a single root device. This root device propagates the spanning-tree information associated with that VLAN to all other devices in the network. Because each device has the same information about the network, this process ensures that the network topology is maintained.

- **Rapid PVST+**—This spanning-tree mode is the same as PVST+ except that it uses a rapid convergence based on the IEEE 802.1w standard. Beginning from 15.2(4)E release, the STP default mode is Rapid PVST+. To provide rapid convergence, the Rapid PVST+ immediately deletes dynamically learned MAC address entries on a per-port basis upon receiving a topology change. By contrast, PVST+ uses a short aging time for dynamically learned MAC address entries.

Rapid PVST+ uses the same configuration as PVST+ (except where noted), and the device needs only minimal extra configuration. The benefit of Rapid PVST+ is that you can migrate a large PVST+ install base to Rapid PVST+ without having to learn the complexities of the Multiple Spanning Tree Protocol (MSTP) configuration and without having to re-provision your network. In Rapid PVST+ mode, each VLAN runs its own spanning-tree instance up to the maximum supported.

- **MSTP**—This spanning-tree mode is based on the IEEE 802.1s standard. You can map multiple VLANs to the same spanning-tree instance, which reduces the number of spanning-tree instances required to support a large number of VLANs. The MSTP runs on top of the RSTP (based on IEEE 802.1w), which provides for rapid convergence of the spanning tree by eliminating the forward delay and by quickly transitioning root ports and designated ports to the forwarding state. In a device stack, the cross-stack rapid transition (CSRT) feature performs the same function as RSTP. You cannot run MSTP without RSTP or CSRT.

Supported Spanning-Tree Instances

In PVST+ or Rapid PVST+ mode, the device or device stack supports up to 128 spanning-tree instances.

In MSTP mode, the device or device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.

Spanning-Tree Interoperability and Backward Compatibility

In a mixed MSTP and PVST+ network, the common spanning-tree (CST) root must be inside the MST backbone, and a PVST+ device cannot connect to multiple MST regions.

When a network contains devices running Rapid PVST+ and devices running PVST+, we recommend that the Rapid PVST+ devices and PVST+ devices be configured for different spanning-tree instances. In the Rapid PVST+ spanning-tree instances, the root device must be a Rapid PVST+ device. In the PVST+ instances, the root device must be a PVST+ device. The PVST+ devices should be at the edge of the network.

All stack members run the same version of spanning tree (all PVST+, all Rapid PVST+, or all MSTP).

Table 30: PVST+, MSTP, and Rapid-PVST+ Interoperability and Compatibility

| | PVST+ | MSTP | Rapid PVST+ |
|-------|--------------|-------------------------|------------------------|
| PVST+ | Yes | Yes (with restrictions) | Yes (reverts to PVST+) |

| | PVST+ | MSTP | Rapid PVST+ |
|-------------|-------------------------|------------------------|------------------------|
| MSTP | Yes (with restrictions) | Yes | Yes (reverts to PVST+) |
| Rapid PVST+ | Yes (reverts to PVST+) | Yes (reverts to PVST+) | Yes |

STP and IEEE 802.1Q Trunks

The IEEE 802.1Q standard for VLAN trunks imposes some limitations on the spanning-tree strategy for a network. The standard requires only one spanning-tree instance for *all* VLANs allowed on the trunks. However, in a network of Cisco devices connected through IEEE 802.1Q trunks, the devices maintain one spanning-tree instance for *each* VLAN allowed on the trunks.

When you connect a Cisco device to a non-Cisco device through an IEEE 802.1Q trunk, the Cisco device uses PVST+ to provide spanning-tree interoperability. If Rapid PVST+ is enabled, the device uses it instead of PVST+. The device combines the spanning-tree instance of the IEEE 802.1Q VLAN of the trunk with the spanning-tree instance of the non-Cisco IEEE 802.1Q device.

However, all PVST+ or Rapid PVST+ information is maintained by Cisco devices separated by a cloud of non-Cisco IEEE 802.1Q devices. The non-Cisco IEEE 802.1Q cloud separating the Cisco devices is treated as a single trunk link between the devices.

Rapid PVST+ is automatically enabled on IEEE 802.1Q trunks, and no user configuration is required. The external spanning-tree behavior on access ports and Inter-Switch Link (ISL) trunk ports is not affected by PVST+.

VLAN-Bridge Spanning Tree

Cisco VLAN-bridge spanning tree is used with the fallback bridging feature (bridge groups), which forwards non-IP protocols such as DECnet between two or more VLAN bridge domains or routed ports. The VLAN-bridge spanning tree allows the bridge groups to form a spanning tree on top of the individual VLAN spanning trees to prevent loops from forming if there are multiple connections among VLANs. It also prevents the individual spanning trees from the VLANs being bridged from collapsing into a single spanning tree.

To support VLAN-bridge spanning tree, some of the spanning-tree timers are increased. To use the fallback bridging feature, you must have the IP services feature set enabled on your device.

Spanning Tree and Device Stacks

When the device stack is operating in PVST+ or Rapid PVST+ mode:

- A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active stack.
- When a new device joins the stack, it sets its bridge ID to the active stack bridge ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root.
- When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.
- If the active stack fails or leaves the stack, the stack members elect a new active stack, and all stack members change their bridge IDs of the spanning trees to the new active stack bridge ID.

- If the device stack is the spanning-tree root and the active stack fails or leaves the stack, the stack members elect a new active stack, and a spanning-tree reconvergence occurs.
- If the device stack is the spanning-tree root and the active stack fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.
- If a neighboring device external to the device stack fails or is powered down, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of losing a device in the active topology.
- If a new device external to the device stack is added to the network, normal spanning-tree processing occurs. Spanning-tree reconvergence might occur as a result of adding a device in the network.

Default Spanning-Tree Configuration

Table 31: Default Spanning-Tree Configuration

| Feature | Default Setting |
|---|---|
| Enable state | Enabled on VLAN 1. |
| Spanning-tree mode | Rapid PVST+ (PVST+ and MSTP disabled.) |
| Device priority | 32768 |
| Spanning-tree port priority (configurable on a per-interface basis) | 128 |
| Spanning-tree port cost (configurable on a per-interface basis) | 1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100 |
| Spanning-tree VLAN port priority (configurable on a per-VLAN basis) | 128 |
| Spanning-tree VLAN port cost (configurable on a per-VLAN basis) | 1000 Mb/s: 4 100 Mb/s: 19 10 Mb/s: 100 |
| Spanning-tree timers | Hello time: 2 seconds Forward-delay time: 15 seconds Maximum-aging time: 20 seconds Transmit hold count: 6 BPDUs |

Note Beginning in Cisco IOS Release 15.2(4)E, the default STP mode is Rapid PVST+.

How to Configure Spanning-Tree Features

Changing the Spanning-Tree Mode

The switch supports three spanning-tree modes: per-VLAN spanning tree plus (PVST+), Rapid PVST+, or multiple spanning tree protocol (MSTP). By default, the device runs the Rapid PVST+ protocol.

If you want to enable a mode that is different from the default mode, this procedure is required.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | spanning-tree mode {pvst mst rapid-pvst} Example: <pre>Device(config)# spanning-tree mode pvst</pre> | Configures a spanning-tree mode. All stack members run the same version of spanning tree. <ul style="list-style-type: none"> • Select pvst to enable PVST+. • Select mst to enable MSTP. • Select rapid-pvst to enable rapid PVST+. |
| Step 4 | interface <i>interface-id</i> Example: <pre>Device(config)# interface GigabitEthernet1/0/1</pre> | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port channels. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48. |
| Step 5 | spanning-tree link-type point-to-point Example: <pre>Device(config-if)# spanning-tree link-type point-to-point</pre> | Specifies that the link type for this port is point-to-point. <p>If you connect this port (local port) to a remote port through a point-to-point link and the local port becomes a designated port, the device negotiates with the remote port and rapidly changes the local port to the forwarding state.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |
| Step 7 | clear spanning-tree detected-protocols Example: Device# clear spanning-tree detected-protocols | If any port on the device is connected to a port on a legacy IEEE 802.1D device, this command restarts the protocol migration process on the entire device. This step is optional if the designated device detects that this device is running rapid PVST+. |

Disabling Spanning Tree

Spanning tree is enabled by default on VLAN 1 and on all newly created VLANs up to the spanning-tree limit. Disable spanning tree only if you are sure there are no loops in the network topology.

Caution When spanning tree is disabled and loops are present in the topology, excessive traffic and indefinite packet duplication can drastically reduce network performance.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no spanning-tree vlan <i>vlan-id</i> Example: Device (config) # no spanning-tree vlan 300 | For <i>vlan-id</i> , the range is 1 to 4094. |
| Step 4 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|--|----------------------------|---------|
| | Device(config)# end | |

Configuring the Root Device

To configure a device as the root for the specified VLAN, use the **spanning-tree vlan *vlan-id* root** global configuration command to modify the device priority from the default value (32768) to a significantly lower value. When you enter this command, the software checks the device priority of the root devices for each VLAN. Because of the extended system ID support, the device sets its own priority for the specified VLAN to 24576 if this value will cause this device to become the root for the specified VLAN.

Use the **diameter** keyword to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree vlan <i>vlan-id</i> root primary [diameter <i>net-diameter</i> Example: Device(config)# spanning-tree vlan 20-24 root primary diameter 4 | Configures a device to become the root for the specified VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • (Optional) For diameter <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7. |

| | Command or Action | Purpose |
|---------------|--|----------------------------------|
| Step 4 | end Example: Device (config)# end | Returns to privileged EXEC mode. |

What to do next

After configuring the device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree vlan *vlan-id* hello-time**, **spanning-tree vlan *vlan-id* forward-time**, and the **spanning-tree vlan *vlan-id* max-age** global configuration commands.

Configuring a Secondary Root Device

When you configure a device as the secondary root, the device priority is modified from the default value (32768) to 28672. With this priority, the device is likely to become the root device for the specified VLAN if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768, and therefore, are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree vlan *vlan-id* root primary** global configuration command.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree vlan <i>vlan-id</i> root secondary [<i>diameter net-diameter</i>] Example: Device (config)# spanning-tree vlan 20-24 root secondary diameter 4 | Configures a device to become the secondary root for the specified VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <ul style="list-style-type: none"> (Optional) For diameter <i>net-diameter</i>, specify the maximum number of devices between any two end stations. The range is 2 to 7. <p>Use the same network diameter value that you used when configuring the primary root device.</p> |
| Step 4 | end Example: Device(config) # end | Returns to privileged EXEC mode. |

Configuring Port Priority

Note If your device is a member of a device stack, you must use the **spanning-tree [vlan *vlan-id*] cost *cost*** interface configuration command instead of the **spanning-tree [vlan *vlan-id*] port-priority *priority*** interface configuration command to select an interface to put in the forwarding state. Assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces (port-channel <i>port-channel-number</i>). |
| Step 4 | spanning-tree port-priority <i>priority</i> | Configures the port priority for an interface. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Example: Device(config-if) # spanning-tree port-priority 0 | For <i>priority</i> , the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority. |
| Step 5 | spanning-tree vlan <i>vlan-id</i> port-priority <i>priority</i> Example: Device(config-if) # spanning-tree vlan 20-25 port-priority 0 | Configures the port priority for a VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>priority</i>, the range is 0 to 240, in increments of 16; the default is 128. Valid values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. The lower the number, the higher the priority. |
| Step 6 | end Example: Device(config-if) # end | Returns to privileged EXEC mode. |

Configuring Path Cost

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config)# interface gigabitethernet 1/0/1 | include physical ports and port-channel logical interfaces (port-channel <i>port-channel-number</i>). |
| Step 4 | spanning-tree cost <i>cost</i> Example: Device(config-if)# spanning-tree cost 250 | Configures the cost for an interface. If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission. For <i>cost</i> , the range is 1 to 200000000; the default value is derived from the media speed of the interface. |
| Step 5 | spanning-tree vlan <i>vlan-id</i> cost <i>cost</i> Example: Device(config-if)# spanning-tree vlan 10,12-15,20 cost 300 | Configures the cost for a VLAN. If a loop occurs, spanning tree uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>cost</i>, the range is 1 to 200000000; the default value is derived from the media speed of the interface. |
| Step 6 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

The **show spanning-tree interface** *interface-id* privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

Configuring the Device Priority of a VLAN

You can configure the device priority and make it more likely that a standalone device or a device in the stack will be chosen as the root device.

Note Exercise care when using this command. For most situations, we recommend that you use the **spanning-tree vlan** *vlan-id* **root primary** and the **spanning-tree vlan** *vlan-id* **root secondary** global configuration commands to modify the device priority.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree vlan <i>vlan-id</i> priority <i>priority</i> Example: Device(config)# spanning-tree vlan 20 priority 8192 | Configures the device priority of a VLAN. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device. Valid priority values are 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. All other values are rejected. |
| Step 4 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring the Hello Time

The hello time is the time interval between configuration messages generated and sent by the root device.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | spanning-tree vlan <i>vlan-id</i> hello-time <i>seconds</i> Example: Device(config)# spanning-tree vlan 20-24 hello-time 3 | Configures the hello time of a VLAN. The hello time is the time interval between configuration messages generated and sent by the root device. These messages mean that the device is alive. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>seconds</i>, the range is 1 to 10; the default is 2. |
| Step 3 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring the Forwarding-Delay Time for a VLAN

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree vlan <i>vlan-id</i> forward-time <i>seconds</i> | Configures the forward time of a VLAN. The forwarding delay is the number of seconds an |

| | Command or Action | Purpose |
|---------------|--|--|
| | Example: Device(config)# spanning-tree vlan 20,25 forward-time 18 | interface waits before changing from its spanning-tree learning and listening states to the forwarding state. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. • For <i>seconds</i>, the range is 4 to 30; the default is 15. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuring the Maximum-Aging Time for a VLAN

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree vlan <i>vlan-id</i> max-age <i>seconds</i> Example: Device(config)# spanning-tree vlan 20 max-age 30 | Configures the maximum-aging time of a VLAN. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration. <ul style="list-style-type: none"> • For <i>vlan-id</i>, you can specify a single VLAN identified by VLAN ID number, a range of VLANs separated by a hyphen, or a series of VLANs separated by a comma. The range is 1 to 4094. |

| | Command or Action | Purpose |
|---------------|--|--|
| | | <ul style="list-style-type: none"> For <i>seconds</i>, the range is 6 to 40; the default is 20. |
| Step 4 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring the Transmit Hold-Count

You can configure the BPDU burst size by changing the transmit hold count value.

Note Changing this parameter to a higher value can have a significant impact on CPU utilization, especially in Rapid PVST+ mode. Lowering this value can slow down convergence in certain scenarios. We recommend that you maintain the default setting.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree transmit hold-count <i>value</i> Example: Device(config)# spanning-tree transmit hold-count 6 | Configures the number of BPDUs that can be sent before pausing for 1 second. For <i>value</i> , the range is 1 to 20; the default is 6. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Monitoring Spanning-Tree Status

Table 32: Commands for Displaying Spanning-Tree Status

| | |
|--|--|
| show spanning-tree active | Displays spanning-tree information on active interfaces only. |
| show spanning-tree detail | Displays a detailed summary of interface information. |
| show spanning-tree vlan <i>vlan-id</i> | Displays spanning-tree information for the specified VLAN. |
| show spanning-tree interface <i>interface-id</i> | Displays spanning-tree information for the specified interface. |
| show spanning-tree interface <i>interface-id</i> portfast | Displays spanning-tree portfast information for the specified interface. |
| show spanning-tree summary [totals] | Displays a summary of interface states or displays the total lines of the state section. |

To clear spanning-tree counters, use the **clear spanning-tree [interface *interface-id*]** privileged EXEC command.

Feature Information for STP

| Release | Modification |
|-----------------------------|------------------------------|
| Cisco IOS Release 15.0(2)EX | This feature was introduced. |

CHAPTER 18

Configuring Multiple Spanning-Tree Protocol

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for MSTP

- For two or more devices to be in the same multiple spanning tree (MST) region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For two or more stacked switches to be in the same MST region, they must have the same VLAN-to-instance map, the same configuration revision number, and the same name.
- For load-balancing across redundant paths in the network to work, all VLAN-to-instance mapping assignments must match; otherwise, all traffic flows on a single link. You can achieve load-balancing across a device stack by manually configuring the path cost.
- For load-balancing between a per-VLAN spanning tree plus (PVST+) and an MST cloud or between a rapid-PVST+ and an MST cloud to work, all MST boundary ports must be forwarding. MST boundary ports are forwarding when the root of the internal spanning tree (IST) of the MST cloud is the root of the common spanning tree (CST). If the MST cloud consists of multiple MST regions, one of the MST

regions must contain the CST root, and all of the other MST regions must have a better path to the root contained within the MST cloud than a path through the PVST+ or rapid-PVST+ cloud. You might have to manually configure the devices in the clouds.

Restrictions for MSTP

- The device stack supports up to 65 MST instances. The number of VLANs that can be mapped to a particular MST instance is unlimited.
- PVST+, Rapid PVST+, and MSTP are supported, but only one version can be active at any time. (For example, all VLANs run PVST+, all VLANs run Rapid PVST+, or all VLANs run MSTP.)
- All stack members must run the same version of spanning tree (all PVST+, Rapid PVST+, or MSTP).
- VLAN Trunking Protocol (VTP) propagation of the MST configuration is not supported. However, you can manually configure the MST configuration (region name, revision number, and VLAN-to-instance mapping) on each device within the MST region by using the command-line interface (CLI) or through the Simple Network Management Protocol (SNMP) support.
- Partitioning the network into a large number of regions is not recommended. However, if this situation is unavoidable, we recommend that you partition the switched LAN into smaller LANs interconnected by routers or non-Layer 2 devices.
- A region can have one member or multiple members with the same MST configuration; each member must be capable of processing rapid spanning tree protocol (RSTP) Bridge Protocol Data Units (BPDUs). There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.
- After configuring a device as the root device, we recommend that you avoid manually configuring the hello time, forward-delay time, and maximum-age time through the **spanning-tree mst hello-time**, **spanning-tree mst forward-time**, and the **spanning-tree mst max-age** global configuration commands.

Table 33: PVST+, MSTP, and Rapid PVST+ Interoperability and Compatibility

| | PVST+ | MSTP | Rapid PVST+ |
|-------------|-------------------------|-------------------------|------------------------|
| PVST+ | Yes | Yes (with restrictions) | Yes (reverts to PVST+) |
| MSTP | Yes (with restrictions) | Yes | Yes (reverts to PVST+) |
| Rapid PVST+ | Yes (reverts to PVST+) | Yes (reverts to PVST+) | Yes |

Information About MSTP

MSTP Configuration

MSTP, which uses RSTP for rapid convergence, enables multiple VLANs to be grouped into and mapped to the same spanning-tree instance, reducing the number of spanning-tree instances needed to support a large number of VLANs. The MSTP provides for multiple forwarding paths for data traffic, enables load balancing,

and reduces the number of spanning-tree instances required to support a large number of VLANs. It improves the fault tolerance of the network because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

Note The multiple spanning-tree (MST) implementation is based on the IEEE 802.1s standard.

The most common initial deployment of MSTP is in the backbone and distribution layers of a Layer 2 switched network. This deployment provides the highly available network required in a service-provider environment.

When the device is in the MST mode, the RSTP, which is based on IEEE 802.1w, is automatically enabled. The RSTP provides rapid convergence of the spanning tree through explicit handshaking that eliminates the IEEE 802.1D forwarding delay and quickly transitions root ports and designated ports to the forwarding state.

Both MSTP and RSTP improve the spanning-tree operation and maintain backward compatibility with equipment that is based on the (original) IEEE 802.1D spanning tree, with existing Cisco-proprietary Multiple Instance STP (MISTP), and with existing Cisco PVST+ and rapid per-VLAN spanning-tree plus (Rapid PVST+).

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same device ID.

MSTP Configuration Guidelines

- When you enable MST by using the **spanning-tree mode mst** global configuration command, RSTP is automatically enabled.
- For configuration guidelines about UplinkFast, BackboneFast, and cross-stack UplinkFast, see the relevant sections in the Related Topics section.
- When the device is in MST mode, it uses the long path-cost calculation method (32 bits) to compute the path cost values. With the long path-cost calculation method, the following path cost values are supported:

| Speed | Path Cost Value |
|----------|-----------------|
| 10 Mb/s | 2,000,000 |
| 100 Mb/s | 200,000 |
| 1 Gb/s | 20,000 |
| 10 Gb/s | 2,000 |
| 100 Gb/s | 200 |

Root Switch

The device maintains a spanning-tree instance for the group of VLANs mapped to it. A device ID, consisting of the device priority and the device MAC address, is associated with each instance. For a group of VLANs, the device with the lowest device ID becomes the root device.

When you configure a device as the root, you modify the device priority from the default value (32768) to a significantly lower value so that the device becomes the root device for the specified spanning-tree instance. When you enter this command, the device checks the device priorities of the root devices. Because of the extended system ID support, the device sets its own priority for the specified instance to 24576 if this value will cause this devices to become the root for the specified spanning-tree instance.

If any root device for the specified instance has a device priority lower than 24576, the device sets its own priority to 4096 less than the lowest device priority. (4096 is the value of the least-significant bit of a 4-bit device priority value. For more information, select "Bridge ID, Device Priority, and Extended System ID" link in Related Topics.

If your network consists of devices that support and do not support the extended system ID, it is unlikely that the device with the extended system ID support will become the root device. The extended system ID increases the device priority value every time the VLAN number is greater than the priority of the connected switches running older software.

The root device for each spanning-tree instance should be a backbone or distribution device. Do not configure an access device as the spanning-tree primary root.

Use the **diameter** keyword, which is available only for MST instance 0, to specify the Layer 2 network diameter (that is, the maximum number of device hops between any two end stations in the Layer 2 network). When you specify the network diameter, the device automatically sets an optimal hello time, forward-delay time, and maximum-age time for a network of that diameter, which can significantly reduce the convergence time. You can use the **hello** keyword to override the automatically calculated hello time.

Multiple Spanning-Tree Regions

For switches to participate in multiple spanning-tree (MST) instances, you must consistently configure the switches with the same MST configuration information. A collection of interconnected switches that have the same MST configuration comprises an MST region.

The MST configuration controls to which MST region each device belongs. The configuration includes the name of the region, the revision number, and the MST VLAN-to-instance assignment map. You configure the device for a region by specifying the MST region configuration on it. You can map VLANs to an MST instance, specify the region name, and set the revision number. For instructions and an example, select the "Specifying the MST Region Configuration and Enabling MSTP" link in Related Topics.

A region can have one or multiple members with the same MST configuration. Each member must be capable of processing RSTP bridge protocol data units (BPDUs). There is no limit to the number of MST regions in a network, but each region can support up to 65 spanning-tree instances. Instances can be identified by any number in the range from 0 to 4094. You can assign a VLAN to only one spanning-tree instance at a time.

IST, CIST, and CST

Unlike PVST+ and Rapid PVST+ in which all the spanning-tree instances are independent, the MSTP establishes and maintains two types of spanning trees:

- An internal spanning tree (IST), which is the spanning tree that runs in an MST region.

Within each MST region, the MSTP maintains multiple spanning-tree instances. Instance 0 is a special instance for a region, known as the internal spanning tree (IST). All other MST instances are numbered from 1 to 4094.

The IST is the only spanning-tree instance that sends and receives BPDUs. All of the other spanning-tree instance information is contained in M-records, which are encapsulated within MSTP BPDUs. Because

the MSTP BPDU carries information for all instances, the number of BPDUs that need to be processed to support multiple spanning-tree instances is significantly reduced.

All MST instances within the same region share the same protocol timers, but each MST instance has its own topology parameters, such as root device ID, root path cost, and so forth. By default, all VLANs are assigned to the IST.

An MST instance is local to the region; for example, MST instance 1 in region A is independent of MST instance 1 in region B, even if regions A and B are interconnected.

- A common and internal spanning tree (CIST), which is a collection of the ISTs in each MST region, and the common spanning tree (CST) that interconnects the MST regions and single spanning trees.

The spanning tree computed in a region appears as a subtree in the CST that encompasses the entire switched domain. The CIST is formed by the spanning-tree algorithm running among switches that support the IEEE 802.1w, IEEE 802.1s, and IEEE 802.1D standards. The CIST inside an MST region is the same as the CST outside a region.

Operations Within an MST Region

The IST connects all the MSTP switches in a region. When the IST converges, the root of the IST becomes the CIST regional root (called the *IST master* before the implementation of the IEEE 802.1s standard). It is the device within the region with the lowest device ID and path cost to the CIST root. The CIST regional root is also the CIST root if there is only one region in the network. If the CIST root is outside the region, one of the MSTP switches at the boundary of the region is selected as the CIST regional root.

When an MSTP device initializes, it sends BPDUs claiming itself as the root of the CIST and the CIST regional root, with both of the path costs to the CIST root and to the CIST regional root set to zero. The device also initializes all of its MST instances and claims to be the root for all of them. If the device receives superior MST root information (lower device ID, lower path cost, and so forth) than currently stored for the port, it relinquishes its claim as the CIST regional root.

During initialization, a region might have many subregions, each with its own CIST regional root. As switches receive superior IST information, they leave their old subregions and join the new subregion that contains the true CIST regional root. All subregions shrink except for the one that contains the true CIST regional root.

For correct operation, all switches in the MST region must agree on the same CIST regional root. Therefore, any two switches in the region only synchronize their port roles for an MST instance if they converge to a common CIST regional root.

Operations Between MST Regions

If there are multiple regions or legacy IEEE 802.1D devices within the network, MSTP establishes and maintains the CST, which includes all MST regions and all legacy STP devices in the network. The MST instances combine with the IST at the boundary of the region to become the CST.

The IST connects all the MSTP devices in the region and appears as a subtree in the CIST that encompasses the entire switched domain. The root of the subtree is the CIST regional root. The MST region appears as a virtual device to adjacent STP devices and MST regions.

Only the CST instance sends and receives BPDUs, and MST instances add their spanning-tree information into the BPDUs to interact with neighboring devices and compute the final spanning-tree topology. Because of this, the spanning-tree parameters related to BPDU transmission (for example, hello time, forward time, max-age, and max-hops) are configured only on the CST instance but affect all MST instances. Parameters related to the spanning-tree topology (for example, device priority, port VLAN cost, and port VLAN priority) can be configured on both the CST instance and the MST instance.

MSTP devices use Version 3 RSTP BPDUs or IEEE 802.1D STP BPDUs to communicate with legacy IEEE 802.1D devices. MSTP devices use MSTP BPDUs to communicate with MSTP devices.

IEEE 802.1s Terminology

Some MST naming conventions used in Cisco's prestandard implementation have been changed to identify some *internal* or *regional* parameters. These parameters are significant only within an MST region, as opposed to external parameters that are relevant to the whole network. Because the CIST is the only spanning-tree instance that spans the whole network, only the CIST parameters require the external rather than the internal or regional qualifiers.

- The CIST root is the root device for the unique instance that spans the whole network, the CIST.
- The CIST external root path cost is the cost to the CIST root. This cost is left unchanged within an MST region. Remember that an MST region looks like a single device for the CIST. The CIST external root path cost is the root path cost calculated between these virtual devices and devices that do not belong to any region.
- The CIST regional root was called the IST master in the prestandard implementation. If the CIST root is in the region, the CIST regional root is the CIST root. Otherwise, the CIST regional root is the closest device to the CIST root in the region. The CIST regional root acts as a root device for the IST.
- The CIST internal root path cost is the cost to the CIST regional root in a region. This cost is only relevant to the IST, instance 0.

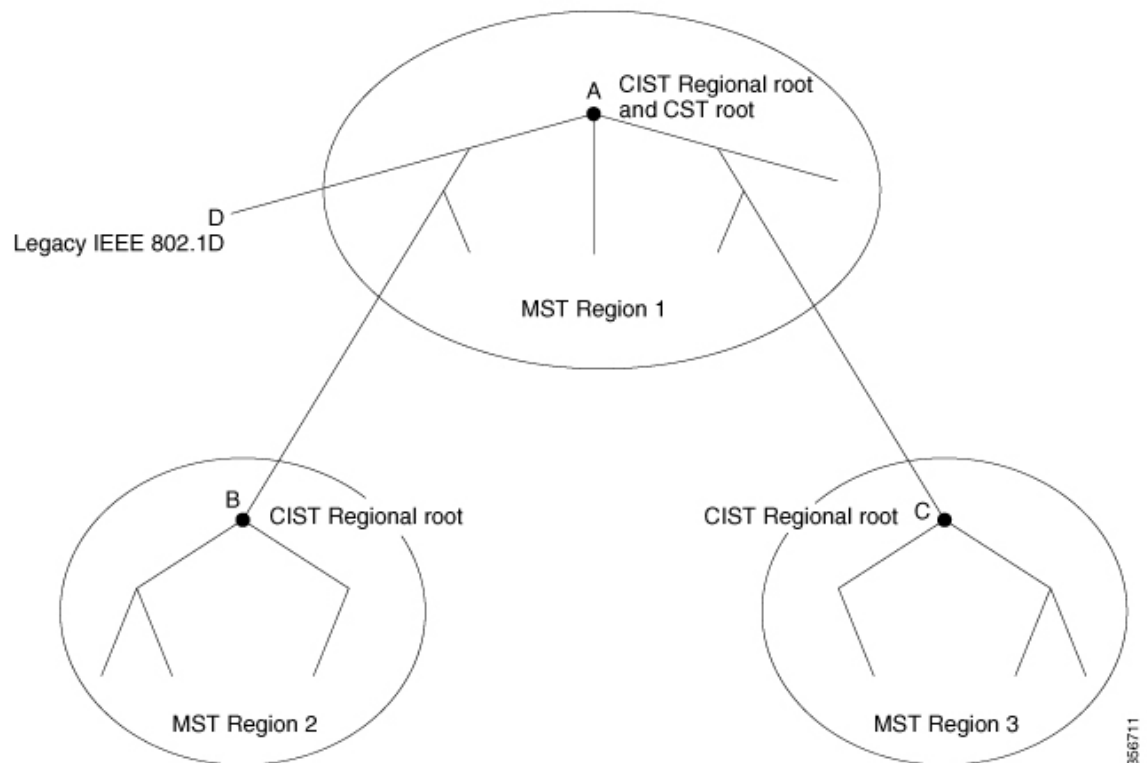

Table 34: Prestandard and Standard Terminology

| IEEE Standard | Cisco Prestandard | Cisco Standard |
|------------------------------|----------------------|-------------------------|
| CIST regional root | IST master | CIST regional root |
| CIST internal root path cost | IST master path cost | CIST internal path cost |
| CIST external root path cost | Root path cost | Root path cost |
| MSTI regional root | Instance root | Instance root |
| MSTI internal root path cost | Root path cost | Root path cost |

Illustration of MST Regions

This figure displays three MST regions and a legacy IEEE 802.1D device (D). The CIST regional root for region 1 (A) is also the CIST root. The CIST regional root for region 2 (B) and the CIST regional root for region 3 (C) are the roots for their respective subtrees within the CIST. The RSTP runs in all regions.

Figure 18: MST Regions, CIST Regional Root, and CST Root

Hop Count

The IST and MST instances do not use the message-age and maximum-age information in the configuration BPDU to compute the spanning-tree topology. Instead, they use the path cost to the root and a hop-count mechanism similar to the IP time-to-live (TTL) mechanism.

By using the **spanning-tree mst max-hops** global configuration command, you can configure the maximum hops inside the region and apply it to the IST and all MST instances in that region. The hop count achieves the same result as the message-age information (triggers a reconfiguration). The root device of the instance always sends a BPDU (or M-record) with a cost of 0 and the hop count set to the maximum value. When a device receives this BPDU, it decrements the received remaining hop count by one and propagates this value as the remaining hop count in the BPDUs it generates. When the count reaches zero, the device discards the BPDU and ages the information held for the port.

The message-age and maximum-age information in the RSTP portion of the BPDU remain the same throughout the region, and the same values are propagated by the region designated ports at the boundary.

Boundary Ports

In the Cisco prestandard implementation, a boundary port connects an MST region to a single spanning-tree region running RSTP, to a single spanning-tree region running PVST+ or rapid PVST+, or to another MST region with a different MST configuration. A boundary port also connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

There is no definition of a boundary port in the IEEE 802.1s standard. The IEEE 802.1Q-2002 standard identifies two kinds of messages that a port can receive:

- internal (coming from the same region)
- external (coming from another region)

When a message is internal, the CIST part is received by the CIST, and each MST instance receives its respective M-record.

When a message is external, it is received only by the CIST. If the CIST role is root or alternate, or if the external BPDU is a topology change, it could have an impact on the MST instances.

An MST region includes both devices and LANs. A segment belongs to the region of its designated port. Therefore, a port in a different region than the designated port for a segment is a boundary port. This definition allows two ports internal to a region to share a segment with a port belonging to a different region, creating the possibility of a port receiving both internal and external messages.

The primary change from the Cisco prestandard implementation is that a designated port is not defined as boundary, unless it is running in an STP-compatible mode.

Note If there is a legacy STP device on the segment, messages are always considered external.

The other change from the Cisco prestandard implementation is that the CIST regional root device ID field is now inserted where an RSTP or legacy IEEE 802.1Q device has the sender device ID. The whole region performs like a single virtual device by sending a consistent sender device ID to neighboring devices. In this example, device C would receive a BPDU with the same consistent sender device ID of root, whether or not A or B is designated for the segment.

IEEE 802.1s Implementation

The Cisco implementation of the IEEE MST standard includes features required to meet the standard, as well as some of the desirable prestandard functionality that is not yet incorporated into the published standard.

Port Role Naming Change

The boundary role is no longer in the final MST standard, but this boundary concept is maintained in Cisco's implementation. However, an MST instance port at a boundary of the region might not follow the state of the corresponding CIST port. Two boundary roles currently exist:

- The boundary port is the root port of the CIST regional root—When the CIST instance port is proposed and is in sync, it can send back an agreement and move to the forwarding state only after all the corresponding MSTI ports are in sync (and thus forwarding). The MSTI ports now have a special *primary* role.
- The boundary port is not the root port of the CIST regional root—The MSTI ports follow the state and role of the CIST port. The standard provides less information, and it might be difficult to understand why an MSTI port can be alternately blocking when it receives no BPDUs (MRecords). In this case, although the boundary role no longer exists, the **show** commands identify a port as boundary in the *type* column of the output.

Interoperation Between Legacy and Standard Devices

Because automatic detection of prestandard devices can fail, you can use an interface configuration command to identify prestandard ports. A region cannot be formed between a standard and a prestandard device, but they can interoperate by using the CIST. Only the capability of load-balancing over different instances is lost in that particular case. The CLI displays different flags depending on the port configuration when a port receives prestandard BPDUs. A syslog message also appears the first time a device receives a prestandard BPDU on a port that has not been configured for prestandard BPDU transmission.

Figure 19: Standard and Prestandard Device Interoperation

Assume that A is a standard device and B a prestandard device, both configured to be in the same region. A is the root device for the CIST, and B has a root port (BX) on segment X and an alternate port (BY) on segment Y. If segment Y flaps, and the port on BY becomes the alternate before sending out a single prestandard BPDU, AY cannot detect that a prestandard device is connected to Y and continues to send standard BPDUs. The port BY is fixed in a boundary, and no load balancing is possible between A and B. The same problem exists on segment X, but B might transmit topology

Note We recommend that you minimize the interaction between standard and prestandard MST implementations.

Detecting Unidirectional Link Failure

This feature is not yet present in the IEEE MST standard, but it is included in this Cisco IOS release. The software checks the consistency of the port role and state in the received BPDUs to detect unidirectional link failures that could cause bridging loops.

When a designated port detects a conflict, it keeps its role, but reverts to the discarding state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

Figure 20: Detecting Unidirectional Link Failure

This figure illustrates a unidirectional link failure that typically creates a bridging loop. Device A is the root device, and its BPDUs are lost on the link leading to device B. RSTP and MST BPDUs include the role and state of the sending port. With this information, device A can detect that device B does not react to the superior

BPDUs it sends and that device B is the designated, not root device. As a result, device A blocks (or keeps

blocking) its port, which prevents the bridging loop.

MSTP and Device Stacks

A device stack appears as a single spanning-tree node to the rest of the network, and all stack members use the same bridge ID for a given spanning tree. The bridge ID is derived from the MAC address of the active stack.

The active stack is the stack root when the stack is the root of the network and no root selection has been made within the stack.

If the device stack is the spanning-tree root and the active stack fails or leaves the stack, the standby switch becomes the new active switch, bridge IDs remain the same, and a spanning-tree reconvergence might occur.

If a device that does not support MSTP is added to a device stack that does support MSTP or the reverse, the device is put into a version mismatch state. If possible, the device is automatically upgraded or downgraded to the same version of software that is running on the device stack.

When a new device joins the stack, it sets its device ID to the device ID. If the newly added device has the lowest ID and if the root path cost is the same among all stack members, the newly added device becomes the stack root. A topology change occurs if the newly added device contains a better root port for the device stack or a better designated port for the LAN connected to the stack. The newly added device causes a topology change in the network if another device connected to the newly added device changes its root port or designated ports.

When a stack member leaves the stack, spanning-tree reconvergence occurs within the stack (and possibly outside the stack). The remaining stack member with the lowest stack port ID becomes the stack root.

If the active stack fails or leaves the stack, the stack members elect a new active stack, and all stack members change the device IDs of the spanning trees to the new active device ID.

Interoperability with IEEE 802.1D STP

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MSTP BPDU (Version 3) associated with a different region, or an RSTP BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device might also continue to assign a boundary role to a port when the device to which this device is connected has joined the region. To restart the protocol migration process (force the renegotiation with neighboring devices), use the **clear spanning-tree detected-protocols** privileged EXEC command.

If all the legacy devices on the link are RSTP devices, they can process MSTP BPDUs as if they are RSTP BPDUs. Therefore, MSTP devices send either a Version 0 configuration and TCN BPDUs or Version 3 MSTP BPDUs on a boundary port. A boundary port connects to a LAN, the designated device of which is either a single spanning-tree device or a device with a different MST configuration.

RSTP Overview

The RSTP takes advantage of point-to-point wiring and provides rapid convergence of the spanning tree. Reconfiguration of the spanning tree can occur in less than 1 second (in contrast to 50 seconds with the default settings in the IEEE 802.1D spanning tree).

Port Roles and the Active Topology

The RSTP provides rapid convergence of the spanning tree by assigning port roles and by learning the active topology. The RSTP builds upon the IEEE 802.1D STP to select the device with the highest device priority (lowest numerical priority value) as the root device. The RSTP then assigns one of these port roles to individual ports:

- Root port—Provides the best path (lowest cost) when the device forwards packets to the root device.
- Designated port—Connects to the designated device, which incurs the lowest path cost when forwarding packets from that LAN to the root device. The port through which the designated device is attached to the LAN is called the designated port.
- Alternate port—Offers an alternate path toward the root device to that provided by the current root port.
- Backup port—Acts as a backup for the path provided by a designated port toward the leaves of the spanning tree. A backup port can exist only when two ports are connected in a loopback by a point-to-point link or when a device has two or more connections to a shared LAN segment.
- Disabled port—Has no role within the operation of the spanning tree.

A port with the root or a designated port role is included in the active topology. A port with the alternate or backup port role is excluded from the active topology.

In a stable topology with consistent port roles throughout the network, the RSTP ensures that every root port and designated port immediately transition to the forwarding state while all alternate and backup ports are always in the discarding state (equivalent to blocking in IEEE 802.1D). The port state controls the operation of the forwarding and learning processes.

Table 35: Port State Comparison

| Operational Status | STP Port State (IEEE 802.1D) | RSTP Port State | Is Port Included in the Active Topology? |
|--------------------|------------------------------|-----------------|--|
| Enabled | Blocking | Discarding | No |
| Enabled | Listening | Discarding | No |
| Enabled | Learning | Learning | Yes |
| Enabled | Forwarding | Forwarding | Yes |
| Disabled | Disabled | Discarding | No |

To be consistent with Cisco STP implementations, this guide defines the port state as *blocking* instead of *discarding*. Designated ports start in the listening state.

Rapid Convergence

The RSTP provides for rapid recovery of connectivity following the failure of a device, a device port, or a LAN. It provides rapid convergence for edge ports, new root ports, and ports connected through point-to-point links as follows:

- Edge ports—If you configure a port as an edge port on an RSTP device by using the **spanning-tree portfast** interface configuration command, the edge port immediately transitions to the forwarding state. An edge port is the same as a Port Fast-enabled port, and you should enable it only on ports that connect to a single end station.
- Root ports—If the RSTP selects a new root port, it blocks the old root port and immediately transitions the new root port to the forwarding state.
- Point-to-point links—If you connect a port to another port through a point-to-point link and the local port becomes a designated port, it negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

Figure 21: Proposal and Agreement Handshaking for Rapid Convergence

Device A is connected to Device B through a point-to-point link, and all of the ports are in the blocking state. Assume that the priority of Device A is a smaller numerical value than the priority of Device B. Device A sends a proposal message (a configuration BPDU with the proposal flag set) to Device B, proposing itself as the designated device.

After receiving the proposal message, Device B selects as its new root port the port from which the proposal message was received, forces all nonedge ports to the blocking state, and sends an agreement message (a BPDU with the agreement flag set) through its new root port.

After receiving Device B's agreement message, Device A also immediately transitions its designated port to the forwarding state. No loops in the network are formed because Device B blocked all of its nonedge ports and because there is a point-to-point link between Devices A and B.

When Device C is connected to Device B, a similar set of handshaking messages are exchanged. Device C selects the port connected to Device B as its root port, and both ends immediately transition to the forwarding state. With each iteration of this handshaking process, one more device joins the active topology. As the network converges, this proposal-agreement handshaking progresses from the root toward the leaves of the spanning tree.

In a device stack, the cross-stack rapid transition (CSRT) feature ensures that a stack member receives acknowledgments from all stack members during the proposal-agreement handshaking before moving the port to the forwarding state. CSRT is automatically enabled when the device is in MST mode.

The device learns the link type from the port duplex mode: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. You can override the default setting that is controlled by the duplex setting by using the **spanning-tree link-type** interface configuration command.

Synchronization of Port Roles

When the device receives a proposal message on one of its ports and that port is selected as the new root port, the RSTP forces all other ports to synchronize with the new root information.

The device is synchronized with superior root information received on the root port if all other ports are synchronized. An individual port on the device is synchronized if

- That port is in the blocking state.
- It is an edge port (a port configured to be at the edge of the network).

If a designated port is in the forwarding state and is not configured as an edge port, it transitions to the blocking state when the RSTP forces it to synchronize with new root information. In general, when the RSTP forces a port to synchronize with root information and the port does not satisfy any of the above conditions, its port state is set to blocking.

Figure 22: Sequence of Events During Rapid Convergence

After ensuring that all of the ports are synchronized, the device sends an agreement message to the designated device corresponding to its root port. When the devices connected by a point-to-point link are in agreement

about their port roles, the RSTP immediately transitions the port states to forwarding.

Bridge Protocol Data Unit Format and Processing

The RSTP BPDU format is the same as the IEEE 802.1D BPDU format except that the protocol version is set to 2. A new 1-byte Version 1 Length field is set to zero, which means that no version 1 protocol information is present.

Table 36: RSTP BPDU Flags

| Bit | Function |
|------|---------------------------------------|
| 0 | Topology change (TC) |
| 1 | Proposal |
| 2–3: | Port role: |
| 00 | Unknown |
| 01 | Alternate port |
| 10 | Root port |
| 11 | Designated port |
| 4 | Learning |
| 5 | Forwarding |
| 6 | Agreement |
| 7 | Topology change acknowledgement (TCA) |

The sending device sets the proposal flag in the RSTP BPDU to propose itself as the designated device on that LAN. The port role in the proposal message is always set to the designated port.

The sending device sets the agreement flag in the RSTP BPDU to accept the previous proposal. The port role in the agreement message is always set to the root port.

The RSTP does not have a separate topology change notification (TCN) BPDU. It uses the topology change (TC) flag to show the topology changes. However, for interoperability with IEEE 802.1D devices, the RSTP device processes and generates TCN BPDUs.

The learning and forwarding flags are set according to the state of the sending port.

Processing Superior BPDU Information

If a port receives superior root information (lower device ID, lower path cost, and so forth) than currently stored for the port, the RSTP triggers a reconfiguration. If the port is proposed and is selected as the new root port, RSTP forces all the other ports to synchronize.

If the BPDU received is an RSTP BPDU with the proposal flag set, the device sends an agreement message after all of the other ports are synchronized. If the BPDU is an IEEE 802.1D BPDU, the device does not set the proposal flag and starts the forward-delay timer for the port. The new root port requires twice the forward-delay time to transition to the forwarding state.

If the superior information received on the port causes the port to become a backup or alternate port, RSTP sets the port to the blocking state but does not send the agreement message. The designated port continues sending BPDUs with the proposal flag set until the forward-delay timer expires, at which time the port transitions to the forwarding state.

Processing Inferior BPDU Information

If a designated port receives an inferior BPDU (such as a higher device ID or a higher path cost than currently stored for the port) with a designated port role, it immediately replies with its own information.

Topology Changes

This section describes the differences between the RSTP and the IEEE 802.1D in handling spanning-tree topology changes.

- **Detection**—Unlike IEEE 802.1D in which *any* transition between the blocking and the forwarding state causes a topology change, *only* transitions from the blocking to the forwarding state cause a topology change with RSTP (only an increase in connectivity is considered a topology change). State changes on an edge port do not cause a topology change. When an RSTP device detects a topology change, it deletes the learned information on all of its nonedge ports except on those from which it received the TC notification.
- **Notification**—Unlike IEEE 802.1D, which uses TCN BPDUs, the RSTP does not use them. However, for IEEE 802.1D interoperability, an RSTP device processes and generates TCN BPDUs.
- **Acknowledgement**—When an RSTP device receives a TCN message on a designated port from an IEEE 802.1D device, it replies with an IEEE 802.1D configuration BPDU with the TCA bit set. However, if the TC-while timer (the same as the topology-change timer in IEEE 802.1D) is active on a root port connected to an IEEE 802.1D device and a configuration BPDU with the TCA bit set is received, the TC-while timer is reset.

This behavior is only required to support IEEE 802.1D devices. The RSTP BPDUs never have the TCA bit set.

- **Propagation**—When an RSTP device receives a TC message from another device through a designated or root port, it propagates the change to all of its nonedge, designated ports and to the root port (excluding

the port on which it is received). The device starts the TC-while timer for all such ports and flushes the information learned on them.

- Protocol migration—For backward compatibility with IEEE 802.1D devices, RSTP selectively sends IEEE 802.1D configuration BPDUs and TCN BPDUs on a per-port basis.

When a port is initialized, the migrate-delay timer is started (specifies the minimum time during which RSTP BPDUs are sent), and RSTP BPDUs are sent. While this timer is active, the device processes all BPDUs received on that port and ignores the protocol type.

If the device receives an IEEE 802.1D BPDU after the port migration-delay timer has expired, it assumes that it is connected to an IEEE 802.1D device and starts using only IEEE 802.1D BPDUs. However, if the RSTP device is using IEEE 802.1D BPDUs on a port and receives an RSTP BPDU after the timer has expired, it restarts the timer and starts using RSTP BPDUs on that port.

Protocol Migration Process

A device running MSTP supports a built-in protocol migration mechanism that enables it to interoperate with legacy IEEE 802.1D devices. If this device receives a legacy IEEE 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only IEEE 802.1D BPDUs on that port. An MSTP device also can detect that a port is at the boundary of a region when it receives a legacy BPDU, an MST BPDU (Version 3) associated with a different region, or an RST BPDU (Version 2).

However, the device does not automatically revert to the MSTP mode if it no longer receives IEEE 802.1D BPDUs because it cannot detect whether the legacy device has been removed from the link unless the legacy device is the designated device. A device also might continue to assign a boundary role to a port when the device to which it is connected has joined the region.

Default MSTP Configuration

Table 37: Default MSTP Configuration

| Feature | Default Setting |
|---|--|
| Spanning-tree mode | MSTP |
| Device priority (configurable on a per-CIST port basis) | 32768 |
| Spanning-tree port priority (configurable on a per-CIST port basis) | 128 |
| Spanning-tree port cost (configurable on a per-CIST port basis) | 1000 Mb/s: 20000 100 Mb/s: 20000 10 Mb/s: 20000 1000 Mb/s: 20000 100 Mb/s: 20000 10 Mb/s: 20000 |
| Hello time | 3 seconds |
| Forward-delay time | 20 seconds |

| Feature | Default Setting |
|--------------------|-----------------|
| Maximum-aging time | 20 seconds |
| Maximum hop count | 20 hops |

About MST-to-PVST+ Interoperability (PVST+ Simulation)

The PVST+ simulation feature enables seamless interoperability between MST and Rapid PVST+. You can enable or disable this per port, or globally. PVST+ simulation is enabled by default.

However, you may want to control the connection between MST and Rapid PVST+ to protect against accidentally connecting an MST-enabled port to a Rapid PVST+-enabled port. Because Rapid PVST+ is the default STP mode, you may encounter many Rapid PVST+-enabled connections.

Disabling this feature causes the switch to stop the MST region from interacting with PVST+ regions. The MST-enabled port moves to a PVST peer inconsistent (blocking) state once it detects it is connected to a Rapid PVST+-enabled port. This port remains in the inconsistent state until the port stops receiving Shared Spanning Tree Protocol (SSTP) BPDUs, and then the port resumes the normal STP transition process.

You can for instance, disable PVST+ simulation, to prevent an incorrectly configured switch from connecting to a network where the STP mode is not MSTP (the default mode is PVST+).

Observe these guidelines when you configure MST switches (in the same region) to interact with PVST+ switches:

- Configure the root for all VLANs inside the MST region as shown in this example:

```
Switch# show spanning-tree mst interface gigabitethernet 1/1
GigabitEthernet1/1 of MST00 is root forwarding
Edge port: no (trunk) port guard : none (default)
Link type: point-to-point (auto) bpdu filter: disable (default)
Boundary : boundary (PVST) bpdu guard : disable (default)
Bpdus sent 10, received 310
```

```
Instance Role Sts Cost Prio.Nbr Vlans mapped
-----
0 Root FWD 20000 128.1 1-2,4-2999,4000-4094
3 Boun FWD 20000 128.1 3,3000-3999
```

The ports that belong to the MST switch at the boundary simulate PVST+ and send PVST+ BPDUs for all the VLANs.

If you enable loop guard on the PVST+ switches, the ports might change to a loop-inconsistent state when the MST switches change their configuration. To correct the loop-inconsistent state, you must disable and re-enable loop guard on that PVST+ switch.

- Do not locate the root for some or all of the VLANs inside the PVST+ side of the MST switch because when the MST switch at the boundary receives PVST+ BPDUs for all or some of the VLANs on its designated ports, root guard sets the port to the blocking state.
- When you connect a PVST+ switch to two different MST regions, the topology change from the PVST+ switch does not pass beyond the first MST region. In such a case, the topology changes are propagated only in the instance to which the VLAN is mapped. The topology change stays local to the first MST region, and the Cisco Access Manager (CAM) entries in the other region are not flushed. To make the topology change visible throughout other MST regions, you can map that VLAN to IST or connect the PVST+ switch to the two regions through access links.

- When you disable the PVST+ simulation, note that the PVST+ peer inconsistency can also occur while the port is already in other states of inconsistency. For example, the root bridge for all STP instances must all be in either the MST region or the Rapid PVST+ side. If the root bridge for all STP instances are not on one side or the other, the software moves the port into a PVST+ simulation-inconsistent state.

Note We recommend that you put the root bridge for all STP instances in the MST region.

About Detecting Unidirectional Link Failure

The dispute mechanism that detects unidirectional link failures is included in the IEEE 802.1D-2004 RSTP and IEEE 802.1Q-2005 MSTP standard, and requires no user configuration.

The switch checks the consistency of the port role and state in the BPDUs it receives, to detect unidirectional link failures that could cause bridging loops. When a designated port detects a conflict, it keeps its role, but reverts to a discarding (blocking) state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

For example, in the figure below, Switch A is the root bridge and Switch B is the designated port. BPDUs from Switch A are lost on the link leading to switch B.

Figure 23: Detecting Unidirectional Link Failure

Since Rapid PVST+ (802.1w) and MST BPDUs include the role and state of the sending port, Switch A detects (from the inferior BPDU), that switch B does not react to the superior BPDUs it sends, because switch B has the role of a designated port and not the root bridge. As a result, switch A blocks (or keeps blocking) its port, thus preventing the bridging loop.

Note these guidelines and limitations relating to the dispute mechanism:

- It works only on switches running RSTP or MST (the dispute mechanism requires reading the role and state of the port initiating BPDUs).
- It may result in loss of connectivity. For example, in the figure below, Bridge A cannot transmit on the port it elected as a root port. As a result of this situation, there is loss of connectivity (r1 and r2 are designated, a1 is root and a2 is alternate. There is only a one way connectivity between A and R).

Figure 24: Loss of Connectivity

- It may cause permanent bridging loops on shared segments. For example, in the figure below, suppose that bridge R has the best priority, and that port b1 cannot receive any traffic from the shared segment 1 and sends inferior designated information on segment 1. Both r1 and a1 can detect this inconsistency. However, with the current dispute mechanism, only r1 will revert to discarding while the root port a1 opens a permanent loop. However, this problem does not occur in Layer 2 switched networks that are connected by point-to-point links.

Figure 25: Bridging Loops on Shared Segments

How to Configure MSTP Features

Specifying the MST Region Configuration and Enabling MSTP

For two or more switches to be in the same MST region, they must have the same VLAN-to-instance mapping, the same configuration revision number, and the same name.

A region can have one member or multiple members with the same MST configuration; each member must be capable of processing RSTP BPDUs. There is no limit to the number of MST regions in a network, but each region can only support up to 65 spanning-tree instances. You can assign a VLAN to only one spanning-tree instance at a time.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree mst configuration Example: Device (config) # spanning-tree mst configuration | Enters MST configuration mode. |
| Step 4 | instance <i>instance-id</i> vlan <i>vlan-range</i> Example: Device (config-mst) # instance 1 vlan 10-20 | Maps VLANs to an MST instance. <ul style="list-style-type: none"> • For <i>instance-id</i>, the range is 0 to 4094. • For vlan <i>vlan-range</i>, the range is 1 to 4094. When you map VLANs to an MST instance, the mapping is incremental, and the VLANs specified in the command are added to or removed from the VLANs that were previously mapped. <p>To specify a VLAN range, use a hyphen; for example, instance 1 vlan 1-63 maps VLANs 1 through 63 to MST instance 1.</p> <p>To specify a VLAN series, use a comma; for example, instance 1 vlan 10, 20, 30 maps VLANs 10, 20, and 30 to MST instance 1.</p> |
| Step 5 | name <i>name</i> Example: Device (config-mst) # name region1 | Specifies the configuration name. The <i>name</i> string has a maximum length of 32 characters and is case sensitive. |
| Step 6 | revision <i>version</i> Example: Device (config-mst) # revision 1 | Specifies the configuration revision number. The range is 0 to 65535. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 7 | show pending Example: Device(config-mst)# show pending | Verifies your configuration by displaying the pending configuration. |
| Step 8 | exit Example: Device(config-mst)# exit | Applies all changes, and returns to global configuration mode. |
| Step 9 | spanning-tree mode mst Example: Device(config)# spanning-tree mode mst | Enables MSTP. RSTP is also enabled. Changing spanning-tree modes can disrupt traffic because all spanning-tree instances are stopped for the previous mode and restarted in the new mode. You cannot run both MSTP and PVST+ or both MSTP and Rapid PVST+ at the same time. |
| Step 10 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuring the Root Device

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. Step 2 in the example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree mst <i>instance-id</i> root primary Example: Device(config)# spanning-tree mst 0 root primary | Configures a device as the root device. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuring a Secondary Root Device

When you configure a device with the extended system ID support as the secondary root, the device priority is modified from the default value (32768) to 28672. The device is then likely to become the root device for the specified instance if the primary root device fails. This is assuming that the other network devices use the default device priority of 32768 and therefore are unlikely to become the root device.

You can execute this command on more than one device to configure multiple backup root devices. Use the same network diameter and hello-time values that you used when you configured the primary root device with the **spanning-tree mst *instance-id* root primary** global configuration command.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | spanning-tree mst <i>instance-id</i> root secondary Example: Device(config)# <code>spanning-tree mst 0 root secondary</code> | Configures a device as the secondary root device. <ul style="list-style-type: none"> For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

Configuring Port Priority

If a loop occurs, the MSTP uses the port priority when selecting an interface to put into the forwarding state. You can assign higher priority values (lower numerical values) to interfaces that you want selected first and lower priority values (higher numerical values) that you want selected last. If all interfaces have the same priority value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

Note If the device is a member of a device stack, you must use the **spanning-tree mst [*instance-id*] cost *cost*** interface configuration command instead of the **spanning-tree mst [*instance-id*] port-priority *priority*** interface configuration command to select a port to put in the forwarding state. Assign lower cost values to ports that you want selected first and higher cost values to ports that you want selected last. For more information, see the path costs topic listed under Related Topics.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 1/0/1 | Specifies an interface to configure, and enters interface configuration mode. |
| Step 4 | spanning-tree mst <i>instance-id</i> port-priority <i>priority</i> Example: Device (config-if) # spanning-tree mst 0 port-priority 64 | Configures port priority. <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. • For <i>priority</i>, the range is 0 to 240 in increments of 16. The default is 128. The lower the number, the higher the priority. The priority values are 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. All other values are rejected. |
| Step 5 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |

The **show spanning-tree mst interface *interface-id*** privileged EXEC command displays information only if the port is in a link-up operative state. Otherwise, you can use the **show running-config interface** privileged EXEC command to confirm the configuration.

Configuring Path Cost

The MSTP path cost default value is derived from the media speed of an interface. If a loop occurs, the MSTP uses cost when selecting an interface to put in the forwarding state. You can assign lower cost values to interfaces that you want selected first and higher cost values that you want selected last. If all interfaces have

the same cost value, the MSTP puts the interface with the lowest interface number in the forwarding state and blocks the other interfaces.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports and port-channel logical interfaces. The port-channel range is 1 to 48. |
| Step 4 | spanning-tree mst <i>instance-id</i> cost <i>cost</i> Example: Device(config-if)# spanning-tree mst 0 cost 17031970 | Configures the cost. <p>If a loop occurs, the MSTP uses the path cost when selecting an interface to place into the forwarding state. A lower path cost represents higher-speed transmission.</p> <ul style="list-style-type: none"> • For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. • For <i>cost</i>, the range is 1 to 200000000; the default value is derived from the media speed of the interface. |

| | Command or Action | Purpose |
|---------------|--|----------------------------------|
| Step 5 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |

The **show spanning-tree mst interface *interface-id*** privileged EXEC command displays information only for ports that are in a link-up operative state. Otherwise, you can use the **show running-config** privileged EXEC command to confirm the configuration.

Configuring the Device Priority

Changing the priority of a device makes it more likely to be chosen as the root device whether it is a standalone device or a device in the stack.

Note Exercise care when using this command. For normal network configurations, we recommend that you use the **spanning-tree mst *instance-id* root primary** and the **spanning-tree mst *instance-id* root secondary** global configuration commands to specify a device as the root or secondary root device. You should modify the device priority only in circumstances where these commands do not work.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID used. This example uses 0 as the instance ID because that was the instance ID set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree mst <i>instance-id</i> priority <i>priority</i> Example: | Configures the device priority. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>Device(config)# spanning-tree mst 0 priority 40960</pre> | <ul style="list-style-type: none"> For <i>instance-id</i>, you can specify a single instance, a range of instances separated by a hyphen, or a series of instances separated by a comma. The range is 0 to 4094. For <i>priority</i>, the range is 0 to 61440 in increments of 4096; the default is 32768. The lower the number, the more likely the device will be chosen as the root device. <p>Priority values are 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. These are the only acceptable values.</p> |
| Step 4 | <pre>end</pre> <p>Example:</p> <pre>Device(config-if)# end</pre> | Returns to privileged EXEC mode. |

Configuring the Hello Time

The hello time is the time interval between configuration messages generated and sent by the root device. This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | <pre>enable</pre> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | <pre>configure terminal</pre> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | spanning-tree mst hello-time <i>seconds</i> Example: <pre>Device(config)# spanning-tree mst hello-time 4</pre> | Configures the hello time for all MST instances. The hello time is the time interval between configuration messages generated and sent by the root device. These messages indicate that the device is alive. For <i>seconds</i> , the range is 1 to 10; the default is 3. |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

Configuring the Forwarding-Delay Time

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | spanning-tree mst forward-time <i>seconds</i> Example: <pre>Device(config)# spanning-tree mst forward-time 25</pre> | Configures the forward time for all MST instances. The forwarding delay is the number of seconds a port waits before changing from its spanning-tree learning and listening states to the forwarding state. For <i>seconds</i> , the range is 4 to 30; the default is 20. |
| Step 4 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|--|------------------------------------|---------|
| | Device (config) # <code>end</code> | |

Configuring the Maximum-Aging Time

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | spanning-tree mst max-age <i>seconds</i> Example: Device (config) # <code>spanning-tree mst max-age 40</code> | Configures the maximum-aging time for all MST instances. The maximum-aging time is the number of seconds a device waits without receiving spanning-tree configuration messages before attempting a reconfiguration. For <i>seconds</i> , the range is 6 to 40; the default is 20. |
| Step 4 | end Example: Device (config) # <code>end</code> | Returns to privileged EXEC mode. |

Configuring the Maximum-Hop Count

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree mst max-hops hop-count Example: Device(config)# spanning-tree mst max-hops 25 | Specifies the number of hops in a region before the BPDU is discarded, and the information held for a port is aged. For <i>hop-count</i> , the range is 1 to 255; the default is 20. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Specifying the Link Type to Ensure Rapid Transitions

If you connect a port to another port through a point-to-point link and the local port becomes a designated port, the RSTP negotiates a rapid transition with the other port by using the proposal-agreement handshake to ensure a loop-free topology.

By default, the link type is controlled from the duplex mode of the interface: a full-duplex port is considered to have a point-to-point connection; a half-duplex port is considered to have a shared connection. If you have a half-duplex link physically connected point-to-point to a single port on a remote device running MSTP, you can override the default setting of the link type and enable rapid transitions to the forwarding state.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

You must also know the specified MST instance ID and the interface used. This example uses 0 as the instance ID and GigabitEthernet1/0/1 as the interface because that was the instance ID and interface set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports, VLANs, and port-channel logical interfaces. The VLAN ID range is 1 to 4094. The port-channel range is 1 to 48. |
| Step 4 | spanning-tree link-type point-to-point Example: Device(config-if)# spanning-tree link-type point-to-point | Specifies that the link type of a port is point-to-point. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Designating the Neighbor Type

A topology could contain both prestandard and IEEE 802.1s standard compliant devices. By default, ports can automatically detect prestandard devices, but they can still receive both standard and prestandard BPDUs. When there is a mismatch between a device and its neighbor, only the CIST runs on the interface.

You can choose to set a port to send only prestandard BPDUs. The prestandard flag appears in all the **show** commands, even if the port is in STP compatibility mode.

This procedure is optional.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies an interface to configure, and enters interface configuration mode. Valid interfaces include physical ports. |
| Step 4 | spanning-tree mst pre-standard Example: Device(config-if)# spanning-tree mst pre-standard | Specifies that the port can send only prestandard BPDUs. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Restarting the Protocol Migration Process

This procedure restarts the protocol migration process and forces renegotiation with neighboring devices. It reverts the device to MST mode. It is needed when the device no longer receives IEEE 802.1D BPDUs after it has been receiving them.

Follow these steps to restart the protocol migration process (force the renegotiation with neighboring devices) on the device.

Before you begin

A multiple spanning tree (MST) must be specified and enabled on the device. For instructions, see Related Topics.

If you want to use the interface version of the command, you must also know the MST interface used. This example uses `GigabitEthernet1/0/1` as the interface because that was the interface set up by the instructions listed under Related Topics.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | Enter one of the following commands: <ul style="list-style-type: none"> • clear spanning-tree detected-protocols • clear spanning-tree detected-protocols interface <i>interface-id</i> Example: Device# clear spanning-tree detected-protocols OR Device# clear spanning-tree detected-protocols interface gigabitethernet 1/0/1 | The device reverts to the MSTP mode, and the protocol migration process restarts. |

What to do next

This procedure may need to be repeated if the device receives more legacy IEEE 802.1D configuration BPDUs (BPDUs with the protocol version set to 0).

Configuring PVST+ Simulation

PVST+ simulation is enabled by default. This means that all ports automatically interoperate with a connected device that is running in Rapid PVST+ mode. If you disabled the feature and want to re-configure it, refer to the following tasks.

To enable PVST+ simulation globally, perform this task:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | spanning-tree mst simulate pvst global Example: Device(config)# <code>spanning-tree mst simulate pvst global</code> | Enables PVST+ simulation globally. To prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+, enter the no version of the command. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

Enabling PVST+ Simulation on a Port

To enable PVST+ simulation on a port, perform this task:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# <code>interface gi1/0/1</code> | Selects a port to configure. |
| Step 4 | spanning-tree mst simulate pvst Example: | Enables PVST+ simulation on the specified interface. To prevent a specified interface from automatically interoperating with a connecting |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config-if)# spanning-tree mst simulate pvst | switch that is not running MST, enter the spanning-tree mst simulate pvst disable command. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show spanning-tree summary Example: Device# show spanning-tree summary | Verifies the configuration. |

Examples

Examples: PVST+ Simulation

This example shows how to prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+:

```
Switch# configure terminal
Switch(config)# no spanning-tree mst simulate pvst global
```

This example shows how to prevent a port from automatically interoperating with a connecting device that is running Rapid PVST+:

```
Switch(config)# interface1/0/1
Switch(config-if)# spanning-tree mst simulate pvst disable
```

The following sample output shows the system message you receive when a SSTP BPDU is received on a port and PVST+ simulation is disabled:

```
Message
SPANTREE_PVST_PEER_BLOCK: PVST BPDU detected on port %s [port number].
```

```
Severity
Critical
```

Explanation

A PVST+ peer was detected on the specified interface on the switch. PVST+ simulation feature is disabled, as a result of which the interface was moved to the spanning tree Blocking state.

Action

Identify the PVST+ switch from the network which might be configured incorrectly.

The following sample output shows the system message you receive when peer inconsistency on the interface is cleared:

```
Message
SPANTREE_PVST_PEER_UNBLOCK: Unblocking port %s [port number].
```

```
Severity
Critical
```

```
Explanation
The interface specified in the error message has been restored to normal
spanning tree state.
```

```
Action
None.
```

This example shows the spanning tree status when port **1/0/1** has been configured to disable PVST+ simulation and is currently in the peer type inconsistent state:

```
Switch# show spanning-tree
VLAN0010
  Spanning tree enabled protocol mstp
  Root ID Priority 32778
        Address 0002.172c.f400
        This bridge is the root
  Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
  Bridge ID Priority 32778 (priority 32768 sys-id-ext 10)
        Address 0002.172c.f400
        Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
        Aging Time 300
Interface      Role Sts Cost          Prio.Nbr Type
-----
Gi1/0/1       Desg BKN*4      128.270 P2p *PVST_Peer_Inc
```

This example shows the spanning tree summary when PVST+ simulation is enabled in the MSTP mode:

```
Switch# show spanning-tree summary
Switch is in mst mode (IEEE Standard)
Root bridge for: MST0
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is long
PVST Simulation Default is enabled
Name          Blocking Listening Learning Forwarding STP Active
-----
MST0          2           0           0           0           2
```

```
-----
1 mst                2                0                0                0                2
```

This example shows the spanning tree summary when PVST+ simulation is disabled in any STP mode:

```
Switch# show spanning-tree summary
Switch is in mst mode (IEEE Standard)
Root bridge for: MST0
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is long
PVST Simulation Default is disabled
```

| Name | Blocking | Listening | Learning | Forwarding | STP Active |
|-------|----------|-----------|----------|------------|------------|
| MST0 | 2 | 0 | 0 | 0 | 2 |
| 1 mst | 2 | 0 | 0 | 0 | 2 |

This example shows the spanning tree summary when the switch is not in MSTP mode, that is, the switch is in PVST or Rapid-PVST mode. The output string displays the current STP mode:

```
Switch# show spanning-tree summary
Switch is in rapid-pvst mode
Root bridge for: VLAN0001, VLAN2001-VLAN2002
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is short
PVST Simulation Default is enabled but inactive in rapid-pvst mode
```

| Name | Blocking | Listening | Learning | Forwarding | STP Active |
|----------|----------|-----------|----------|------------|------------|
| VLAN0001 | 2 | 0 | 0 | 0 | 2 |
| VLAN2001 | 2 | 0 | 0 | 0 | 2 |
| VLAN2002 | 2 | 0 | 0 | 0 | 2 |
| 3 vlans | 6 | 0 | 0 | 0 | 6 |

This example shows the interface details when PVST+ simulation is globally enabled, or the default configuration:

```
Switch# show spanning-tree interface1/0/1 detail
```

```
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is enabled by default
  BPDU: sent 132, received 1
```

This example shows the interface details when PVST+ simulation is globally disabled:

```
Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is disabled by default
  BPDU: sent 132, received 1
```

This example shows the interface details when PVST+ simulation is explicitly enabled on the port:

```
Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is enabled
  BPDU: sent 132, received 1
```

This example shows the interface details when the PVST+ simulation feature is disabled and a PVST Peer inconsistency has been detected on the port:

```
Switch# show spanning-tree interface1/0/1 detail
Port 269 (GigabitEthernet1/0/1) of VLAN0002 is broken (PVST Peer Inconsistent)
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is disabled
  BPDU: sent 132, received 1
```

Examples: Detecting Unidirectional Link Failure

This example shows the spanning tree status when port `1/0/1 detail` has been configured to disable PVST+ simulation and the port is currently in the peer type inconsistent state:

```
Switch# show spanning-tree
VLAN0010
```

```

```

Monitoring MST Configuration and Status

Table 38: Commands for Displaying MST Status

| | |
|---|--|
| show spanning-tree mst configuration | Displays the MST region configuration. |
| show spanning-tree mst configuration digest | Displays the MD5 digest included in the current MSTCI. |
| show spanning-tree mst | Displays MST information for the all instances. Note This command displays information for ports in a link state. |
| show spanning-tree mst <i>instance-id</i> | Displays MST information for the specified instance. Note This command displays information only if the port is in an operative state. |
| show spanning-tree mst interface <i>interface-id</i> | Displays MST information for the specified interface. |

Feature Information for MSTP

- [Feature Information for Optional Spanning-Tree Features, on page 336](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restriction for Optional Spanning-Tree Features

- PortFast minimizes the time that interfaces must wait for spanning tree to converge, so it is effective only when used on interfaces connected to end stations. If you enable PortFast on an interface connecting to another switch, you risk creating a spanning-tree loop.

Information About Optional Spanning-Tree Features

PortFast

PortFast immediately brings an interface configured as an access or trunk port to the forwarding state from a blocking state, bypassing the listening and learning states.

Figure 26: PortFast-Enabled Interfaces

You can use PortFast on interfaces connected to a single workstation or server to allow those devices to immediately connect to the network, rather than waiting for the spanning tree to

converge. Interfaces connected to a single workstation or server should not receive bridge protocol data units (BPDUs). An interface with PortFast enabled goes through the normal cycle of spanning-tree status changes when the switch is restarted.

You can enable this feature by enabling it on either the interface or on all nontrunking ports.

BPDU Guard

The Bridge Protocol Data Unit (BPDU) guard feature can be globally enabled on the switch or can be enabled per port, but the feature operates with some differences.

When you enable BPDU guard at the global level on PortFast edge-enabled ports, spanning tree shuts down ports that are in a PortFast edge-operational state if any BPDU is received on them. In a valid configuration, PortFast edge-enabled ports do not receive BPDUs. Receiving a BPDU on a Port Fast edge-enabled port means an invalid configuration, such as the connection of an unauthorized device, and the BPDU guard feature puts the port in the error-disabled state. When this happens, the switch shuts down the entire port on which the violation occurred.

When you enable BPDU guard at the interface level on any port without also enabling the PortFast edge feature, and the port receives a BPDU, it is put in the error-disabled state.

The BPDU guard feature provides a secure response to invalid configurations because you must manually put the interface back in service. Use the BPDU guard feature in a service-provider network to prevent an access port from participating in the spanning tree.

BPDU Filtering

The BPDU filtering feature can be globally enabled on the switch or can be enabled per interface, but the feature operates with some differences.

Enabling BPDU filtering on PortFast edge-enabled interfaces at the global level keeps those interfaces that are in a PortFast edge-operational state from sending or receiving BPDUs. The interfaces still send a few BPDUs at link-up before the switch begins to filter outbound BPDUs. You should globally enable BPDU filtering on a switch so that hosts connected to these interfaces do not receive BPDUs. If a BPDU is received

on a PortFast edge-enabled interface, the interface loses its PortFast edge-operational status, and BPDU filtering is disabled.

Enabling BPDU filtering on an interface without also enabling the PortFast edge feature keeps the interface from sending or receiving BPDUs.

Caution Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature for the entire switch or for an interface.

UplinkFast

Figure 27: Switches in a Hierarchical Network

Switches in hierarchical networks can be grouped into backbone switches, distribution switches, and access switches. This complex network has distribution switches and access switches that each have at least one redundant link that spanning tree blocks to prevent

loops. If a switch loses connectivity, it begins using the alternate paths as soon as the spanning tree selects a new root port. You can accelerate the choice of a new root port when a link or switch fails or when the spanning tree reconfigures itself by enabling UplinkFast. The root port transitions to the forwarding state immediately without going through the listening and learning states, as it would with the normal spanning-tree procedures.

When the spanning tree reconfigures the new root port, other interfaces flood the network with multicast packets, one for each address that was learned on the interface. You can limit these bursts of multicast traffic by reducing the max-update-rate parameter (the default for this parameter is 150 packets per second). However, if you enter zero, station-learning frames are not generated, so the spanning-tree topology converges more slowly after a loss of connectivity.

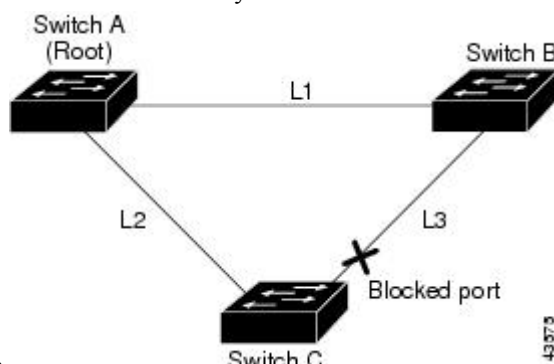

Note UplinkFast is most useful in wiring-closet switches at the access or edge of the network. It is not appropriate for backbone devices. This feature might not be useful for other types of applications.

UplinkFast provides fast convergence after a direct link failure and achieves load-balancing between redundant Layer 2 links using uplink groups. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.

Figure 28: UplinkFast Example Before Direct Link Failure

This topology has no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in

a blocking state.

Figure 29: UplinkFast Example After Direct Link Failure

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked interface on Switch C and transitions it to the forwarding state without going through the listening and learning states. This change takes approximately 1 to

5 seconds.

Cross-Stack UplinkFast

Cross-Stack UplinkFast (CSUF) provides a fast spanning-tree transition (fast convergence in less than 1 second under normal network conditions) across a switch stack. During the fast transition, an alternate redundant link on the switch stack is placed in the forwarding state without causing temporary spanning-tree loops or loss of connectivity to the backbone. With this feature, you can have a redundant and resilient network in some configurations. CSUF is automatically enabled when you enable the UplinkFast feature.

CSUF might not provide a fast transition all the time; in these cases, the normal spanning-tree transition occurs, completing in 30 to 40 seconds. For more information, see [Related Topics](#).

How Cross-Stack UplinkFast Works

Cross-Stack UplinkFast (CSUF) ensures that one link in the stack is elected as the path to the root.

Figure 30: Cross-Stack UplinkFast Topology

The stack-root port on Switch 1 provides the path to the root of the spanning tree. The alternate stack-root ports on Switches 2 and 3 can provide an alternate path to the spanning-tree root if the current stack-root switch fails or if its link to the spanning-tree root fails.

Link 1, the root link, is in the spanning-tree forwarding state. Links 2 and 3 are alternate redundant links that are in the spanning-tree blocking state. If Switch 1 fails, if its stack-root port fails, or if Link 1 fails, CSUF selects either the alternate stack-root port on Switch 2 or Switch 3 and puts it into the forwarding state in less than 1 second.

When certain link loss or spanning-tree events occur (described in the following topic), the Fast Uplink Transition Protocol uses the neighbor list to send fast-transition requests to stack members.

The switch sending the fast-transition request needs to do a fast transition to the forwarding state of a port that it has chosen as the root port, and it must obtain an acknowledgment from each stack switch before performing the fast transition.

Each switch in the stack decides if the sending switch is a better choice than itself to be the stack root of this spanning-tree instance by comparing the root, cost, and bridge ID. If the sending switch is the best choice as the stack root, each switch in the stack returns an acknowledgment; otherwise, it sends a fast-transition request. The sending switch then has not received acknowledgments from all stack switches.

When acknowledgments are received from all stack switches, the Fast Uplink Transition Protocol on the sending switch immediately transitions its alternate stack-root port to the forwarding state. If acknowledgments from all stack switches are not obtained by the sending switch, the normal spanning-tree transitions (blocking, listening, learning, and forwarding) take place, and the spanning-tree topology converges at its normal rate ($2 * \text{forward-delay time} + \text{max-age time}$).

The Fast Uplink Transition Protocol is implemented on a per-VLAN basis and affects only one spanning-tree instance at a time.

Events That Cause Fast Convergence

Depending on the network event or failure, the CSUF fast convergence might or might not occur.

Fast convergence (less than 1 second under normal network conditions) occurs under these circumstances:

- The stack-root port link fails.
If two switches in the stack have alternate paths to the root, only one of the switches performs the fast transition.
- The failed link, which connects the stack root to the spanning-tree root, recovers.
- A network reconfiguration causes a new stack-root switch to be selected.
- A network reconfiguration causes a new port on the current stack-root switch to be chosen as the stack-root port.

Note The fast transition might not occur if multiple events occur simultaneously. For example, if a stack member is powered off, and at the same time, the link connecting the stack root to the spanning-tree root comes back up, the normal spanning-tree convergence occurs.

Normal spanning-tree convergence (30 to 40 seconds) occurs under these conditions:

- The stack-root switch is powered off, or the software failed.
- The stack-root switch, which was powered off or failed, is powered on.
- A new switch, which might become the stack root, is added to the stack.

BackboneFast

BackboneFast detects indirect failures in the core of the backbone. BackboneFast is a complementary technology to the UplinkFast feature, which responds to failures on links directly connected to access switches.

BackboneFast optimizes the maximum-age timer, which controls the amount of time the switch stores protocol information received on an interface. When a switch receives an inferior BPDU from the designated port of another switch, the BPDU is a signal that the other switch might have lost its path to the root, and BackboneFast tries to find an alternate path to the root.

BackboneFast starts when a root port or blocked interface on a switch receives inferior BPDUs from its designated switch. An inferior BPDU identifies a switch that declares itself as both the root bridge and the designated switch. When a switch receives an inferior BPDU, it means that a link to which the switch is not directly connected (an indirect link) has failed (that is, the designated switch has lost its connection to the root switch). Under spanning-tree rules, the switch ignores inferior BPDUs for the maximum aging time (default is 20 seconds).

The switch tries to find if it has an alternate path to the root switch. If the inferior BPDU arrives on a blocked interface, the root port and other blocked interfaces on the switch become alternate paths to the root switch. (Self-looped ports are not considered alternate paths to the root switch.) If the inferior BPDU arrives on the root port, all blocked interfaces become alternate paths to the root switch. If the inferior BPDU arrives on the root port and there are no blocked interfaces, the switch assumes that it has lost connectivity to the root switch, causes the maximum aging time on the root port to expire, and becomes the root switch according to normal spanning-tree rules.

If the switch has alternate paths to the root switch, it uses these alternate paths to send a root link query (RLQ) request. The switch sends the RLQ request on all alternate paths to learn if any stack member has an alternate root to the root switch and waits for an RLQ reply from other switches in the network and in the stack. The switch sends the RLQ request on all alternate paths and waits for an RLQ reply from other switches in the network.

When a stack member receives an RLQ reply from a nonstack member on a blocked interface and the reply is destined for another nonstacked switch, it forwards the reply packet, regardless of the spanning-tree interface state.

When a stack member receives an RLQ reply from a nonstack member and the response is destined for the stack, the stack member forwards the reply so that all the other stack members receive it.

If the switch discovers that it still has an alternate path to the root, it expires the maximum aging time on the interface that received the inferior BPDU. If all the alternate paths to the root switch indicate that the switch has lost connectivity to the root switch, the switch expires the maximum aging time on the interface that received the RLQ reply. If one or more alternate paths can still connect to the root switch, the switch makes all interfaces on which it received an inferior BPDU its designated ports and moves them from the blocking state (if they were in the blocking state), through the listening and learning states, and into the forwarding state.

Figure 31: BackboneFast Example Before Indirect Link Failure

This is an example topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that connects directly to Switch B

B is in the blocking state.

Figure 32: BackboneFast Example After Indirect Link Failure

If link L1 fails, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, it detects the failure, elects itself the root, and begins sending BPDUs to Switch C, identifying itself as the root. When Switch C receives the inferior BPDUs from Switch B, Switch C assumes that an indirect failure has occurred. At that point, BackboneFast allows the blocked interface on Switch C to move immediately to the listening state without waiting for the maximum aging time for the interface to expire. BackboneFast then transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A. The root-switch election takes approximately 30 seconds, twice the Forward Delay time if the default Forward Delay time of 15 seconds is set. BackboneFast reconfigures the topology to account for the failure of link

Figure 33: Adding a Switch in a Shared-Medium Topology

If a new switch is introduced into a shared-medium topology, BackboneFast is not activated because the inferior BPDUs did not come from the recognized designated switch (Switch B). The new switch begins sending inferior BPDUs that indicate it is the root switch. However, the other switches ignore these inferior BPDUs, and the new switch learns that Switch B is the designated switch to Switch A, the root

EtherChannel Guard

You can use EtherChannel guard to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the switch interfaces are configured in an EtherChannel,

but the interfaces on the other device are not. A misconfiguration can also occur if the channel parameters are not the same at both ends of the EtherChannel.

If the switch detects a misconfiguration on the other device, EtherChannel guard places the switch interfaces in the error-disabled state, and displays an error message.

Root Guard

Figure 34: Root Guard in a Service-Provider Network

The Layer 2 network of a service provider (SP) can include many connections to switches that are not owned by the SP. In such a topology, the spanning tree can reconfigure itself and select a customer switch as the root switch. You can avoid this situation by enabling root guard on SP switch interfaces that connect to switches in your customer's network. If spanning-tree calculations cause an interface in the customer network to be selected as the root port, root guard then places the interface in the root-inconsistent (blocked) state to prevent the customer's switch from becoming the root switch or being in the path to the root.

If a switch outside the SP network becomes the root switch, the interface is blocked (root-inconsistent state), and spanning tree selects a new root switch. The customer's switch does not become the root switch and is not in the path to the root.

If the switch is operating in multiple spanning-tree (MST) mode, root guard forces the interface to be a designated port. If a boundary port is blocked in an internal spanning-tree (IST) instance because of root guard, the interface also is blocked in all MST instances. A boundary port is an interface that connects to a LAN, the designated switch of which is either an IEEE 802.1D switch or a switch with a different MST region configuration.

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. VLANs can be grouped and mapped to an MST instance.

Caution Misuse of the root guard feature can cause a loss of connectivity.

Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is enabled on the entire switched network. Loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in PVST+ or rapid-PVST+ mode, loop guard prevents alternate and root ports from becoming designated ports, and spanning tree does not send BPDUs on root or alternate ports.

When the switch is operating in MST mode, BPDUs are not sent on nonboundary ports only if the interface is blocked by loop guard in all MST instances. On a boundary port, loop guard blocks the interface in all MST instances.

STP PortFast Port Types

You can configure a spanning tree port as an edge port, a network port, or a normal port. A port can be in only one of these states at a given time. The default spanning tree port type is normal. You can configure the port type either globally or per interface.

Depending on the type of device to which the interface is connected, you can configure a spanning tree port as one of these port types:

- A PortFast edge port—is connected to a Layer 2 host. This can be either an access port or an edge trunk port (**portfast edge trunk**). This type of port interface immediately transitions to the forwarding state, bypassing the listening and learning states. Use PortFast edge on Layer 2 access ports connected to a single workstation or server to allow those devices to connect to the network immediately, rather than waiting for spanning tree to converge.

Even if the interface receives a bridge protocol data unit (BPDU), spanning tree does not place the port into the blocking state. Spanning tree sets the port's operating state to *non-port fast* even if the configured state remains *port fast edge* and starts participating in the topology change.

Note If you configure a port connected to a Layer 2 switch or bridge as an edge port, you might create a bridging loop.

- A PortFast network port—is connected only to a Layer 2 switch or bridge. Bridge Assurance is enabled only on PortFast network ports. For more information, refer to *Bridge Assurance*.

Note If you configure a port that is connected to a Layer 2 host as a spanning tree network port, the port will automatically move into the blocking state.

- A PortFast normal port—is the default type of spanning tree port.

Note Beginning with Cisco IOS Release 15.2(4)E, or IOS XE 3.8.0E, if you enter the **spanning-tree portfast** [trunk] command in the global or interface configuration mode, the system automatically saves it as **spanning-tree portfast edge** [trunk].

Bridge Assurance

You can use Bridge Assurance to help prevent looping conditions that are caused by unidirectional links (one-way traffic on a link or port), or a malfunction in a neighboring switch. Here a malfunction refers to a switch that is not able to run STP any more, while still forwarding traffic (a brain dead switch).

BPDUs are sent out on all operational network ports, including alternate and backup ports, for each hello time period. Bridge Assurance monitors the receipt of BPDUs on point-to-point links on all network ports. When a port does not receive BPDUs within the allotted hello time period, the port is put into a blocked state (the same as a port inconsistent state, which stops forwarding of frames). When the port resumes receipt of BPDUs, the port resumes normal spanning tree operations.

Note Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.

The following example shows how Bridge Assurance protects your network from bridging loops.

The following figure shows a network with normal STP topology.

Figure 35: Network with Normal STP Topology

354159

The following figure demonstrates a potential network problem when the device fails (brain dead) and Bridge Assurance is not enabled on the network.

Figure 36: Network Loop Due to a Malfunctioning Switch

354160

The following figure shows the network with Bridge Assurance enabled, and the STP topology progressing normally with bidirectional BDPUs issuing from every STP network port.

Figure 37: Network with STP Topology Running Bridge Assurance

The following figure shows how the potential network problem shown in figure *Network Loop Due to a Malfunctioning Switch* does not occur when you have Bridge Assurance enabled on your network.

Figure 38: Network Problem Averted with Bridge Assurance Enabled

The system generates syslog messages when a port is block and unblocked. The following sample output shows the log that is generated for each of these states:

BRIDGE_ASSURANCE_BLOCK

```
Sep 17 09:48:16.249 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_BLOCK: Bridge Assurance blocking port
GigabitEthernet1/0/1 on VLAN0001.
```

BRIDGE_ASSURANCE_UNBLOCK

```
Sep 17 09:48:58.426 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_UNBLOCK: Bridge Assurance unblocking
port GigabitEthernet1/0/1 on VLAN0001.
```

Follow these guidelines when enabling Bridge Assurance:

- It can only be enabled or disabled globally.
- It applies to all operational network ports, including alternate and backup ports.

- Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.
- For Bridge Assurance to work properly, it must be supported and configured on both ends of a point-to-point link. If the device on one side of the link has Bridge Assurance enabled and the device on the other side does not, the connecting port is blocked and in a Bridge Assurance inconsistent state. We recommend that you enable Bridge Assurance throughout your network.
- To enable Bridge Assurance on a port, BPDU filtering and BPDU Guard must be disabled.
- You can enable Bridge Assurance in conjunction with Loop Guard.
- You can enable Bridge Assurance in conjunction with Root Guard. The latter is designed to provide a way to enforce the root bridge placement in the network.

How to Configure Optional Spanning-Tree Features

Enabling PortFast

An interface with the PortFast feature enabled is moved directly to the spanning-tree forwarding state without waiting for the standard forward-time delay.

If you enable the voice VLAN feature, the PortFast feature is automatically enabled. When you disable voice VLAN, the PortFast feature is not automatically disabled.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution Use PortFast only when connecting a single end station to an access or trunk port. Enabling this feature on an interface connected to a switch or hub could prevent spanning tree from detecting and disabling loops in your network, which could cause broadcast storms and address-learning problems.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 1/0/2 | Specifies an interface to configure, and enters interface configuration mode. |
| Step 4 | spanning-tree portfast [trunk] Example: Device (config-if) # spanning-tree portfast trunk | Enables PortFast on an access port connected to a single workstation or server. By specifying the trunk keyword, you can enable PortFast on a trunk port. Note To enable PortFast on trunk ports, you must use the spanning-tree portfast trunk interface configuration command. The spanning-tree portfast command will not work on trunk ports. Make sure that there are no loops in the network between the trunk port and the workstation or server before you enable PortFast on a trunk port. By default, PortFast is disabled on all interfaces. |
| Step 5 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |

What to do next

You can use the **spanning-tree portfast default** global configuration command to globally enable the PortFast feature on all nontrunking ports.

Enabling BPDU Guard

You can enable the BPDU guard feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution Configure PortFast edge only on ports that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree portfast edge bpduguard default Example: Device(config)# spanning-tree portfast edge bpduguard default | Globally enables BPDU guard. |
| Step 4 | interface interface-id Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the interface connected to an end station, and enters interface configuration mode. |
| Step 5 | spanning-tree portfast edge Example: Device(config-if)# spanning-tree portfast edge | Enables the PortFast edge feature. |
| Step 6 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

What to do next

To prevent the port from shutting down, you can use the **errdisable detect cause bpduguard shutdown vlan** global configuration command to shut down just the offending VLAN on the port where the violation occurred.

You also can use the **spanning-tree bpduguard enable** interface configuration command to enable BPDU guard on any port without also enabling the PortFast edge feature. When the port receives a BPDU, it is put in the error-disabled state.

Enabling BPDU Filtering

You can also use the **spanning-tree bpdupfilter enable** interface configuration command to enable BPDU filtering on any interface without also enabling the PortFast edge feature. This command prevents the interface from sending or receiving BPDUs.

Caution Enabling BPDU filtering on an interface is the same as disabling spanning tree on it and can result in spanning-tree loops.

You can enable the BPDU filtering feature if your switch is running PVST+, Rapid PVST+, or MSTP.

Caution Configure PortFast edge only on interfaces that connect to end stations; otherwise, an accidental topology loop could cause a data packet loop and disrupt switch and network operation.

This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree portfast edge bpdupfilter default Example: Device(config)# spanning-tree portfast edge bpdupfilter default | Globally enables BPDU filtering. By default, BPDU filtering is disabled. |
| Step 4 | interface interface-id Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the interface connected to an end station, and enters interface configuration mode. |
| Step 5 | spanning-tree portfast edge Example: | Enables the PortFast edge feature on the specified interface. |

| | Command or Action | Purpose |
|---------------|--|----------------------------------|
| | Device(config-if)# spanning-tree portfast edge | |
| Step 6 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Enabling UplinkFast for Use with Redundant Links

Note When you enable UplinkFast, it affects all VLANs on the switch or switch stack. You cannot configure UplinkFast on an individual VLAN.

You can configure the UplinkFast or the Cross-Stack UplinkFast (CSUF) feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable UplinkFast and CSUF.

Before you begin

UplinkFast cannot be enabled on VLANs that have been configured with a switch priority. To enable UplinkFast on a VLAN with switch priority configured, first restore the switch priority on the VLAN to the default value using the **no spanning-tree vlan *vlan-id* priority** global configuration command.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree uplinkfast [max-update-rate <i>pkts-per-second</i>] Example: Device(config)# spanning-tree uplinkfast max-update-rate 200 | Enables UplinkFast. (Optional) For <i>pkts-per-second</i> , the range is 0 to 32000 packets per second; the default is 150. If you set the rate to 0, station-learning frames are not generated, and the spanning-tree |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>topology converges more slowly after a loss of connectivity.</p> <p>When you enter this command, CSUF also is enabled on all nonstack port interfaces.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

When UplinkFast is enabled, the switch priority of all VLANs is set to 49152. If you change the path cost to a value less than 3000 and you enable UplinkFast or UplinkFast is already enabled, the path cost of all interfaces and VLAN trunks is increased by 3000 (if you change the path cost to 3000 or above, the path cost is not altered). The changes to the switch priority and the path cost reduce the chance that a switch will become the root switch.

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you enable the UplinkFast feature using these instructions, CSUF is automatically globally enabled on nonstack port interfaces.

Disabling UplinkFast

This procedure is optional.

Follow these steps to disable UplinkFast and Cross-Stack UplinkFast (CSUF).

Before you begin

UplinkFast must be enabled.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 3 | no spanning-tree uplinkfast Example: Device(config)# no spanning-tree uplinkfast | Disables UplinkFast and CSUF on the switch and all of its VLANs. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

When UplinkFast is disabled, the switch priorities of all VLANs and path costs of all interfaces are set to default values if you did not modify them from their defaults.

When you disable the UplinkFast feature using these instructions, CSUF is automatically globally disabled on nonstack port interfaces.

Enabling BackboneFast

You can enable BackboneFast to detect indirect link failures and to start the spanning-tree reconfiguration sooner.

You can configure the BackboneFast feature for Rapid PVST+ or for the MSTP, but the feature remains disabled (inactive) until you change the spanning-tree mode to PVST+.

This procedure is optional. Follow these steps to enable BackboneFast on the switch.

Before you begin

If you use BackboneFast, you must enable it on all switches in the network. BackboneFast is not supported on Token Ring VLANs. This feature is supported for use with third-party switches.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|----------------------------------|
| Step 3 | spanning-tree backbonefast Example: Device (config)# spanning-tree backbonefast | Enables BackboneFast. |
| Step 4 | end Example: Device (config)# end | Returns to privileged EXEC mode. |

Enabling EtherChannel Guard

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable EtherChannel Guard on the device.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree etherchannel guard misconfig Example: Device (config)# spanning-tree etherchannel guard misconfig | Enables EtherChannel guard. |
| Step 4 | end Example: Device (config)# end | Returns to privileged EXEC mode. |

What to do next

You can use the **show interfaces status err-disabled** privileged EXEC command to show which device ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the **show etherchannel summary** privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the **shutdown** and **no shutdown** interface configuration commands on the port-channel interfaces that were misconfigured.

Enabling Root Guard

Root guard enabled on an interface applies to all the VLANs to which the interface belongs. Do not enable the root guard on interfaces to be used by the UplinkFast feature. With UplinkFast, the backup interfaces (in the blocked state) replace the root port in the case of a failure. However, if root guard is also enabled, all the backup interfaces used by the UplinkFast feature are placed in the root-inconsistent state (blocked) and are prevented from reaching the forwarding state.

Note You cannot enable both root guard and loop guard at the same time.

You can enable this feature if your switch is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional.

Follow these steps to enable root guard on the switch.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device (config)# interface gigabitethernet 1/0/2 | Specifies an interface to configure, and enters interface configuration mode. |
| Step 4 | spanning-tree guard root Example: | Enables root guard on the interface. By default, root guard is disabled on all interfaces. |

| | Command or Action | Purpose |
|---------------|---|----------------------------------|
| | Device(config-if) # spanning-tree guard root | |
| Step 5 | end Example: Device(config-if) # end | Returns to privileged EXEC mode. |

Enabling Loop Guard

You can use loop guard to prevent alternate or root ports from becoming designated ports because of a failure that leads to a unidirectional link. This feature is most effective when it is configured on the entire switched network. Loop guard operates only on interfaces that are considered point-to-point by the spanning tree.

Note You cannot enable both loop guard and root guard at the same time.

You can enable this feature if your device is running PVST+, Rapid PVST+, or MSTP.

This procedure is optional. Follow these steps to enable loop guard on the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | Enter one of the following commands: <ul style="list-style-type: none"> • show spanning-tree active • show spanning-tree mst Example: Device# show spanning-tree active or Device# show spanning-tree mst | Verifies which interfaces are alternate or root ports. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree loopguard default Example: Device(config) # spanning-tree loopguard default | Enables loop guard. By default, loop guard is disabled. |

| | Command or Action | Purpose |
|---------------|--|----------------------------------|
| Step 4 | end Example: Device(config) # end | Returns to privileged EXEC mode. |

Enabling PortFast Port Types

This section describes the different steps to enable Portfast Port types.

Configuring the Default Port State Globally

To configure the default PortFast state, perform this task:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | spanning-tree portfast [edge network normal] default Example: Device(config) # spanning-tree portfast default | Configures the default state for all interfaces on the switch. You have these options: <ul style="list-style-type: none"> • (Optional) edge—Configures all interfaces as edge ports. This assumes all ports are connected to hosts/servers. • (Optional) network—Configures all interfaces as spanning tree network ports. This assumes all ports are connected to switches and bridges. Bridge Assurance is enabled on all network ports by default. • (Optional) normal—Configures all interfaces normal spanning tree ports. These ports can be connected to any type of device. • default—The default port type is normal. |

| | Command or Action | Purpose |
|---------------|---|----------------------------------|
| Step 4 | end Example: Device (config) # end | Returns to privileged EXEC mode. |

Configuring PortFast Edge on a Specified Interface

Interfaces configured as edge ports immediately transition to the forwarding state, without passing through the blocking or learning states, on linkup.

Note Because the purpose of this type of port is to minimize the time that access ports must wait for spanning tree to converge, it is most effective when used on access ports. If you enable PortFast edge on a port connecting to another switch, you risk creating a spanning tree loop.

To configure an edge port on a specified interface, perform this task:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> port-channel <i>port_channel_number</i> Example: Device (config) # interface gigabitethernet 1/0/1 port-channel <i>port_channel_number</i> | Specifies an interface to configure. |
| Step 4 | spanning-tree portfast edge [trunk] Example: Device (config-if) # spanning-tree portfast trunk | Enables edge behavior on a Layer 2 access port connected to an end workstation or server. <ul style="list-style-type: none"> • (Optional) trunk—Enables edge behavior on a trunk port. Use this keyword if the link is a trunk. Use this command only on ports that are connected to end host devices |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>that terminate VLANs and from which the port should never receive STP BPDUs. Such end host devices include workstations, servers, and ports on routers that are not configured to support bridging.</p> <ul style="list-style-type: none"> • Use the no version of the command to disable PortFast edge. |
| Step 5 | <p><code>end</code></p> <p>Example:</p> <pre>Device(config-if)# end</pre> | Exits configuration mode. |
| Step 6 | <p>show running interface <i>interface-id</i> port-channel <i>port_channel_number</i></p> <p>Example:</p> <pre>Device# show running interface gigabitethernet 1/0/1 port-channel port_channel_number</pre> | Verifies the configuration. |

Configuring a PortFast Network Port on a Specified Interface

Ports that are connected to Layer 2 switches and bridges can be configured as network ports.

Note Bridge Assurance is enabled only on PortFast network ports. For more information, refer to *Bridge Assurance*.

To configure a port as a network port, perform this task.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | interface <i>interface-id</i> port-channel <i>port_channel_number</i> Example: <pre>Device(config)# interface gigabitethernet 1/0/1 port-channel port_channel_number</pre> | Specifies an interface to configure. |
| Step 4 | spanning-tree portfast network Example: <pre>Device(config-if)# spanning-tree portfast network</pre> | Enables edge behavior on a Layer 2 access port connected to an end workstation or server. <ul style="list-style-type: none"> Configures the port as a network port. If you have enabled Bridge Assurance globally, it automatically runs on a spanning tree network port. Use the no version of the command to disable PortFast. |
| Step 5 | end Example: <pre>Device(config-if)# end</pre> | Exits configuration mode. |
| Step 6 | show running interface <i>interface-id</i> port-channel <i>port_channel_number</i> Example: <pre>Device# show running interface gigabitethernet 1/0/1 port-channel port_channel_number</pre> | Verifies the configuration. |

Enabling Bridge Assurance

To configure the Bridge Assurance, perform the steps given below:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# <code>configure terminal</code> | |
| Step 3 | spanning-tree bridge assurance Example: Device(config)# <code>spanning-tree bridge assurance</code> | Enables Bridge Assurance on all network ports on the switch. Bridge Assurance is enabled by default. Use the no version of the command to disable the feature. Disabling Bridge Assurance causes all configured network ports to behave as normal spanning tree ports. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 5 | show spanning-tree summary Example: Device# <code>show spanning-tree summary</code> | Displays spanning tree information and shows if Bridge Assurance is enabled. |

Examples

Examples: Configuring PortFast Edge on a Specified Interface

This example shows how to enable edge behavior on GigabitEthernet interface 1/0/1:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# spanning-tree portfast edge
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show running-config interface gigabitethernet1/0/1
Building configuration...
Current configuration:
!
interface GigabitEthernet1/0/1
no ip address
switchport
switchport access vlan 200
switchport mode access
spanning-tree portfast edge
end
```

This example shows how you can display that port GigabitEthernet 1/0/1 is currently in the edge state:

```

Switch# show spanning-tree vlan 200
VLAN0200
Spanning tree enabled protocol rstp
Root ID Priority 2
Address 001b.2a68.5fc0
Cost 3
Port 125 (GigabitEthernet5/9)
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
Bridge ID Priority 2 (priority 0 sys-id-ext 2)
Address 7010.5c9c.5200
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
Aging Time 0 sec
Interface Role Sts Cost Prio.Nbr Type
-----
Gi1/0/1 Desg FWD 4 128.1 P2p Edge

```

Examples: Configuring a PortFast Network Port on a Specified Interface

This example shows how to configure GigabitEthernet interface 1/0/1 as a network port:

```

Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/1
Switch(config-if)# spanning-tree portfast network
Switch(config-if)# end
Switch#

```

This example shows how to verify the configuration:

```

Switch# show running-config interface gigabitethernet1/0/1
Building configuration...
Current configuration:
!
interface GigabitEthernet1/0/1
no ip address
switchport
switchport access vlan 200
switchport mode access
spanning-tree portfast network
end

```

This example shows the output for show spanning-tree vlan

```

Switch# show spanning-tree vlan
Sep 17 09:51:36.370 PDT: %SYS-5-CONFIG_I: Configured from console by console2

VLAN0002
Spanning tree enabled protocol rstp
Root ID      Priority    2
Address      7010.5c9c.5200
This bridge is the root

Monitoring the Spanning-Tree Status

Table 39: Commands for Monitoring the Spanning-Tree Status

| Command | Purpose |
|---|--|
| <code>show spanning-tree active</code> | Displays spanning-tree information on active interfaces only. |
| <code>show spanning-tree detail</code> | Displays a detailed summary of interface information. |
| <code>show spanning-tree interface <i>interface-id</i></code> | Displays spanning-tree information for the specified interface. |
| <code>show spanning-tree mst interface <i>interface-id</i></code> | Displays MST information for the specified interface. |
| <code>show spanning-tree summary [totals]</code> | Displays a summary of interface states or displays the total lines of spanning-tree state section. |
| <code>show spanning-tree mst interface <i>interface-id</i> portfast edge</code> | Displays spanning-tree portfast information for the specified interface. |

Feature Information for Optional Spanning-Tree Features

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Overview of Resilient Ethernet Protocol

Resilient Ethernet Protocol (REP) is a Cisco-proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

A REP segment is a chain of ports connected to each other and configured with a segment ID. Each segment consists of standard (nonedge) segment ports and two user-configured edge ports. A device can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link, only two ports can belong to the same segment. REP is supported only on Trunk Ethernet Flow Point (EFP) interfaces.

The following figure shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all the ports are operational (as in the segment on the left), a

single port is blocked, as shown by the diagonal line. When there is a failure in the network, the blocked port returns to the forwarding state to minimize network disruption.

Figure 39: REP Open Segment

The segment shown in the figure above is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop, and you can safely connect the segment edges to any network. All the hosts connected to devices inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure occurs on any segment or on any port on a REP segment, REP unblocks all the ports to ensure that connectivity is available through the other gateway.

The segment shown in the following figure is a ring segment, with both the edge ports located on the same device. With this configuration, you can create a redundant connection between any two devices in the segment.

Figure 40: REP Ring Segment

REP segments have the following characteristics:

- If all the ports in a segment are operational, one port (referred to as the *alternate* port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ports in the segment control the blocked state of VLANs.
- If one or more ports in a segment is not operational, and cause a link failure, all the ports forward traffic on all the VLANs to ensure connectivity.
- In case of a link failure, alternate ports are unblocked as quickly as possible. When the failed link is up, a logically blocked port per VLAN is selected with minimal disruption to the network.

You can construct almost any type of network based on REP segments. REP also supports VLAN load balancing, which is controlled by the primary edge port (any port in the segment).

In access ring-topologies, the neighboring switch might not support REP as shown in the following figure. In this scenario, you can configure the non-REP-facing ports (E1 and E2) as edge no-neighbor ports. These ports inherit all the properties of edge ports, and you can configure them the same as any edge port, including configuring them to send STP or REP topology change notices to the aggregation switch. In this scenario, the STP topology change notice (TCN) that is sent is a multiple spanning-tree (MST) STP message.

Figure 41: Edge No-Neighbor Ports

REP has these limitations:

- You must configure each segment port; an incorrect configuration might cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

Link Integrity

REP does not use an end-to-end polling function between edge ports to verify link integrity. It implements local link failure detection. The REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All the VLANs are blocked on an interface until the neighbor is detected. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge) associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment.

A segment port does not become operational if:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- A neighbor does not acknowledge a local port as a peer.

Each port creates an adjacency with its immediate neighbor. After the neighbor adjacencies are created, the ports negotiate with each other to determine the blocked port for the segment, which will function as the alternate port. All the other ports become unblocked. By default, REP packets are sent to a bridge protocol data unit-class MAC address. The packets can also be sent to a Cisco multicast address, which is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by the devices not running REP.

Fast Convergence

REP runs on a physical link basis and not on a per-VLAN basis. Only one hello message is required for all the VLANs, and this reduces the load on the protocol. We recommend that you create VLANs consistently on all the switches in a given segment and configure the same allowed VLANs on the REP trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the entire network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring an administrative VLAN for the entire domain or for a particular segment.

VLAN Load Balancing

One edge port in the REP segment acts as the primary edge port; and another as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all the other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:

- By entering the port ID of the interface. To identify the port ID of a port in the segment, enter the **show interface rep detail** interface configuration command for the port.
- By entering the **preferred** keyword to select the port that you previously configured as the preferred alternate port with the **rep segment segment-id preferred** interface configuration command.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port. The neighbor offset number range is -256 to $+256$; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

Note Configure offset numbers on the primary edge port by identifying a port's downstream position from the primary (or secondary) edge port. Never enter an offset value of 1 because that is the offset number of the primary edge port.

The following figure shows neighbor offset numbers for a segment, where E1 is the primary edge port and E2 is the secondary edge port. The numbers inside the ring are numbers offset from the primary edge port; the numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all the ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number would then be 1 and E1 would be -1.

Figure 42: Neighbor Offset Numbers in a Segment

When the REP segment is complete, all the VLANs are blocked. When you configure VLAN load balancing, you must also configure triggers in one of two ways:

- Manually trigger VLAN load balancing at any time by entering the **rep preempt segment** *segment-id* privileged EXEC command on the switch that has the primary edge port.
- Configure a preempt delay time by entering the **rep preempt delay** *seconds* interface configuration command. After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

Note When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port sends out a message to alert all the interfaces in the segment about the preemption. When the secondary port receives the message, the message is sent to the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all the VLANs. Only the primary edge port initiates VLAN load balancing, which is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load-balancing configuration.

Reconfigure the primary edge port to reconfigure load balancing. When you change the load-balancing configuration, the primary edge port waits for the **rep preempt segment** command or for the configured preempt delay period after a port failure and recovery, before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load-balancing status does not change. Configuring a new edge port might cause a new topology configuration.

Spanning Tree Interaction

REP does not interact with the STP or the Flex Link feature, but can coexist with both. A port that belongs to a segment is removed from spanning tree control, and STP BPDUs are not accepted or sent from segment ports. Therefore, STP cannot run on a segment.

To migrate from an STP ring configuration to an REP segment configuration, begin by configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments. Since each segment always contains a blocked port, multiple segments means multiple blocked

ports and a potential loss of connectivity. After the segment is configured in both directions up to the location of the edge ports, configure the edge ports.

REP Ports

REP segments consist of Failed, Open, or Alternate ports:

- A port configured as a regular segment port starts as a failed port.
- After the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all the VLANs on the interface. Blocked-port negotiations occur, and when the segment settles, one blocked port remains in the alternate role and all the other ports become open ports.
- When a failure occurs in a link, all the ports move to the Failed state. When the Alternate port receives the failure notification, it changes to the Open state, forwarding all the VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. For VLAN load balancing, you must configure two edge ports in the segment.

A segment port that is reconfigured as a spanning tree port restarts according to the spanning tree configuration. By default, this is a designated blocking port. If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

How to Configure Resilient Ethernet Protocol

A segment is a collection of ports connected to one another in a chain and configured with a segment ID. To configure REP segments, configure the REP administrative VLAN (or use the default VLAN 1) and then add the ports to the segment, using interface configuration mode. You should configure two edge ports in a segment, with one of them being the primary edge port and the other the secondary edge port by default. A segment should have only one primary edge port. If you configure two ports in a segment as primary edge ports, for example, ports on different switches, the REP selects one of them to serve as the segment's primary edge port. If required, you can configure the location to which segment topology change notices (STCNs) and VLAN load balancing are to be sent.

Default REP Configuration

REP is disabled on all the interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.

When REP is enabled, the task of sending segment topology change notices (STCNs) is disabled, all the VLANs are blocked, and the administrative VLAN is VLAN 1.

When VLAN load balancing is enabled, the default is manual preemption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual preemption is to block all the VLANs in the primary edge port.

REP Configuration Guidelines

Follow these guidelines when configuring REP:

- We recommend that you begin by configuring one port and then configure contiguous ports to minimize the number of segments and the number of blocked ports.
- If more than two ports in a segment fail when no external neighbors are configured, one port goes into a forwarding state for the data path to help maintain connectivity during configuration. In the **show rep interface** command output, the Port Role for this port is displayed as **Fail Logical Open**; the Port Role for the other failed port is displayed as **Fail No Ext Neighbor**. When the external neighbors for the failed ports are configured, the ports go through the alternate port transitions and eventually go to an open state, or remain as the alternate port, based on the alternate port selection mechanism.
- REP ports must be Layer 2 IEEE 802.1Q or Trunk ports.
- We recommend that you configure all the trunk ports in a segment with the same set of allowed VLANs.
- Be careful when configuring REP through a Telnet connection because REP blocks all the VLANs until another REP interface sends a message to unblock it. You might lose connectivity to the router if you enable REP in a Telnet session that accesses the router through the same interface.
- You cannot run REP and STP or REP and Flex Links on the same segment or interface.
- If you connect an STP network to an REP segment, be sure that the connection is at the segment edge. An STP connection that is not at the edge might cause a bridging loop because STP does not run on REP segments. All the STP BPDUs are dropped at REP interfaces.
- You must configure all the trunk ports in a segment with the same set of allowed VLANs. If this is not done, misconfiguration occurs.
- If REP is enabled on two ports on a switch, both the ports must be either regular segment ports or edge ports. REP ports follow these rules:
 - There is no limit to the number of REP ports on a switch. However, only two ports on a switch can belong to the same REP segment.
 - If only one port on a switch is configured in a segment, the port should be an edge port.
 - If two ports on a switch belong to the same segment, they must both be edge ports, regular segment ports, or one regular port and one edge no-neighbor port. An edge port and regular segment port on a switch cannot belong to the same segment.
 - If two ports on a switch belong to the same segment, and one is configured as an edge port and one as a regular segment port (a misconfiguration), the edge port is treated as a regular segment port.
- REP interfaces come up in a blocked state and remain in a blocked state until they are safe to be unblocked. You must, therefore, be aware of the status of REP interfaces to avoid sudden connection losses.
- REP sends all the LSL PDUs in the untagged frames to the native VLAN. The BPA message sent to a Cisco multicast address is sent to the administration VLAN, which is VLAN 1 by default.
- You can configure the duration for which a REP interface remains up without receiving a hello from a neighbor. Use the **rep lsl-age-timer** value interface configuration command to set the time from 120 ms to 10000 ms. The LSL hello timer is then set to the age-timer value divided by 3. In normal operation, three LSL hellos are sent before the age timer on the peer switch expires and checks for hello messages.
 - EtherChannel port channel interfaces do not support LSL age-timer values less than 1000 ms. If you try to configure a value less than 1000 ms on a port channel, you receive an error message and the command is rejected.

- REP ports cannot be configured as one of the following port types:
 - Switched Port Analyzer (SPAN) destination port
 - Tunnel port
 - Access port
- REP is supported on EtherChannels, but not on an individual port that belongs to an EtherChannel.
- There can be a maximum of 64 REP segments per switch.

Configuring REP Administrative VLAN

To avoid the delay created by link-failure messages, and VLAN-blocking notifications during load balancing, REP floods packets to a regular multicast address at the hardware flood layer (HFL). These messages are flooded to the whole network, and not just the REP segment. You can control the flooding of these messages by configuring an administrative VLAN.

Follow these guidelines when configuring the REP administrative VLAN:

- If you do not configure an administrative VLAN, the default is VLAN 1.
- You can configure one admin VLAN on the switch for all segments.
- The administrative VLAN cannot be the RSPAN VLAN.

To configure the REP administrative VLAN, follow these steps, beginning in privileged EXEC mode:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | rep admin vlan <i>vlan-id</i> Example: Device(config)# rep admin vlan 2 | Specifies the administrative VLAN. The range is from 2 to 4094. To set the admin VLAN to 1, which is the default, enter the no rep admin vlan global configuration command. |
| Step 3 | end Example: Device(config)# end | Exits global configuration mode and returns to privileged EXEC mode. |
| Step 4 | show interface [<i>interface-id</i>] rep detail Example: Device# show interface gigabitethernet1/1 rep detail | (Optional) Verifies the configuration on a REP interface. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | copy running-config startup config Example: Device# <code>copy running-config startup config</code> | (Optional) Saves your entries in the switch startup configuration file. |

Configuring a REP Interface

To configure REP, enable REP on each segment interface and identify the segment ID. This task is mandatory, and must be done before other REP configurations. You must also configure a primary and secondary edge port on each segment. All the other steps are optional.

Follow these steps to enable and configure REP on an interface:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device# <code>interface gigabitethernet1/1</code> | Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). |
| Step 4 | switchport mode trunk Example: Device# <code>switchport mode trunk</code> | Configures the interface as a Layer 2 trunk port. |
| Step 5 | rep segment <i>segment-id</i> [edge [no-neighbor] [primary]] [preferred] Example: Device# <code>rep segment 1 edge no-neighbor primary</code> | Enables REP on the interface and identifies a segment number. The segment ID range is from 1 to 1024. <p>Note You must configure two edge ports, including one primary edge port, for each segment.</p> <p>These optional keywords are available:</p> |

| | Command or Action | Purpose |
|---------------|--|--|
| | | <ul style="list-style-type: none"> • (Optional) edge—Configures the port as an edge port. Each segment has only two edge ports. Entering the keyword edge without the keyword primary configures the port as the secondary edge port. • (Optional) primary—Configures the port as the primary edge port, the port on which you can configure VLAN load balancing. • (Optional) no-neighbor—Configures a port with no external REP neighbors as an edge port. The port inherits all the properties of an edge port, and you can configure the properties the same way you would for an edge port. <p>Note Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the keyword primary on both the switches, the configuration is valid. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the show rep topology privileged EXEC command.</p> <ul style="list-style-type: none"> • (Optional) preferred—Indicates that the port is the preferred alternate port or the preferred port for VLAN load balancing. <p>Note Configuring a port as preferred does not guarantee that it becomes the alternate port; it merely gives the port a slight edge over equal contenders. The alternate port is usually a previously failed port.</p> |
| Step 6 | <pre>rep stcn {interface <i>interface id</i> segment <i>id-list</i> stp} Example: Device# rep stcn segment 25-50</pre> | <p>(Optional) Configures the edge port to send segment topology change notices (STCNs).</p> <ul style="list-style-type: none"> • interface <i>interface-id</i>—Designates a physical interface or port channel to receive STCNs. |

| | Command or Action | Purpose |
|---------------|--|--|
| | | <ul style="list-style-type: none"> • segment <i>id-list</i>—Identifies one or more segments to receive STCNs. The range is from 1 to 1024. • stp—Sends STCNs to STP networks. <p>Note Spanning Tree (MST) mode is required on edge no-neighbor nodes when rep stcn stp command is configured for sending STCNs to STP networks.</p> |
| Step 7 | <p>rep block port {<i>id port-id</i> <i>neighbor-offset</i> preferred} vlan {<i>vlan-list</i> all}</p> <p>Example:</p> <pre>Device# rep block port id 0009001818D68700 vlan 1-100</pre> | <p>(Optional) Configures VLAN load balancing on the primary edge port, identifies the REP alternate port in one of three ways (id port-id, <i>neighbor_offset</i>, preferred), and configures the VLANs to be blocked on the alternate port.</p> <ul style="list-style-type: none"> • id port-id—Identifies the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the show interface type number rep [detail] privileged EXEC command. • <i>neighbor_offset</i>—Number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of 0 is invalid. Enter -1 to identify the secondary edge port as the alternate port. <p>Note Because you enter the rep block port command at the primary edge port (offset number 1), you cannot enter an offset value of 1 to identify an alternate port.</p> <ul style="list-style-type: none"> • preferred—Selects the regular segment port previously identified as the preferred alternate port for VLAN load balancing. • vlan <i>vlan-list</i>—Blocks one VLAN or a range of VLANs. • vlan all—Blocks all the VLANs. <p>Note Enter this command only on the REP primary edge port.</p> |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 8 | rep preempt delay <i>seconds</i> Example: Device# rep preempt delay 100 | (Optional) Configures a preempt time delay. <ul style="list-style-type: none"> • Use this command if you want VLAN load balancing to be automatically triggered after a link failure and recovery. • The time delay range is between 15 to 300 seconds. The default is manual preemption with no time delay. Note Enter this command only on the REP primary edge port. |
| Step 9 | rep lsl-age-timer <i>value</i> Example: Device# rep lsl-age-timer 2000 | (Optional) Configures a time (in milliseconds) for which the REP interface remains up without receiving a hello from a neighbor. The range is from 120 to 10000 ms in 40-ms increments. The default is 5000 ms (5 seconds). Note <ul style="list-style-type: none"> • EtherChannel port channel interfaces do not support LSL age-timer values that are less than 1000 ms. • Both the ports on the link should have the same LSL age configured in order to avoid link flaps. |
| Step 10 | end Example: Device (config)# end | Exits global configuration mode and returns to privileged EXEC mode. |
| Step 11 | show interface [<i>interface-id</i>] rep [detail] Example: Device (config)# show interface gigabitethernet1/1 rep detail | (Optional) Displays the REP interface configuration. |
| Step 12 | copy running-config startup-config Example: Device (config)# copy running-config startup-config | (Optional) Saves your entries in the router startup configuration file. |

Setting Manual Preemption for VLAN Load Balancing

If you do not enter the **rep preempt delay seconds** interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all the other segment configurations have been completed before manually preempting VLAN load balancing. When you enter the **rep preempt delay segment segment-id** command, a confirmation message is displayed before the command is executed because preemption might cause network disruption.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | rep preempt segment segment-id Example: Device# rep preempt segment 100 The command will cause a momentary traffic disruption. Do you still want to continue? [confirm] | Manually triggers VLAN load balancing on the segment. You need to confirm the command before it is executed. |
| Step 4 | show rep topology segment segment-id Example: Device# show rep topology segment 100 | (Optional) Displays REP topology information. |
| Step 5 | end Example: Device# end | Exits privileged EXEC mode. |

Configuring SNMP Traps for REP

You can configure a router to send REP-specific traps to notify the Simple Network Management Protocol (SNMP) server of link-operational status changes and port role changes.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | snmp mib rep trap-rate <i>value</i> Example: Device(config)# snmp mib rep trap-rate 500 | Enables the switch to send REP traps, and sets the number of traps sent per second. <ul style="list-style-type: none"> • Enter the number of traps sent per second. The range is from 0 to 1000. The default is 0 (no limit is imposed; a trap is sent at every occurrence). |
| Step 3 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 4 | show running-config Example: Device# show running-config | (Optional) Displays the running configuration, which can be used to verify the REP trap configuration. |
| Step 5 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the switch startup configuration file. |

Monitoring Resilient Ethernet Protocol Configuration

You can display the rep interface and rep topology details using the commands in this topic.

- **show interface** [*interface-id*] **rep** [**detail**]

Displays REP configuration and status for an interface or for all the interfaces.

- (Optional) **detail**—Displays interface-specific REP information.

Example:

```
Device# show interfaces TenGigabitEthernet4/1 rep detail
```

```
TenGigabitEthernet4/1 REP enabled
Segment-id: 3 (Primary Edge)
PortID: 03010015FA66FF80
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 02040015FA66FF804050
Port Role: Open
```

```

Blocked VLAN: <empty>
Admin-vlan: 1
Preempt Delay Timer: disabled
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 999, tx: 652
HFL PDU rx: 0, tx: 0
BPA TLV rx: 500, tx: 4
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 6, tx: 5
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 135, tx: 136

```

- **show rep topology** [*segment segment-id*] [*archive*] [*detail*]

Displays REP topology information for a segment or for all the segments, including the primary and secondary edge ports in the segment.

- (Optional) **archive**—Displays the last stable topology.

Note An archive topology is not retained when the switch reloads.

- (Optional) **detail**—Displays detailed archived information.

Example:

```
Device# show rep topology
```

```

REP Segment 1
BridgeName      PortName      Edge Role
-----
10.64.106.63    Te5/4         Pri  Open
10.64.106.228   Te3/4         Open
10.64.106.228   Te3/3         Open
10.64.106.67    Te4/3         Open
10.64.106.67    Te4/4         Alt
10.64.106.63    Te4/4         Sec  Open

REP Segment 3
BridgeName      PortName      Edge Role

10.64.106.63    Gi50/1        Pri  Open
SVT_3400_2      Gi0/3         Open
SVT_3400_2      Gi0/4         Open
10.64.106.68    Gi40/2        Open
10.64.106.68    Gi40/1        Open
10.64.106.63    Gi50/2        Sec  Alt

```

Configuration Examples for Resilient Ethernet Protocol

This section provides the following configuration examples:

Example: Configuring the REP Administrative VLAN

This example shows how to configure the administrative VLAN as VLAN 100, and verify the configuration by entering the **show interface rep detail** command on one of the REP interfaces:

```
Device# configure terminal
Device(config)# rep admin vlan 100
Device(config)# end
Device# show interface gigabitethernet1/1 rep detail

GigabitEthernet1/1 REP enabled
Segment-id: 2 (Edge)
PortID: 00010019E7144680
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 0002001121A2D5800E4D
Port Role: Open
Blocked Vlan: <empty>
Admin-vlan: 100
Preempt Delay Timer: disabled
LSL Ageout Timer: 5000 ms
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
STCN Propagate to: none
LSL PDU rx: 3322, tx: 1722
HFL PDU rx: 32, tx: 5
BPA TLV rx: 16849, tx: 508
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 118, tx: 118
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 4214, tx: 4190
```

The following example shows how to create an administrative VLAN per segment. Here, VLAN 2 is configured as the administrative VLAN only for REP segment 2. All the remaining segments that are not configured have VLAN 1 as the administrative VLAN by default.

```
Device# configure terminal
Device(config)# rep admin vlan 2 segment 2
Device(config)# end
```

Example: Configuring a REP Interface

This example shows how to configure an interface as the primary edge port for segment 1, to send STCNs to segments 2 through 5, and to configure the alternate port as the port with port ID 0009001818D68700 to block all the VLANs after a preemption delay of 60 seconds after a segment port failure and recovery. The interface is configured to remain up for 6000 ms without receiving a hello from a neighbor.

```
Switch# configure terminal
Switch (conf)# interface gigabitethernet1/1
Switch (conf-if)# rep segment 1 edge primary
Switch (conf-if)# rep stcn segment 2-5
Switch (conf-if)# rep block port 0009001818D68700 vlan all
Switch (conf-if)# rep preempt delay 60
Switch (conf-if)# rep lsl-age-timer 6000
Switch (conf-if)# end
```

This example shows how to configure the same configuration when the interface has no external REP neighbor:

```

Switch# configure terminal
Switch (conf)# interface gigabitethernet1/1
Switch (conf-if)# rep segment 1 edge no-neighbor primary
Switch (conf-if)# rep stcn segment 2-5
Switch (conf-if)# rep block port 0009001818D68700 vlan all
Switch (conf-if)# rep preempt delay 60
Switch (conf-if)# rep lsl-age-timer 6000
Switch (conf-if)# end

```

This example shows how to configure the VLAN blocking configuration shown in the Figure 5. The alternate port is the neighbor with neighbor offset number 4. After manual preemption, VLANs 100 to 200 are blocked at this port, and all the other VLANs are blocked at the primary edge port E1 (Gigabit Ethernet port 1/1).

Figure 43: Example of VLAN Blocking

```

Switch# configure terminal
Switch (conf)# interface gigabitethernet1/1
Switch (conf-if)# rep segment 1 edge primary
Switch (conf-if)# rep block port 4 vlan 100-200
Switch (conf-if)# end

```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for EtherChannels

- All ports in an EtherChannel must be assigned to the same VLAN or they must be configured as trunk ports.
- When the ports in an EtherChannel are configured as trunk ports, all the ports must be configured with the same mode (either Inter-Switch Link [ISL] or IEEE 802.1Q).
- Port Aggregation Protocol (PAgP) can be enabled only in single-switch EtherChannel configurations; PAgP cannot be enabled on cross-stack EtherChannels.

Information About EtherChannels

EtherChannel Overview

EtherChannel provides fault-tolerant high-speed links between switches, routers, and servers. You can use the EtherChannel to increase the bandwidth between the wiring closets and the data center, and you can deploy it anywhere in the network where bottlenecks are likely to occur. EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention.

An EtherChannel consists of individual Ethernet links bundled into a single logical link.

Figure 44: Typical EtherChannel Configuration

Each EtherChannel can consist of up to eight compatibly configured Ethernet ports.

The LAN Lite feature set supports up to six EtherChannels. The LAN Base feature set supports up to 24 EtherChannels.

EtherChannel Modes

You can configure an EtherChannel in one of these modes: Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), or On. Configure both ends of the EtherChannel in the same mode:

- When you configure one end of an EtherChannel in either PAgP or LACP mode, the system negotiates with the other end of the channel to determine which ports should become active. If the remote port cannot negotiate an EtherChannel, the local port is put into an independent state and continues to carry data traffic as would any other single link. The port configuration does not change, but the port does not participate in the EtherChannel.
- When you configure an EtherChannel in the **on** mode, no negotiations take place. The switch forces all compatible ports to become active in the EtherChannel. The other end of the channel (on the other switch) must also be configured in the **on** mode; otherwise, packet loss can occur.

EtherChannel on Devices

You can create an EtherChannel on a device, on a single device in the stack, or on multiple devices in the stack (known as cross-stack EtherChannel).

Figure 45: Single-Switch EtherChannel

Figure 46: Cross-Stack EtherChannel

EtherChannel Link Failover

If a link within an EtherChannel fails, traffic previously carried over that failed link moves to the remaining links within the EtherChannel. If traps are enabled on the switch, a trap is sent for a failure that identifies the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one link in an EtherChannel are blocked from returning on any other link of the EtherChannel.

Channel Groups and Port-Channel Interfaces

An EtherChannel comprises a channel group and a port-channel interface. The channel group binds physical ports to the port-channel interface. Configuration changes applied to the port-channel interface apply to all the physical ports bound together in the channel group.

Figure 47: Relationship of Physical Ports, Channel Group and Port-Channel Interface

The **channel-group** command binds the physical port and the port-channel interface together. Each EtherChannel has a port-channel logical interface numbered from 1 to 24. This port-channel interface number corresponds to the one specified with the **channel-group** interface configuration command.

- With Layer 2 ports, use the **channel-group** interface configuration command to dynamically create the port-channel interface.

You also can use the **interface port-channel** *port-channel-number* global configuration command to manually create the port-channel interface, but then you must use the **channel-group** *channel-group-number* command to bind the logical interface to a physical port. The *channel-group-number* can be the same as the *port-channel-number*, or you can use a new number. If you use a new number, the **channel-group** command dynamically creates a new port channel.

Port Aggregation Protocol

The Port Aggregation Protocol (PAgP) is a Cisco-proprietary protocol that can be run only on Cisco devices and on those devices licensed by vendors to support PAgP. PAgP facilitates the automatic creation of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP cannot be enabled on cross-stack EtherChannels.

By using PAgP, the device or device stack learns the identity of partners capable of supporting PAgP and the capabilities of each port. It then dynamically groups similarly configured ports (on a single device in the stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, PAgP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, PAgP adds the group to the spanning tree as a single device port.

PAgP Modes

PAgP modes specify whether a port can send PAgP packets, which start PAgP negotiations, or only respond to PAgP packets received.

Table 41: EtherChannel PAgP Modes

| Mode | Description |
|------------------|---|
| auto | Places a port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This setting minimizes the transmission of PAgP packets. This mode is not supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel). |
| desirable | Places a port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This mode is not supported when the EtherChannel members are from different switches in the switch stack (cross-stack EtherChannel). |

Switch ports exchange PAgP packets only with partner ports configured in the **auto** or **desirable** modes. Ports configured in the **on** mode do not exchange PAgP packets.

Both the **auto** and **desirable** modes enable ports to negotiate with partner ports to form an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different PAgP modes as long as the modes are compatible. For example:

- A port in the **desirable** mode can form an EtherChannel with another port that is in the **desirable** or **auto** mode.
- A port in the **auto** mode can form an EtherChannel with another port in the **desirable** mode.

A port in the **auto** mode cannot form an EtherChannel with another port that is also in the **auto** mode because neither port starts PAgP negotiation.

Silent Mode

If your switch is connected to a partner that is PAgP-capable, you can configure the switch port for nonsilent operation by using the **non-silent** keyword. If you do not specify **non-silent** with the **auto** or **desirable** mode, silent mode is assumed.

Use the silent mode when the switch is connected to a device that is not PAgP-capable and seldom, if ever, sends packets. An example of a silent partner is a file server or a packet analyzer that is not generating traffic. In this case, running PAgP on a physical port connected to a silent partner prevents that switch port from ever becoming operational. However, the silent setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission.

PAgP Learn Method and Priority

Network devices are classified as PAgP physical learners or aggregate-port learners. A device is a physical learner if it learns addresses by physical ports and directs transmissions based on that knowledge. A device is an aggregate-port learner if it learns addresses by aggregate (logical) ports. The learn method must be configured the same at both ends of the link.

When a device and its partner are both aggregate-port learners, they learn the address on the logical port-channel. The device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.

PAGP cannot automatically detect when the partner device is a physical learner and when the local device is an aggregate-port learner. Therefore, you must manually set the learning method on the local device to learn addresses by physical ports. You also must set the load-distribution method to source-based distribution, so that any given source MAC address is always sent on the same physical port.

You also can configure a single port within the group for all transmissions and use other ports for hot-standby. The unused ports in the group can be swapped into operation in just a few seconds if the selected single port loses hardware-signal detection. You can configure which port is always selected for packet transmission by changing its priority with the **pagp port-priority** interface configuration command. The higher the priority, the more likely that the port will be selected.

Note The device supports address learning only on aggregate ports even though the **physical-port** keyword is provided in the CLI. The **pagp learn-method** command and the **pagp port-priority** command have no effect on the device hardware, but they are required for PAGP interoperability with devices that only support address learning by physical ports, such as the Catalyst 1900 switch.

When the link partner of the device is a physical learner, we recommend that you configure the device as a physical-port learner by using the **pagp learn-method physical-port** interface configuration command. Set the load-distribution method based on the source MAC address by using the **port-channel load-balance src-mac** global configuration command. The device then sends packets to the physical learner using the same port in the EtherChannel from which it learned the source address. Only use the **pagp learn-method** command in this situation.

PAGP Interaction with Virtual Switches and Dual-Active Detection

A virtual switch can be two or more core switches connected by virtual switch links (VSLs) that carry control and data traffic between them. One of the switches is in active mode. The others are in standby mode. For redundancy, remote switches are connected to the virtual switch by remote satellite links (RSLs).

If the VSL between two switches fails, one switch does not know the status of the other. Both switches could change to the active mode, causing a *dual-active situation* in the network with duplicate configurations (including duplicate IP addresses and bridge identifiers). The network might go down.

To prevent a dual-active situation, the core switches send PAGP protocol data units (PDUs) through the RSLs to the remote switches. The PAGP PDUs identify the active switch, and the remote switches forward the PDUs to core switches so that the core switches are in sync. If the active switch fails or resets, the standby switch takes over as the active switch. If the VSL goes down, one core switch knows the status of the other and does not change its state.

PAGP Interaction with Other Features

The Dynamic Trunking Protocol (DTP) and the Cisco Discovery Protocol (CDP) send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive PAGP protocol data units (PDUs) on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel.

PAGP sends and receives PAGP PDUs only from ports that are up and have PAGP enabled for the auto or desirable mode.

Link Aggregation Control Protocol

The LACP is defined in IEEE 802.3ad and enables Cisco devices to manage Ethernet channels between devices that conform to the IEEE 802.3ad protocol. LACP facilitates the automatic creation of EtherChannels by exchanging LACP packets between Ethernet ports.

By using LACP, the device or device stack learns the identity of partners capable of supporting LACP and the capabilities of each port. It then dynamically groups similarly configured ports into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints. For example, LACP groups the ports with the same speed, duplex mode, native VLAN, VLAN range, and trunking status and type. After grouping the links into an EtherChannel, LACP adds the group to the spanning tree as a single device port.

The independent mode behavior of ports in a port channel is changed. With CSCtn96950, by default, standalone mode is enabled. When no response is received from an LACP peer, ports in the port channel are moved to suspended state.

LACP Modes

LACP modes specify whether a port can send LACP packets or only receive LACP packets.

Table 42: EtherChannel LACP Modes

| Mode | Description |
|----------------|--|
| active | Places a port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets. |
| passive | Places a port into a passive negotiating state in which the port responds to LACP packets that it receives, but does not start LACP packet negotiation. This setting minimizes the transmission of LACP packets. |

Both the **active** and **passive LACP** modes enable ports to negotiate with partner ports to an EtherChannel based on criteria such as port speed, and for Layer 2 EtherChannels, based on trunk state and VLAN numbers.

Ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A port in the **active** mode can form an EtherChannel with another port that is in the **active** or **passive** mode.
- A port in the **passive** mode cannot form an EtherChannel with another port that is also in the **passive** mode because neither port starts LACP negotiation.

LACP Interaction with Other Features

The DTP and the CDP send and receive packets over the physical ports in the EtherChannel. Trunk ports send and receive LACP PDUs on the lowest numbered VLAN.

In Layer 2 EtherChannels, the first port in the channel that comes up provides its MAC address to the EtherChannel. If this port is removed from the bundle, one of the remaining ports in the bundle provides its MAC address to the EtherChannel.

LACP sends and receives LACP PDUs only from ports that are up and have LACP enabled for the active or passive mode.

EtherChannel On Mode

EtherChannel **on** mode can be used to manually configure an EtherChannel. The **on** mode forces a port to join an EtherChannel without negotiations. The **on** mode can be useful if the remote device does not support PAgP or LACP. In the **on** mode, a usable EtherChannel exists only when the devices at both ends of the link are configured in the **on** mode.

Ports that are configured in the **on** mode in the same channel group must have compatible port characteristics, such as speed and duplex. Ports that are not compatible are suspended, even though they are configured in the **on** mode.

Caution You should use care when using the **on** mode. This is a manual configuration, and ports on both ends of the EtherChannel must have the same configuration. If the group is misconfigured, packet loss or spanning-tree loops can occur.

Load-Balancing and Forwarding Methods

EtherChannel balances the traffic load across the links in a channel by reducing part of the binary pattern formed from the addresses in the frame to a numerical value that selects one of the links in the channel. You can specify one of several different load-balancing modes, including load distribution based on MAC addresses, IP addresses, source addresses, destination addresses, or both source and destination addresses. The selected mode applies to all EtherChannels configured on the device.

Note Layer 3 Equal-cost multi path (ECMP) load balancing is based on source IP address, destination IP address, source port, destination port, and layer 4 protocol. Fragmented packets will be treated on two different links based on the algorithm calculated using these parameters. Any changes in one of these parameters will result in load balancing.

You configure the load-balancing and forwarding method by using the **port-channel load-balance** global configuration command.

MAC Address Forwarding

With source-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the source-MAC address of the incoming packet. Therefore, to provide load-balancing, packets from different hosts use different ports in the channel, but packets from the same host use the same port in the channel.

With destination-MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on the destination host's MAC address of the incoming packet. Therefore,

packets to the same destination are forwarded over the same port, and packets to a different destination are sent on a different port in the channel.

With source-and-destination MAC address forwarding, when packets are forwarded to an EtherChannel, they are distributed across the ports in the channel based on both the source and destination MAC addresses. This forwarding method, a combination source-MAC and destination-MAC address forwarding methods of load distribution, can be used if it is not clear whether source-MAC or destination-MAC address forwarding is better suited on a particular device. With source-and-destination MAC-address forwarding, packets sent from host A to host B, host A to host C, and host C to host B could all use different ports in the channel.

IP Address Forwarding

With source-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the source-IP address of the incoming packet. To provide load balancing, packets from different IP addresses use different ports in the channel, and packets from the same IP address use the same port in the channel.

With destination-IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on the destination-IP address of the incoming packet. To provide load balancing, packets from the same IP source address sent to different IP destination addresses could be sent on different ports in the channel. Packets sent from different source IP addresses to the same destination IP address are always sent on the same port in the channel.

With source-and-destination IP address-based forwarding, packets are distributed across the ports in the EtherChannel based on both the source and destination IP addresses of the incoming packet. This forwarding method, a combination of source-IP and destination-IP address-based forwarding, can be used if it is not clear whether source-IP or destination-IP address-based forwarding is better suited on a particular device. In this method, packets sent from the IP address A to IP address B, from IP address A to IP address C, and from IP address C to IP address B could all use different ports in the channel.

Load-Balancing Advantages

Different load-balancing methods have different advantages, and the choice of a particular load-balancing method should be based on the position of the device in the network and the kind of traffic that needs to be load-distributed.

Figure 48: Load Distribution and Forwarding Methods

In the following figure, an EtherChannel of four workstations communicates with a router. Because the router is a single MAC-address device, source-based forwarding on the device EtherChannel ensures that the device uses all available bandwidth to the router. The router is configured for destination-based forwarding because

the large number of workstations ensures that the traffic is evenly distributed from the router EtherChannel.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination-MAC address always chooses the same link in the channel. Using source addresses or IP addresses might result in better load-balancing.

EtherChannel Load Deferral Overview

In an Instant Access system, the EtherChannel Load Deferral feature allows ports to be bundled into port channels, but prevents the assignment of group mask values to these ports. This prevents the traffic from being forwarded to new instant access stack members and reduce data loss following a stateful switchover (SSO).

Cisco Catalyst Instant Access creates a single network touch point and a single point of configuration across distribution and access layer switches. Instant Access enables the merging of physical distribution and access layer switches into a single logical entity with a single point of configuration, management, and troubleshooting. The following illustration represents a sample network where an Instant Access system interacts with a switch (Catalyst 2960-X Series Switches) that is connected via a port channel to stacked clients (Member 1 and Member 2).

When the EtherChannel Load Deferral feature is configured and a new Instant Access client stack member comes up, ports of this newly-joined stack member is bundled into the port channel. In the transition period, the data path is not fully established on the distribution switch (Catalyst 6000 Series Switches), and traffic originating from the access layer switch (Catalyst 2960-X Series Switches) reaches the non-established ports and the traffic gets lost.

When load share deferral is enabled on a port channel, the assignment of a member port's load share is delayed for a period that is configured globally by the **port-channel load-defer** command. During the deferral period, the load share of a deferred member port is set to 0. In this state, the deferred port is capable of receiving data and control traffic, and of sending control traffic, but the port is prevented from sending data traffic to the virtual switching system (VSS). Upon expiration of the global deferral timer, the deferred member port exits the deferral state and the port assumes its normal configured load share.

Load share deferral is applied only if at least one member port of the port channel is currently active with a nonzero load share. If a port enabled for load share deferral is the first member bringing up the EtherChannel, the deferral feature does not apply and the port will forward traffic immediately.

This feature is enabled on a per port-channel basis; however, the load deferral timer is configured globally and not per port-channel. As a result, when a new port is bundled, the timer starts only if it is not already running. If some other ports are already deferred then the new port will be deferred only for the remaining amount of time.

The load deferral is stopped as soon as a member in one of the deferred port channels is unbundled. As a result, all the ports that were deferred is assigned a group-mask in the event of an unbundling during the deferral period.

Note When you try to enable this feature on a stack member switch, the following message is displayed:

```
Load share deferral is supported only on stand-alone stack.
```

EtherChannel and Device Stacks

If a stack member that has ports participating in an EtherChannel fails or leaves the stack, the active device removes the failed stack member device ports from the EtherChannel. The remaining ports of the EtherChannel, if any, continue to provide connectivity.

When a device is added to an existing stack, the new device receives the running configuration from the active device and updates itself with the EtherChannel-related stack configuration. The stack member also receives the operational information (the list of ports that are up and are members of a channel).

When two stacks merge that have EtherChannels configured between them, self-looped ports result. Spanning tree detects this condition and acts accordingly. Any PAgP or LACP configuration on a winning device stack is not affected, but the PAgP or LACP configuration on the losing device stack is lost after the stack reboots.

For a mixed stack containing one or more Catalyst 2960-S switches, we recommend that you configure no more than six EtherChannels on the stack.

Device Stack and PAgP

With PAgP, if the active device fails or leaves the stack, the standby device becomes the new active device. The new active device synchronizes the configuration of the stack members to that of the active device. The PAgP configuration is not affected after an active device change unless the EtherChannel has ports residing on the old active device.

Switch Stacks and LACP

With LACP, the system ID uses the stack MAC address from the active switch, and if the active switch changes, the LACP system ID can change. If the LACP system ID changes, the entire EtherChannel will flap, and there will be an STP reconvergence. Use the **stack-mac persistent timer** command to control whether or not the stack MAC address changes during a active switch failover.

Default EtherChannel Configuration

The default EtherChannel configuration is described in this table.

Table 43: Default EtherChannel Configuration

| Feature | Default Setting |
|--------------------------------|--|
| Channel groups | None assigned. |
| Port-channel logical interface | None defined. |
| PAgP mode | No default. |
| PAgP learn method | Aggregate-port learning on all ports. |
| PAgP priority | 128 on all ports. |
| LACP mode | No default. |
| LACP learn method | Aggregate-port learning on all ports. |
| LACP port priority | 32768 on all ports. |
| LACP system priority | 32768. |
| LACP system ID | LACP system priority and the device or stack MAC address. |
| Load-balancing | Load distribution on the device is based on the source-MAC address of the incoming packet. |

EtherChannel Configuration Guidelines

If improperly configured, some EtherChannel ports are automatically disabled to avoid network loops and other problems. Follow these guidelines to avoid configuration problems:

- Do not try to configure more than 24 EtherChannels on the device or device stack.
- In a mixed switch stack that contains one or more Catalyst 2960-S switches, do not configure more than six EtherChannels on the switch stack.
- Configure a PAgP EtherChannel with up to eight Ethernet ports of the same type.
- Configure a LACP EtherChannel with up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode.
- Configure all ports in an EtherChannel to operate at the same speeds and duplex modes.
- Enable all ports in an EtherChannel. A port in an EtherChannel that is disabled by using the **shutdown** interface configuration command is treated as a link failure, and its traffic is transferred to one of the remaining ports in the EtherChannel.

- When a group is first created, all ports follow the parameters set for the first port to be added to the group. If you change the configuration of one of these parameters, you must also make the changes to all ports in the group:
 - Allowed-VLAN list
 - Spanning-tree path cost for each VLAN
 - Spanning-tree port priority for each VLAN
 - Spanning-tree Port Fast setting
- Do not configure a port to be a member of more than one EtherChannel group.
- Do not configure an EtherChannel in both the PAgP and LACP modes. EtherChannel groups running PAgP and LACP can coexist on the same device or on different devices in the stack. Individual EtherChannel groups can run either PAgP or LACP, but they cannot interoperate.
- Do not configure a secure port as part of an EtherChannel or the reverse.
- Do not configure a port that is an active or a not-yet-active member of an EtherChannel as an IEEE 802.1x port. If you try to enable IEEE 802.1x on an EtherChannel port, an error message appears, and IEEE 802.1x is not enabled.
- If EtherChannels are configured on device interfaces, remove the EtherChannel configuration from the interfaces before globally enabling IEEE 802.1x on a device by using the **dot1x system-auth-control** global configuration command.
- For cross-stack EtherChannel configurations, ensure that all ports targeted for the EtherChannel are either configured for LACP or are manually configured to be in the channel group using the **channel-group channel-group-number mode on** interface configuration command. The PAgP protocol is not supported on cross-stack EtherChannels.

Layer 2 EtherChannel Configuration Guidelines

When configuring Layer 2 EtherChannels, follow these guidelines:

- Assign all ports in the EtherChannel to the same VLAN, or configure them as trunks. Ports with different native VLANs cannot form an EtherChannel.
- An EtherChannel supports the same allowed range of VLANs on all the ports in a trunking Layer 2 EtherChannel. If the allowed range of VLANs is not the same, the ports do not form an EtherChannel even when PAgP is set to the **auto** or **desirable** mode.
- Ports with different spanning-tree path costs can form an EtherChannel if they are otherwise compatibly configured. Setting different spanning-tree path costs does not, by itself, make ports incompatible for the formation of an EtherChannel.

Auto-LAG

The auto-LAG feature provides the ability to auto create EtherChannels on ports connected to a switch. By default, auto-LAG is disabled globally and is enabled on all port interfaces. The auto-LAG applies to a switch only when it is enabled globally.

On enabling auto-LAG globally, the following scenarios are possible:

- All port interfaces participate in creation of auto EtherChannels provided the partner port interfaces have EtherChannel configured on them. For more information, see the "The supported auto-LAG configurations between the actor and partner devices" table below.
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.
- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

Table 44: The supported auto-LAG configurations between the actor and partner devices

| Actor/Partner | Active | Passive | Auto |
|---------------|--------|---------|------|
| Active | Yes | Yes | Yes |
| Passive | Yes | No | Yes |
| Auto | Yes | Yes | Yes |

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels.

You cannot add any configurations in an existing auto created EtherChannel. To add, you should first convert it into a manual EtherChannel by executing the **port-channel<channel-number>persistent**.

Note Auto-LAG uses the LACP protocol to create auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring the auto-LAG feature.

- When auto-LAG is enabled globally and on the port interface, and if you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.
- A port interface will not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.
- When auto-LAG is enabled and auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.
- The auto-LAG is supported only on Layer 2 EtherChannel. It is not supported on Layer 3 interface and Layer 3 EtherChannel.
- The auto-LAG is supported on cross-stack EtherChannel.

How to Configure EtherChannels

After you configure an EtherChannel, configuration changes applied to the port-channel interface apply to all the physical ports assigned to the port-channel interface, and configuration changes applied to the physical port affect only the port where you apply the configuration.

Configuring Layer 2 EtherChannels

You configure Layer 2 EtherChannels by assigning ports to a channel group with the **channel-group** interface configuration command. This command automatically creates the port-channel logical interface.

If you enabled PAgP on a port in the **auto** or **desirable** mode, you must reconfigure it for either the **on** mode or the LACP mode before adding this port to a cross-stack EtherChannel. PAgP does not support cross-stack EtherChannels.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1 | Specifies a physical port, and enters interface configuration mode. Valid interfaces are physical ports. For a PAgP EtherChannel, you can configure up to eight ports of the same type and speed for the same group. For a LACP EtherChannel, you can configure up to 16 Ethernet ports of the same type. Up to eight ports can be active, and up to eight ports can be in standby mode. |
| Step 3 | switchport mode {access trunk} Example: Device(config-if)# switchport mode access | Assigns all ports as static-access ports in the same VLAN, or configure them as trunks. If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094. |
| Step 4 | switchport access vlan <i>vlan-id</i> Example: Device(config-if)# switchport access vlan 22 | (Optional) If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094. |

| | Command or Action | Purpose |
|--------|--|---|
| Step 5 | <p>channel-group <i>channel-group-number</i> mode {auto [non-silent] desirable [non-silent] on } { active passive }</p> <p>Example:</p> <pre>Device(config-if) # channel-group 5 mode auto</pre> | <p>Assigns the port to a channel group, and specifies the PAgP or the LACP mode.</p> <p>For <i>channel-group-number</i>, the range is 1 to 24.</p> <p>For mode, select one of these keywords:</p> <ul style="list-style-type: none"> • auto —Enables PAgP only if a PAgP device is detected. It places the port into a passive negotiating state, in which the port responds to PAgP packets it receives but does not start PAgP packet negotiation. This keyword is not supported when EtherChannel members are from different devices in the device stack. • desirable —Unconditionally enables PAgP. It places the port into an active negotiating state, in which the port starts negotiations with other ports by sending PAgP packets. This keyword is not supported when EtherChannel members are from different devices in the device stack. • on —Forces the port to channel without PAgP or LACP. In the on mode, an EtherChannel exists only when a port group in the on mode is connected to another port group in the on mode. • non-silent —(Optional) If your device is connected to a partner that is PAgP-capable, configures the device port for nonsilent operation when the port is in the auto or desirable mode. If you do not specify non-silent, silent is assumed. The silent setting is for connections to file servers or packet analyzers. This setting allows PAgP to operate, to attach the port to a channel group, and to use the port for transmission. • active —Enables LACP only if a LACP device is detected. It places the port into an active negotiating state in which the port starts negotiations with other ports by sending LACP packets. • passive —Enables LACP on the port and places it into a passive negotiating state in which the port responds to LACP packets |

| | Command or Action | Purpose |
|---------------|--|---|
| | | that it receives, but does not start LACP packet negotiation. |
| Step 6 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring EtherChannel Load-Balancing

You can configure EtherChannel load-balancing by using source-based or destination-based forwarding methods.

This task is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | port-channel load-balance { dst-ip dst-mac src-dst-ip src-dst-mac src-ip src-mac } Example: Device(config)# port-channel load-balance src-mac | Configures an EtherChannel load-balancing method. The default is src-mac . Select one of these load-distribution methods: <ul style="list-style-type: none"> • dst-ip—Specifies destination-host IP address. • dst-mac—Specifies the destination-host MAC address of the incoming packet. • src-dst-ip—Specifies the source and destination host IP address. • src-dst-mac—Specifies the source and destination host MAC address. • src-ip—Specifies the source host IP address. • src-mac—Specifies the source MAC address of the incoming packet. |

| | Command or Action | Purpose |
|---------------|---|----------------------------------|
| Step 3 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuring Port Channel Load Deferral

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Switch> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Switch# configure terminal | Enters global configuration mode. |
| Step 3 | port-channel load-defer <i>seconds</i> Example: Switch(config)# port-channel load-defer 60 | Configures the port load share deferral interval for all port channels. <ul style="list-style-type: none"> • <i>seconds</i>—The time interval during which load sharing is initially 0 for deferred port channels. The range is 1 to 1800 seconds; the default is 120 seconds |
| Step 4 | interface <i>type number</i> Example: Switch(config)# interface port-channel 10 | Configures a port channel interface and enters interface configuration mode. |
| Step 5 | port-channel load-defer Example: Switch(config-if)# port-channel load-defer | Enables port load share deferral on the port channel. |
| Step 6 | end Example: Switch(config-if)# end | Exits interface configuration mode and returns to privileged EXEC mode. |
| Step 7 | show etherchannel <i>channel-group</i> port-channel Example: Switch# show etherchannel 1 port-channel | Displays port channel information. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 8 | show platform pm group-masks Example: Switch# show platform pm group-masks | Display EtherChannel group masks information. |

Example

The following is sample output from the **show etherchannel *channel-group* port-channel** command. If the *channel-group* argument is not specified, the command displays information about all channel groups are displayed.

```
Switch# show etherchannel 1 port-channel
```

```
Port-channels in the group:
```

```
-----
```

```
Port-channel: Po1
```

```
-----
```

```
Age of the Port-channel      = 0d:00h:37m:08s
Logical slot/port           = 9/1             Number of ports = 0
GC                           = 0x00000000     HotStandBy port = null
Port state                   = Port-channel Ag-Not-Inuse
Protocol                     = -
Port security                 = Disabled
Load share deferral          = Enabled        defer period = 120 sec   time left = 0 sec
```

The following is sample output from the **show platform pm group-masks** command. Deferred ports have the group mask of 0xFFFF, when the defer timer is running.

```
Switch# show platform pm group-masks
```

```

Configuring the PAgP Learn Method and Priority

This task is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the port for transmission, and enters interface configuration mode. |
| Step 3 | pagp learn-method physical-port Example: Device(config-if)# pagp learn-method physical port | <p>Selects the PAgP learning method.</p> <p>By default, aggregation-port learning is selected, which means the device sends packets to the source by using any of the ports in the EtherChannel. With aggregate-port learning, it is not important on which physical port the packet arrives.</p> <p>Selects physical-port to connect with another device that is a physical learner.</p> <p>Make sure to configure the port-channel load-balance global configuration command to src-mac.</p> <p>The learning method must be configured the same at both ends of the link.</p> |
| Step 4 | pagp port-priority <i>priority</i> Example: Device(config-if)# pagp port-priority 200 | <p>Assigns a priority so that the selected port is chosen for packet transmission.</p> <p>For <i>priority</i>, the range is 0 to 255. The default is 128. The higher the priority, the more likely that the port will be used for PAgP transmission.</p> |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring LACP Hot-Standby Ports

When enabled, LACP tries to configure the maximum number of LACP-compatible ports in a channel, up to a maximum of 16 ports. Only eight LACP links can be active at one time. The software places any additional links in a hot-standby mode. If one of the active links becomes inactive, a link that is in the hot-standby mode becomes active in its place.

If you configure more than eight links for an EtherChannel group, the software automatically decides which of the hot-standby ports to make active based on the LACP priority. To every link between systems that operate LACP, the software assigns a unique priority made up of these elements (in priority order):

- LACP system priority
- System ID (the device MAC address)
- LACP port priority
- Port number

In priority comparisons, numerically lower values have higher priority. The priority decides which ports should be put in standby mode when there is a hardware limitation that prevents all compatible ports from aggregating.

Determining which ports are active and which are hot standby is a two-step procedure. First the system with a numerically lower system priority and system ID is placed in charge of the decision. Next, that system decides which ports are active and which are hot standby, based on its values for port priority and port number. The port priority and port number values for the other system are not used.

You can change the default values of the LACP system priority and the LACP port priority to affect how the software selects active and standby links.

Configuring the LACP System Priority

You can configure the system priority for all the EtherChannels that are enabled for LACP by using the **lACP system-priority** global configuration command. You cannot configure a system priority for each LACP-configured channel. By changing this value from the default, you can affect how the software selects active and standby links.

You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Follow these steps to configure the LACP system priority. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>configure terminal</code> | |
| Step 3 | lacp system-priority <i>priority</i> Example: Device(config)# <code>lacp system-priority 32000</code> | Configures the LACP system priority. The range is 1 to 65535. The default is 32768. The lower the value, the higher the system priority. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

Configuring the LACP Port Priority

By default, all ports use the same port priority. If the local system has a lower value for the system priority and the system ID than the remote system, you can affect which of the hot-standby links become active first by changing the port priority of LACP EtherChannel ports to a lower value than the default. The hot-standby ports that have lower port numbers become active in the channel first. You can use the **show etherchannel summary** privileged EXEC command to see which ports are in the hot-standby mode (denoted with an H port-state flag).

Note If LACP is not able to aggregate all the ports that are compatible (for example, the remote system might have more restrictive hardware limitations), all the ports that cannot be actively included in the EtherChannel are put in the hot-standby state and are used only if one of the channeled ports fails.

Follow these steps to configure the LACP port priority. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/2 | Specifies the port to be configured, and enters interface configuration mode. |
| Step 4 | lacp port-priority <i>priority</i> Example: Device(config-if)# lacp port-priority 32000 | Configures the LACP port priority. The range is 1 to 65535. The default is 32768. The lower the value, the more likely that the port will be used for LACP transmission. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Configuring the LACP Port Channel Min-Links Feature

You can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

To configure the minimum number of links that are required for a port channel. Perform the following tasks.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface port-channel <i>channel-number</i> Example: | Enters interface configuration mode for a port-channel. For <i>channel-number</i> , the range is 1 to 63. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config)# interface port-channel 2 | |
| Step 4 | port-channel min-links min-links-number Example: Device(config-if)# port-channel min-links 3 | Specifies the minimum number of member ports that must be in the link-up state and bundled in the EtherChannel for the port channel interface to transition to the link-up state. For <i>min-links-number</i> , the range is 2 to 8. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuring LACP Fast Rate Timer

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the **lACP rate** command to set the rate at which LACP control packets are received by an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface {fastethernet gigabitethernet tengigabitethernet} slot/port Example: Device(config)# interface gigabitEthernet 2/1 | Configures an interface and enters interface configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 4 | lACP rate {normal fast} Example: <pre>Device(config-if)# lACP rate fast</pre> | Configures the rate at which LACP control packets are received by an LACP-supported interface. <ul style="list-style-type: none"> • To reset the timeout rate to its default, use the no lACP rate command. |
| Step 5 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show lACP internal Example: <pre>Device# show lACP internal Device# show lACP counters</pre> | Verifies your configuration. |

Configuring Auto-LAG Globally

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | [no] port-channel auto Example: <pre>Device(config)# port-channel auto</pre> | Enables the auto-LAG feature on a switch globally. Use the no form of this command to disable the auto-LAG feature on the switch globally. <p>Note By default, the auto-LAG feature is enabled on the port.</p> |
| Step 4 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config)# end | |
| Step 5 | show etherchannel auto Example: Device# show etherchannel auto | Displays that EtherChannel is created automatically. |

Configuring Auto-LAG on a Port Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface interface-id Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the port interface to be enabled for auto-LAG, and enters interface configuration mode. |
| Step 4 | [no] channel-group auto Example: Device(config-if)# channel-group auto | (Optional) Enables auto-LAG feature on individual port interface. Use the no form of this command to disable the auto-LAG feature on individual port interface. Note By default, the auto-LAG feature is enabled on the port. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | show etherchannel auto Example: Device# show etherchannel auto | Displays that EtherChannel is created automatically. |

What to do next

Configuring Persistence with Auto-LAG

You use the persistence command to convert the auto created EtherChannel into a manual one and allow you to add configuration on the existing EtherChannel.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | port-channel <i>channel-number</i> persistent Example: Device# port-channel 1 persistent | Converts the auto created EtherChannel into a manual one and allows you to add configuration on the EtherChannel. |
| Step 3 | show etherchannel summary Example: Device# show etherchannel summary | Displays the EtherChannel information. |

Monitoring EtherChannel, PAgP, and LACP Status

You can display EtherChannel, PAgP, and LACP status using the commands listed in this table.

Table 45: Commands for Monitoring EtherChannel, PAgP, and LACP Status

| Command | Description |
|--|---|
| clear lacp { <i>channel-group-number</i> counters counters } | Clears LACP channel-group information and traffic counters. |
| clear pagp { <i>channel-group-number</i> counters counters } | Clears PAgP channel-group information and traffic counters. |
| show etherchannel [<i>channel-group-number</i> { detail load-balance port port-channel protocol summary }] [detail load-balance port port-channel protocol auto summary] | Displays EtherChannel information in a brief, detailed, and one-line summary form. Also displays the load-balance or frame-distribution scheme, port, port-channel, protocol, and Auto-LAG information. |
| show pagp [<i>channel-group-number</i>] { counters internal neighbor } | Displays PAgP information such as traffic information, the internal PAgP configuration, and neighbor information. |

| Command | Description |
|--|---|
| show pagp [<i>channel-group-number</i>] dual-active | Displays the dual-active detection status. |
| show lacp [<i>channel-group-number</i>] { counters internal neighbor sys-id } | Displays LACP information such as traffic information, the internal LACP configuration, and neighbor information. |
| show running-config | Verifies your configuration entries. |
| show etherchannel load-balance | Displays the load balance or frame distribution scheme among ports in the port channel. |

Configuration Examples for Configuring EtherChannels

Configuring Layer 2 EtherChannels: Examples

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the PAGP mode **desirable**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode desirable non-silent
Device(config-if-range)# end
```

This example shows how to configure an EtherChannel on a single device in the stack. It assigns two ports as static-access ports in VLAN 10 to channel 5 with the LACP mode **active**:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/1 -2
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode active
Device(config-if-range)# end
```

This example shows how to configure a cross-stack EtherChannel. It uses LACP passive mode and assigns two ports on stack member 1 and one port on stack member 2 as static-access ports in VLAN 10 to channel 5:

```
Device# configure terminal
Device(config)# interface range gigabitethernet2/0/4 -5
Device(config-if-range)# switchport mode access
Device(config-if-range)# switchport access vlan 10
Device(config-if-range)# channel-group 5 mode passive
Device(config-if-range)# exit
Device(config)# interface gigabitethernet3/0/3
Device(config-if)# switchport mode access
```

```
Device(config-if)# switchport access vlan 10
Device(config-if)# channel-group 5 mode passive
Device(config-if)# exit
```

PoE or LACP negotiation errors may occur if you configure two ports from switch to the access point (AP). This scenario can be avoided if the port channel configuration is on the switch side. For more details, see the following example:

```
interface Port-channel1
  switchport access vlan 20
  switchport mode access
  switchport nonegotiate
  no port-channel standalone-disable <--this one
  spanning-tree portfast
```

Note If the port reports LACP errors on port flap, you should include the following command as well: **no errdisable detect cause pagp-flap**

Example: Configuring Port Channel Load Deferral

```
Switch# configure terminal
Switch(config)# port-channel load-defer 60
Switch(config)# interface port-channel 10
Switch(config-if)# port-channel load-defer
Switch(config-if)# end
```

Configuring Auto LAG: Examples

This example shows how to configure Auto-LAG on a switch

```
device> enable
device# configure terminal
device (config)# port-channel auto
device (config-if)# end
device# show etherchannel auto
```

The following example shows the summary of EtherChannel that was created automatically.

```
device# show etherchannel auto
Flags:  D - down          P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3       S - Layer2
        U - in use       f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
        A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators:          1

Group  Port-channel  Protocol    Ports
```

```
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1      Pol(SUA)          LACP          Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)
```

The following example shows the summary of auto EtherChannel after executing the **port-channel 1 persistent** command.

```
device# port-channel 1 persistent

device# show etherchannel summary
Switch# show etherchannel summary
Flags:  D - down          P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3       S - Layer2
        U - in use       f - failed to allocate aggregator
        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
        A - formed by Auto LAG

Number of channel-groups in use: 1
Number of aggregators:          1

Group  Port-channel  Protocol  Ports
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
1      Pol(SU)          LACP          Gi1/0/45(P) Gi2/0/21(P) Gi3/0/21(P)
```

Configuring LACP Port Channel Min-Links: Examples

This example shows how to configure LACP port-channel min-links:

```
device > enable
device# configure terminal
device(config)# interface port-channel 5
device(config-if)# port-channel min-links 3
device# show etherchannel 25 summary
device# end
```

When the minimum links requirement is not met in standalone switches, the port-channel is flagged and assigned SM/SN or RM/RN state.

```
device# show etherchannel 5 summary

Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
U - in use N- not in use, no aggregation
f - failed to allocate aggregator
M - not in use, no aggregation due to minimum links not met
m- not in use, port not aggregated due to minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
Number of channel-groups in use: 6
Number of aggregators: 6

Group  Port-channel  Protocol  Ports
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
6      Po25(RM)          LACP          Gi1/3/1(D) Gi1/3/2(D) Gi2/2/25(D) Gi2/2/26(W)
```

Example: Configuring LACP Fast Rate Timer

This example shows you how to configure the LACP rate:

```
device> enable
device# configure terminal
device(config)# interface gigabitEthernet 2/1
device(config-if)# lacp rate fast
device(config-if)# exit
device(config)# end
device# show lacp internal
device# show lacp counters
```

The following is sample output from the **show lacp internal** command:

```
device# show lacp internal
Flags: S - Device is requesting Slow LACPDUs
F - Device is requesting Fast LACPDUs
A - Device is in Active mode P - Device is in Passive mode
Channel group 25
LACP port Admin Oper Port Port
Port Flags State Priority Key Key Number State
Tel/49 FA bndl 32768 0x19 0x19 0x32 0x3F

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Configuring Link-State Tracking

- This feature is supported only on the LAN Base image.
- You can configure only two link-state groups per switch.
- An interface cannot be a member of more than one link-state group.
- An interface that is defined as an upstream interface in a link-state group cannot also be defined as a downstream interface in the link-state group.
- Do not enable link-state tracking on individual interfaces that will part of a downstream EtherChannel interface.

Understanding Link-State Tracking

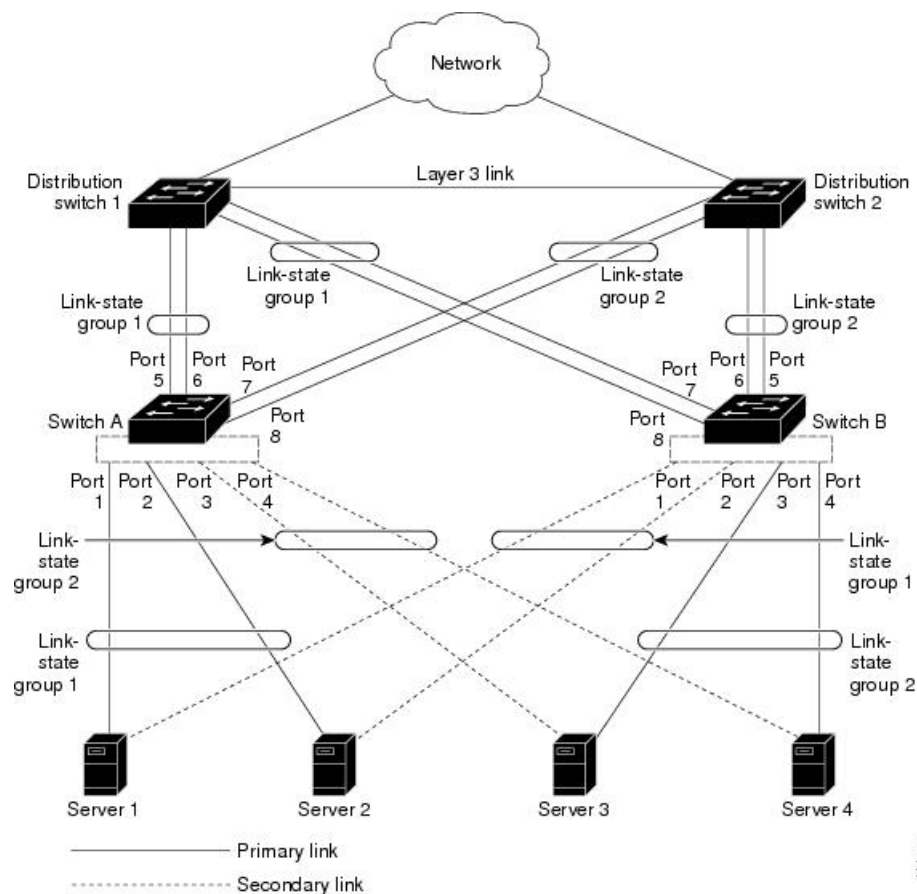

Link-state tracking, also known as trunk failover, binds the link state of multiple interfaces. Link-state tracking can be with server NIC adapter teaming to provide redundancy in the network. When the server NIC adapters are configured in a primary or secondary relationship, and the link is lost on the primary interface, network connectivity is transparently changed to the secondary interface.

Note An interface can be an aggregation of ports (an EtherChannel) or a single physical port in either access or trunk mode .

The configuration in this figure ensures that the network traffic flow is balanced.

Figure 49: Typical Link-State Tracking Configuration

- For links to switches and other network devices
 - Server 1 and server 2 use switch A for primary links and switch B for secondary links.
 - Server 3 and server 4 use switch B for primary links and switch A for secondary links.
- Link-state group 1 on switch A

- Switch A provides primary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.
- Port 5 and port 6 are connected to distribution switch 1 through link-state group 1. Port 5 and port 6 are the upstream interfaces in link-state group 1.
- Link-state group 2 on switch A
 - Switch A provides secondary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.
 - Port 7 and port 8 are connected to distribution switch 2 through link-state group 2. Port 7 and port 8 are the upstream interfaces in link-state group 2.
- Link-state group 2 on switch B
 - Switch B provides primary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.
 - Port 5 and port 6 are connected to distribution switch 2 through link-state group 2. Port 5 and port 6 are the upstream interfaces in link-state group 2.
- Link-state group 1 on switch B
 - Switch B provides secondary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.
 - Port 7 and port 8 are connected to distribution switch 1 through link-state group 1. Port 7 and port 8 are the upstream interfaces in link-state group 1.

In a link-state group, the upstream ports can become unavailable or lose connectivity because the distribution switch or router fails, the cables are disconnected, or the link is lost. These are the interactions between the downstream and upstream interfaces when link-state tracking is enabled:

- If any of the upstream interfaces are in the link-up state, the downstream interfaces can change to or remain in the link-up state.
- If all of the upstream interfaces become unavailable, link-state tracking automatically puts the downstream interfaces in the error-disabled state. Connectivity to and from the servers is automatically changed from the primary server interface to the secondary server interface. For example, in the previous figure, if the upstream link for port 6 is lost, the link states of downstream ports 1 and 2 do not change. However, if the link for upstream port 5 is also lost, the link state of the downstream ports changes to the link-down state. Connectivity to server 1 and server 2 is then changed from link-state group 1 to link-state group 2. The downstream ports 3 and 4 do not change state because they are in link-group 2.
- If the link-state group is configured, link-state tracking is disabled, and the upstream interfaces lose connectivity, the link states of the downstream interfaces remain unchanged. The server does not recognize that upstream connectivity has been lost and does not failover to the secondary interface.

You can recover a downstream interface link-down condition by removing the failed downstream port from the link-state group. To recover multiple downstream interfaces, disable the link-state group.

How to Configure Link-State Tracking

To enable link-state tracking, create a link-state group and specify the interfaces that are assigned to the group. This task is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | link state track <i>number</i> Example: Device(config)# link state track 2 | Creates a link-state group and enables link-state tracking. The group number can be 1 or 2; the default is 1. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet2/0/1 | Specifies a physical interface or range of interfaces to configure, and enters interface configuration mode. Valid interfaces include switch ports in access or trunk mode (IEEE 802.1q) or routed ports. Note Do not enable link-state tracking on individual interfaces that will be part of an Etherchannel interface. |
| Step 4 | link state group [<i>number</i>]{<u>upstream</u> downstream} Example: Device(config-if)# link state group 2 upstream | Specifies a link-state group and configures the interface as either an upstream or downstream interface in the group. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |

Monitoring Link-State Tracking

You can display link-state tracking status using the command in this table.

Table 46: Commands for Monitoring Link-State Tracking Status

| Command | Description |
|--|--|
| <code>show link state group [number] [detail]</code> | Displays the link-state group information. |

Configuring Link-State Tracking: Example

This example shows how to create the link-state group 1 and configure the interfaces in the link-state group.

```
Device# configure terminal
Device(config)# link state track 1
Device(config-if)# interface range gigabitethernet1/0/21-22
Device(config-if)# link state group 1 upstream
Device(config-if)# interface gigabitethernet1/0/1
Device(config-if)# link state group 1 downstream
Device(config-if)# interface gigabitethernet1/0/3
Device(config-if)# link state group 1 downstream
Device(config-if)# interface gigabitethernet1/0/5
Device(config-if)# link state group 1 downstream
Device(config-if)# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Configuring Flex Links and MAC Address-Table Move Update

- This feature is supported only on the LAN Base image.
- Flex Links are supported only on Layer 2 ports and port channels.
- You can configure up to 16 backup links.
- You can configure only one Flex Links backup link for any active link, and it must be a different interface from the active interface.

- An interface can belong to only one Flex Links pair. An interface can be a backup link for only one active link. An active link cannot belong to another Flex Links pair.
- Neither of the links can be a port that belongs to an EtherChannel. However, you can configure two port channels (EtherChannel logical interfaces) as Flex Links, and you can configure a port channel and a physical interface as Flex Links, with either the port channel or the physical interface as the active link.
- A backup link does not have to be the same type (Gigabit Ethernet or port channel) as the active link. However, you should configure both Flex Links with similar characteristics so that there are no loops or changes in behavior if the standby link begins to forward traffic.
- STP is disabled on Flex Links ports. A Flex Links port does not participate in STP, even if the VLANs present on the port are configured for STP. When STP is not enabled, be sure that there are no loops in the configured topology.

Information About Flex Links and MAC Address-Table Move Update

Flex Links

Flex Links are a pair of a Layer 2 interfaces (device ports or port channels) where one interface is configured to act as a backup to the other. The feature provides an alternative solution to the Spanning Tree Protocol (STP). Users can disable STP and still retain basic link redundancy. Flex Links are typically configured in service provider or enterprise networks where customers do not want to run STP on the device. If the device is running STP, Flex Links are not necessary because STP already provides link-level redundancy or backup.

You configure Flex Links on one Layer 2 interface (the active link) by assigning another Layer 2 interface as the Flex Links or backup link. On devices, the Flex Links can be on the same device or on another device in the stack. When one of the links is up and forwarding traffic, the other link is in standby mode, ready to begin forwarding traffic if the other link shuts down. At any given time, only one of the interfaces is in the linkup state and forwarding traffic. If the primary link shuts down, the standby link starts forwarding traffic. When the active link comes back up, it goes into standby mode and does not forward traffic. STP is disabled on Flex Links interfaces.

Flex Links Configuration

In the following figure, ports 1 and 2 on device A are connected to uplink switches B and C. Because they are configured as Flex Links, only one of the interfaces is forwarding traffic; the other is in standby mode. If port 1 is the active link, it begins forwarding traffic between port 1 and switch B; the link between port 2 (the backup link) and switch C is not forwarding traffic. If port 1 goes down, port 2 comes up and starts forwarding traffic to switch C. When port 1 comes back up, it goes into standby mode and does not forward traffic; port 2 continues forwarding traffic.

You can also configure a preemption function, specifying the preferred port for forwarding traffic. For example, you can configure the Flex Links pair with preemption mode. In the scenario shown, when port 1 comes back up and has more bandwidth than port 2, port 1 begins forwarding traffic after 60 seconds. Port 2 becomes the standby port. You do this by entering the **switchport backup interface preemption mode bandwidth** and **switchport backup interface preemption delay** interface configuration commands.

Figure 50: Flex Links Configuration Example

If a primary (forwarding) link goes down, a trap notifies the network management stations. If the standby link goes down, a trap notifies the users.

Flex Links are supported only on Layer 2 ports and port channels, not on VLANs or on Layer 3 ports.

VLAN Flex Links Load Balancing and Support

VLAN Flex Links load balancing allows users to configure a Flex Links pair so that both ports simultaneously forward the traffic for some mutually exclusive VLANs. For example, if Flex Links ports are configured for 1 to 100 VLANs, the traffic of the first 50 VLANs can be forwarded on one port and the rest on the other port. If one of the ports fail, the other active port forwards all the traffic. When the failed port comes back up, it resumes forwarding traffic in the preferred VLANs. In addition to providing the redundancy, this Flex Links pair can be used for load balancing. Flex Links VLAN load balancing does not impose any restrictions on uplink devices.

Figure 51: VLAN Flex Links Load-Balancing Configuration Example

The following figure displays a VLAN Flex Links load-balancing configuration.

Multicast Fast Convergence with Flex Links Failover

Multicast fast convergence reduces the multicast traffic convergence time after a Flex Links failure. Multicast fast convergence is implemented by a combination of learning the backup link as an mrouter port, generating IGMP reports, and leaking IGMP reports.

Learning the Other Flex Links Port as the mrouter Port

In a typical multicast network, there is a querier for each VLAN. A device deployed at the edge of a network has one of its Flex Links ports receiving queries. Flex Links ports are also always forwarding at any given time.

A port that receives queries is added as an mrouter port on the device. An mrouter port is part of all the multicast groups learned by the device. After a changeover, queries are received by the other Flex Links port.

The other Flex Links port is then learned as the mrouter port. After changeover, multicast traffic then flows through the other Flex Links port. To achieve faster convergence of traffic, both Flex Links ports are learned as mrouter ports whenever either Flex Links port is learned as the mrouter port. Both Flex Links ports are always part of multicast groups.

Although both Flex Links ports are part of the groups in normal operation mode, all traffic on the backup port is blocked. The normal multicast data flow is not affected by the addition of the backup port as an mrouter port. When the changeover happens, the backup port is unblocked, allowing the traffic to flow. In this case, the upstream multicast data flows as soon as the backup port is unblocked.

Generating IGMP Reports

When the backup link comes up after the changeover, the upstream new distribution device does not start forwarding multicast data, because the port on the upstream router, which is connected to the blocked Flex Links port, is not part of any multicast group. The reports for the multicast groups were not forwarded by the downstream device because the backup link is blocked. The data does not flow on this port, until it learns the multicast groups, which occurs only after it receives reports.

The reports are sent by hosts when a general query is received, and a general query is sent within 60 seconds in normal scenarios. When the backup link starts forwarding, to achieve faster convergence of multicast data, the downstream device immediately sends proxy reports for all the learned groups on this port without waiting for a general query.

Leaking IGMP Reports

To achieve multicast traffic convergence with minimal loss, a redundant data path must be set up before the Flex Links active link goes down. This can be achieved by leaking only IGMP report packets on the Flex Links backup link. These leaked IGMP report messages are processed by upstream distribution routers, so multicast data traffic gets forwarded to the backup interface. Because all incoming traffic on the backup interface is dropped at the ingress of the access device, no duplicate multicast traffic is received by the host. When the Flex Links active link fails, the access device starts accepting traffic from the backup link immediately. The only disadvantage of this scheme is that it consumes bandwidth on the link between the distribution devices and on the backup link between the distribution and access devices. This feature is disabled by default and can be configured by using the **switchport backup interface *interface-id* multicast fast-convergence** command.

When this feature has been enabled at changeover, the device does not generate the proxy reports on the backup port, which became the forwarding port.

MAC Address-Table Move Update

The MAC address-table move update feature allows the device to provide rapid bidirectional convergence when a primary (forwarding) link goes down and the standby link begins forwarding traffic.

Figure 52: MAC Address-Table Move Update Example

In the following figure, switch A is an access switch, and ports 1 and 2 on switch A are connected to uplink devices B and D through a Flex Links pair. Port 1 is forwarding traffic, and port 2 is in the backup state. Traffic from the PC to the server is forwarded from port 1 to port 3. The MAC address of the PC has been

learned on port 3 of device C. Traffic from the server to the PC is forwarded from port 3 to port 1.

If the MAC address-table move update feature is not configured and port 1 goes down, port 2 starts forwarding traffic. However, for a short time, device C keeps forwarding traffic from the server to the PC through port 3, and the PC does not get the traffic because port 1 is down. If device C removes the MAC address of the PC on port 3 and relearns it on port 4, traffic can then be forwarded from the server to the PC through port 2.

If the MAC address-table move update feature is configured and enabled on the devices, and port 1 goes down, port 2 starts forwarding traffic from the PC to the server. The device sends a MAC address-table move update packet from port 2. Device C gets this packet on port 4 and immediately learns the MAC address of the PC on port 4, which reduces the reconvergence time.

You can configure the access device, device A, to *send* MAC address-table move update messages. You can also configure the uplink devices B, C, and D to *get* and process the MAC address-table move update messages. When device C gets a MAC address-table move update message from device A, device C learns the MAC address of the PC on port 4. Device C updates the MAC address table, including the forwarding table entry for the PC.

Device A does not need to wait for the MAC address-table update. The device detects a failure on port 1 and immediately starts forwarding server traffic from port 2, the new forwarding port. This change occurs in less than 100 milliseconds (ms). The PC is directly connected to device A, and the connection status does not change. Device A does not need to update the PC entry in the MAC address table.

Flex Links VLAN Load Balancing Configuration Guidelines

- For Flex Links VLAN load balancing, you must choose the preferred VLANs on the backup interface.
- You cannot configure a preemption mechanism and VLAN load balancing for the same Flex Links pair.

MAC Address-Table Move Update Configuration Guidelines

- You can enable and configure this feature on the access device to *send* the MAC address-table move updates.
- You can enable and configure this feature on the uplink devices to *get* the MAC address-table move updates.

Default Flex Links and MAC Address-Table Move Update Configuration

- Flex Links is not configured, and there are no backup interfaces defined.
- The preemption mode is off.
- The preemption delay is 35 seconds.
- The MAC address-table move update feature is not configured on the device.

How to Configure Flex Links and the MAC Address-Table Move Update Feature

Configuring Flex Links

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(conf) # interface gigabitethernet1/0/1 | Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 24. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | switchport backup interface <i>interface-id</i> Example: <pre>Device(conf-if)# switchport backup interface gigabitethernet1/0/2</pre> | Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface. When one link is forwarding traffic, the other interface is in standby mode. |
| Step 4 | end Example: <pre>Device(conf-if)# end</pre> | Returns to privileged EXEC mode. |

Configuring a Preemption Scheme for a Pair of Flex Links

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode |
| Step 2 | interface <i>interface-id</i> Example: <pre>Device(conf)# interface gigabitethernet1/0/1</pre> | Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 24. |
| Step 3 | switchport backup interface <i>interface-id</i> Example: <pre>Device(conf-if)# switchport backup interface gigabitethernet1/0/2</pre> | Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface. When one link is forwarding traffic, the other interface is in standby mode. |
| Step 4 | switchport backup interface <i>interface-id</i> preemption mode [forced bandwidth off] Example: <pre>Device(conf-if)# switchport backup interface gigabitethernet1/0/2 preemption mode forced</pre> | Configures a preemption mechanism and delay for a Flex Links interface pair. You can configure the preemption as: <ul style="list-style-type: none"> • forced—(Optional) The active interface always preempts the backup. • bandwidth—(Optional) The interface with the higher bandwidth always acts as the active interface. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <ul style="list-style-type: none"> • off—(Optional) No preemption occurs from active to backup. |
| Step 5 | switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i> Example: Device(conf-if)# switchport backup interface gigabitethernet1/0/2 preemption delay 50 | Configures the time delay until a port preempts another port. Note Setting a delay time only works with forced and bandwidth modes. |
| Step 6 | end Example: Device(conf-if)# end | Returns to privileged EXEC mode. |
| Step 7 | show interface [<i>interface-id</i>] switchport backup Example: Device# show interface gigabitethernet1/0/2 switchport backup | Verifies the configuration. |
| Step 8 | copy running-config startup config Example: Device# copy running-config startup config | (Optional) Saves your entries in the device startup configuration file. |

Configuring VLAN Load Balancing on Flex Links

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: | Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device (config)# interface gigabitethernet2/0/6 | (logical interface). The port-channel range is 1 to 24. |
| Step 3 | switchport backup interface <i>interface-id</i> prefer vlan <i>vlan-range</i> Example: Device (config-if)# switchport backup interface gigabitethernet2/0/8 prefer vlan 2 | Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface and specifies the VLANs carried on the interface. The VLAN ID range is 1 to 4094. |
| Step 4 | end Example: Device (config-if)# end | Returns to privileged EXEC mode. |

Configuring MAC Address-Table Move Update

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device# interface gigabitethernet1/0/1 | Specifies the interface, and enters interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 24. |
| Step 3 | Use one of the following: <ul style="list-style-type: none"> • switchport backup interface <i>interface-id</i> • switchport backup interface <i>interface-id</i> mmu primary vlan <i>vlan-id</i> Example: Device (config-if)# switchport backup interface gigabitethernet0/2 mmu primary vlan 2 | Configures a physical Layer 2 interface (or port channel), as part of a Flex Links pair with the interface. The MAC address-table move update VLAN is the lowest VLAN ID on the interface. Configure a physical Layer 2 interface (or port channel) and specifies the VLAN ID on the interface, which is used for sending the MAC address-table move update. When one link is forwarding traffic, the other interface is in standby mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 4 | end Example: Device (config-if) # end | Returns to global configuration mode. |
| Step 5 | mac address-table move update transmit Example: Device (config) # mac address-table move update transmit | Enables the access device to send MAC address-table move updates to other devices in the network if the primary link goes down and the device starts forwarding traffic through the standby link. Enter command mac address-table move update on the device, for MMU packets to update MAC tables. When the primary link comes back up, the MAC tables need to reconverge and this command will transmit the MMU, that will establish the behavior. |
| Step 6 | end Example: Device (config) # end | Returns to privileged EXEC mode. |

Configuring a Device to Obtain and Process MAC Address-Table Move Update Messages

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode |
| Step 2 | mac address-table move update receive Example: Device (config) # mac address-table move update receive | Enables the device to obtain and processes the MAC address-table move updates. |
| Step 3 | end Example: Device (config) # end | Returns to privileged EXEC mode. |

Monitoring Flex Links, Multicast Fast Convergence, and MAC Address-Table Move Update

| Command | Purpose |
|--|--|
| <code>show interface [interface-id] switchport backup</code> | Displays the Flex Links backup interface configured for an interface (including the backup interface and the state of each active and backup interface). |
| <code>show ip igmp profile address-table move update profile-id</code> | Displays the specified IGMP profile or all the IGMP profiles configured on the device. |
| <code>show mac address-table move update</code> | Displays the MAC address-table move update information on the device. |

Configuration Examples for Flex Links

Configuring Flex Links: Examples

This example shows how to verify the configuration after you configure an interface with a backup interface:

```
Device# show interface switchport backup

Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----
GigabitEthernet1/0/1 GigabitEthernet1/0/2 Active Up/Backup Standby
```

This example shows how to verify the configuration after you configure the preemption mode as forced for a backup interface pair:

```
Device# show interface switchport backup detail

Switch Backup Interface Pairs:
Active Interface Backup Interface State
-----
GigabitEthernet1/0/211 GigabitEthernet1/0/2 Active Up/Backup Standby
Interface Pair : Gi1/0/1, Gi1/0/2
Preemption Mode : forced
Preemption Delay : 50 seconds
Bandwidth : 100000 Kbit (Gi1/0/1), 100000 Kbit (Gi1/0/2)
Mac Address Move Update Vlan : auto
```

Configuring VLAN Load Balancing on Flex Links: Examples

In the following example, VLANs 1 to 50, 60, and 100 to 120 are configured on the device:

```
Device(config)# interface gigabitethernet 2/0/6
Device(config-if)# switchport backup interface gigabitethernet 2/0/8 prefer vlan 60,100-120
```

When both interfaces are up, Gi2/0/8 forwards traffic for VLANs 60 and 100 to 120 and Gi2/0/6 forwards traffic for VLANs 1 to 50.

```
Device# show interfaces switchport backup
```

```
Switch Backup Interface Pairs:
```

| Active Interface | Backup Interface | State |
|----------------------|----------------------|--------------------------|
| GigabitEthernet2/0/6 | GigabitEthernet2/0/8 | Active Up/Backup Standby |

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface goes down (LINK_DOWN), VLANs preferred on this interface are moved to the peer interface of the Flex Links pair. In this example, if interface Gi2/0/6 goes down, Gi2/0/8 carries all VLANs of the Flex Links pair.

```
Device# show interfaces switchport backup
```

```
Switch Backup Interface Pairs:
```

| Active Interface | Backup Interface | State |
|----------------------|----------------------|-----------------------|
| GigabitEthernet2/0/6 | GigabitEthernet2/0/8 | Active Down/Backup Up |

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface comes up, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Gi2/0/6 comes up, VLANs preferred on this interface are blocked on the peer interface Gi2/0/8 and forwarded on Gi2/0/6.

```
Device# show interfaces switchport backup
```

```
Switch Backup Interface Pairs:
```

| Active Interface | Backup Interface | State |
|----------------------|----------------------|--------------------------|
| GigabitEthernet2/0/6 | GigabitEthernet2/0/8 | Active Up/Backup Standby |

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

```
Device# show interfaces switchport backup detail
```

```
Switch Backup Interface Pairs:
```

| Active Interface | Backup Interface | State |
|-------------------|-------------------|-----------------------|
| FastEthernet1/0/3 | FastEthernet1/0/4 | Active Down/Backup Up |

```
Vlans Preferred on Active Interface: 1-2,5-4094
```

```

Vlans Preferred on Backup Interface: 3-4
Preemption Mode : off
Bandwidth : 10000 Kbit (Fa1/0/3), 100000 Kbit (Fa1/0/4)
Mac Address Move Update Vlan : auto

```

Configuring the MAC Address-Table Move Update: Examples

This example shows how to verify the configuration after you configure an access device to send MAC address-table move updates:

```

Device# show mac address-table move update

Switch-ID : 010b.4630.1780
Dst mac-address : 0180.c200.0010
Vlans/Macs supported : 1023/8320
Default/Current settings: Rcv Off/On, Xmt Off/On
Max packets per min : Rcv 40, Xmt 60
Rcv packet count : 5
Rcv conforming packet count : 5
Rcv invalid packet count : 0
Rcv packet count this min : 0
Rcv threshold exceed count : 0
Rcv last sequence# this min : 0

```

Configuring Multicast Fast Convergence with Flex Links Failover: Examples

These are configuration examples for learning the other Flex Links port as the mrouter port when Flex Links is configured on GigabitEthernet1/0/11 and GigabitEthernet1/0/12, and output for the **show interfaces switchport backup** command:

```

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface GigabitEthernet1/0/11
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# switchport backup interface GigabitEthernet1/0/12
Device(config-if)# exit
Device(config)# interface GigabitEthernet1/0/12
Device(config-if)# switchport trunk encapsulation dot1q
Device(config-if)# switchport mode trunk
Device(config-if)# end
Device# show interfaces switchport backup detail
Switch Backup Interface Pairs:
Active Interface Backup Interface State
GigabitEthernet1/0/11 GigabitEthernet1/0/12 Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : Off
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)

```

```
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLANs 1 and 401, with their queries reaching the device through GigabitEthernet1/0/11:

```
Device# show ip igmp snooping querier
```

```
Vlan  IP Address  IGMP Version  Port
-----
1     10.0.0.10    v2            Gi1/0/11
401   41.41.41.1   v2            Gi1/0/11
```

This example is output for the **show ip igmp snooping mrouter** command for VLANs 1 and 401:

```
Device# show ip igmp snooping mrouter
```

```
Vlan  ports
----  -
1     Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401   Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both Flex Links ports are part of learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Device# show ip igmp snooping groups
```

```
Vlan  Group    Type   Version  Port List
-----
1     228.1.5.1  igmp   v2       Gi1/0/11, Gi1/0/12, Gi2/0/11
1     228.1.5.2  igmp   v2       Gi1/0/11, Gi1/0/12, Gi2/0/11
```

When a host responds to the general query, the device forwards this report on all the mrouter ports. In this example, when a host sends a report for the group 228.1.5.1, it is forwarded only on GigabitEthernet1/0/11, because the backup port GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding.

As soon as this port starts forwarding, the device sends proxy reports for the groups 228.1.5.1 and 228.1.5.2 on behalf of the host. The upstream router learns the groups and starts forwarding multicast data. This is the default behavior of Flex Links. This behavior changes when the user configures fast convergence using the **switchport backup interface gigabitEthernet 1/0/12 multicast fast-convergence** command. This example shows turning on this feature:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# interface gigabitEthernet 1/0/11
Device(config-if)# switchport backup interface gigabitEthernet 1/0/12 multicast
fast-convergence
Device(config-if)# exit
Device# show interfaces switchport backup detail
```

```
Switch Backup Interface Pairs:
Active      Interface      Backup Interface State
-----
GigabitEthernet1/0/11  GigabitEthernet1/0/12  Active Up/Backup Standby
Preemption Mode : off
Multicast Fast Convergence : On
```

```
Bandwidth : 100000 Kbit (Gi1/0/11), 100000 Kbit (Gi1/0/12)
Mac Address Move Update Vlan : auto
```

This output shows a querier for VLAN 1 and 401 with their queries reaching the device through GigabitEthernet1/0/11:

```
Device# show ip igmp snooping querier
```

```
Vlan  IP Address  IGMP Version  Port
-----
1     10.0.0.10    v2            Gi1/0/11
401   41.41.41.1   v2            Gi1/0/11
```

This is output for the **show ip igmp snooping mrouter** command for VLAN 1 and 401:

```
Device# show ip igmp snooping mrouter
```

```
Vlan  ports
----  -
1     Gi1/0/11(dynamic), Gi1/0/12(dynamic)
401   Gi1/0/11(dynamic), Gi1/0/12(dynamic)
```

Similarly, both the Flex Links ports are a part of the learned groups. In this example, GigabitEthernet2/0/11 is a receiver/host in VLAN 1, which is interested in two multicast groups:

```
Device# show ip igmp snooping groups
```

```
Vlan  Group  Type  Version  Port List
-----
1     228.1.5.1  igmp  v2      Gi1/0/11, Gi1/0/12, Gi2/0/11
1     228.1.5.2  igmp  v2      Gi1/0/11, Gi1/0/12, Gi2/0/11
```

Whenever a host responds to the general query, the device forwards this report on all the mrouter ports. When you turn on this feature through the command-line port, and when a report is forwarded by the device on GigabitEthernet1/0/11, it is also leaked to the backup port GigabitEthernet1/0/12. The upstream router learns the groups and starts forwarding multicast data, which is dropped at the ingress because GigabitEthernet1/0/12 is blocked. When the active link, GigabitEthernet1/0/11, goes down, the backup port, GigabitEthernet1/0/12, begins forwarding. You do not need to send any proxy reports as the multicast data is already being forwarded by the upstream router. By leaking reports to the backup port, a redundant multicast path has been set up, and the time taken for the multicast traffic convergence is very minimal.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Configuring UDLD

The following are restrictions for configuring UniDirectional Link Detection (UDLD):

- A UDLD-capable port cannot detect a unidirectional link if it is connected to a UDLD-incapable port of another device.
- When configuring the mode (normal or aggressive), make sure that the same mode is configured on both sides of the link.

Caution

Loop guard works only on point-to-point links. We recommend that each end of the link has a directly connected device that is running STP.

Information About UDLD

UniDirectional Link Detection (UDLD) is a Layer 2 protocol that enables devices connected through fiber-optic or twisted-pair Ethernet cables to monitor the physical configuration of the cables and detect when a unidirectional link exists. All connected devices must support UDLD for the protocol to successfully identify and disable unidirectional links. When UDLD detects a unidirectional link, it disables the affected port and alerts you. Unidirectional links can cause a variety of problems, including spanning-tree topology loops.

Modes of Operation

UDLD has two modes of operation: normal (the default) and aggressive. In normal mode, UDLD can detect unidirectional links due to misconnected ports on fiber-optic connections. In aggressive mode, UDLD can also detect unidirectional links due to one-way traffic on fiber-optic and twisted-pair links and to misconnected ports on fiber-optic links.

In normal and aggressive modes, UDLD works with the Layer 1 mechanisms to learn the physical status of a link. At Layer 1, autonegotiation takes care of physical signaling and fault detection. UDLD performs tasks that autonegotiation cannot perform, such as detecting the identities of neighbors and shutting down misconnected ports. When you enable both autonegotiation and UDLD, the Layer 1 and Layer 2 detections work together to prevent physical and logical unidirectional connections and the malfunctioning of other protocols.

A unidirectional link occurs whenever traffic sent by a local device is received by its neighbor but traffic from the neighbor is not received by the local device.

Normal Mode

In normal mode, UDLD detects a unidirectional link when fiber strands in a fiber-optic port are misconnected and the Layer 1 mechanisms do not detect this misconnection. If the ports are connected correctly but the traffic is one way, UDLD does not detect the unidirectional link because the Layer 1 mechanism, which is supposed to detect this condition, does not do so. In this case, the logical link is considered undetermined, and UDLD does not disable the port.

When UDLD is in normal mode, if one of the fiber strands in a pair is disconnected, as long as autonegotiation is active, the link does not stay up because the Layer 1 mechanisms detects a physical problem with the link. In this case, UDLD does not take any action and the logical link is considered undetermined.

Aggressive Mode

In aggressive mode, UDLD detects a unidirectional link by using the previous detection methods. UDLD in aggressive mode can also detect a unidirectional link on a point-to-point link on which no failure between the two devices is allowed. It can also detect a unidirectional link when one of these problems exists:

- On fiber-optic or twisted-pair links, one of the ports cannot send or receive traffic.
- On fiber-optic or twisted-pair links, one of the ports is down while the other is up.
- One of the fiber strands in the cable is disconnected.

In these cases, UDLD disables the affected port.

In a point-to-point link, UDLD hello packets can be considered as a heart beat whose presence guarantees the health of the link. Conversely, the loss of the heart beat means that the link must be shut down if it is not possible to reestablish a bidirectional link.

If both fiber strands in a cable are working normally from a Layer 1 perspective, UDLD in aggressive mode detects whether those fiber strands are connected correctly and whether traffic is flowing bidirectionally between the correct neighbors. This check cannot be performed by autonegotiation because autonegotiation operates at Layer 1.

Methods to Detect Unidirectional Links

UDLD operates by using two methods:

- Neighbor database maintenance
- Event-driven detection and echoing

Neighbor Database Maintenance

UDLD learns about other UDLD-capable neighbors by periodically sending a hello packet (also called an advertisement or probe) on every active port to keep each device informed about its neighbors.

When the device receives a hello message, it caches the information until the age time (hold time or time-to-live) expires. If the device receives a new hello message before an older cache entry ages, the device replaces the older entry with the new one.

Whenever a port is disabled and UDLD is running, whenever UDLD is disabled on a port, or whenever the device is reset, UDLD clears all existing cache entries for the ports affected by the configuration change. UDLD sends at least one message to inform the neighbors to flush the part of their caches affected by the status change. The message is intended to keep the caches synchronized.

Event-Driven Detection and Echoing

UDLD relies on echoing as its detection operation. Whenever a UDLD device learns about a new neighbor or receives a resynchronization request from an out-of-sync neighbor, it restarts the detection window on its side of the connection and sends echo messages in reply. Because this behavior is the same on all UDLD neighbors, the sender of the echoes expects to receive an echo in reply.

If the detection window ends and no valid reply message is received, the link might shut down, depending on the UDLD mode. When UDLD is in normal mode, the link might be considered undetermined and might not be shut down. When UDLD is in aggressive mode, the link is considered unidirectional, and the port is disabled.

UDLD Reset Options

If an interface becomes disabled by UDLD, you can use one of the following options to reset UDLD:

- The **udld reset** interface configuration command.
- The **shutdown** interface configuration command followed by the **no shutdown** interface configuration command restarts the disabled port.
- The **no udld {aggressive | enable}** global configuration command followed by the **udld {aggressive | enable}** global configuration command reenables the disabled ports.

- The **no udd port** interface configuration command followed by the **udd port [aggressive]** interface configuration command reenables the disabled fiber-optic port.
- The **errdisable recovery cause udd** global configuration command enables the timer to automatically recover from the UDLD error-disabled state, and the **errdisable recovery interval interval** global configuration command specifies the time to recover from the UDLD error-disabled state.

Default UDLD Configuration

Table 47: Default UDLD Configuration

| Feature | Default Setting |
|--|---|
| UDLD global enable state | Globally disabled |
| UDLD per-port enable state for fiber-optic media | Disabled on all Ethernet fiber-optic ports |
| UDLD per-port enable state for twisted-pair (copper) media | Disabled on all Ethernet 10/100 and 1000BASE-TX ports |
| UDLD aggressive mode | Disabled |

How to Configure UDLD

Enabling UDLD Globally

Follow these steps to enable UDLD in the aggressive or normal mode and to set the configurable message timer on all fiber-optic ports on the device.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | udd {aggressive enable message time message-timer-interval} Example: Device(config)# udd enable message time 10 | Specifies the UDLD mode of operation: <ul style="list-style-type: none"> • aggressive—Enables UDLD in aggressive mode on all fiber-optic ports. • enable—Enables UDLD in normal mode on all fiber-optic ports on the device. UDLD is disabled by default. An individual interface configuration overrides the setting of the udd enable global configuration command. |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <ul style="list-style-type: none"> • message time <i>message-timer-interval</i>—Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are detected to be bidirectional. The range is from 1 to 90 seconds; the default value is 15. <p>Note This command affects fiber-optic ports only. Use the udld interface configuration command to enable UDLD on other port types.</p> <p>Use the no form of this command, to disable UDLD.</p> |
| Step 3 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Enabling UDLD on an Interface

Follow these steps either to enable UDLD in the aggressive or normal mode or to disable UDLD on a port.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Specifies the port to be enabled for UDLD, and enters interface configuration mode. |
| Step 3 | udld port [aggressive] Example: | UDLD is disabled by default. <ul style="list-style-type: none"> • udld port—Enables UDLD in normal mode on the specified port. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config-if) # <code>udld port aggressive</code> | <ul style="list-style-type: none"> • udld port aggressive—(Optional) Enables UDLD in aggressive mode on the specified port. <p>Note Use the no udld port interface configuration command to disable UDLD on a specified fiber-optic port.</p> |
| Step 4 | end Example: Device(config-if) # <code>end</code> | Returns to privileged EXEC mode. |

Monitoring and Maintaining UDLD

| Command | Purpose |
|---|---|
| <code>show udld [interface-id neighbors]</code> | Displays the UDLD status for the specified port or for all ports. |

CHAPTER 25

Configuring the PPPoE Intermediate Agent

- [Restrictions for PPPoE Intermediate Agent, on page 419](#)
- [Information about PPPoE Intermediate Agent, on page 419](#)
- [How to Configure PPPoE IA, on page 420](#)
- [Configuration Examples for PPPoE IA, on page 428](#)

- [Clearing Packet Counters, on page 432](#)
- [Debugging PPPoE Intermediate Agent, on page 432](#)
- [Troubleshooting Tips, on page 433](#)
- [Feature Information for Configuring the PPPoE Intermediate Agent, on page 433](#)

Restrictions for PPPoE Intermediate Agent

PPPoE Intermediate Agent is not supported on routed interfaces.

Information about PPPoE Intermediate Agent

PPPoE Intermediate Agent (PPPoE IA) is placed between a subscriber and BRAS to help the service provider BRAS distinguish between end hosts connected over Ethernet to an access switch. On the access switch, PPPoE IA enables Subscriber Line Identification by appropriately tagging Ethernet frames of different users. (The tag contains specific information such as which subscriber is connected to the switch and VLAN.) PPPoE IA acts as mini security firewall between host and BRAS by intercepting all PPPoE Active Discovery (PAD) messages on a per-port per-VLAN basis. It provides specific security feature such as verifying the intercepted PAD message from untrusted port, performing per-port PAD message rate limiting, inserting and removing VSA Tags into and from PAD messages, respectively.

DSL Forum TR-101 [1] offers a means by which the PPPoE Discovery packets are tagged at the service provider's access switch with subscriber line specific information. The mechanism specifies using VSA of the PPPoE Discovery packets to add the line specific information at the switch. Even though you can perform Subscriber Line Identification (SLI) in another way (recreating virtual paths and circuits using stacked VLAN tags), DSL Forum 2004-071 [4] recommends the PPPoE Intermediate Agent mechanism. It cites lower provisioning costs and simpler co-ordination between OSS systems in charge of access switch and BRAS. PPPoE Intermediate Agent helps the service provider, BRAS, distinguish between end hosts connected over Ethernet to an access switch.

How to Configure PPPoE IA

Enabling PPPoE IA on a Switch

Note By default, PPPoE IA is disabled globally.

Follow these steps to enable or disable PPPoE IA globally on the switch:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config t | Enters the global configuration mode. |
| Step 3 | pppoe intermediate-agent Example: Device(config)# pppoe intermediate-agent | Enables PPPoE IA globally on the switch. |

Configuring the Access Node Identifier for PPPoE IA on a Switch

Follow these steps to set the Access Node Identifier of the switch.

Note By default, access-node-id is not set.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | <p>pppoe intermediate-agent <i>format-type</i> access-node-id string <i>word</i></p> <p>Example:</p> <pre>Device(config)# pppoe intermediate-agent format-type access-node-id string abcd</pre> | <p>Sets the access node identifier.</p> <ul style="list-style-type: none"> • access-node-identifier string <i>word</i> – ASCII string literal value for the access-node-identifier. |

Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch

This functionality overrides the default automatic generation of circuit-id by the system.

The options available are sp, sv, pv and spv denoting slot:port, slot-vlan, port-vlan, and slot-port-vlan combinations, respectively. Valid delimiters are # . , ; / space.

The no form of this command without WORD, options, and delimiters, reverts to the default automatic generation of circuit-id.

This command does not affect the circuit ID configured explicitly per-interface or per-interface per-VLAN with the **pppoe intermediate-agent format-type circuit-id**.

Follow these steps to set an identifier string word with option spv delimited by “:”

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# config t</pre> | Enters the global configuration mode. |
| Step 3 | <p>pppoe intermediate-agent format-type identifier-string string <i>word</i>option {sp sv pv spv} delimiter {, . ; / #}</p> <p>Example:</p> <pre>Device(config)# pppoe intermediate-agent format-type identifier-string string word option spv delimiter :</pre> | <p>Sets the identifier string.</p> <ul style="list-style-type: none"> • option {sp sv pv spv} – sp = slot + port, sv = slot + vlan, pv = port + vlan, spv = slot +port+vlan. • delimiter {, . ; / #} – Delimiter between slot/port/vlan portions of 'option'. |

Configuring the Generic Error Message for PPPoE IA on a Switch

Follow these steps to to configure a generic message of **packet_length>1484**:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |
| Step 3 | pppoe intermediate-agent format-type generic-error-message string <i>string</i> Example: Device(config)# pppoe intermediate-agent format-type generic-error-message string packet_length>1484 | Sets the generic error message. <ul style="list-style-type: none"> • generic-error-message string <i>string</i> – ASCII string literal value for the generic-error-message. |

Enabling PPPoE IA on an Interface

Follow these steps to enable PPPoE IA on FastEthernet 3/1:

Before you begin

Note Enabling PPPoE IA on an interface does not ensure that incoming packets are tagged. For this to happen PPPoE IA must be enabled globally, and at least one interface that connects the switch to PPPoE server has a trusted PPPoE IA setting. Refer to the following section for details.

This functionality enables the PPPoE IA feature on an interface. The pppoe intermediate-agent command has an effect only if the PPPoE IA feature was enabled globally with this command. (You need to enable globally to activate PPPoE IA static ACL and on an interface for PPPoE IA processing of PPPoE discovery packets received on that interface.)

This setting applies to all frames passing through this interface, regardless of the VLAN they belong to. By default the PPPoE IA feature is disabled on all interfaces. You need to run this command on every interface that requires this feature.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters the global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device# config terminal | |
| Step 3 | interface <i>interface-id</i> Example: Device(config) interface FastEthernet 3/1 | Enter interface configuration mode and the physical interface identification. |
| Step 4 | pppoe intermediate-agent Example: Device(config-if) pppoe intermediate-agent | Enables PPPoE IA on the interface. |

Configuring the PPPoE IA Trust Setting on an Interface

Note Interfaces that connect the switch to PPPoE server are configured as trusted. Interfaces that connect the switch to users (PPPoE clients) are untrusted.

Follow these steps to set FastEthernet interface 3/2 as trusted:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config) interface FastEthernet 3/2 | Enter interface configuration mode and the physical interface identification. |
| Step 4 | pppoe intermediate-agent trust Example: Device(config-if) pppoe intermediate-agent trust | Sets the trust configuration of an interface. |

Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface

Note The parameter for rate limiting is the number of packets per second. If the incoming packet rate exceeds this value, the port shuts down.

Follow these steps to to set a rate limit on an interface :

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)interface FastEthernet 3/1 | Enters interface configuration mode and the physical interface identification. |
| Step 4 | pppoe intermediate-agent limit rate <i>number</i> Example: Device(config-if)pppoe intermediate-agent limit rate 30 | Limits the rate of the PPPoE Discovery packets arriving on an interface. |

Configuring PPPoE IA Vendor-tag Stripping on an Interface

Note Generally, you would configure vendor-tag stripping on an interfaces connected to the PPPoE server. If you configure stripping, incoming packets are stripped of their VSAs (which carry subscriber and line identification information). For this to happen, the PPPoE Intermediate agent must be enabled to make the pppoe intermediate-agent vendor-tag strip command effective, and the interface must be set to trust. In isolation, the command has no effect.

Note BRAS automatically strips the vendor-specific tag off of the PPPoE discovery packets before sending them downstream to the access switch. To operate with older BRAS which does not possess this capability, use the pppoe intermediate-agent vendor-tag strip command on the interface connecting the access switch to BRAS.

Follow these steps to enable vendor-tag stripping :

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config) interface FastEthernet 3/2 | Enters interface configuration mode and the physical interface identification. |
| Step 4 | pppoe intermediate-agent vendor-tag strip Example: Device(config-if) pppoe intermediate-agent vendor-tag strip | Enables vendor-tag stripping on PPPoE Discovery packets from PPPoE Server (or BRAS). |

Configuring PPPoE Intermediate Agent Circuit-ID and Remote-ID on an Interface

The **[no] pppoe intermediate-agent format-type circuit-id** command sets the circuit ID on an interface and overrides the automatic generation of circuit ID by the switch. Without this command, one default tag (for example, Ethernet x/y:z on the PPPoE to which the user is connected) inserted by an intermediate-agent.

The **[no] pppoe intermediate-agent format-type remote-id** command sets the remote ID on an interface.

This functionality causes tagging of PADI, PADR, and PADT packets (belonging to PPPoE Discovery stage) received on this physical interface with circuit ID or remote ID. This happens regardless of their VLAN if PPPoE IA is not enabled for that VLAN.

You should use remote ID instead of circuit ID for subscriber line identification. You should configure this setting on every interface where you enabled PPPoE IA because it is not set by default. The default value for remote-id is the switch MAC address (for all physical interfaces).

Follow these steps to configure the circuit ID as root and the remote ID as granite:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 3 | interface <i>interface-id</i> Example: Device(config)interface FastEthernet 3/1 | Enters interface configuration mode and the physical interface identification. |
| Step 4 | pppoe intermediate-agent format-type {circuit-id remote-id} string <i>string</i> Example: Device(config-if)pppoe intermediate-agent format-type circuit-id string root | Sets circuit-id or remote-id for an interface. <ul style="list-style-type: none"> • circuit-id string string – ASCII string literal value for circuit-id. • remote-id string string – ASCII string literal value for remote-id. |

Enabling PPPoE IA for a Specific VLAN on an Interface

Note The **pppoe intermediate-agent** command in the vlan-range mode is not dependent on the same command in interface mode. The **pppoe intermediate-agent** command will take effect independently of the command in the interface mode. To make this happen, PPPoE IA must be enabled globally and at least one interface is connected to the PPPoE server.

Follow these steps to to enable PPPoE IA on a specific VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# config terminal | Enters the global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)interface FastEthernet 3/1 | Enters interface configuration mode and the physical interface identification. |
| Step 4 | vlan-range { <i>vlan-id</i> <i>vlan-list</i> <i>vlan-range</i> } Example: Device(config-if)vlan-range 5 | Enters the vlan-range mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | pppoe intermediate-agent Example: Device(config-if-vlan-range) pppoe intermediate-agent | Enables PPPoE IA on the specified interfaces. |

Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface

Note The circuit-id and remote-id configurations in vlan-range mode are affected only if PPPoE IA is enabled globally and in vlan-range mode.

Note The vlan-range mode commands configure PPPoE IA for either a specific VLAN, multiple VLANs, or VLAN range, depending on what you specify in the syntax.

In this section you set the circuit ID and remote ID for a specific VLAN on an interface. The command overrides the circuit ID and remote ID specified for this physical interface and the switch uses the WORD value to tag packets received on this VLAN. This parameter is unset by default.

The default value of remote-id is the switch MAC address (for all VLANs). You would set this parameter to encode subscriber-specific information.

Follow these steps to set the circuit-id and the remote-id :

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | interface <i>interface-id</i> Example: Device(config)# int g3/7 | Enters interface configuration mode and the physical interface identification. |
| Step 2 | vlan-range <i>vlan-range</i> Example: Device(config-if)# vlan-range5 | Enters the vlan-range mode. |
| Step 3 | pppoe intermediate-agent Example: Device(config-if)# pppoe intermediate-agent | Enables PPPoE IA on the specified interfaces. |
| Step 4 | pppoe intermediate-agent format-type {circuit-id remote-id} string <i>string</i> Example: | Sets circuit-id or remote-id for an interface. <ul style="list-style-type: none"> • circuit-id string string – ASCII string literal value for circuit-id. |

| | Command or Action | Purpose |
|--|---|---|
| | Device(config-if)pppoe intermediate-agent format-type circuit-id string root | <ul style="list-style-type: none"> remote-id string string – ASCII string literal value for remote-id. |

Configuration Examples for PPPoE IA

Example: Enabling PPPoE Intermediate Agent on a Switch

This examples shows how to enable or disable PPPoE IA globally on the switch

```
Device> enable
Device# configure terminal
Device(config)# pppoe intermediate-agent
```

Example: Configuring the Access Node Identifier for PPPoE IA on a Switch

This example shows how to to set an access node identifier of abcd:

```
Device> enable
Device# configure terminal
Device(config)#pppoe intermediate-agent format-type access-node-id string abcd
```

Example: Configuring the Identifier String, Option, and Delimiter for PPPoE IA on a Switch

This example shows how to set an identifier string word with option spv delimited by “.”:

```
Device> enable
Device# configure terminal
Device(config)#pppoe intermediate-agent format-type
  identifier-string string word
option spv delimiter :
```

Example: Configuring the Generic Error Message for PPPoE IA on a Switch

This example shows how to configure a generic message of packet_length>1484:

```
Device> enable
Device# configure terminal
Device(config)#pppoe intermediate-agent format-type generic-error-message string
packet_length>1484
```

Example: Enabling PPPoE IA on an Interface

This example shows how to enable PPPoE IA on FastEthernet 3/1:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent
```

Example: Configuring the PPPoE Intermediate Agent Trust Setting on an Interface

The following example shows how to set FastEthernet interface 3/2 as trusted:

```
Device> enable
Device# configure terminal
Device(config)interface FastEthernet 3/2
Device(config-if)pppoe intermediate-agent trust
```

Example: Configuring PPPoE Intermediate Agent Rate Limiting Setting on an Interface

This example shows how to set a rate limit of 30 at FastEthernet 3/1:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent limit rate 30
```

Example: Configuring PPPoE IA Vendor-tag Stripping on an Interface

The following example shows how to enable stripping on FastEthernet 3/2:

```
Device> enable
Device# configure terminal
Device(config)interface FastEthernet 3/2
Device(config-if)pppoe intermediate-agent vendor-tag strip
```

Example: Configuring PPPoE IA Circuit-ID and Remote-ID on an Interface

The following example shows how to configure the circuit ID as root and the remote ID as granite:

```
Device> enable
Device# configure terminal
Device(config) interface FastEthernet 3/1
Device(config-if)pppoe intermediate-agent format-type circuit-id string root
Device(config-if)pppoe intermediate-agent format-type remote-id string granite
```

Example: Enabling PPPoE IA for a Specific VLAN on an Interface

The following example shows how to enable PPPOE IA on a specific VLAN:

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

The following examples shows how to enable PPPoE IA on a comma-separated VLAN list

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5,6
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

The following example shows how to enable PPPoE IA on a VLAN-range such as “x-y.”

```
Switch# configure terminal
Switch(config)# interface FastEthernet 3/1
Switch(config-if)# vlan-range 5-9
Switch(config-if-vlan-range)# pppoe intermediate-agent
```

Example: Configuring PPPoE IA Circuit-ID and Remote-ID for a VLAN on an Interface

The following example shows how to set the circuit-id to aaa and the remote-id as ccc on interface g3/7:

```
Switch(config)# int g3/7
Switch(config-if)# vlan-range 5
Switch(config-if)# pppoe intermediate-agent
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type circuit-id string aaa
Switch(config-if-vlan-range)# pppoe intermediate-agent format-type remote-id string ccc
```

Displaying Configuration Parameters

The **show pppoe intermediate-agent [info | statistics][interface {interface}]** command displays the various configuration parameters, statistics, and counters stored for PPPoE.

The **info** keyword appears if the PPPoE Intermediate Agent is enabled globally on an interface or on a VLAN (in an interface). It also informs you about the access node ID and generic error message of the switch, as well as the identifier string options, delimiter values configured globally, global circuit id and remote id configuration by using the following command:

```
Switch(config)# pppoe intermediate-agent format-type ?
access-node-id          Access Node Identifier
circuit-id              Circuit Id
generic-error-message   Generic Error Message
identifier-string        Identifier String
remote-id               Remote Id
```

The **info** keyword also displays the circuit ID, remote ID, trust and rate limit configurations, and vendor tag strip setting for all interfaces and for all VLANs pertaining to those interfaces. If any of these parameters are not set, they are not displayed.

The **statistics** option displays the number of PADI/PADR/PADT packets received, and the time the last packet was received on all interfaces and on all VLANs pertaining to those interfaces.

If **interface** is specified, information or statistics applicable only to that physical interface and pertaining VLANs is displayed.

Although PPOE IA is supported on PVLANS, be aware that no PVLAN association (primary and secondary VLAN mapping) information is displayed.

The PPPoE IA show commands such as **show pppoe intermediate-agent info**, **show pppoe intermediate-agent info interface g3/7**, or **show pppoe intermediate-agent statistics** do not provide information about private VLAN association (primary and secondary VLAN mapping).

However, they do provide information about VLANs regardless of private or normal VLANs, as the following example illustrate:

```
Switch# show pppoe intermediate-agent info
Switch PPPOE Intermediate-Agent is enabled
PPPOE Intermediate-Agent trust/rate is configured on the following Interfaces:

Interface          IA          Trusted    Vsa Strip    Rate limit (pps)
```

```

-----
GigabitEthernet3/4      no      yes      yes      unlimited PPPOE
Intermediate-Agent is
configured on following VLANs:
2-3
GigabitEthernet3/7      no      no      no      unlimited OE Intermediate-Agent
is
configured on following VLANs:
-3

Switch# show pppoe intermediate-agent info interface g3/7
Interface              IA      Trusted  Vsa Strip  Rate limit (pps)
-----
GigabitEthernet3/7    yes     no       no         unlimited oE Intermediate-Agent
is
configured on following VLANs:
-3

Switch# show pppoe intermediate-agent statistics
PPPOE IA Per-Port Statistics
-----

Interface : GigabitEthernet3/7 Packets received
All = 0
PADI = 0 PADO = 0
PADR = 0 PADS = 0
PADT = 0
Packets dropped:
Rate-limit exceeded = 0
Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0

```

The following statistics will be displayed when PPPoE IA feature is enabled on every VLAN interface and the PAD packet counters have a non-zero value.

```

switch# sh run int gi2/0/1
Building configuration...
Current configuration : 135 bytes
!
interface GigabitEthernet2/0/1
switchport mode trunk
pppoe intermediate-agent
vlan-range 200-201
pppoe intermediate-agent
end

Switch# show pppoe intermediate-agent statistics interface gi2/0/3
Interface: GigabitEthernet2/0/3
Packets received
All = 0
PADI = 0 PADO = 0
PADR = 0 PADS = 0
PADT = 0
Packets dropped:
Rate-limit exceeded = 0
Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0

Switch# show pppoe intermediate-agent statistics interface gi2/0/3
Interface: GigabitEthernet2/0/1
Packets received

```

```

All = 50
PADI = 20 PADO = 0
PADR = 20 PADS = 0
PADT = 10
Packets dropped: Rate-limit exceeded = 0
Server responses from untrusted ports = 0
Client requests towards untrusted ports = 0
Malformed PPPoE Discovery packets = 0
Vlan 200: Packets received PADI = 2 PADO = 0 PADR = 2 PADS = 0 PADT = 1
Vlan 201: Packets received PADI = 2 PADO = 0 PADR = 2 PADS = 0 PADT = 1

```

Clearing Packet Counters

This section illustrates how to clear packet counters on all interfaces (per-port and per-port-per-VLAN).

The following example illustrates how to do this:

```

Switch# clear pppoe intermediate-agent statistics
Issuing of the above command clears the counters for all PPPoE discovery packets
(PADI,PADO,PADR,PADS,PADT) received on DUT.

```

Debugging PPPoE Intermediate Agent

The **debug pppoe intermediate-agent [packet | event | all]** command enables you to display useful PPPoE information that assists in debugging. This command is disabled by default.

The **packet** option of the command displays the contents of a packet received in the software: source and destination MAC address of Ethernet frame, code, version and type of PPPoE Discovery packet and a list of TAGs present.

The **event** option of the command echoes important messages (interface state change to errdisabled due to PPPoE discovery packets entering at a rate exceeding the configured limit). it is the only event shown by the **debug pppoe intermediate-agent event** command.

The **all** option enables both package and event options.

The following example illustrates how to enter the debug command with the packet option:

```

Switch# debug pppoe intermediate-agent packet
PPPOE IA Packet debugging is on
*Sep 2 06:12:56.133: PPPOE_IA: Process new PPPoE packet, Message type: PADI, input interface:

Gi3/7, vlan : 2 MAC da: ffff.ffff.ffff, MAC sa: aabb.cc00.0000
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/8)
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADO, input interface:

Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADO, input interface:

Gi3/8, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: aabb.cc80.0000
*Sep 2 06:12:56.137: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/7)
*Sep 2 06:12:56.137: PPPOE_IA: Process new PPPoE packet, Message type: PADR, input interface:

Gi3/7, vlan : 2 MAC da: 001d.e64c.6512, MAC sa: aabb.cc00.0000

```

```
*Sep 2 06:12:56.145: PPPOE_IA: received new PPPOE packet from inputinterface
(GigabitEthernet3/4)
*Sep 2 06:12:56.145: PPPOE_IA: Process new PPPoE packet, Message type: PAD      ut interface:
Gi3/4, vlan : 2 MAC da: aabb.cc00.0000, MAC sa: 001d.e64c.6512
```

The following example illustrates how to enter the debug command with the event option:

```
Switch# PPPOE I
*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_ERRDISABLE_WARNING: PPPOE IA received 5 PPPOE
packets on interface Gi3/7
*Jul 30 19:00:10.254: %PPPOE_IA-4-PPPOE_IA_RATE_LIMIT_EXCEEDED: The interface Gi3/7 is
receiving more than the threshold set
*Jul 30 19:00:10.394: %PM-4-ERR_DISABLE:                               detected on
Gi3/7, putting Gi3/7 in err-disable stat
```

Troubleshooting Tips

When the **radius-server attribute 31 remote-id** global configuration command is entered in the PPPoE Agent Remote-ID Tag and DSL Line Characteristics feature configuration on the BRAS, the **debug radius** privileged EXEC command can be used to generate a report that includes information about the incoming access interface, where discovery frames are received, and about the session being established in PPPoE extended NAS-Port format (format d)

Feature Information for Configuring the PPPoE Intermediate Agent

Table 48: Feature Information for Configuring the PPPoE Intermediate Agent

| Feature Name | Releases | Feature Information |
|--------------------------|------------------------|---|
| PPPoE Intermediate Agent | Cisco IOS XE 15.2(6)E2 | Supports Point-to-point protocol over Ethernet intermediate agent (PPPoE IA) which is placed between a subscriber and broadband remote access server (BRAS). PPPoE IA helps the service provider BRAS to distinguish between end hosts connected over Ethernet to an access switch. |

CHAPTER 26

Configuring Flexible NetFlow

- [Prerequisites for Flexible NetFlow, on page 437](#)
- [Restrictions for Flexible NetFlow, on page 438](#)
- [Information About Flexible Netflow, on page 440](#)
- [How to Configure Flexible Netflow, on page 447](#)
- [Monitoring Flexible NetFlow, on page 458](#)
- [Configuration Examples for Flexible NetFlow, on page 458](#)
- [Additional References for NetFlow, on page 459](#)
- [Feature Information for Flexible NetFlow, on page 460](#)

Prerequisites for Flexible NetFlow

- Flexible NetFlow is supported on the Catalyst 2960-X Switch and the Catalyst 2960-XR Switch with a Cisco ONE for Access license. Catalyst 2960-XR is not stackable with the Catalyst 2960-X platform.
- One of the following must be enabled on your device and on any interfaces on which you want to enable Flexible NetFlow: Cisco Express Forwarding or distributed Cisco Express Forwarding.
- The targets for attaching a NetFlow monitor are the following:
 - **Port**—Monitor attachment is only supported on physical interfaces and not on logical interfaces, such as EtherChannels. The physical interface could be a routed port or a switched port.
 - **VLAN**—Monitor attachment is supported on VLAN interfaces only (SVI) and not on a Layer 2 VLAN.
- You are familiar with the Flexible NetFlow key fields as they are defined in the following commands:
 - **match datalink**—Datalink (layer2) fields
 - **match ipv4**—IPv4 fields
 - **match ipv6**—IPv6 fields
 - **match transport**—Transport layer fields
- You are familiar with the Flexible NetFlow non key fields as they are defined in the following commands:
 - **collect counter**—Counter fields

- **collect flow**—Flow identifying fields
- **collect interface**—Interface fields
- **collect timestamp**—Timestamp fields
- **collect transport**—Transport layer fields

Restrictions for Flexible NetFlow

The following restrictions apply to Flexible NetFlow and Flexible NetFlow Lite:

General Restrictions:

- InterSwitch Link (ISL) is not supported.
- Policy-based NetFlow is not supported.
- Cisco TrustSec monitoring is not supported.
- Access control lists (ACL)-based NetFlow is not supported.
- Only NetFlow Version 9 is supported for Flexible NetFlow exporter using the *export-protocol* command option.
- NetFlow Version 5 is not supported.

Flow Record Restrictions:

- When a flow monitor has configured the **collect interface output** command as the collect field in the flow record, the field will return a value of **NULL** when a flow gets created for any of the following addresses:
 - L2 broadcast and multicast
 - L3 broadcast and multicast
 - L2 unknown destination.

When a flow monitor has the collect interface output configured as the collect field in the flow record, the output interface is detected based on the destination IP address on the device. For the different flow monitors, you must configure the following commands:

- IPv4 flow monitor--Configure the **match ipv4 destination address** command.
- IPv6 flow monitor--Configure the **match ipv6 destination address** command.
- Datalink flow monitor--Configure the **match datalink mac destination address input** command.
- Predefined flow records are not supported.

Monitor Restrictions:

- Monitor attachment is only supported in the ingress direction.
- One monitor per interface is supported, although multiple exporters per interface are supported.

- Only permanent and normal cache is supported for the monitor; immediate cache is not supported.
- Changing any monitor parameter will not be supported when it is applied on any of the interfaces or VLANs.
- When both the port and VLANs have monitors attached, then VLAN monitor will overwrite the port monitor for traffic coming on the port.
- Flow monitor type and traffic type (type means IPv4, IPv6, and data link) should be same for the flows to be created.
- You cannot attach an IP and a port-based monitor to an interface. A 48-port device supports a maximum of 48 monitors (IP or port-based) and for 256 SVIs, you can configure up to 256 monitors (IP or port-based).
- When running the **show flow monitor** *flow_name* **cache** command, the device displays cache information from an earlier switch software version (Catalyst 2960-S) with all fields entered as zero. Ignore these fields, as they are inapplicable to the switch.

Sampler Restrictions:

- For both port and VLANs, a total of only 4 samplers (random or deterministic) are supported on the device.
- The sampling minimum rate for both modes is 1 out of 32 flows, and the sampling maximum rate for both modes is 1 out of 1022 flows.
- Use the **ip flow monitor** *monitor_name* sampler *sampler_name* **input** command to associate a sampler with a monitor while attaching it to an interface.
- When you attach a monitor using a deterministic sampler, every attachment with the same sampler uses one new free sampler from the switch (hardware) out of the 4 available samplers. You are not allowed to attach a monitor with any sampler, beyond 4 attachments.

When you attach a monitor using a random sampler, only the first attachment uses a new sampler from the switch (hardware). The remainder of all of the attachments using the same sampler, share the same sampler.

Because of this behavior, when using a deterministic sampler, you can always make sure that the correct number of flows are sampled by comparing the sampling rate and what the device sends. If the same random sampler is used with multiple interfaces, flows from any interface can always be sampled, and flows from other interfaces can always be skipped.

Stacking Restrictions:

- Each device in a stack (hardware) can support the creation of a maximum of 16,000 flows at any time. But as the flows are periodically pushed to the software cache, the software cache can hold a much larger amount of flows (1048 Kb flows). From the hardware flow cache, every 20 seconds (termed as poll timer), 200 flows (termed as poll entries) are pushed to software.
 - Use the **remote command all show platform hulf-fnf poll** command to report on the current NetFlow polling parameters of each switch.
 - Use the **show platform hulf-fnf poll** command to report on the current NetFlow polling parameters of the active switch.
- Network flows and statistics are collected at the line rate.

Information About Flexible Netflow

Flexible NetFlow Overview

Flexible NetFlow uses flows to provide statistics for accounting, network monitoring, and network planning.

A flow is a unidirectional stream of packets that arrives on a source interface and has the same values for the keys. A key is an identified value for a field within the packet. You create a flow using a flow record to define the unique keys for your flow.

The device supports the Flexible NetFlow feature that enables enhanced network anomalies and security detection. Flexible NetFlow allows you to define an optimal flow record for a particular application by selecting the keys from a large collection of predefined fields.

All key values must match for the packet to count in a given flow. A flow might gather other fields of interest, depending on the export record version that you configure. Flows are stored in the Flexible NetFlow cache.

You can export the data that Flexible NetFlow gathers for your flow by using an exporter and export this data to a remote system such as a Flexible NetFlow collector. The Flexible NetFlow collector can use an IPv4 address.

You define the size of the data that you want to collect for a flow using a monitor. The monitor combines the flow record and exporter with the Flexible NetFlow cache information.

Original NetFlow and Benefits of Flexible NetFlow

Flexible NetFlow allows the flow to be user defined. The benefits of Flexible NetFlow include:

- High-capacity flow recognition, including scalability and aggregation of flow information.
- Enhanced flow infrastructure for security monitoring and DDoS detection and identification.
- New information from packets to adapt flow information to a particular service or operation in the network. The flow information available will be customizable by Flexible NetFlow users.
- Extensive use of Cisco's flexible and extensible NetFlow Version 9.
- A comprehensive IP accounting feature that can be used to replace many accounting features, such as IP accounting, Border Gateway Protocol (BGP) Policy Accounting, and persistent caches.
- Supports Unicast, Multicast and Broadcast traffic and flows for these traffic is added.

Flexible NetFlow allows you to understand network behavior with more efficiency, with specific flow information tailored for various services used in the network. The following are some example applications for a Flexible NetFlow feature:

- Flexible NetFlow enhances Cisco NetFlow as a security monitoring tool. For instance, new flow keys can be defined for packet length or MAC address, allowing users to search for a specific type of attack in the network.
- Flexible NetFlow allows you to quickly identify how much application traffic is being sent between hosts by specifically tracking TCP or UDP applications by the class of service (CoS) in the packets.

- The accounting of traffic entering a Multiprotocol Label Switching (MPLS) or IP core network and its destination for each next hop per class of service. This capability allows the building of an edge-to-edge traffic matrix.

The figure below is an example of how Flexible NetFlow might be deployed in a network.

Figure 53: Typical Deployment for Flexible NetFlow

Flexible NetFlow Components

Flexible NetFlow consists of components that can be used together in several variations to perform traffic analysis and data export. The user-defined flow records and the component structure of Flexible NetFlow facilitates the creation of various configurations for traffic analysis and data export on a networking device with a minimum number of configuration commands. Each flow monitor can have a unique combination of flow record, flow exporter, and cache type. If you change a parameter such as the destination IP address for a flow exporter, it is automatically changed for all the flow monitors that use the flow exporter. The same flow monitor can be used in conjunction with different flow samplers to sample the same type of network traffic at different rates on different interfaces. The following sections provide more information on Flexible NetFlow components:

Flow Records

In Flexible NetFlow a combination of key and nonkey fields is called a record. Flexible NetFlow records are assigned to Flexible NetFlow flow monitors to define the cache that is used for storing flow data.

A flow record defines the keys that Flexible NetFlow uses to identify packets in the flow, as well as other fields of interest that Flexible NetFlow gathers for the flow. You can define a flow record with any combination of keys and fields of interest. The device supports a rich set of keys. A flow record also defines the types of counters gathered per flow. You can configure 64-bit packet or byte counters. The device enables the following match fields as the defaults when you create a flow record:

- match datalink—Layer 2 attributes
- match ipv4—IPv4 attributes
- match ipv6—IPv6 attributes
- match transport—Transport layer fields

- match wireless—Wireless fields

User-Defined Records

Flexible NetFlow enables you to define your own records for a Flexible NetFlow flow monitor cache by specifying the key and nonkey fields to customize the data collection to your specific requirements. When you define your own records for a Flexible NetFlow flow monitor cache, they are referred to as *user-defined records*. The values in nonkey fields are added to flows to provide additional information about the traffic in the flows. A change in the value of a nonkey field does not create a new flow. In most cases the values for nonkey fields are taken from only the first packet in the flow. Flexible NetFlow enables you to capture counter values such as the number of bytes and packets in a flow as nonkey fields.

Flexible NetFlow adds a new Version 9 export format field type for the header and packet section types. Flexible NetFlow will communicate to the NetFlow collector the configured section sizes in the corresponding Version 9 export template fields. The payload sections will have a corresponding length field that can be used to collect the actual size of the collected section.

Flow Exporters

Flow exporters export the data in the flow monitor cache to a remote system, such as a server running NetFlow collector, for analysis and storage. Flow exporters are created as separate entities in the configuration. Flow exporters are assigned to flow monitors to provide data export capability for the flow monitors. You can create several flow exporters and assign them to one or more flow monitors to provide several export destinations. You can create one flow exporter and apply it to several flow monitors.

NetFlow Data Export Format Version 9

The basic output of NetFlow is a flow record. Several different formats for flow records have evolved as NetFlow has matured. The most recent evolution of the NetFlow export format is known as Version 9. The distinguishing feature of the NetFlow Version 9 export format is that it is template-based. Templates provide an extensible design to the record format, a feature that should allow future enhancements to NetFlow services without requiring concurrent changes to the basic flow-record format. Using templates provides several key benefits:

- Third-party business partners who produce applications that provide collector or display services for NetFlow do not have to recompile their applications each time a new NetFlow feature is added. Instead, they should be able to use an external data file that documents the known template formats.
- New features can be added to NetFlow quickly without breaking current implementations.
- NetFlow is “future-proofed” against new or developing protocols because the Version 9 format can be adapted to provide support for them.

The Version 9 export format consists of a packet header followed by one or more template flow or data flow sets. A template flow set provides a description of the fields that will be present in future data flow sets. These data flow sets may occur later within the same export packet or in subsequent export packets. Template flow and data flow sets can be intermingled within a single export packet, as illustrated in the figure below.

Figure 54: Version 9 Export Packet

NetFlow Version 9 will periodically export the template data so the NetFlow collector will understand what data is to be sent and also export the data flow set for the template. The key advantage to Flexible NetFlow

is that the user configures a flow record, which is effectively converted to a Version 9 template and then forwarded to the collector. The figure below is a detailed example of the NetFlow Version 9 export format, including the header, template flow, and data flow sets.

Figure 55: Detailed Example of the NetFlow Version 9 Export Format

Flow Monitors

Flow monitors are the Flexible NetFlow component that is applied to interfaces to perform network traffic monitoring.

Flow data is collected from the network traffic and added to the flow monitor cache during the monitoring process based on the key and nonkey fields in the flow record.

Flexible NetFlow can be used to perform different types of analysis on the same traffic. In the figure below, packet 1 is analyzed using a record designed for standard traffic analysis on the input interface

Figure 56: Example of Using a Flow Monitor to Analyze Incoming Traffic

356472

The figure below shows a more complex example of how you can apply different types of flow monitors with custom records.

Figure 57: Complex Example of Using Multiple Types of Flow Monitors with Custom Records

Normal

The default cache type is “normal”. In this mode, the entries in the cache are aged out according to the timeout active and timeout inactive settings. When a cache entry is aged out, it is removed from the cache and exported via any exporters configured.

Flow Samplers

Flow samplers are created as separate components in a router’s configuration. Flow samplers are used to reduce the load on the device that is running Flexible NetFlow by limiting the number of packets that are selected for analysis.

Samplers use random sampling techniques (modes); that is, a randomly selected sampling position is used each time a sample is taken.

Flow sampling exchanges monitoring accuracy for router performance. When you apply a sampler to a flow monitor, the overhead load on the router of running the flow monitor is reduced because the number of packets that the flow monitor must analyze is reduced. The reduction in the number of packets that are analyzed by the flow monitor causes a corresponding reduction in the accuracy of the information stored in the flow monitor’s cache.

Samplers are combined with flow monitors when they are applied to an interface with the **ip flow monitor** command.

Supported Flexible NetFlow Fields

The following is the list of supported key fields in Flexible NetFlow:

- Source MAC and Destination MAC
- Datalink EtherType
- IPv4 source address

- IPv4 destination address
- IPv6 source address
- IPv6 destination address
- IPv4 TOS
- IPv6 traffic-class
- IPv6 flow label
- IPv4 protocol
- IPv6 protocol
- Layer 4 source port
- Layer 4 destination port

The following is the list of supported non-key fields in Flexible NetFlow:

- Interface input
- Interface output
- Bytes long
- Packets long
- Timestamp absolute first
- Timestamp absolute last
- Cumulative TCP flag
- Sampler ID

Default Settings

The following table lists the Flexible NetFlow default settings for the device.

Table 49: Default Flexible NetFlow Settings

| Setting | Default |
|-----------------------|---|
| Flow active timeout | 1800 seconds Note The default value for this setting may be too high for your specific Flexible NetFlow configuration. You may want to consider changing it to a lower value of 180 or 300 seconds. |
| Flow timeout inactive | Enabled, 30 seconds |
| Flow update timeout | 1800 seconds |

| Setting | Default |
|--------------------|---------------|
| Default cache size | 16640 entries |

In Cisco IOS Release 15.2(5)E1, Flexible NetFlow polling was changed from 200 entries every 20 seconds to 2000 entries every 5 seconds. Based on this change, the current flow count will reflect the actual hardware flow count, and continuously active flows will experience active timeout. All flows will be exported as per the configured timeout values.

How to Configure Flexible Netflow

To configure Flexible Netflow, follow these general steps:

1. Create a flow record by specifying keys and non-key fields to the flow.
2. Create an optional flow exporter by specifying the protocol and transport destination port, destination, and other parameters.
3. Create a flow monitor based on the flow record and flow exporter.
4. Create an optional sampler.
5. Apply the flow monitor to a Layer 2 port, Layer 3 port, or VLAN.

Creating a Flow Record

Perform this task to configure a customized flow record.

Customized flow records are used to analyze traffic data for a specific purpose. A customized flow record must have at least one **match** criterion for use as the key field and typically has at least one **collect** criterion for use as a nonkey field.

There are hundreds of possible permutations of customized flow records. This task shows the steps that are used to create one of the possible permutations. Modify the steps in this task as appropriate to create a customized flow record for your requirements.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 3 | flow record <i>record-name</i> Example: <pre>Device(config)# flow record FLOW-RECORD-1</pre> | Creates a flow record and enters Flexible NetFlow flow record configuration mode. <ul style="list-style-type: none"> This command also allows you to modify an existing flow record. |
| Step 4 | description <i>description</i> Example: <pre>Device(config-flow-record)# description Used for basic traffic analysis</pre> | (Optional) Creates a description for the flow record. |
| Step 5 | match {ipv4 ipv6} {destination source} address Example: <pre>Device(config-flow-record)# match ipv4 destination address</pre> | Note This example configures the IPv4 destination address as a key field for the record. For information about the other key fields available for the match ipv4 command, and the other match commands that are available to configure key fields. |
| Step 6 | Repeat Step 5 as required to configure additional key fields for the record. | — |
| Step 7 | Choose the required collect fields: <ul style="list-style-type: none"> collect counter {bytes [permanent long] packets }[permanent long] collect timestamp sys-uptime {first last} Example: <pre>Device(config-flow-record)# collect counter bytes long</pre> | Configures the number of bytes as a nonkey field for the record. |
| Step 8 | Repeat the above step as required to configure additional nonkey fields for the record. | — |
| Step 9 | end Example: <pre>Device(config-flow-record)# end</pre> | Exits Flexible NetFlow flow record configuration mode and returns to privileged EXEC mode. |
| Step 10 | show flow record <i>record-name</i> Example: <pre>Device# show flow record FLOW_RECORD-1</pre> | (Optional) Displays the current status of the specified flow record. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 11 | show running-config flow record <i>record-name</i> Example: <pre>Device# show running-config flow record FLOW_RECORD-1</pre> | (Optional) Displays the configuration of the specified flow record. |

Creating a Flow Exporter

You can create a flow export to define the export parameters for a flow.

Note Each flow exporter supports only one destination. If you want to export the data to multiple destinations, you must configure multiple flow exporters and assign them to the flow monitor.

You can export to a destination using IPv4 address.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | flow exporter <i>name</i> Example: <pre>Device(config)# flow exporter ExportTest</pre> | Creates a flow exporter and enters flow exporter configuration mode. |
| Step 3 | description <i>string</i> Example: <pre>Device(config-flow-exporter)# description ExportV9</pre> | (Optional) Describes this flow record as a maximum 63-character string. |
| Step 4 | destination { <i>ipv4-address</i> } [vrf <i>vrf-name</i>] Example: <pre>Device(config-flow-exporter)# destination 192.0.2.1 (IPv4 destination)</pre> | Sets the IPv4 destination address or hostname for this exporter. |

| | Command or Action | Purpose |
|----------------|--|---|
| Step 5 | <p>dscp <i>value</i></p> <p>Example:</p> <pre>Device(config-flow-exporter)# dscp 0</pre> | (Optional) Specifies the differentiated services codepoint value. The range is from 0 to 63. The default is 0. |
| Step 6 | <p>source { <i>source type</i> }</p> <p>Example:</p> <pre>Device(config-flow-exporter)# source gigabitEthernet1/0/1</pre> | (Optional) Specifies the interface to use to reach the NetFlow collector at the configured destination. The following interfaces can be configured as source: |
| Step 7 | <p>transport udp <i>number</i></p> <p>Example:</p> <pre>Device(config-flow-exporter)# transport udp 200</pre> | (Optional) Specifies the UDP port to use to reach the NetFlow collector. The range is from 1 to 65536 |
| Step 8 | <p>ttl <i>seconds</i></p> <p>Example:</p> <pre>Device(config-flow-exporter)# ttl 210</pre> | (Optional) Configures the time-to-live (TTL) value for datagrams sent by the exporter. The range is from 1 to 255 seconds. The default is 255. |
| Step 9 | <p>export-protocol {netflow-v9}</p> <p>Example:</p> <pre>Device(config-flow-exporter)# export-protocol netflow-v9</pre> | Specifies the version of the NetFlow export protocol used by the exporter. |
| Step 10 | <p>end</p> <p>Example:</p> <pre>Device(config-flow-record)# end</pre> | Returns to privileged EXEC mode. |
| Step 11 | <p>show flow exporter [name <i>record-name</i>]</p> <p>Example:</p> <pre>Device# show flow exporter ExportTest</pre> | (Optional) Displays information about NetFlow flow exporters. |
| Step 12 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config</pre> | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|-----------------------------|---------|
| | <code>startup-config</code> | |

What to do next

Define a flow monitor based on the flow record and flow exporter.

Creating a Flow Monitor

Perform this required task to create a customized flow monitor.

Each flow monitor has a separate cache assigned to it. Each flow monitor requires a record to define the contents and layout of its cache entries. These record formats can be a user-defined format. An advanced user can create a customized format using the **flow record** command.

Before you begin

If you want to use a customized record, you must create the customized record before you can perform this task. If you want to add a flow exporter to the flow monitor for data export, you must create the exporter before you can complete this task.

Note You must use the **no ip flow monitor** command to remove a flow monitor from all of the interfaces to which you have applied it before you can modify the parameters for the **record** command on the flow monitor.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | flow monitor <i>monitor-name</i> Example: Device(config)# flow monitor FLOW-MONITOR-1 | Creates a flow monitor and enters Flexible NetFlow flow monitor configuration mode. <ul style="list-style-type: none"> • This command also allows you to modify an existing flow monitor. |
| Step 4 | description <i>description</i> Example: | (Optional) Creates a description for the flow monitor. |

| | Command or Action | Purpose |
|----------------|--|--|
| | Device(config-flow-monitor)# description Used for basic ipv4 traffic analysis | |
| Step 5 | record { <i>record-name</i> } Example: Device(config-flow-monitor)# record FLOW-RECORD-1 | Specifies the record for the flow monitor. |
| Step 6 | cache { <i>entries number</i> timeout { <i>active</i> <i>inactive</i> update } <i>seconds</i> { normal } } | timeout active seconds —Configure the active flow timeout. This defines the granularity of the traffic analysis. The range is from 30 to 604800 seconds. The default is 1800. Typical values are 60 or 300 seconds. See the Configuring Data Export for Cisco IOS Flexible NetFlow with Flow Exporters document for recommended values. |
| Step 7 | Repeat Step 6 as required to finish modifying the cache parameters for this flow monitor. | — |
| Step 8 | exporter <i>exporter-name</i> Example: Device(config-flow-monitor)# exporter EXPORTER-1 | (Optional) Specifies the name of an exporter that was created previously. |
| Step 9 | end Example: Device(config-flow-monitor)# end | Exits Flexible NetFlow flow monitor configuration mode and returns to privileged EXEC mode. |
| Step 10 | show flow monitor [[<i>name</i>] <i>monitor-name</i> [cache [<i>format</i> { <i>csv</i> <i>record</i> <i>table</i> }]]] Example: Device# show flow monitor FLOW-MONITOR-2 cache | (Optional) Displays the status for a Flexible NetFlow flow monitor. |
| Step 11 | show running-config flow monitor <i>monitor-name</i> Example: Device# show running-config flow monitor FLOW_MONITOR-1 | (Optional) Displays the configuration of the specified flow monitor. |
| Step 12 | copy running-config startup-config Example: | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

Creating a Sampler

You can create a sampler to define the NetFlow sampling rate for a flow.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | sampler <i>name</i> Example: Device(config)# <code>sampler SampleTest</code> | Creates a sampler and enters flow sampler configuration mode. |
| Step 3 | description <i>string</i> Example: Device(config-flow-sampler)# <code>description samples</code> | (Optional) Describes this flow record as a maximum 63-character string. |
| Step 4 | mode {deterministic {<i>m</i> - <i>n</i>} random {<i>m</i> - <i>n</i>}} Example: Device(config-flow-sampler)# <code>mode random 1 out-of 1022</code> | Defines the random sample mode. You can configure either a random or deterministic sampler to an interface. Select <i>m</i> packets out of an <i>n</i> packet window. The window size to select packets from ranges from 32 to 1022. Note the following when configuring a sampler to an interface: <ul style="list-style-type: none"> • When you attach a monitor using deterministic sampler (for example, s1), every attachment with same sampler s1 uses one new free sampler from the device (hardware) out of 4 available samplers. Therefore, beyond 4 attachments, you are not allowed to attach a monitor with any sampler. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> • In contrast, when you attach a monitor using random sampler (for example-again, s1), only the first attachment uses a new sampler from the device (hardware). The rest of all attachments using the same sampler s1, share the same sampler. • Due to this behavior, when using a deterministic sampler, you can always make sure the correct number of flows are sampled by comparing the sampling rate and what the device sends. If the same random sampler is used with multiple interfaces, flows from an interface can always be sampled, and the flows from other interfaces could be always skipped. |
| Step 5 | end Example: <pre>Device(config-flow-sampler)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show sampler <i>[name]</i> Example: <pre>Device show sample SampleTest</pre> | (Optional) Displays information about NetFlow samplers. |
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

What to do next

Apply the flow monitor to a source interface or a VLAN.

Applying a Flow to an Interface

You can apply a flow monitor and an optional sampler to an interface.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface type Example: Device(config)# interface GigabitEthernet1/0/1 | Enters interface configuration mode and configures an interface. You cannot attach a NetFlow monitor to a port channel interface. If both service module interfaces are part of an EtherChannel, you should attach the monitor to both physical interfaces. |
| Step 3 | {ip flow monitor ipv6 flow monitor}name [sampler name] {input} Example: Device(config-if)# ip flow monitor MonitorTest input | Associate an IPv4 or an IPv6 flow monitor, and an optional sampler to the interface for input packets. To monitor datalink L2 traffic flows, you would use datalink flow monitor name sampler sampler-name {input} interface command. This specific command associates a datalink L2 flow monitor and required sampler to the interface for input packets. When a datalink flow monitor is assigned to an interface or VLAN record, it only creates flows for non-IPv6 or non-IPv4 traffic. |
| Step 4 | end Example: Device(config-flow-monitor)# end | Returns to privileged EXEC mode. |
| Step 5 | show flow interface [interface-type number] Example: Device# show flow interface | (Optional) Displays information about NetFlow on an interface. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring NetFlow on SVI

You can apply a flow monitor and an optional sampler to a SVI.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface vlan <i>vlan-id</i> Example: Device(config)# interface vlan 30 | Specifies the SVI for the configuration. |
| Step 3 | ip flow monitor <i>monitor name</i> [sampler <i>sampler name</i>] {input output} Example: Device(config-if)# ip flow monitor MonitorTest input | Associates a flow monitor and an optional sampler to the SVI for input packets. |
| Step 4 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Layer 2 NetFlow

You can define Layer 2 keys in Flexible NetFlow records that you can use to capture flows in Layer 2 interfaces.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | flow record <i>name</i> | Enters flow record configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <p>Example:</p> <pre>Device(config)# flow record L2_record Device(config-flow-record)#</pre> | |
| Step 3 | <p>match datalink {ethertype mac {destination {address input} source {address input}}}</p> <p>Example:</p> <pre>Device(config-flow-record)# match datalink mac source address input Device(config-flow-record)# match datalink mac destination address input</pre> | <p>Specifies the Layer 2 attribute as a key. In this example, the keys are the source and destination MAC addresses from the packet at input.</p> <p>Note When a datalink flow monitor is assigned to an interface or VLAN record, it only creates flows for non-IPv4 or non-IPv6 traffic.</p> |
| Step 4 | <p>match { ipv4 {destination protocol source tos} ipv6 {destination flow-label protocol source traffic-class} transport {destination-port source-port}}</p> <p>Example:</p> <pre>Device(config-flow-record)# match ipv4 protocol Device(config-flow-record)# match ipv4 tos</pre> | <p>Specifies additional Layer 2 attributes as a key. In this example, the keys are IPv4 protocol and ToS.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config-flow-record)# end</pre> | <p>Returns to privileged EXEC mode.</p> |
| Step 6 | <p>show flow record [name]</p> <p>Example:</p> <pre>Device# show flow record</pre> | <p>(Optional) Displays information about NetFlow on an interface.</p> |
| Step 7 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | <p>(Optional) Saves your entries in the configuration file.</p> |

Monitoring Flexible NetFlow

The commands in the following table can be used to monitor Flexible NetFlow.

Table 50: Flexible NetFlow Monitoring Commands

| Command | Purpose |
|--|---|
| show flow exporter [broker export-ids name <i>name</i> statistics templates] | Displays information about NetFlow flow exporters and statistics. |
| show flow exporter [name <i>exporter-name</i>] | Displays information about NetFlow flow exporters and statistics. |
| show flow interface | Displays information about NetFlow interfaces. |
| show flow monitor [name <i>monitor-name</i>] | Displays information about NetFlow flow monitors and statistics. |
| show flow monitor statistics | Displays the statistics for the flow monitor |
| show flow monitor <i>monitor-name</i> cache format { table record csv } | Displays the contents of the cache for the flow monitor, in the format specified. |
| show flow record [name <i>record-name</i>] | Displays information about NetFlow flow records. |
| show sampler [broker name <i>name</i>] | Displays information about NetFlow samplers. |

Configuration Examples for Flexible NetFlow

Example: Configuring a Flow

This example shows how to create a flow and apply it to an interface:

```

Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.

Device(config)# flow export export1
Device(config-flow-exporter)# destination 10.0.101.254
Device(config-flow-exporter)# transport udp 2055
Device(config-flow-exporter)# exit
Device(config)# flow record record1
Device(config-flow-record)# match ipv4 source address
Device(config-flow-record)# match ipv4 destination address
Device(config-flow-record)# match ipv4 protocol
Device(config-flow-record)# match transport source-port
Device(config-flow-record)# match transport destination-port

Device(config-flow-record)# collect counter byte long
Device(config-flow-record)# collect counter packet long

```

```

Device(config-flow-record)# collect timestamp absolute first
Device(config-flow-record)# collect timestamp absolute last
Device(config-flow-record)# exit
Device(config)# flow monitor monitor1
Device(config-flow-monitor)# record record1
Device(config-flow-monitor)# exporter export1
Device(config-flow-monitor)# exit
Device(config)# interface tenGigabitEthernet 1/0/1
Device(config-if)# ip flow monitor monitor1 input
Device(config-if)# end

```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for OpenFlow

The Prerequisites for OpenFlow are as follows:

- A Cisco device and its corresponding operating system that supports the installation of OpenFlow.

Refer to the corresponding release notes for information about which operating system release supports the features and necessary infrastructure.

Note Note: Release notes for [Cisco Catalyst 2960X/XR Series Switches](#)

- A controller installed on a connected server.

Table 52: Controller Support

| OpenFlow Version | Supported Controllers |
|------------------|--|
| OpenFlow 1.0 | Extensible Network Controller (XNC) 1.0, POX, Cisco Open SDN Controller, or Ixia controllers |
| OpenFlow 1.3 | Ixia, CiscoOpen SDN Controller, or OpenDaylight |

Restrictions for OpenFlow

The Restrictions for OpenFlow are as listed below:

- OpenFlow supports only a subset of OpenFlow 1.3 functions. For more information, see the Cisco OpenFlow Feature Support section.
- You cannot configure more than one OpenFlow logical switch. The logical switch ID has a value of 1.
- OpenFlow hybrid model (ships-in-the-night) is supported. VLANs configured for OpenFlow logical switch ports should not overlap with regular device interfaces.
- The OpenFlow logical switch ports must not be configured in a mode other than trunk port.
- You cannot configure a bridge domain, Virtual LANs, virtual routing and forwarding (VRF) or port-channel interfaces on an OpenFlow logical switch. You can only configure physical interfaces.
- You cannot make additional configurations to an interface configured as a port of OpenFlow Logical Switch without removing the configuration as a port of OpenFlow Logical Switch.
- In stack scenarios, consisting of active/member switches, whenever the active switch goes down, all current configuration will exist in newly elected active switch. However, the flows have to program again from the controller.
- MIBs and XMLs are not supported.
- Cisco Catalyst 2960X/XR switch supports 1000 L2 flows with EtherType, 200 L2 flows without EtherType, and 500 L3 flows.
- A maximum of 48 ports can be assigned for Openflow operation.
- In general, the maximum sustained flow programming rate from the controller should not exceed 50 (added or deleted) flows per second. For flows that have more than 1 match criteria (more than input port + 1 match), the sustained controller programming rate should not exceed 40 flows per second.
- The maximum burst flow programming rate from the controller should not exceed 1000 flows, spaced by 30-second time intervals. A minimum of 30-second time interval should be maintained between addition or deletion of flows.
- The rate of PACKET_IN messages sent to the controller should be rate-limited to 300 packets per second, using configuration.

Information About Open Flow

Overview of OpenFlow

OpenFlow is a standard communications interface defined between the control and forwarding plane for direct access to and manipulation of the forwarding plane of network devices such as switches and routers from multiple vendors.

OpenFlow Switch Specification Version 1.0.1 (Wire Protocol 0x01), referred to as OpenFlow 1.0, and OpenFlow Switch Specification Version 1.3.0 (Wire Protocol 0x04), referred to as OpenFlow 1.3, are based on the concept of an Ethernet switch with an internal flow table and standardized interface to allow traffic flows on a device to be added or removed. OpenFlow 1.3 defines the communication channel between OpenFlow and controllers.

A generic OpenFlow controller will interact with an specialized OpenFlow agent that translates the OpenFlow configuration into IOS configurations and configures the data plane.

Support of OpenFlow on catalyst 2960X/XR is limited to only software forwarding (due to ASIC limitations). The software forwarding of flows will happen at the OpenFlow agent with support of 12 tuples matches consisting of single table with both L2 and L3 fields together. The match criteria can be match on all 12 tuple fields or any of the 12 tuple fields.

The corresponding actions to the matching criteria can be:

- Push / Pop of Vlan
- Output the packet to port
- Drop the packet
- Set/Decrement IP TTL value
- Modify of L2/L3/L4 fields of Ethernet frame

The Physical ports can be configured as OpenFlow ports or as normal port. The flows in the flow table will be installed based on the priority of the flow.

Note Priority 0 flows are not supported.

Cisco supports a subset of OpenFlow 1.0 and OpenFlow 1.3 functions. A controller can be Extensible Network Controller (XNC) 1.0, or any controller compliant with OpenFlow 1.3.

OpenFlow Controller Operation

OpenFlow controller (referred to as controller) controls the switch and inserts flows with a subset of OpenFlow 1.3 and 1.0 match and action criteria through OpenFlow logical switch.

Cisco OpenFlow Feature Support

The following is a subset of OpenFlow 1.3 and OpenFlow 1.0 functions that are supported by OpenFlow.

Table 53: Cisco OpenFlow Feature Support

| Feature | Notes |
|---|---|
| Configuration of physical interfaces as OpenFlow logical switch ports | <p>Bridge domain, Virtual LANs and Virtual Routing and Forwarding (VRF), and port-channel interfaces are not supported.</p> <p>Only L2 interfaces can be OpenFlow logical switch ports.</p> |
| Supported OpenFlow message types | <p>Controller to switch:</p> <ul style="list-style-type: none"> • Handshake • Switch Configuration • Modify State (Port Modification message is not supported) • Read State • Packet-Out • Barrier <p>Asynchronous messages:</p> <ul style="list-style-type: none"> • Packet-In • Flow Removed • Port Status • Error <p>Symmetric messages:</p> <ul style="list-style-type: none"> • Hello • Echo Request • Echo Reply • Vendor |
| Connection to controllers | <p>You can connect up to eight controllers.</p> <p>Connection to the controller through a management interface or a switched virtual interface (SVI) is supported.</p> <p>Connection via TCP and TLS is supported.</p> |

| Feature | Notes |
|-----------------------------|---|
| Multiple actions | <p>If multiple actions are associated with a flow, they are processed in the order specified. The output action should be the last action in the action list. Any action after the output action is not supported, and can cause the flow to fail and return an error to the controller.</p> <p>Flows defined on the controller must follow the these guidelines:</p> <ul style="list-style-type: none"> • The flow can have only one output action. • Some action combinations which are not supported may be rejected at flow programming time. • The flow should not have an output-to-controller action in combination with other rewrite actions. |
| Supported OpenFlow counters | <p>Per Table—Active entries, packet lookups, and packet matches.</p> <p>Per Flow—Received Packets, Received bytes, Duration (seconds), Duration (milliseconds).</p> <p>Per Port—Received or transmitted packets, and bytes.</p> <p>Per Controller— Flow addition, modification, deletion, error messages, echo requests or replies, barrier requests or replies, connection attempts, successful connections, packet in or packet out.</p> |
| Default forwarding rule | <p>All packets that cannot be matched to programmed flows are dropped by default. You can configure sending unmatched packets to the controller. You can modify the default action taken on unmatched packets either using the default-miss command or by the controller.</p> |
| Idle timeout | <p>A minimum Idle timeout of 14 seconds is supported for 700 flows and 48 ports.</p> <p>The statistics collection interval influences the minimum idle timeout. When the interval is set to 7 seconds, the timeout is a minimum of 14 seconds. 700 flows are supported with the 14-second idle timeout.</p> <p>When using an idle timeout of less than 25 seconds, the number of L3 flows should be limited to 700.</p> |

Supported Match and Actions and Pipelines

Table 54: Supported Match and Actions and Pipelines

| Feature | Notes |
|-----------|---|
| Pipelines | Pipelines are mandatory for logical switch. The logical switch supports only pipeline 1. The logical switch supports only table 0. |

| Feature | Notes |
|------------------|-------|
| Forwarding Table | |

| Feature | Notes |
|---------|---|
| | <p>Match Criteria:</p> <ul style="list-style-type: none"> • Input Port • Ethernet type • Source Mac Address • Dest Mac Address • VLAN ID • IP TOS (DSCP bits) • IP Protocol (except for lower 8 bits of ARP code) • IPv4 Source Address • IPv4 Destination Address • Layer 4 Source Port • Layer 4 Destination Port • IPv6 Source Address • IPv6 Destination Address <p>Action Criteria:</p> <ul style="list-style-type: none"> • Forward: Controller • Forward: Port • Forward: Drop • Forward: Controller + Port • Set VLAN ID • New VLAN ID • Replace VLAN ID • Strip VLAN Header • Modify Source MAC • Modify Destination MAC • Modify IPv4 Source Address • Modify IPv4 Destination Address • Modify IPv4 TOS bits • Modify L4 source port • Modify L4 destination port • Decrement TTL |

| Feature | Notes |
|------------------------|-------------------------------|
| Number of flows | 1000 |
| Configuration of VLANs | VLAN range is from 1 to 4094. |

Configuring OpenFlow

To configure OpenFlow logical switch and the IP address of a controller, perform this task:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | feature openflow Example: Device (config)# feature openflow | Enables Open Flow Agent support on the switch. |
| Step 4 | openflow Example: Device (config)# openflow | Enables Open Flow Agent support on the switch. |
| Step 5 | switch <i>logical-switch-id</i> pipeline <i>logical-id</i> Example: Device (config-ofa-switch)# switch 1 pipeline 1 | Specifies an ID for a logical switch that is used for OpenFlow switching and enters logical switch configuration mode. The only logical switch ID supported is 1. Configures a pipeline. This step is mandatory for a logical switch configuration. The only pipeline ID supported is 1. |

| | Command or Action | Purpose |
|--------|--|---|
| Step 6 | <p>controller [ipv4 <i>ip-address</i>] [port <i>tcp-port</i>] [vrf <i>vrf-name</i>] [security {none tls}]</p> <p>Example:</p> <pre>Device(config-ofa-switch)# controller ipv4 10.1.1.1 tcp 6633</pre> | <p>Specifies the IPv4 address, port number used by the controller to connect to the logical switch. Repeat this step if you need to configure additional controllers. You can configure up to eight controllers. If TLS is used in this step, configure TLS trustpoints in the next step.</p> <p>If unspecified, by default, Controllers use TCP port 6633.</p> <p>A connection to a controller is initiated by the logical switch.</p> |
| Step 7 | <p>of-port interface <i>interface-name</i></p> <p>Example:</p> <pre>Device(config-ofa-switch)# of-port interface GigabitEthernet1/0/23 Device(config-ofa-switch)# of-port interface TenGigabitEthernet1/1/2</pre> | <p>Adds interfaces to the logical switch configuration.</p> <p>Observe these guidelines:</p> <ul style="list-style-type: none"> • Do not abbreviate the interface type. Ensure that the interface type is spelled out completely and is as shown in the examples. • If the keyword is abbreviated, the interface is not configured. • The interface must be designated for the OpenFlow logical switch only. <p>Repeat this step to configure additional interfaces.</p> |
| Step 8 | <p>default-miss <i>action-for-unmatched-flows</i></p> <p>Example:</p> <pre>Device(config-ofa-switch)# default-miss continue-controller</pre> | <p>Configures the action to be taken for packets that do not match any of the flow defined. The supported options are:</p> <ul style="list-style-type: none"> • forward the packets using the normal routing tables • forward the packets to the controller • drop the packets <p>The default option is to forward the packets using the normal routing tables.</p> |
| Step 9 | <p>protocol-version {1.1 1.3 negotiate}</p> <p>Example:</p> <pre>Device(config-ofa-switch)# protocol-version negotiate</pre> | <p>Configures the protocol version. Supported values are:</p> <ul style="list-style-type: none"> • 1.0—Configures device to connect to 1.0 controllers only. • 1.3—Configures device to connect to 1.3 controllers only.. |

| | Command or Action | Purpose |
|----------------|---|---|
| | | <ul style="list-style-type: none"> • negotiate—Negotiates the protocol version with the controller. Device uses 1.3 for negotiation. <p>The default value is 1.0.</p> |
| Step 10 | shutdown Example: <pre>Device(config-ofa-switch)# shutdown</pre> | Disables a logical switch, bringing down the tcp/ip connection and removing flows from the dataplane. |
| Step 11 | datapath-id <i>datapath-id</i> Example: <pre>Device(config-ofa-switch)# datapath-id 0x222</pre> | <p>Configures a unique datapath ID for the switch.</p> <p>This step is mandatory for a logical switch configuration.</p> <p>Enter a 64-bit hexadecimal value.</p> |
| Step 12 | tls trust-point local <i>local-trust-point</i> remote <i>remote-trust-point</i> Example: <pre>Device(config-ofa-switch)# tls trust-point local myCA remote myCA</pre> | (Optional) Specifies the local and remote TLS trustpoints to be used for the controller connection. |
| Step 13 | probe-interval <i>probe-interval</i> Example: <pre>Device(config-ofa-switch)# probe-interval 7</pre> | <p>(Optional) Configures the interval (in seconds) at which the controller is probed.</p> <p>After the configured interval of time passes, if the switch has not received any messages from the controller, the switch sends an echo request (echo_request) to the controller. It should normally receive an echo reply (echo_reply). If no message is seen for the duration of another probe interval, the switch presumes that the controller is down and disconnects the controller connection. The switch tries to reconnect periodically.</p> <p>The default value is 5 seconds; the range is from 5 to 65535 seconds.</p> |
| Step 14 | rate-limit packet_in <i>controllet-packet-rate</i> burst <i>maximum-packets-to-controller</i> Example: <pre>Device(config-ofa-switch)# rate-limit packet_in 300 burst 50</pre> | <p>(Optional) Configures the maximum packet rate sent to the controller and the maximum packets burst sent to the controller in a second.</p> <p>The default value is zero, that is, an indefinite packet rate and packet burst is permitted.</p> <p>This rate limit is for OpenFlow. It is not related to the rate limit of the device (data plane) configured by COPP.</p> |

| | Command or Action | Purpose |
|---------|---|---|
| Step 15 | <p>max-backoff <i>backoff-timer</i></p> <p>Example:</p> <pre>Device(config-ofta-switch)# max-backoff 8</pre> | <p>(Optional) Configures the duration (in seconds) for which the device must wait before attempting to initiate a connection with the controller.</p> <p>The device initially tries to initiate connection frequently, as the number of unsuccessful attempts increases, the device tries less frequently, that is, the waiting period between attempts also increases. The backoff timer configures the maximum period that the device waits in-between each retry.</p> <p>The default value is 8 seconds; the range is from 1 to 65535 seconds.</p> |
| Step 16 | <p>logging flow-mod</p> <p>Example:</p> <pre>Device(config-ofta-switch)# logging flow-mod</pre> | <p>(Optional) Enables logging of flow changes, including addition, deletion, and modification of flows.</p> <p>Logging of flow changes is a CPU intensive activity and should not be enabled for a large number of flows.</p> <p>Logging of flow changes is disabled by default.</p> <p>Flow changes are logged in syslog and can be viewed using the show logging command.</p> |
| Step 17 | <p>statistics collection-interval <i>interval</i></p> <p>Example:</p> <pre>Device(config-ofta-switch)# statistics collection-interval 7</pre> | <p>Configures the statistics collection interval (in seconds) for all configured flows of OpenFlow. Observe these guidelines:</p> <ul style="list-style-type: none"> • The default interval value is 7 seconds. • The minimum interval is 7 seconds; the maximum is 82 seconds. • You can also specify a value of 0, this disables statistics collection. • Flows with an idle timeout value less than 2 * interval are rejected. <p>Configured interval value is displayed in the output of the show openflow switch 1 command.</p> |
| Step 18 | <p>end</p> <p>Example:</p> <pre>Device(config-ofta-switch)# end</pre> | <p>Returns to privileged EXEC mode.</p> <p>Alternatively, you can also press Ctrl-Z to exit global configuration mode.</p> |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 19 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring OpenFlow

You can monitor OpenFlow parameters using the following commands:

| Commands | Description |
|--|---|
| show openflow switch <i>switch-id</i> | Displays information related to OpenFlow on the logical switch. |
| show openflow switch <i>switch-id</i> controllers [stats] | Displays information related to the connection status between an OpenFlow logical switch and connected Controllers. |
| show openflow switch <i>switch-id</i> ports | Displays the mapping between physical device interfaces and ports of OpenFlow logical switch. |
| show openflow <i>switch-id</i> flows | Displays flows defined for the device by controllers. |
| show openflow switch <i>switch-id</i> stats | Displays send and receive statistics for each port defined for an OpenFlow logical switch. |
| show running-config section openflow | Displays configurations made for OpenFlow. |
| show openflow hardware capabilities | Displays OpenFlow hardware configurations. |

Configuration Examples for OpenFlow

This example shows how you can view information related to OpenFlow on the logical switch.

```
Device#show openflow switch 1

Logical Switch Context
Id: 1
Switch type: Forwarding

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for QoS

Before configuring standard QoS, you must have a thorough understanding of these items:

- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. For example, is the traffic on your network bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.

QoS ACL Guidelines

Follow these guidelines when configuring QoS with access control lists (ACLs):

- It is not possible to match IP fragments against configured IP extended ACLs to enforce QoS. IP fragments are sent as best-effort. IP fragments are denoted by fields in the IP header.
- Only one ACL per class map and only one **match** class-map configuration command per class map are supported. The ACL can have multiple ACEs, which match fields against the contents of the packet.
- A trust statement in a policy map requires multiple hardware entries per ACL line. If an input service policy map contains a trust statement in an ACL, the access list might be too large to fit into the available QoS hardware memory, and an error can occur when you apply the policy map to a port. Whenever possible, you should minimize the number of lines in a QoS ACL.

Policing Guidelines

Note To use policing, the switch must be running the LAN Base image.

- The port ASIC device, which controls more than one physical port, supports 256 policers (255 user-configurable policers plus 1 policer reserved for system internal use). The maximum number of user-configurable policers supported per port is 63. Policers are allocated on demand by the software and are constrained by the hardware and ASIC boundaries.
You cannot reserve policers per port; there is no guarantee that a port will be assigned to any policer.
- Only one policer is applied to a packet on an ingress port. Only the average rate and committed burst parameters are configurable.
- On a port configured for QoS, all traffic received through the port is classified, policed, and marked according to the policy map attached to the port. On a trunk port configured for QoS, traffic in all VLANs received through the port is classified, policed, and marked according to the policy map attached to the port.
- If you have EtherChannel ports configured on your switch, you must configure QoS classification, policing, mapping, and queueing on the individual physical ports that comprise the EtherChannel. You must decide whether the QoS configuration should match on all ports in the EtherChannel.
- If you need to modify a policy map of an existing QoS policy, first remove the policy map from all interfaces, and then modify or copy the policy map. After you finish the modification, apply the modified policy map to the interfaces. If you do not first remove the policy map from all interfaces, high CPU usage can occur, which, in turn, can cause the console to pause for a very long time.

General QoS Guidelines

These are the general QoS guidelines:

- You configure QoS only on physical ports; there is no support for it at the VLAN level.
- Control traffic (such as spanning-tree bridge protocol data units [BPDUs] and routing update packets) received by the switch are subject to all ingress QoS processing.

- You are likely to lose data when you change queue settings; therefore, try to make changes when traffic is at a minimum.
- The switch supports homogeneous stacking and mixed stacking. Mixed stacking is supported only with the Catalyst 2960-S switches. A homogenous stack can have up to eight stack members, while a mixed stack can have up to four stack members. All switches in a switch stack must be running the LAN Base image.

Restrictions for QoS

The following are the restrictions for QoS:

- To use these features, the switch must be running the LAN Base image: stacking, DSCP, auto-QoS, trusted boundary, policing, marking, mapping tables, and weighted tail drop.
- Ingress queueing is not supported.
- The switch supports 4 default egress queues, with the option to enable an additional 4 egress queues for a total of 8. This option is only available on a standalone switch running the LAN Base image.
- We recommend that you do not enable 8 egress queues by using the **mls qos srr-queue output queues 8** command, when running the following features in your configuration:
 - Auto-QoS
 - Auto SmartPort
 - EnergyWise

Running these features with 8 egress queue enabled in a single configuration is not supported on the switch.

- You can configure QoS only on physical ports. VLAN-based QoS is not supported. You configure the QoS settings, such as classification, queueing, and scheduling, and apply the policy map to a port. When configuring QoS on a physical port, you apply a nonhierarchical policy map to a port.
- If the switch is running the LAN Lite image you can:
 - Configure ACLs, but you cannot attach them to physical interfaces. You can attach them to VLAN interfaces to filter traffic to the CPU.
 - Enable only cos trust at interface level.
 - Enable SRR shaping and sharing at interface level.
 - Enable Priority queueing at interface level.
 - Enable or disable **mls qos rewrite ip dscp**.
- The switch must be running the LAN Base image to use the following QoS features:
 - Policy maps
 - Policing and marking
 - Mapping tables

- WTD

Information About QoS

QoS Implementation

Typically, networks operate on a best-effort delivery basis, which means that all traffic has equal priority and an equal chance of being delivered in a timely manner. When congestion occurs, all traffic has an equal chance of being dropped.

When you configure the QoS feature, you can select specific network traffic, prioritize it according to its relative importance, and use congestion-management and congestion-avoidance techniques to provide preferential treatment. Implementing QoS in your network makes network performance more predictable and bandwidth utilization more effective.

The QoS implementation is based on the Differentiated Services (Diff-Serv) architecture, a standard from the Internet Engineering Task Force (IETF). This architecture specifies that each packet is classified upon entry into the network.

The classification is carried in the IP packet header, using 6 bits from the deprecated IP type of service (ToS) field to carry the classification (*class*) information. Classification can also be carried in the Layer 2 frame.

Figure 58: QoS Classification Layers in Frames and Packets

The special bits in the Layer 2 frame or a Layer 3 packet are shown in the following

figure:

Layer 2 Frame Prioritization Bits

Layer 2 Inter-Switch Link (ISL) frame headers have a 1-byte User field that carries an IEEE 802.1p class of service (CoS) value in the three least-significant bits. On ports configured as Layer 2 ISL trunks, all traffic is in ISL frames.

Layer 2 802.1Q frame headers have a 2-byte Tag Control Information field that carries the CoS value in the three most-significant bits, which are called the User Priority bits. On ports configured as Layer 2 802.1Q trunks, all traffic is in 802.1Q frames except for traffic in the native VLAN.

Other frame types cannot carry Layer 2 CoS values.

Layer 2 CoS values range from 0 for low priority to 7 for high priority.

Layer 3 Packet Prioritization Bits

Layer 3 IP packets can carry either an IP precedence value or a Differentiated Services Code Point (DSCP) value. QoS supports the use of either value because DSCP values are backward-compatible with IP precedence values.

IP precedence values range from 0 to 7. DSCP values range from 0 to 63.

End-to-End QoS Solution Using Classification

All switches and routers that access the Internet rely on the class information to provide the same forwarding treatment to packets with the same class information and different treatment to packets with different class information. The class information in the packet can be assigned by end hosts or by switches or routers along the way, based on a configured policy, detailed examination of the packet, or both. Detailed examination of the packet is expected to occur closer to the edge of the network, so that the core switches and routers are not overloaded with this task.

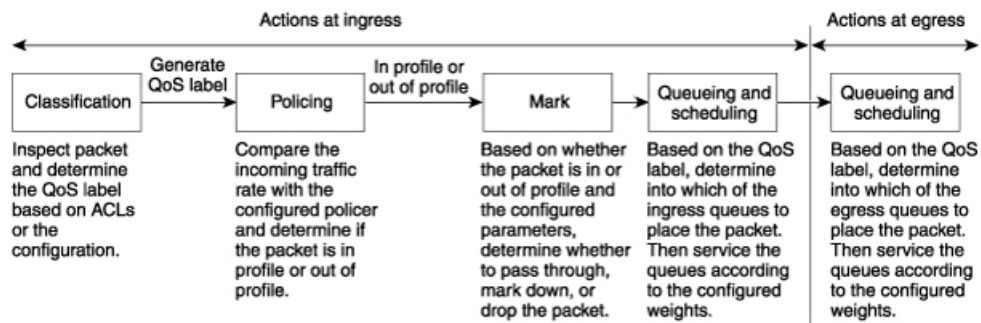

Switches and routers along the path can use the class information to limit the amount of resources allocated per traffic class. The behavior of an individual device when handling traffic in the Diff-Serv architecture is called per-hop behavior. If all devices along a path provide a consistent per-hop behavior, you can construct an end-to-end QoS solution.

Implementing QoS in your network can be a simple task or complex task and depends on the QoS features offered by your internetworking devices, the traffic types and patterns in your network, and the granularity of control that you need over incoming and outgoing traffic.

QoS Basic Model

To implement QoS, the switch must distinguish packets or flows from one another (classify), assign a label to indicate the given quality of service as the packets move through the switch, make the packets comply with the configured resource usage limits (police and mark), and provide different treatment (queue and schedule) in all situations where resource contention exists. The switch also needs to ensure that traffic sent from it meets a specific traffic profile (shape).

Figure 59: QoS Basic Wired Model

Actions at Ingress Port

Actions at the ingress port include classifying traffic, policing, marking, and scheduling:

- Classifying a distinct path for a packet by associating it with a QoS label. The switch maps the CoS or DSCP in the packet to a QoS label to distinguish one kind of traffic from another. The QoS label that is generated identifies all future QoS actions to be performed on this packet.
- Policing determines whether a packet is in or out of profile by comparing the rate of the incoming traffic to the configured policer. The policer limits the bandwidth consumed by a flow of traffic. The result is passed to the marker.

- Marking evaluates the policer and configuration information for the action to be taken when a packet is out of profile and determines what to do with the packet (pass through a packet without modification, marking down the QoS label in the packet, or dropping the packet).

Note Queueing and scheduling are only supported at egress and not at ingress on the switch.

Actions at Egress Port

Actions at the egress port include queueing and scheduling:

- Queueing evaluates the QoS packet label and the corresponding DSCP or CoS value before selecting which of the four egress queues to use. Because congestion can occur when multiple ingress ports simultaneously send data to an egress port, WTD differentiates traffic classes and subjects the packets to different thresholds based on the QoS label. If the threshold is exceeded, the packet is dropped.
- Scheduling services the four egress queues based on their configured SRR shared or shaped weights. One of the queues (queue 1) can be the expedited queue, which is serviced until empty before the other queues are serviced.

Classification Overview

Classification is the process of distinguishing one kind of traffic from another by examining the fields in the packet. Classification is enabled only if QoS is globally enabled on the switch. By default, QoS is globally disabled, so no classification occurs.

During classification, the switch performs a lookup and assigns a QoS label to the packet. The QoS label identifies all QoS actions to be performed on the packet and from which queue the packet is sent.

The QoS label is based on the DSCP or the CoS value in the packet and decides the queuing and scheduling actions to perform on the packet. The label is mapped according to the trust setting and the packet type as shown in the Classification Flowchart.

You specify which fields in the frame or packet that you want to use to classify incoming traffic.

Non-IP Traffic Classification

The following table describes the non-IP traffic classification options for your QoS configuration.

Table 55: Non-IP Traffic Classifications

| Non-IP Traffic Classification | Description |
|-------------------------------|--|
| Trust the CoS value | Trust the CoS value in the incoming frame (configure the port to trust CoS), and then use the configurable CoS-to-DSCP map to generate a DSCP value for the packet. Layer 2 ISL frame headers carry the CoS value in the 3 least-significant bits of the 1-byte User field. Layer 2 802.1Q frame headers carry the CoS value in the 3 most-significant bits of the Tag Control Information field. CoS values range from 0 for low priority to 7 for high priority. |

| Non-IP Traffic Classification | Description |
|--|--|
| Trust the DSCP or trust IP precedence value | Trust the DSCP or trust IP precedence value in the incoming frame. These configurations are meaningless for non-IP traffic. If you configure a port with either of these options and non-IP traffic is received, the switch assigns a CoS value and generates an internal DSCP value from the CoS-to-DSCP map. The switch uses the internal DSCP value to generate a CoS value representing the priority of the traffic. |
| Perform classification based on configured Layer 2 MAC ACL | Perform the classification based on a configured Layer 2 MAC access control list (ACL), which can examine the MAC source address, the MAC destination address, and other fields. If no ACL is configured, the packet is assigned 0 as the DSCP and CoS values, which means best-effort traffic. Otherwise, the policy-map action specifies a DSCP or CoS value to assign to the incoming frame. |

After classification, the packet is sent to the policing and marking stages.

IP Traffic Classification

The following table describes the IP traffic classification options for your QoS configuration.

Table 56: IP Traffic Classifications

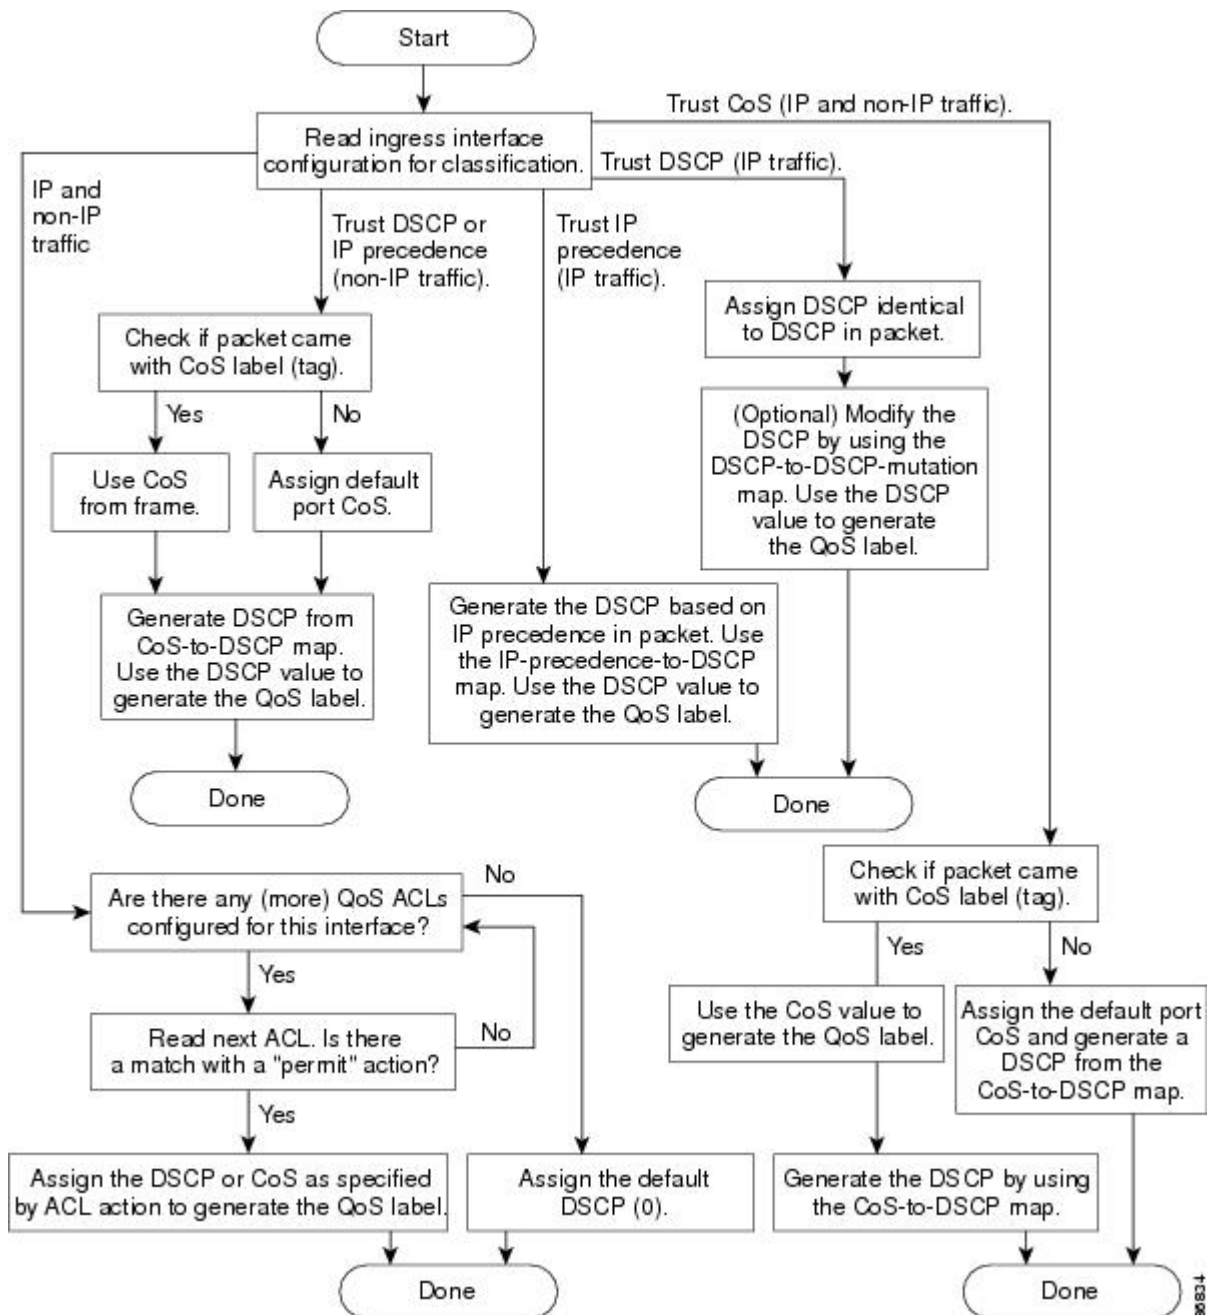

| IP Traffic Classification | Description |
|-------------------------------|--|
| Trust the DSCP value | Trust the DSCP value in the incoming packet (configure the port to trust DSCP), and assign the same DSCP value to the packet. The IETF defines the 6 most-significant bits of the 1-byte ToS field as the DSCP. The priority represented by a particular DSCP value is configurable. DSCP values range from 0 to 63. You can also classify IP traffic based on IPv6 DSCP. For ports that are on the boundary between two QoS administrative domains, you can modify the DSCP to another value by using the configurable DSCP-to-DSCP-mutation map. |
| Trust the IP precedence value | Trust the IP precedence value in the incoming packet (configure the port to trust IP precedence), and generate a DSCP value for the packet by using the configurable IP-precedence-to-DSCP map. The IP Version 4 specification defines the 3 most-significant bits of the 1-byte ToS field as the IP precedence. IP precedence values range from 0 for low priority to 7 for high priority. You can also classify IP traffic based on IPv6 precedence. |
| Trust the CoS value | Trust the CoS value (if present) in the incoming packet, and generate a DSCP value for the packet by using the CoS-to-DSCP map. If the CoS value is not present, use the default port CoS value. |

| IP Traffic Classification | Description |
|--------------------------------|---|
| IP standard or an extended ACL | Perform the classification based on a configured IP standard or an extended ACL, which examines various fields in the IP header. If no ACL is configured, the packet is assigned 0 as the DSCP and CoS values, which means best-effort traffic. Otherwise, the policy-map action specifies a DSCP or CoS value to assign to the incoming frame. |
| Override configured CoS | Override the configured CoS of incoming packets, and apply the default port CoS value to them. For IPv6 packets, the DSCP value is rewritten by using the CoS-to-DSCP map and by using the default CoS of the port. You can do this for both IPv4 and IPv6 traffic. |

After classification, the packet is sent to the policing and marking stages.

Classification Flowchart

Figure 60: Classification Flowchart

Access Control Lists

You can use IP standard, IP extended, or Layer 2 MAC ACLs to define a group of packets with the same characteristics (class). You can also classify IP traffic based on IPv6 ACLs.

In the QoS context, the permit and deny actions in the access control entries (ACEs) have different meanings from security ACLs:

- If a match with a permit action is encountered (first-match principle), the specified QoS-related action is taken.
- If a match with a deny action is encountered, the ACL being processed is skipped, and the next ACL is processed.

Note Deny action is supported in Cisco IOS Release 3.7.4E and later releases.

- If no match with a permit action is encountered and all the ACEs have been examined, no QoS processing occurs on the packet, and the offers best-effort service to the packet.
- If multiple ACLs are configured on a port, the lookup stops after the packet matches the first ACL with a permit action, and QoS processing begins.

Note When creating an access list, note that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.

After a traffic class has been defined with the ACL, you can attach a policy to it. A policy might contain multiple classes with actions specified for each one of them. A policy might include commands to classify the class as a particular aggregate (for example, assign a DSCP) or rate-limit the class. This policy is then attached to a particular port on which it becomes effective.

You implement IP ACLs to classify IP traffic by using the **access-list** global configuration command; you implement Layer 2 MAC ACLs to classify non-IP traffic by using the **mac access-list extended** global configuration command.

Classification Based on Class Maps and Policy Maps

To use policy maps, the switch must be running the LAN Base image.

A class map is a mechanism that you use to name a specific traffic flow (or class) and to isolate it from all other traffic. The class map defines the criteria used to match against a specific traffic flow to further classify it. The criteria can include matching the access group defined by the ACL or matching a specific list of DSCP or IP precedence values. If you have more than one type of traffic that you want to classify, you can create another class map and use a different name. After a packet is matched against the class-map criteria, you further classify it through the use of a policy map.

A policy map specifies which traffic class to act on. Actions can include trusting the CoS, DSCP, or IP precedence values in the traffic class; setting a specific DSCP or IP precedence value in the traffic class; or specifying the traffic bandwidth limitations and the action to take when the traffic is out of profile. Before a policy map can be effective, you must attach it to a port.

You create a class map by using the **class-map** global configuration command or the **class** policy-map configuration command. You should use the **class-map** command when the map is shared among many ports. When you enter the **class-map** command, the switch enters the class-map configuration mode. In this mode, you define the match criterion for the traffic by using the **match** class-map configuration command.

You can configure a default class by using the **class class-default** policy-map configuration command. Unclassified traffic (traffic specified in the other traffic classes configured on the policy-map) is treated as default traffic.

You create and name a policy map by using the **policy-map** global configuration command. When you enter this command, the switch enters the policy-map configuration mode. In this mode, you specify the actions to take on a specific traffic class by using the **class**, **trust**, or **set** policy-map configuration and policy-map class configuration commands.

The policy map can contain the **police** and **police aggregate** policy-map class configuration commands, which define the policer, the bandwidth limitations of the traffic, and the action to take if the limits are exceeded.

To enable the policy map, you attach it to a port by using the **service-policy** interface configuration command.

Policing and Marking Overview

After a packet is classified and has a DSCP-based or CoS-based QoS label assigned to it, the policing and marking process can begin.

Policing involves creating a policer that specifies the bandwidth limits for the traffic. Packets that exceed the limits are *out of profile* or *nonconforming*. Each policer decides on a packet-by-packet basis whether the packet is in or out of profile and specifies the actions on the packet. These actions, carried out by the marker, include passing through the packet without modification, dropping the packet, or modifying (marking down) the assigned DSCP of the packet and allowing the packet to pass through. The configurable policed-DSCP map provides the packet with a new DSCP-based QoS label. Marked-down packets use the same queues as the original QoS label to prevent packets in a flow from getting out of order.

Note All traffic, regardless of whether it is bridged or routed, is subjected to a policer, if one is configured. As a result, bridged packets might be dropped or might have their DSCP or CoS fields modified when they are policed and marked.

You can configure policing on a physical port. After you configure the policy map and policing actions, attach the policy to a port by using the **service-policy** interface configuration command.

Physical Port Policing

In policy maps on physical ports, you can create the following types of policers:

- **Individual**—QoS applies the bandwidth limits specified in the policer separately to each matched traffic class. You configure this type of policer within a policy map by using the **police** policy-map class configuration command.
- **Aggregate**—QoS applies the bandwidth limits specified in an aggregate policer cumulatively to all matched traffic flows. You configure this type of policer by specifying the aggregate policer name within a policy map by using the **police aggregate** policy-map class configuration command. You specify the bandwidth limits of the policer by using the **mls qos aggregate-policer** global configuration command. In this way, the aggregate policer is shared by multiple classes of traffic within a policy map.

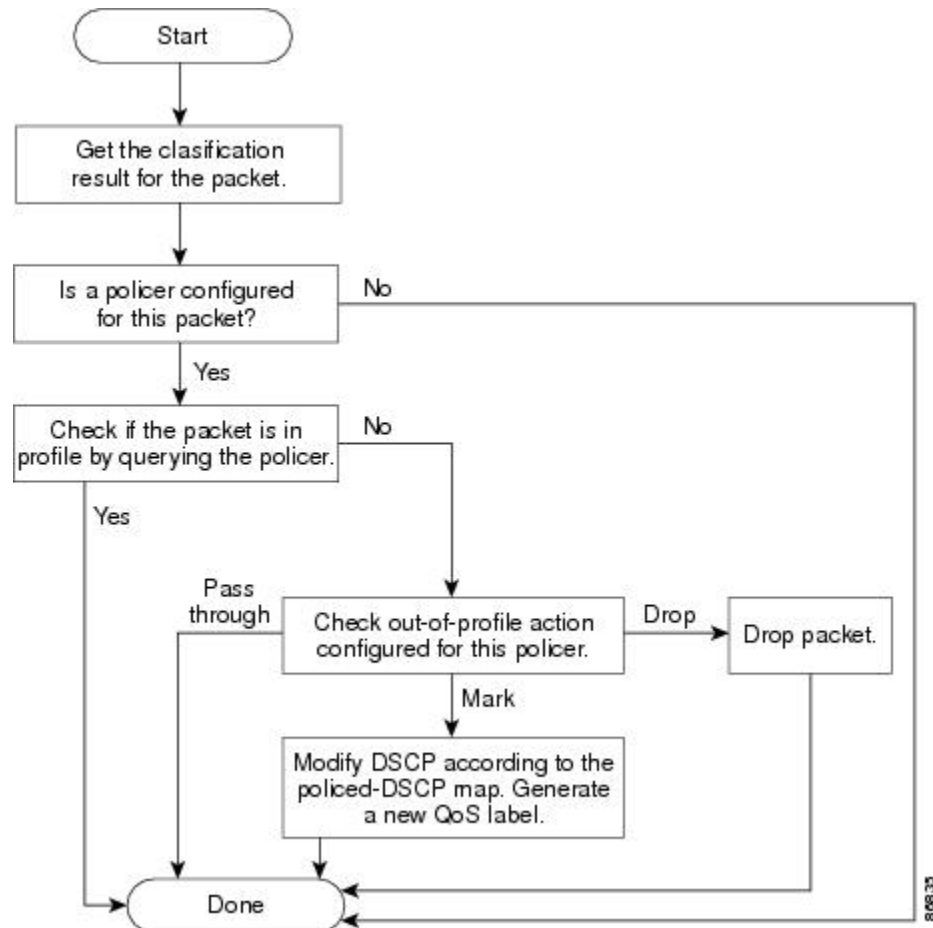

Policing uses a token-bucket algorithm. As each frame is received by the switch, a token is added to the bucket. The bucket has a hole in it and leaks at a rate that you specify as the average traffic rate in bits per second. Each time a token is added to the bucket, the switch verifies that there is enough room in the bucket. If there is not enough room, the packet is marked as nonconforming, and the specified policer action is taken (dropped or marked down).

How quickly the bucket fills is a function of the bucket depth (burst-byte), the rate at which the tokens are removed (rate-bps), and the duration of the burst above the average rate. The size of the bucket imposes an upper limit on the burst length and limits the number of frames that can be transmitted back-to-back. If the

burst is short, the bucket does not overflow, and no action is taken against the traffic flow. However, if a burst is long and at a higher rate, the bucket overflows, and the policing actions are taken against the frames in that burst.

You configure the bucket depth (the maximum burst that is tolerated before the bucket overflows) by using the `burst-byte` option of the **police** policy-map class configuration command or the **mls qos aggregate-policer** global configuration command. You configure how fast (the average rate) that the tokens are removed from the bucket by using the `rate-bps` option of the **police** policy-map class configuration command or the **mls qos aggregate-policer** global configuration command.

Figure 61: Policing and Marking Flowchart on Physical Ports

Mapping Tables Overview

During QoS processing, the switch represents the priority of all traffic (including non-IP traffic) with a QoS label based on the DSCP or CoS value from the classification stage.

The following table describes QoS processing and mapping tables.

Table 57: QoS Processing and Mapping Tables

| QoS Processing Stage | Mapping Table Usage |
|-----------------------------|---|
| Classification | <p>During the classification stage, QoS uses configurable mapping tables to derive a corresponding DSCP or CoS value from a received CoS, DSCP, or IP precedence value. These maps include the CoS-to-DSCP map and the IP-precedence-to-DSCP map.</p> <p>You configure these maps by using the mls qos map cos-dscp and the mls qos map ip-prec-dscp global configuration commands.</p> <p>On an ingress port configured in the DSCP-trusted state, if the DSCP values are different between the QoS domains, you can apply the configurable DSCP-to-DSCP-mutation map to the port that is on the boundary between the two QoS domains.</p> <p>You configure this map by using the mls qos map dscp-mutation global configuration command.</p> |
| Policing | <p>During policing stage, QoS can assign another DSCP value to an IP or a non-IP packet (if the packet is out of profile and the policer specifies a marked-down value). This configurable map is called the policed-DSCP map.</p> <p>You configure this map by using the mls qos map policed-dscp global configuration command.</p> |
| Pre-scheduling | <p>Before the traffic reaches the scheduling stage, QoS stores the packet in an egress queue according to the QoS label. The QoS label is based on the DSCP or the CoS value in the packet and selects the queue through the DSCP output queue threshold maps or through the CoS output queue threshold maps. In addition to an egress queue, the QoS label also identifies the WTD threshold value.</p> <p>You configure these maps by using the mls qos srr-queue { output } dscp-map and the mls qos srr-queue { output } cos-map global configuration commands.</p> |

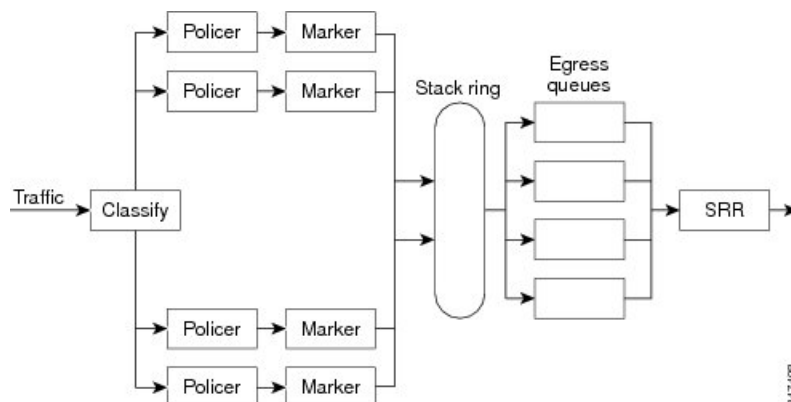

The CoS-to-DSCP, DSCP-to-CoS, and the IP-precedence-to-DSCP maps have default values that might or might not be appropriate for your network.

The default DSCP-to-DSCP-mutation map and the default policed-DSCP map are null maps; they map an incoming DSCP value to the same DSCP value. The DSCP-to-DSCP-mutation map is the only map you apply to a specific port. All other maps apply to the entire switch.

Queueing and Scheduling Overview

The switch has queues at specific points to help prevent congestion.

Figure 62: Egress Queue Location on Switch

Note The switch supports 4 egress queues by default and there is an option to enable a total of 8 egress queues. The 8 egress queue configuration is only supported on a standalone switch.

Weighted Tail Drop

Egress queues use an enhanced version of the tail-drop congestion-avoidance mechanism called weighted tail drop (WTD). WTD is implemented on queues to manage the queue lengths and to provide drop precedences for different traffic classifications.

As a frame is enqueued to a particular queue, WTD uses the frame's assigned QoS label to subject it to different thresholds. If the threshold is exceeded for that QoS label (the space available in the destination queue is less than the size of the frame), the switch drops the frame.

Each queue has three threshold values. The QoS label determines which of the three threshold values is subjected to the frame. Of the three thresholds, two are configurable (explicit) and one is not (implicit).

Figure 63: WTD and Queue Operation

The following figure shows an example of WTD operating on a queue whose size is 1000 frames. Three drop percentages are configured: 40 percent (400 frames), 60 percent (600 frames), and 100 percent (1000 frames). These percentages indicate that up to 400 frames can be queued at the 40-percent threshold, up to 600 frames at the 60-percent threshold, and up to 1000 frames at the 100-percent

threshold.

In the example, CoS values 6 and 7 have a greater importance than the other CoS values, and they are assigned to the 100-percent drop threshold (queue-full state). CoS values 4 and 5 are assigned to the 60-percent threshold, and CoS values 0 to 3 are assigned to the 40-percent threshold.

Suppose the queue is already filled with 600 frames, and a new frame arrives. It contains CoS values 4 and 5 and is subjected to the 60-percent threshold. If this frame is added to the queue, the threshold will be exceeded, so the switch drops it.

SRR Shaping and Sharing

Egress queues are serviced by shaped round robin (SRR), which controls the rate at which packets are sent. On the egress queues, SRR sends packets to the egress port.

You can configure SRR on egress queues for sharing or for shaping.

In shaped mode, the egress queues are guaranteed a percentage of the bandwidth, and they are rate-limited to that amount. Shaped traffic does not use more than the allocated bandwidth even if the link is idle. Shaping provides a more even flow of traffic over time and reduces the peaks and valleys of bursty traffic. With shaping, the absolute value of each weight is used to compute the bandwidth available for the queues.

In shared mode, the queues share the bandwidth among them according to the configured weights. The bandwidth is guaranteed at this level but not limited to it. For example, if a queue is empty and no longer requires a share of the link, the remaining queues can expand into the unused bandwidth and share it among them. With sharing, the ratio of the weights controls the frequency of dequeuing; the absolute values are meaningless. Shaping and sharing is configured per interface. Each interface can be uniquely configured.

Queueing and Scheduling on Ingress Queues

Figure 64: Queueing and Scheduling Flowchart for Ingress Ports on Catalyst 3750-E and 3750-X Switches

The following figure shows queueing and scheduling flowcharts for ingress ports on Catalyst 3750-E and

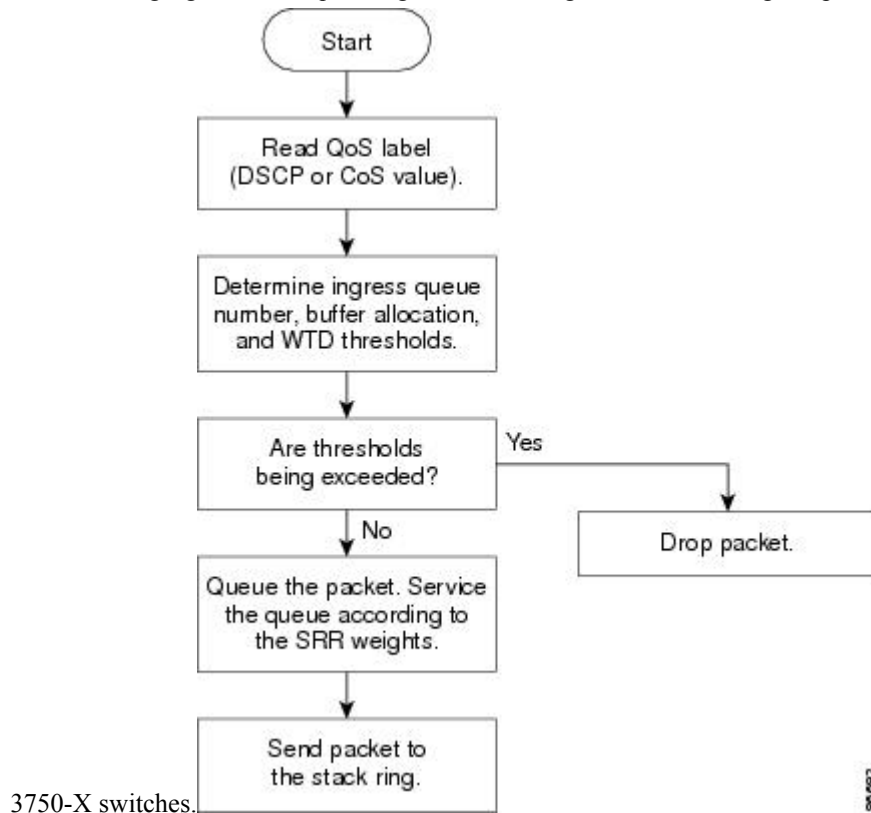

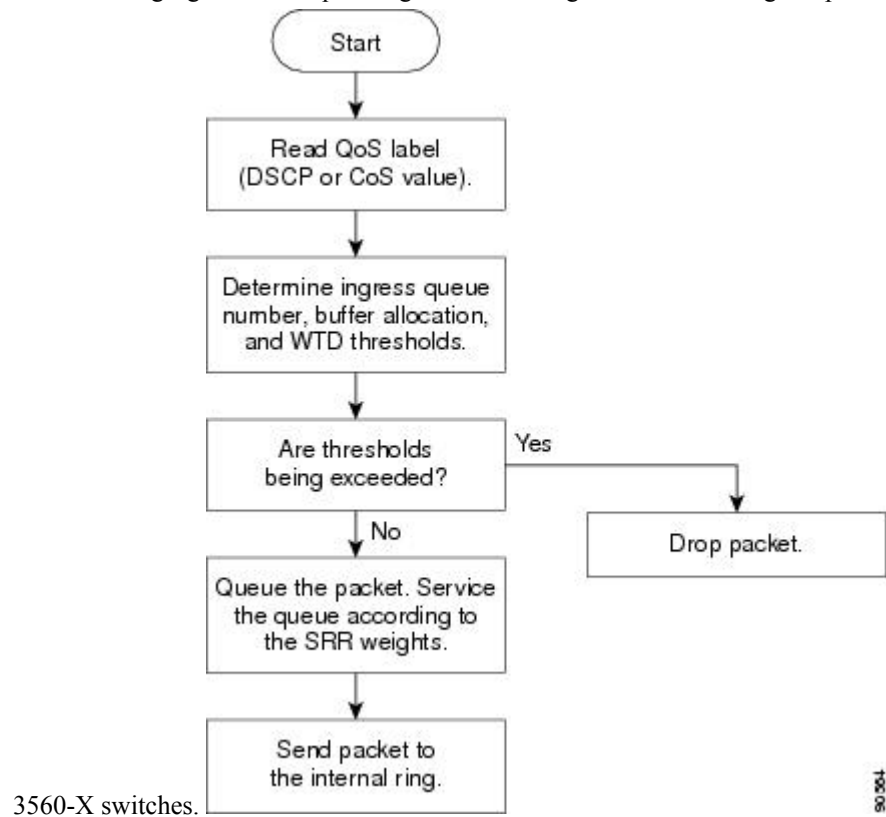

Figure 65: Queueing and Scheduling Flowchart for Ingress Ports on Catalyst 3560-E and 3560-X Switches

The following figure shows queueing and scheduling flowcharts for ingress ports on Catalyst 3560-E and

Note SRR services the priority queue for its configured share before servicing the other queue.

Configurable Ingress Queue Types

The switch supports two configurable ingress queue types, which are serviced by SRR in shared mode only.

Note The switch also uses two nonconfigurable queues for traffic that are essential for proper network and stack operation.

The following table describes the two configurable ingress queues.

Table 58: Configurable Ingress Queue Types

| Queue Type | Function |
|------------|---|
| Normal | <p>User traffic that is considered to be normal priority.</p> <p>You can configure three different thresholds to differentiate among the flows.</p> <p>Use the following global configuration commands:</p> <ul style="list-style-type: none"> • mls qos srr-queue input threshold • mls qos srr-queue input dscp-map • mls qos srr-queue input cos-map |
| Expedite | <p>High-priority user traffic such as differentiated services (DF) expedited forwarding or voice traffic.</p> <p>You can configure the bandwidth required for this traffic as a percentage of the total traffic or total stack by using the mls qos srr-queue input priority-queue global configuration command.</p> <p>The expedite queue has guaranteed bandwidth.</p> |

You assign each packet that flows through the switch to a queue and to a threshold. Specifically, you map DSCP or CoS values to an ingress queue and map DSCP or CoS values to a threshold ID. You use the **mls qos srr-queue input dscp-map queue queue-id {dscp1...dscp8 | threshold threshold-id dscp1...dscp8}** or the **mls qos srr-queue input cos-map queue queue-id {cos1...cos8 | threshold threshold-id cos1...cos8}** global configuration command. You can display the DSCP input queue threshold map and the CoS input queue threshold map by using the **show mls qos maps privileged EXEC** command.

WTD Thresholds

The queues use WTD to support distinct drop percentages for different traffic classes. Each queue has three drop thresholds: two configurable (*explicit*) WTD thresholds and one nonconfigurable (*implicit*) threshold preset to the queue-full state.

You assign the two explicit WTD threshold percentages for threshold ID 1 and ID 2 to the ingress queues by using the **mls qos srr-queue input threshold queue-id threshold-percentage1 threshold-percentage2** global configuration command. Each threshold value is a percentage of the total number of allocated buffers for the queue. The drop threshold for threshold ID 3 is preset to the queue-full state, and you cannot modify it.

Buffer and Bandwidth Allocation

You define the ratio (allocate the amount of space) with which to divide the ingress buffers between the two queues (normal and expedite) by using the **mls qos srr-queue input buffers percentage1 percentage2** global configuration command. The buffer allocation together with the bandwidth allocation control how much data can be buffered and sent before packets are dropped. You allocate bandwidth as a percentage by using the **mls qos srr-queue input bandwidth weight1 weight2** global configuration command. The ratio of the weights is the ratio of the frequency in which the SRR scheduler sends packets from each queue.

Priority Queueing

You can configure one ingress queue as the priority queue by using the **mls qos srr-queue input priority-queue queue-id bandwidth weight** global configuration command. The priority queue should be used for traffic

(such as voice) that requires guaranteed delivery because this queue is guaranteed part of the bandwidth regardless of the load on the stack or internal ring.

SRR services the priority queue for its configured weight as specified by the **bandwidth** keyword in the **mls qos srr-queue input priority-queue *queue-id* bandwidth *weight*** global configuration command. Then, SRR shares the remaining bandwidth with both ingress queues and services them as specified by the weights configured with the **mls qos srr-queue input bandwidth *weight1 weight2*** global configuration command.

You can combine the above commands to prioritize traffic by placing packets with particular DSCPs or CoSs into certain queues, by allocating a large queue size or by servicing the queue more frequently, and by adjusting queue thresholds so that packets with lower priorities are dropped.

Queueing and Scheduling on Egress Queues

The following figure shows queueing and scheduling flowcharts for egress ports on the switch.

Figure 66: Queueing and Scheduling Flowchart for Egress Ports on the Switch

Note If the expedite queue is enabled, SRR services it until it is empty before servicing the other three queues.

Egress Expedite Queue

Each port supports four egress queues, one of which (queue 1) can be the egress expedite queue. These queues are assigned to a queue-set. All traffic exiting the switch flows through one of these four queues and is subjected to a threshold based on the QoS label assigned to the packet.

Note If the expedite queue is enabled, SRR services it until it is empty before servicing the other three queues.

Egress Queue Buffer Allocation

The following figure shows the egress queue buffer.

Figure 67: Egress Queue Buffer Allocation

The buffer space is divided between the common pool and the reserved pool. The switch uses a buffer allocation scheme to reserve a minimum amount of buffers for each egress queue, to prevent any queue or port from consuming all the buffers and depriving other queues, and to control whether to grant buffer space to a requesting queue. The switch detects whether the target queue has not consumed more buffers than its reserved amount (under-limit), whether it has consumed all of its maximum buffers (over limit), and whether the common pool is empty (no free buffers) or not empty (free buffers). If the queue is not over-limit, the switch can allocate buffer space from the reserved pool or from the common pool (if it is not empty). If there are no free buffers in the common pool or if the queue is over-limit, the switch drops the

Buffer and Memory Allocation

You guarantee the availability of buffers, set drop thresholds, and configure the maximum memory allocation for a queue-set by using the **mls qos queue-set output *qset-id* threshold *queue-id* drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold** global configuration command. Each threshold value is a percentage of the queue's allocated memory, which you specify by using the **mls qos queue-set output *qset-id* buffers *allocation1* ... *allocation4*** global configuration command. The sum of all the allocated buffers represents the reserved pool, and the remaining buffers are part of the common pool.

Through buffer allocation, you can ensure that high-priority traffic is buffered. For example, if the buffer space is 400, you can allocate 70 percent of it to queue 1 and 10 percent to queues 2 through 4. Queue 1 then has 280 buffers allocated to it, and queues 2 through 4 each have 40 buffers allocated to them.

You can guarantee that the allocated buffers are reserved for a specific queue in a queue-set. For example, if there are 100 buffers for a queue, you can reserve 50 percent (50 buffers). The switch returns the remaining 50 buffers to the common pool. You also can enable a queue in the full condition to obtain more buffers than are reserved for it by setting a maximum threshold. The switch can allocate the needed buffers from the common pool if the common pool is not empty.

Note The switch supports 4 egress queues by default, although there is an option to enable a total of 8 egress queues. Use the **mls qos srr-queue output queues 8** global configuration command to enable all 8 egress queues. Once 8 egress queues are enabled, you are able to configure thresholds and buffers for all 8 queues. The 8 egress queue configuration is only supported on a standalone switch.

Queues and WTD Thresholds

You can assign each packet that flows through the switch to a queue and to a threshold.

Specifically, you map DSCP or CoS values to an egress queue and map DSCP or CoS values to a threshold ID. You use the **mls qos srr-queue output dscp-map queue** *queue-id* {*dscp1...dscp8* | **threshold** *threshold-id* *dscp1...dscp8*} or the **mls qos srr-queue output cos-map queue** *queue-id* {*cos1...cos8* | **threshold** *threshold-id* *cos1...cos8*} global configuration command. You can display the DSCP output queue threshold map and the CoS output queue threshold map by using the **show mls qos maps** privileged EXEC command.

The queues use WTD to support distinct drop percentages for different traffic classes. Each queue has three drop thresholds: two configurable (*explicit*) WTD thresholds and one nonconfigurable (*implicit*) threshold preset to the queue-full state. You assign the two WTD threshold percentages for threshold ID 1 and ID 2. The drop threshold for threshold ID 3 is preset to the queue-full state, and you cannot modify it. You map a port to queue-set by using the **queue-set qset-id** interface configuration command. Modify the queue-set configuration to change the WTD threshold percentages.

Note The switch supports 4 egress queues by default, although there is an option to enable a total of 8 egress queues. Use the **mls qos srr-queue output queues 8** global configuration command to enable all 8 egress queues. Once 8 egress queues are enabled, you are able to configure thresholds and buffers for all 8 queues. The 8 egress queue configuration is only supported on a standalone switch.

Shaped or Shared Mode

SRR services each queue-set in shared or shaped mode. You map a port to a queue-set by using the **queue-set** *qset-id* interface configuration command.

You assign shared or shaped weights to the port by using the **srr-queue bandwidth share** *weight1 weight2 weight3 weight4* or the **srr-queue bandwidth shape** *weight1 weight2 weight3 weight4* interface configuration command.

The buffer allocation together with the SRR weight ratios control how much data can be buffered and sent before packets are dropped. The weight ratio is the ratio of the frequency in which the SRR scheduler sends packets from each queue.

All four queues participate in the SRR unless the expedite queue is enabled, in which case the first bandwidth weight is ignored and is not used in the ratio calculation. The expedite queue is a priority queue, and it is serviced until empty before the other queues are serviced. You enable the expedite queue by using the **priority-queue out** interface configuration command.

You can combine the commands described in this section to prioritize traffic by placing packets with particular DSCPs or CoSs into certain queues, by allocating a large queue size or by servicing the queue more frequently, and by adjusting queue thresholds so that packets with lower priorities are dropped.

Note The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Note The switch supports 4 egress queues by default, although there is an option to enable a total of 8 egress queues. Use the **mls qos srr-queue output queues 8** global configuration command to enable all 8 egress queues. Once 8 egress queues are enabled, you are able to configure thresholds, buffers, bandwidth share weights, and bandwidth shape weights for all 8 queues. The 8 egress queue configuration is only supported on a standalone switch.

Packet Modification

A packet is classified, policed, and queued to provide QoS. The following packet modifications can occur during the process to provide QoS:

- For IP and non-IP packets, classification involves assigning a QoS label to a packet based on the DSCP or CoS of the received packet. However, the packet is not modified at this stage; only an indication of the assigned DSCP or CoS value is carried along.
- During policing, IP and non-IP packets can have another DSCP assigned to them (if they are out of profile and the policer specifies a markdown DSCP). Once again, the DSCP in the packet is not modified, but an indication of the marked-down value is carried along. For IP packets, the packet modification occurs at a later stage; for non-IP packets the DSCP is converted to CoS and used for queueing and scheduling decisions.
- Depending on the QoS label assigned to a frame and the mutation chosen, the DSCP and CoS values of the frame are rewritten. If you do not configure a table map and if you configure the port to trust the DSCP of the incoming frame, the DSCP value in the frame is not changed, but the CoS is rewritten according to the DSCP-to-CoS map. If you configure the port to trust the CoS of the incoming frame and it is an IP packet, the CoS value in the frame is not changed, but the DSCP might be changed according to the CoS-to-DSCP map.

The input mutation causes the DSCP to be rewritten depending on the new value of DSCP chosen. The set action in a policy map also causes the DSCP to be rewritten.

Standard QoS Default Configuration

Standard QoS is disabled by default.

When QoS is disabled, there is no concept of trusted or untrusted ports because the packets are not modified. The CoS, DSCP, and IP precedence values in the packet are not changed.

Traffic is switched in pass-through mode. The packets are switched without any rewrites and classified as best effort without any policing.

When QoS is enabled using the **mls qos** global configuration command and all other QoS settings are at their defaults, traffic is classified as best effort (the DSCP and CoS value is set to 0) without any policing. No policy maps are configured. The default port trust state on all ports is untrusted.

Note Starting Cisco IOS Release 15.2(1)E, IPv6 QoS is supported on switches running the LAN base license with lanbase-routing template.

Default Ingress Queue Configuration

The following tables describe the default ingress queue configurations.

The following table shows the default ingress queue configuration when QoS is enabled. For the bandwidth allocation feature, bandwidth is equally shared between the queues. SRR sends packets in shared mode only. Queue 2 is the priority queue. SRR services the priority queue for its configured share before servicing the other queue.

Table 59: Default Ingress Queue Configuration

| Feature | Queue 1 | Queue 2 |
|--------------------------|-------------|-------------|
| Buffer allocation | 90 percent | 10 percent |
| Bandwidth allocation | 4 | 4 |
| Priority queue bandwidth | 0 | 10 |
| WTD drop threshold 1 | 100 percent | 100 percent |
| WTD drop threshold 2 | 100 percent | 100 percent |

The following table shows the default CoS input queue threshold map when QoS is enabled.

Table 60: Default CoS Input Queue Threshold Map

| CoS Value | Queue ID–Threshold ID |
|-----------|-----------------------|
| 0–4 | 1–1 |
| 5 | 2–1 |
| 6, 7 | 1–1 |

The following table shows the default DSCP input queue threshold map when QoS is enabled.

Table 61: Default DSCP Input Queue Threshold Map

| DSCP Value | Queue ID–Threshold ID |
|------------|-----------------------|
| 0–39 | 1–1 |
| 40–47 | 2–1 |
| 48–63 | 1–1 |

Default Egress Queue Configuration

The following tables describe the default egress queue configurations.

Note The switch supports 4 egress queues by default, although there is an option to enable a total of 8 egress queues. Use the **mls qos srr-queue output queues 8** global configuration command to enable all 8 egress queues. Once 8 egress queues are enabled, you are able to configure thresholds and buffers for all 8 queues. The 8 egress queue configuration is only supported on a standalone switch.

The following table shows the default egress queue configuration for each queue-set when QoS is enabled. All ports are mapped to queue-set 1. The port bandwidth limit is set to 100 percent and rate unlimited. Note that for the SRR shaped weights (absolute) feature, a shaped weight of zero indicates that the queue is operating in shared mode. Note that for the SRR shared weights feature, one quarter of the bandwidth is allocated to each queue.

Table 62: Default Egress Queue Configuration

| Feature | Queue 1 | Queue 2 | Queue 3 | Queue 4 |
|-------------------------------|-------------|-------------|-------------|-------------|
| Buffer allocation | 25 percent | 25 percent | 25 percent | 25 percent |
| WTD drop threshold 1 | 100 percent | 200 percent | 100 percent | 100 percent |
| WTD drop threshold 2 | 100 percent | 200 percent | 100 percent | 100 percent |
| Reserved threshold | 50 percent | 50 percent | 50 percent | 50 percent |
| Maximum threshold | 400 percent | 400 percent | 400 percent | 400 percent |
| SRR shaped weights (absolute) | 25 | 0 | 0 | 0 |
| SRR shared weights | 25 | 25 | 25 | 25 |

The following table shows the default CoS output queue threshold map when QoS is enabled.

Table 63: Default CoS Output Queue Threshold Map

| CoS Value | Queue ID–Threshold ID |
|-----------|-----------------------|
| 0, 1 | 2–1 |
| 2, 3 | 3–1 |
| 4 | 4–1 |
| 5 | 1–1 |
| 6, 7 | 4–1 |

The following table shows the default DSCP output queue threshold map when QoS is enabled.

Table 64: Default DSCP Output Queue Threshold Map

| DSCP Value | Queue ID–Threshold ID |
|------------|-----------------------|
| 0–15 | 2–1 |
| 16–31 | 3–1 |
| 32–39 | 4–1 |
| 40–47 | 1–1 |
| 48–63 | 4–1 |

The following table displays the default egress queue configuration when the 8 egress queue configuration is enabled using the **mls qos srr-queue output queues 8** command.

Table 65: Default 8 Egress Queue Configuration

| Feature | Queue 1 | Queue 2 | Queue 3 | Queue 4 | Queue 5 | Queue 6 | Queue 7 | Queue 8 |
|----------------------|---------|---------|---------|---------|---------|---------|---------|---------|
| Buffer allocation | 10 | 30 | 10 | 10 | 10 | 10 | 10 | 10 |
| WTD drop threshold 1 | 100 | 1600 | 100 | 100 | 100 | 100 | 100 | 100 |
| WTD drop threshold 2 | 100 | 2000 | 100 | 100 | 100 | 100 | 100 | 100 |
| Reserved threshold | 100 | 100 | 100 | 100 | 100 | 100 | 100 | 100 |
| Maximum threshold | 400 | 2400 | 400 | 400 | 400 | 400 | 400 | 400 |
| SRR shaped weights | 25 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| SRR shared weights | 25 | 25 | 25 | 25 | 25 | 25 | 25 | 25 |

The following table displays the default CoS output queue threshold map when QoS is enabled and the 8 egress queue configuration is enabled using the **mls qos srr-queue output queues 8** command.

Table 66: Default CoS Output 8 Queue Threshold Map

| CoS | Egress Queue | Threshold ID | 4 Egress Queue Mapping |
|-----|--------------|--------------|------------------------|
| 0 | 2 | 1 | 2 |
| 1 | 3 | 1 | 2 |
| 2 | 4 | 1 | 3 |
| 3 | 5 | 1 | 3 |
| 4 | 6 | 1 | 4 |
| 5 | 1 | 1 | 1 |
| 6 | 7 | 1 | 4 |
| 7 | 8 | 1 | 4 |

The following table displays the default DSCP output queue threshold map when QoS is enabled and the 8 egress queue configuration is enabled using the **mls qos srr-queue output queues 8** command.

Table 67: Default DSCP Output 8 Queue Threshold Map

| DSCP | Egress Queue | Threshold ID | 4 Egress Queue Mapping |
|-------|--------------|--------------|------------------------|
| 0-7 | 2 | 1 | 2 |
| 8-15 | 3 | 1 | 2 |
| 16-23 | 4 | 1 | 3 |
| 24-31 | 5 | 1 | 3 |
| 32-39 | 6 | 1 | 4 |
| 40-47 | 1 | 1 | 1 |
| 48-55 | 7 | 1 | 4 |
| 56-63 | 8 | 1 | 4 |

Default Mapping Table Configuration

The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value.

The default policed-DSCP map is a null map, which maps an incoming DSCP value to the same DSCP value (no markdown).

DSCP Maps

Default CoS-to-DSCP Map

When DSCP transparency mode is disabled, the DSCP values are derived from CoS as per the following table. If these values are not appropriate for your network, you need to modify them.

Note The DSCP transparency mode is disabled by default. If it is enabled (**no mls qos rewrite ip dscp** interface configuration command), DSCP rewrite will not happen.

Table 68: Default CoS-to-DSCP Map

| CoS Value | DSCP Value |
|-----------|------------|
| 0 | 0 |
| 1 | 8 |
| 2 | 16 |
| 3 | 24 |
| 4 | 32 |
| 5 | 40 |
| 6 | 48 |
| 7 | 56 |

Default IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic. The following table shows the default IP-precedence-to-DSCP map. If these values are not appropriate for your network, you need to modify them.

Table 69: Default IP-Precedence-to-DSCP Map

| IP Precedence Value | DSCP Value |
|---------------------|------------|
| 0 | 0 |
| 1 | 8 |
| 2 | 16 |
| 3 | 24 |
| 4 | 32 |
| 5 | 40 |
| 6 | 48 |

| IP Precedence Value | DSCP Value |
|---------------------|------------|
| 7 | 56 |

Default DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues. The following table shows the default DSCP-to-CoS map. If these values are not appropriate for your network, you need to modify them.

Table 70: Default DSCP-to-CoS Map

| DSCP Value | CoS Value |
|------------|-----------|
| 0–7 | 0 |
| 8–15 | 1 |
| 16–23 | 2 |
| 24–31 | 3 |
| 32–39 | 4 |
| 40–47 | 5 |
| 48–55 | 6 |
| 56–63 | 7 |

How to Configure QoS

Enabling QoS Globally

By default, QoS is disabled on the switch.

The following procedure to enable QoS globally is required.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | mls qos Example: | Enables QoS globally. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <pre>Device(config)# mls qos</pre> | QoS operates with the default settings described in the related topic sections below. Note To disable QoS, use the no mls qos global configuration command. |
| Step 3 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | show mls qos Example: <pre>Device# show mls qos</pre> | Verifies the QoS configuration. |
| Step 5 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Enabling VLAN-Based QoS on Physical Ports

By default, VLAN-based QoS is disabled on all physical switch ports. You can enable VLAN-based QoS on a switch port.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: <pre>Device(config)# interface gigabitethernet 1/0/1</pre> | Specifies the physical port, and enter interface configuration mode. |
| Step 3 | mls qos vlan-based | Enables VLAN-based QoS on the port. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Example: Device(config-if)# mls qos vlan-based | Note Use the no mls qos vlan-based interface configuration command to disable VLAN-based QoS on the physical port. |
| Step 4 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface <i>interface-id</i> Example: Device# show mls qos interface gigabitethernet 1/0/1 | Verifies if VLAN-based QoS is enabled on the physical port. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Classification Using Port Trust States

These sections describe how to classify incoming traffic by using port trust states.

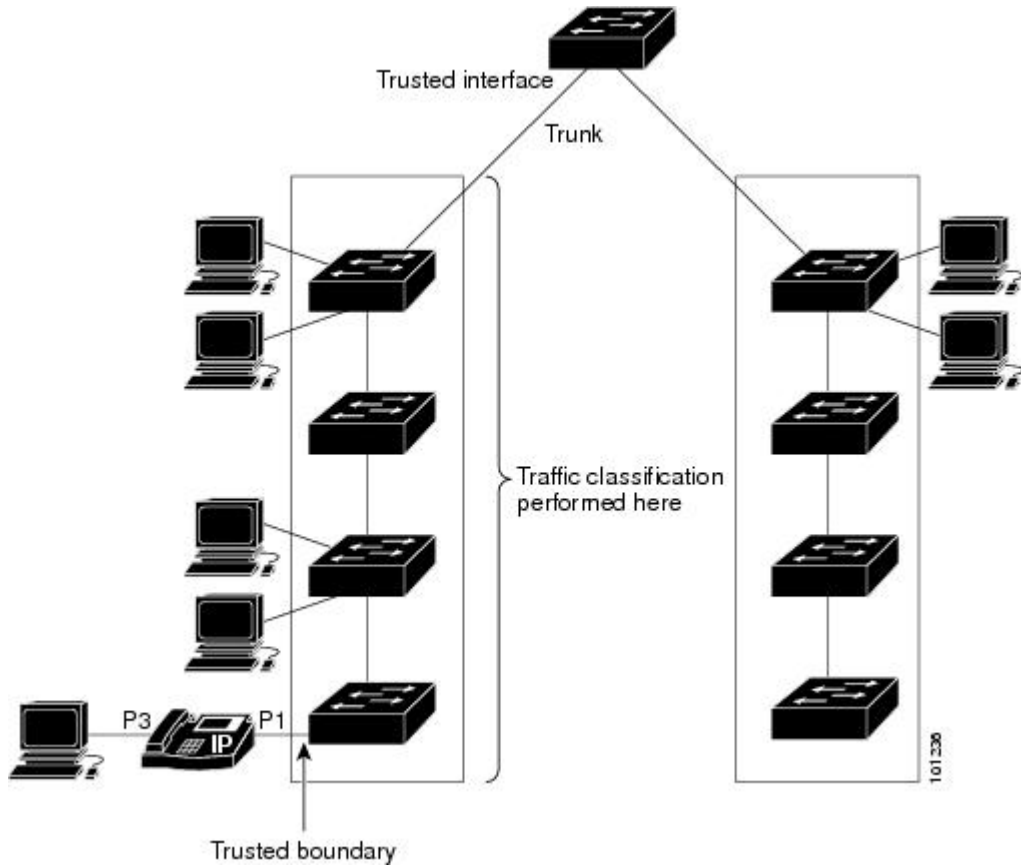

Note Depending on your network configuration, you must perform one or more of these tasks in this module or one or more of the tasks in the [Configuring a QoS Policy](#).

Configuring the Trust State on Ports Within the QoS Domain

Packets entering a QoS domain are classified at the edge of the QoS domain. When the packets are classified at the edge, the switch port within the QoS domain can be configured to one of the trusted states because there is no need to classify the packets at every switch within the QoS domain.

Figure 68: Port Trusted States on Ports Within the QoS Domain

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 1/0/2</code> | Specifies the port to be trusted, and enters interface configuration mode. Valid interfaces are physical ports. |
| Step 3 | mls qos trust [<i>cos</i> <i>dscp</i> <i>ip-precedence</i>] Example: Device(config-if)# <code>mls qos trust cos</code> | Configures the port trust state. By default, the port is not trusted. If no keyword is specified, the default is dscp . The keywords have these meanings: |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <ul style="list-style-type: none"> • cos—Classifies an ingress packet by using the packet CoS value. For an untagged packet, the port default CoS value is used. The default port CoS value is 0. • dscp—Classifies an ingress packet by using the packet DSCP value. For a non-IP packet, the packet CoS value is used if the packet is tagged; for an untagged packet, the default port CoS is used. Internally, the switch maps the CoS value to a DSCP value by using the CoS-to-DSCP map. • ip-precedence—Classifies an ingress packet by using the packet IP-precedence value. For a non-IP packet, the packet CoS value is used if the packet is tagged; for an untagged packet, the default port CoS is used. Internally, the switch maps the CoS value to a DSCP value by using the CoS-to-DSCP map. <p>To return a port to its untrusted state, use the no mls qos trust interface configuration command.</p> |
| Step 4 | end Example: <pre>Device(config-if)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface Example: <pre>Device# show mls qos interface</pre> | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring the CoS Value for an Interface

QoS assigns the CoS value specified with the **mls qos cos** interface configuration command to untagged frames received on trusted and untrusted ports.

Beginning in privileged EXEC mode, follow these steps to define the default CoS value of a port or to assign the default CoS to all incoming packets on the port.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id Example: Device(config)# interface gigabitethernet 1/1/1 | Specifies the port to be configured, and enters interface configuration mode. Valid interfaces include physical ports. |
| Step 3 | mls qos cos {default-cos override} Example: Device(config-if)# mls qos override | Configures the default CoS value for the port. <ul style="list-style-type: none"> • For <i>default-cos</i>, specify a default CoS value to be assigned to a port. If the packet is untagged, the default CoS value becomes the packet CoS value. The CoS range is 0 to 7. The default is 0. • Use the override keyword to override the previously configured trust state of the incoming packet and to apply the default port CoS value to the port on all incoming packets. By default, CoS override is disabled. <p>Use the override keyword when all incoming packets on specified ports deserve higher or lower priority than packets entering from other ports. Even if a port was previously set to trust DSCP, CoS, or IP precedence, this command overrides the previously configured trust state, and all the incoming CoS values are assigned the default CoS value configured with this command. If an incoming packet is tagged, the CoS value of the packet is modified with the default CoS of the port at the ingress port.</p> <p>Note To return to the default setting, use the no mls qos cos {default-cos override} interface configuration command.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface Example: Device# show mls qos interface | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring a Trusted Boundary to Ensure Port Security

In a typical network, you connect a Cisco IP Phone to a port and cascade devices that generate data packets from the back of the telephone. The Cisco IP Phone guarantees the voice quality through a shared data link by marking the CoS level of the voice packets as high priority (CoS = 5) and by marking the data packets as low priority (CoS = 0). Traffic sent from the telephone to the is typically marked with a tag that uses the 802.1Q header. The header contains the VLAN information and the class of service (CoS) 3-bit field, which is the priority of the packet.

For most Cisco IP Phone configurations, the traffic sent from the telephone to the should be trusted to ensure that voice traffic is properly prioritized over other types of traffic in the network. By using the **mls qos trust cos** interface configuration command, you configure the port to which the telephone is connected to trust the CoS labels of all traffic received on that port. Use the **mls qos trust dscp** interface configuration command to configure a routed port to which the telephone is connected to trust the DSCP labels of all traffic received on that port.

With the trusted setting, you also can use the trusted boundary feature to prevent misuse of a high-priority queue if a user bypasses the telephone and connects the PC directly to the . Without trusted boundary, the CoS labels generated by the PC are trusted by the (because of the trusted CoS setting). By contrast, trusted boundary uses CDP to detect the presence of a Cisco IP Phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the port and prevents misuse of a high-priority queue. Note that the trusted boundary feature is not effective if the PC and Cisco IP Phone are connected to a hub that is connected to the .

In some situations, you can prevent a PC connected to the Cisco IP Phone from taking advantage of a high-priority data queue. You can use the **switchport priority extend cos** interface configuration command to configure the telephone through the CLI to override the priority of the traffic received from the PC.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | cdp run Example: Device(config)# cdp run | Enables CDP globally. By default, CDP is enabled. |
| Step 3 | interface interface-id Example: Device(config)# interface gigabitethernet 2/1/1 | Specifies the port connected to the Cisco IP Phone, and enters interface configuration mode. Valid interfaces include physical ports. |
| Step 4 | cdp enable Example: Device(config-if)# cdp enable | Enables CDP on the port. By default, CDP is enabled. |
| Step 5 | Use one of the following: <ul style="list-style-type: none"> • mls qos trust cos • mls qos trust dscp Example: Device(config-if)# mls qos trust cos | Configures the port to trust the CoS value in traffic received from the Cisco IP Phone. or Configures the routed port to trust the DSCP value in traffic received from the Cisco IP Phone. By default, the port is not trusted. |
| Step 6 | mls qos trust device cisco-phone Example: Device(config-if)# mls qos trust device cisco-phone | Specifies that the Cisco IP Phone is a trusted device. You cannot enable both trusted boundary and auto-QoS (auto qos voip interface configuration command) at the same time; they are mutually exclusive. Note To disable the trusted boundary feature, use the no mls qos trust device interface configuration command. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 7 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 8 | show mls qos interface Example: Device# show mls qos interface | Verifies your entries. |
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Enabling DSCP Transparency Mode

The switch supports the DSCP transparency feature. It affects only the DSCP field of a packet at egress. By default, DSCP transparency is disabled. The switch modifies the DSCP field in an incoming packet, and the DSCP field in the outgoing packet is based on the quality of service (QoS) configuration, including the port trust setting, policing and marking, and the DSCP-to-DSCP mutation map.

If DSCP transparency is enabled by using the **no mls qos rewrite ip dscp** command, the switch does not modify the DSCP field in the incoming packet, and the DSCP field in the outgoing packet is the same as that in the incoming packet.

Regardless of the DSCP transparency configuration, the switch modifies the internal DSCP value of the packet, which the switch uses to generate a class of service (CoS) value that represents the priority of the traffic. The switch also uses the internal DSCP value to select an egress queue and threshold.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos Example: Device(config)# mls qos | Enables QoS globally. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | no mls qos rewrite ip dscp Example: <pre>Device(config)# no mls qos rewrite ip dscp</pre> | Enables DSCP transparency. The switch is configured to not modify the DSCP field of the IP packet. |
| Step 4 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface [interface-id] Example: <pre>Device# show mls qos interface gigabitethernet 2/1/1</pre> | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

DSCP Transparency Mode

To configure the switch to modify the DSCP value based on the trust setting or on an ACL by disabling DSCP transparency, use the **mls qos rewrite ip dscp** global configuration command.

If you disable QoS by using the **no mls qos** global configuration command, the CoS and DSCP values are not changed (the default QoS setting).

If you enter the **no mls qos rewrite ip dscp** global configuration command to enable DSCP transparency and then enter the **mls qos trust [cos | dscp]** interface configuration command, DSCP transparency is still enabled.

Note For Catalyst 2960-L switches, DSCP transparency is enabled by default.

Configuring the DSCP Trust State on a Port Bordering Another QoS Domain

If you are administering two separate QoS domains between which you want to implement QoS features for IP traffic, you can configure the ports bordering the domains to a DSCP-trusted state. The receiving port accepts the DSCP-trusted value and avoids the classification stage of QoS. If the two domains use different DSCP values, you can configure the DSCP-to-DSCP-mutation map to translate a set of DSCP values to match the definition in the other domain.

Figure 69: DSCP-Trusted State on a Port Bordering Another QoS Domain

10 1235

Beginning in privileged EXEC mode, follow these steps to configure the DSCP-trusted state on a port and modify the DSCP-to-DSCP-mutation map. To ensure a consistent mapping strategy across both QoS domains, you must perform this procedure on the ports in both domains.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos map dscp-mutation <i>dscp-mutation-name in-dscp to out-dscp</i> Example: Device(config)# mls qos map dscp-mutation gigabitethernet1/0/2-mutation 10 11 12 13 to 30 | Modifies the DSCP-to-DSCP-mutation map. The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value. <ul style="list-style-type: none"> • For <i>dscp-mutation-name</i>, enter the mutation map name. You can create more than one map by specifying a new name. • For <i>in-dscp</i>, enter up to eight DSCP values separated by spaces. Then enter the to keyword. • For <i>out-dscp</i>, enter a single DSCP value. The DSCP range is 0 to 63. |
| Step 3 | interface interface-id Example: Device(config)# interface | Specifies the port to be trusted, and enter interface configuration mode. Valid interfaces include physical ports. |

| | Command or Action | Purpose |
|---------------|--|--|
| | <code>gigabitethernet1/0/2</code> | |
| Step 4 | <p>mls qos trust dscp</p> <p>Example:</p> <pre>Device(config-if)# mls qos trust dscp</pre> | <p>Configures the ingress port as a DSCP-trusted port. By default, the port is not trusted.</p> <p>Note To return a port to its non-trusted state, use the no mls qos trust interface configuration command.</p> |
| Step 5 | <p>mls qos dscp-mutation <i>dscp-mutation-name</i></p> <p>Example:</p> <pre>Device(config-if)# mls qos dscp-mutation gigabitethernet1/0/2-mutation</pre> | <p>Applies the map to the specified ingress DSCP-trusted port.</p> <p>For <i>dscp-mutation-name</i>, specify the mutation map name created in Step 2.</p> <p>You can configure multiple DSCP-to-DSCP-mutation maps on an ingress port.</p> <p>Note To return to the default DSCP-to-DSCP-mutation map values, use the no mls qos map dscp-mutation <i>dscp-mutation-name</i> global configuration command.</p> |
| Step 6 | <p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | <p>show mls qos maps dscp-mutation</p> <p>Example:</p> <pre>Device# show mls qos maps dscp-mutation</pre> | Verifies your entries. |
| Step 8 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | <p>(Optional) Saves your entries in the configuration file.</p> <p>Note To return a port to its non-trusted state, use the no mls qos trust interface configuration command. To return to the default DSCP-to-DSCP-mutation map values, use the no mls qos map dscp-mutation <i>dscp-mutation-name</i> global configuration command.</p> |

Configuring a QoS Policy

Configuring a QoS policy typically requires the following tasks:

- Classifying traffic into classes
- Configuring policies applied to those traffic classes
- Attaching policies to ports

These sections describe how to classify, police, and mark traffic. Depending on your network configuration, you must perform one or more of the modules in this section.

Classifying Traffic by Using ACLs

You can classify IP traffic by using IPv4 standard ACLs, IPv4 extended ACLs, or IPv6 ACLs.

You can classify non-IP traffic by using Layer 2 MAC ACLs.

Creating an IP Standard ACL for IPv4 Traffic

Before you begin

Before you perform this task, determine which access lists you will be using for your QoS configuration.

Procedure

| | Command or Action | Purpose |
|--------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | access-list access-list-number {deny permit} source [source-wildcard] Example: Device(config)# access-list 1 permit 192.2.255.0 10.1.1.255 | Creates an IP standard ACL, repeating the command as many times as necessary. <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number. The range is 1 to 99 and 1300 to 1999. • Use the permit keyword to permit a certain type of traffic if the conditions are matched. Use the deny keyword to deny a certain type of traffic if conditions are matched. • For <i>source</i>, enter the network or host from which the packet is being sent. You can use the any keyword as an abbreviation for 0.0.0.0 255.255.255.255. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <p>be applied to the source. Place ones in the bit positions that you want to ignore.</p> <p>When you create an access list, remember that by default the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.</p> <p>Note To delete an access list, use the no access-list <i>access-list-number</i> global configuration command.</p> |
| Step 3 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | <p>show access-lists</p> <p>Example:</p> <pre>Device# show access-lists</pre> | Verifies your entries. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Creating an IP Extended ACL for IPv4 Traffic

Before you begin

Before you perform this task, determine which access lists you will be using for your QoS configuration.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | <p>access-list <i>access-list-number</i> {deny permit} <i>protocol source source-wildcard destination destination-wildcard</i></p> | Creates an IP extended ACL, repeating the command as many times as necessary. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <p>Example:</p> <pre>Device(config)# access-list 100 permit ip any any dscp 32</pre> | <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number. The range is 100 to 199 and 2000 to 2699. • Use the permit keyword to permit a certain type of traffic if the conditions are matched. Use the deny keyword to deny a certain type of traffic if conditions are matched. • For <i>protocol</i>, enter the name or number of an IP protocol. Use the question mark (?) to see a list of available protocol keywords. • For <i>source</i>, enter the network or host from which the packet is being sent. You specify this by using dotted decimal notation, by using the any keyword as an abbreviation for <i>source</i> 0.0.0.0 <i>source-wildcard</i> 255.255.255.255, or by using the host keyword for <i>source</i> 0.0.0.0. • For <i>source-wildcard</i>, enter the wildcard bits by placing ones in the bit positions that you want to ignore. You specify the wildcard by using dotted decimal notation, by using the any keyword as an abbreviation for <i>source</i> 0.0.0.0 <i>source-wildcard</i> 255.255.255.255, or by using the host keyword for <i>source</i> 0.0.0.0. • For <i>destination</i>, enter the network or host to which the packet is being sent. You have the same options for specifying the <i>destination</i> and <i>destination-wildcard</i> as those described by <i>source</i> and <i>source-wildcard</i>. <p>When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.</p> <p>Note To delete an access list, use the no access-list <i>access-list-number</i> global configuration command.</p> |
| Step 3 | <p>end</p> <p>Example:</p> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config)# end | |
| Step 4 | show access-lists Example: Device# show access-lists | Verifies your entries. |
| Step 5 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Creating an IPv6 ACL for IPv6 Traffic

Before you begin

Before you perform this task, determine which access lists you will be using for your QoS configuration.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | ipv6 access-list <i>access-list-name</i> Example: Device(config)# ipv6 access-list ipv6_Name_ACL | Creates an IPv6 ACL and enters IPv6 access-list configuration mode. Accesses list names cannot contain a space or quotation mark or begin with a numeric. Note To delete an access list, use the no ipv6 access-list <i>access-list-number</i> global configuration command. |
| Step 3 | {deny permit} protocol {source-ipv6-prefix/prefix-length any host source-ipv6-address} [operator [port-number]] {destination-ipv6-prefix/ prefix-length any host destination-ipv6-address} [operator [port-number]] [dscp value] [fragments] [log] [log-input] [routing] [sequence value] [time-range name] | Enters deny or permit to specify whether to deny or permit the packet if conditions are matched. These are the conditions: For <i>protocol</i> , enter the name or number of an Internet protocol: ahp , esp , icmp , ipv6 , pcp , stcp , tcp , or udp , or an integer in the range 0 to 255 representing an IPv6 protocol number. |

| Command or Action | Purpose |
|---|--|
| <p>Example:</p> <pre>Device(config-ipv6-acl)# permit ip host 10::1 host 11::2 host</pre> | <ul style="list-style-type: none"> • The <i>source-ipv6-prefix/prefix-length</i> or <i>destination-ipv6-prefix/prefix-length</i> is the source or destination IPv6 network or class of networks for which to set deny or permit conditions, specified in hexadecimal and using 16-bit values between colons (see RFC 2373). • Enter any as an abbreviation for the IPv6 prefix <code>::/0</code>. • For host <i>source-ipv6-address</i> or <i>destination-ipv6-address</i>, enter the source or destination IPv6 host address for which to set deny or permit conditions, specified in hexadecimal using 16-bit values between colons. • (Optional) For <i>operator</i>, specify an operand that compares the source or destination ports of the specified protocol. Operands are lt (less than), gt (greater than), eq (equal), neq (not equal), and range. If the operator follows the <i>source-ipv6-prefix/prefix-length</i> argument, it must match the source port. If the operator follows the <i>destination-ipv6-prefix/prefix-length</i> argument, it must match the destination port. • (Optional) The <i>port-number</i> is a decimal number from 0 to 65535 or the name of a TCP or UDP port. You can use TCP port names only when filtering TCP. You can use UDP port names only when filtering UDP. • (Optional) Enter dscp value to match a differentiated services code point value against the traffic class value in the Traffic Class field of each IPv6 packet header. The acceptable range is from 0 to 63. • (Optional) Enter fragments to check noninitial fragments. This keyword is visible only if the protocol is IPv6. • (Optional) Enter log to cause a logging message to be sent to the console about the packet that matches the entry. Enter log-input to include the input interface in |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>the log entry. Logging is supported only for router ACLs.</p> <ul style="list-style-type: none"> • (Optional) Enter routing to specify that IPv6 packets be routed. • (Optional) Enter sequence value to specify the sequence number for the access list statement. The acceptable range is from 1 to 4294967295. • (Optional) Enter time-range name to specify the time range that applies to the deny or permit statement. |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config-ipv6-acl)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>show ipv6 access-list</p> <p>Example:</p> <pre>Device# show ipv6 access-list</pre> | Verifies the access list configuration. |
| Step 6 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Creating a Layer 2 MAC ACL for Non-IP Traffic

Before you begin

Before you perform this task, determine that Layer 2 MAC access lists are required for your QoS configuration.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|--------|---|---|
| Step 2 | <p>mac access-list extended <i>name</i></p> <p>Example:</p> <pre>Device(config)# mac access-list extended maclist1</pre> | <p>Creates a Layer 2 MAC ACL by specifying the name of the list.</p> <p>After entering this command, the mode changes to extended MAC ACL configuration.</p> <p>Note To delete an access list, use the no mac access-list extended access-list-name global configuration command.</p> |
| Step 3 | <p>{permit deny} {host <i>src-MAC-addr mask</i> any host <i>dst-MAC-addr</i> <i>dst-MAC-addr mask</i>} [<i>type mask</i>]</p> <p>Example:</p> <pre>Device(config-ext-macl) # permit 0001.0000.0001 0.0.0 0002.0000.0001 0.0.0</pre> <pre>Device(config-ext-macl) # permit 0001.0000.0002 0.0.0 0002.0000.0002 0.0.0 xns-idp</pre> | <p>Specifies the type of traffic to permit or deny if the conditions are matched, entering the command as many times as necessary.</p> <ul style="list-style-type: none"> For <i>src-MAC-addr</i>, enter the MAC address of the host from which the packet is being sent. You specify this by using the hexadecimal format (H.H.H), by using the any keyword as an abbreviation for <i>source</i> 0.0.0, <i>source-wildcard</i> ffff.fff.fff, or by using the host keyword for <i>source</i> 0.0.0. For <i>mask</i>, enter the wildcard bits by placing ones in the bit positions that you want to ignore. For <i>dst-MAC-addr</i>, enter the MAC address of the host to which the packet is being sent. You specify this by using the hexadecimal format (H.H.H), by using the any keyword as an abbreviation for <i>source</i> 0.0.0, <i>source-wildcard</i> ffff.fff.fff, or by using the host keyword for <i>source</i> 0.0.0. (Optional) For <i>type mask</i>, specify the Ethertype number of a packet with Ethernet II or SNAP encapsulation to identify the protocol of the packet. For <i>type</i>, the range is from 0 to 65535, typically specified in hexadecimal. For <i>mask</i>, enter the <i>don't care</i> bits applied to the Ethertype before testing for a match. <p>When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.</p> |
| Step 4 | <p>end</p> <p>Example:</p> | <p>Returns to privileged EXEC mode.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device (config-ext-macl) # end | |
| Step 5 | show access-lists [<i>access-list-number</i> <i>access-list-name</i>] Example: Device# show access-lists | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Classifying Traffic by Using Class Maps

You use the **class-map** global configuration command to name and to isolate a specific traffic flow (or class) from all other traffic. The class map defines the criteria to use to match against a specific traffic flow to further classify it. Match statements can include criteria such as an ACL, IP precedence values, or DSCP values. The match criterion is defined with one match statement entered within the class-map configuration mode.

Note You can also create class maps during policy map creation by using the **class** policy-map configuration command.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | Use one of the following: <ul style="list-style-type: none"> • access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>] • access-list <i>access-list-number</i> {deny permit} <i>protocol source</i> [<i>source-wildcard</i>] <i>destination</i> [<i>destination-wildcard</i>] • ipv6 access-list <i>access-list-name</i> {deny permit} <i>protocol</i> {<i>source-ipv6-prefix/prefix-length</i> any | Creates an IP standard or extended ACL, an IPv6 ACL for IP traffic, or a Layer 2 MAC ACL for non-IP traffic, repeating the command as many times as necessary. When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <p>host <i>source-ipv6-address</i> { <i>operator</i> [<i>port-number</i>] { <i>destination-ipv6-prefix/prefix-length</i> any host destination-ipv6-address } [<i>operator</i> [<i>port-number</i>] [dscp <i>value</i>] [fragments] [log] [log-input] [routing] [sequence value] [time-range name]</p> <ul style="list-style-type: none"> • mac access-list extended <i>name</i> { permit deny } { host <i>src-MAC-addr mask</i> any host <i>dst-MAC-addr</i> <i>dst-MAC-addr mask</i> } [<i>type mask</i>] <p>Example:</p> <pre>Device(config)# access-list 103 permit ip any any dscp 10</pre> | |
| Step 3 | <p>class-map [match-all match-any] <i>class-map-name</i></p> <p>Example:</p> <pre>Device(config)# class-map class1</pre> | <p>Creates a class map, and enters class-map configuration mode.</p> <p>By default, no class maps are defined.</p> <ul style="list-style-type: none"> • (Optional) Use the match-all keyword to perform a logical-AND of all matching statements under this class map. All match criteria in the class map must be matched. • (Optional) Use the match-any keyword to perform a logical-OR of all matching statements under this class map. One or more match criteria must be matched. • For <i>class-map-name</i>, specify the name of the class map. <p>If neither the match-all or match-any keyword is specified, the default is match-all.</p> <p>Note To delete an existing class map, use the no class-map [match-all match-any] <i>class-map-name</i> global configuration command.</p> |
| Step 4 | <p>match { access-group <i>acl-index-or-name</i> ip dscp <i>dscp-list</i> ip precedence <i>ip-precedence-list</i> }</p> <p>Example:</p> <pre>Device(config-cmap)# match ip dscp 10 11 12</pre> | <p>Defines the match criterion to classify traffic.</p> <p>By default, no match criterion is defined.</p> <p>Only one match criterion per class map is supported, and only one ACL per class map is supported.</p> |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> For access-group <i>acl-index-or-name</i>, specify the number or name of the ACL created in Step 2. To filter IPv6 traffic with the match access-group command, create an IPv6 ACL, as described in Step 2. For ip dscp <i>dscp-list</i>, enter a list of up to eight IP DSCP values to match against incoming packets. Separate each value with a space. The range is 0 to 63. For ip precedence <i>ip-precedence-list</i>, enter a list of up to eight IP-precedence values to match against incoming packets. Separate each value with a space. The range is 0 to 7. <p>Note To remove a match criterion, use the no match {access-group <i>acl-index-or-name</i> ip dscp ip precedence} class-map configuration command.</p> |
| Step 5 | end Example: <pre>Device(config-cmap)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | show class-map Example: <pre>Device# show class-map</pre> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: <pre>Device# copy-running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Classifying Traffic by Using Class Maps and Filtering IPv6 Traffic

To apply the primary match criteria to only IPv4 traffic, use the **match protocol** command with the **ip** keyword. To apply the primary match criteria to only IPv6 traffic, use the **match protocol** command with the **ipv6** keyword.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | class-map {match-all} class-map-name Example: Device(config)# <code>class-map cm-1</code> | Creates a class map, and enters class-map configuration mode. By default, no class maps are defined. When you use the match protocol command, only the match-all keyword is supported. <ul style="list-style-type: none"> For <i>class-map-name</i>, specify the name of the class map. If neither the match-all or match-any keyword is specified, the default is match-all . Note To delete an existing class map, use the no class-map [match-all match-any] class-map-name global configuration command. |
| Step 3 | match protocol [ip / ipv6] Example: Device(config-cmap)# <code>match protocol ip</code> | (Optional) Specifies the IP protocol to which the class map applies: <ul style="list-style-type: none"> Use the argument <i>ip</i> to specify IPv4 traffic and <i>ipv6</i> to specify IPv6 traffic. When you use the match protocol command, only the match-all keyword is supported for the class-map command. |
| Step 4 | match {ip dscp dscp-list ip precedence ip-precedence-list} Example: Device(config-cmap)# <code>match ip dscp 10</code> | Defines the match criterion to classify traffic. By default, no match criterion is defined. <ul style="list-style-type: none"> For ip dscp dscp-list, enter a list of up to eight IP DSCP values to match against incoming packets. Separate each value with a space. The range is 0 to 63. For ip precedence ip-precedence-list, enter a list of up to eight IP-precedence values to match against incoming packets. Separate each value with a space. The range is 0 to 7. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note To remove a match criterion, use the no match { access-group <i>acl-index-or-name</i> ip dscp ip precedence } class-map configuration command. |
| Step 5 | end Example: Device(config-cmap)# end | Returns to privileged EXEC mode. |
| Step 6 | show class-map Example: Device# show class-map | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Classifying, Policing, and Marking Traffic on Physical Ports by Using Policy Maps

You can configure a policy map on a physical port that specifies which traffic class to act on. Actions can include trusting the CoS, DSCP, or IP precedence values in the traffic class; setting a specific DSCP or IP precedence value in the traffic class; and specifying the traffic bandwidth limitations for each matched traffic class (policer) and the action to take when the traffic is out of profile (marking).

A policy map also has these characteristics:

- A policy map can contain multiple class statements, each with different match criteria and policers.
- A policy map can contain a predefined default traffic class explicitly placed at the end of the map.
- A separate policy-map class can exist for each type of traffic received through a port.

Follow these guidelines when configuring policy maps on physical ports:

- You can attach only one policy map per ingress port.
- If you configure the IP-precedence-to-DSCP map by using the **mls qos map ip-prec-dscp** *dscp1...dscp8* global configuration command, the settings only affect packets on ingress interfaces that are configured to trust the IP precedence value. In a policy map, if you set the packet IP precedence value to a new value by using the **set ip precedence** *new-precedence* policy-map class configuration command, the egress DSCP value is not affected by the IP-precedence-to-DSCP map. If you want the egress DSCP value to be different than the ingress value, use the **set dscp new-dscp** policy-map class configuration command.

- If you enter or have used the **set ip dscp** command, the changes this command to **set dscp** in its configuration.
- You can use the **set ip precedence** or the **set precedence** policy-map class configuration command to change the packet IP precedence value. This setting appears as set ip precedence in the configuration.
- A policy-map and a port trust state can both run on a physical interface. The policy-map is applied before the port trust state.
- When you configure a default traffic class by using the **class class-default** policy-map configuration command, unclassified traffic (traffic that does not meet the match criteria specified in the traffic classes) is treated as the default traffic class (class-default).

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | class-map [match-all match-any] <i>class-map-name</i> Example: Device(config)# class-map ipclass1 | Creates a class map, and enters class-map configuration mode. By default, no class maps are defined. <ul style="list-style-type: none"> • (Optional) Use the match-all keyword to perform a logical-AND of all matching statements under this class map. All match criteria in the class map must be matched. • (Optional) Use the match-any keyword to perform a logical-OR of all matching statements under this class map. One or more match criteria must be matched. • For <i>class-map-name</i>, specify the name of the class map. If neither the match-all or match-any keyword is specified, the default is match-all . |
| Step 3 | policy-map <i>policy-map-name</i> Example: Device(config-cmap)# policy-map flowit | Creates a policy map by entering the policy map name, and enters policy-map configuration mode. By default, no policy maps are defined. The default behavior of a policy map is to set the DSCP to 0 if the packet is an IP packet and to set the CoS to 0 if the packet is tagged. No policing is performed. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>Note To delete an existing policy map, use the no policy-map <i>policy-map-name</i> global configuration command.</p> |
| Step 4 | <p>class [<i>class-map-name</i> class-default]</p> <p>Example:</p> <pre>Device(config-pmap)# class ipclass1</pre> | <p>Defines a traffic classification, and enters policy-map class configuration mode.</p> <p>By default, no policy map class-maps are defined.</p> <p>If a traffic class has already been defined by using the class-map global configuration command, specify its name for <i>class-map-name</i> in this command.</p> <p>A class-default traffic class is pre-defined and can be added to any policy. It is always placed at the end of a policy map. With an implied match any included in the class-default class, all packets that have not already matched the other traffic classes will match class-default.</p> <p>Note To delete an existing class map, use the no class <i>class-map-name</i> policy-map configuration command.</p> |
| Step 5 | <p>trust [cos dscp ip-precedence]</p> <p>Example:</p> <pre>Device(config-pmap-c)# trust dscp</pre> | <p>Configures the trust state, which QoS uses to generate a CoS-based or DSCP-based QoS label.</p> <p>This command is mutually exclusive with the set command within the same policy map. If you enter the trust command, go to Step 6.</p> <p>By default, the port is not trusted. If no keyword is specified when the command is entered, the default is dscp.</p> <p>The keywords have these meanings:</p> <ul style="list-style-type: none"> • cos—QoS derives the DSCP value by using the received or default port CoS value and the CoS-to-DSCP map. • dscp—QoS derives the DSCP value by using the DSCP value from the ingress packet. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by using the default port |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <p>CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map.</p> <ul style="list-style-type: none"> • ip-precedence—QoS derives the DSCP value by using the IP precedence value from the ingress packet and the IP-precedence-to-DSCP map. For non-IP packets that are tagged, QoS derives the DSCP value by using the received CoS value; for non-IP packets that are untagged, QoS derives the DSCP value by using the default port CoS value. In either case, the DSCP value is derived from the CoS-to-DSCP map. <p>Note To return to the untrusted state, use the no trust policy-map configuration command</p> |
| Step 6 | <p>set {dscp <i>new-dscp</i> ip precedence <i>new-precedence</i>}</p> <p>Example:</p> <pre>Device(config-pmap-c)# set dscp 45</pre> | <p>Classifies IP traffic by setting a new value in the packet.</p> <ul style="list-style-type: none"> • For dscp <i>new-dscp</i>, enter a new DSCP value to be assigned to the classified traffic. The range is 0 to 63. • For ip precedence <i>new-precedence</i>, enter a new IP-precedence value to be assigned to the classified traffic. The range is 0 to 7. <p>Note To remove an assigned DSCP or IP precedence value, use the no set {dscp <i>new-dscp</i> ip precedence <i>new-precedence</i>} policy-map configuration command.</p> |
| Step 7 | <p>police <i>rate-bps burst-byte</i> [exceed-action {drop policed-dscp-transmit}]</p> <p>Example:</p> <pre>Device(config-pmap-c)# police 100000 80000 drop</pre> | <p>Defines a policer for the classified traffic. By default, no policer is defined.</p> <ul style="list-style-type: none"> • For <i>rate-bps</i>, specify average traffic rate in bits per second (b/s). The range is 8000 to 10000000000. • For <i>burst-byte</i>, specify the normal burst size in bytes. The range is 8000 to 1000000. • (Optional) Specifies the action to take when the rates are exceeded. Use the exceed-action drop keywords to drop the |

| | Command or Action | Purpose |
|----------------|--|--|
| | | <p>packet. Use the exceed-action policed-dscp-transmit keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet.</p> <p>Note To remove an existing policer, use the no police rate-bps burst-byte [exceed-action {drop policed-dscp-transmit}] policy-map configuration command.</p> |
| Step 8 | <p>exit</p> <p>Example:</p> <pre>Device (config-pmap-c) # exit</pre> | Returns to policy map configuration mode. |
| Step 9 | <p>exit</p> <p>Example:</p> <pre>Device (config-pmap) # exit</pre> | Returns to global configuration mode. |
| Step 10 | <p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device (config) # interface gigabitethernet 2/0/1</pre> | <p>Specifies the port to attach to the policy map, and enters interface configuration mode.</p> <p>Valid interfaces include physical ports.</p> |
| Step 11 | <p>service-policy input <i>policy-map-name</i></p> <p>Example:</p> <pre>Device (config-if) # service-policy input flowit</pre> | <p>Specifies the policy-map name, and applies it to an ingress port.</p> <p>Only one policy map per ingress port is supported.</p> <p>Note To remove the policy map and port association, use the no service-policy input policy-map-name interface configuration command.</p> |
| Step 12 | <p>end</p> <p>Example:</p> <pre>Device (config-if) # end</pre> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 13 | show policy-map [<i>policy-map-name</i> [class <i>class-map-name</i>]] Example: Device# show policy-map | Verifies your entries. |
| Step 14 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Classifying, Policing, and Marking Traffic by Using Aggregate Policers

By using an aggregate policer, you can create a policer that is shared by multiple traffic classes within the same policy map. However, you cannot use the aggregate policer across different policy maps or ports.

You can configure aggregate policers only in nonhierarchical policy maps on physical ports.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos aggregate-policer <i>aggregate-policer-name</i> <i>rate-bps</i> <i>burst-byte</i> exceed-action { drop policed-dscp-transmit } Example: Device(config)# mls qos aggregate-policer transmit1 48000 8000 exceed-action policed-dscp-transmit | Defines the policer parameters that can be applied to multiple traffic classes within the same policy map. By default, no aggregate policer is defined. <ul style="list-style-type: none"> • For <i>aggregate-policer-name</i>, specify the name of the aggregate policer. • For <i>rate-bps</i>, specify average traffic rate in bits per second (b/s). The range is 8000 to 10000000000. • For <i>burst-byte</i>, specify the normal burst size in bytes. The range is 8000 to 1000000. • Specifies the action to take when the rates are exceeded. Use the exceed-action drop keywords to drop the packet. Use the exceed-action policed-dscp-transmit |

| | Command or Action | Purpose |
|---------------|---|---|
| | | keywords to mark down the DSCP value (by using the policed-DSCP map) and to send the packet. |
| Step 3 | class-map [match-all match-any] <i>class-map-name</i> Example: Device (config) # class-map ipclass1 | Creates a class map to classify traffic as necessary. |
| Step 4 | policy-map <i>policy-map-name</i> Example: Device (config-cmap) # policy-map aggflow1 | Creates a policy map by entering the policy map name, and enters policy-map configuration mode. |
| Step 5 | class [<i>class-map-name</i> class-default] Example: Device (config-cmap-p) # class ipclass1 | Defines a traffic classification, and enters policy-map class configuration mode. |
| Step 6 | police aggregate <i>aggregate-policer-name</i> Example: Device (configure-cmap-p) # police aggregate transmit1 | <p>Applies an aggregate policer to multiple classes in the same policy map.</p> <p>For <i>aggregate-policer-name</i>, enter the name specified in Step 2.</p> <p>To remove the specified aggregate policer from a policy map, use the no police aggregate <i>aggregate-policer-name</i> policy map configuration command. To delete an aggregate policer and its parameters, use the no mls qos aggregate-policer <i>aggregate-policer-name</i> global configuration command.</p> |
| Step 7 | exit Example: Device (configure-cmap-p) # exit | Returns to global configuration mode. |
| Step 8 | interface <i>interface-id</i> Example: Device (config) # interface gigabitethernet 2/0/1 | <p>Specifies the port to attach to the policy map, and enters interface configuration mode.</p> <p>Valid interfaces include physical ports.</p> |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 9 | service-policy input <i>policy-map-name</i> Example: Device(config-if)# service-policy input aggflow1 | Specifies the policy-map name, and applies it to an ingress port. Only one policy map per ingress port is supported. |
| Step 10 | end Example: Device(configure-if)# end | Returns to privileged EXEC mode. |
| Step 11 | show mls qos aggregate-policer [<i>aggregate-policer-name</i>] Example: Device# show mls qos aggregate-policer transmit1 | Verifies your entries. |
| Step 12 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring DSCP Maps

Configuring the CoS-to-DSCP Map

You use the CoS-to-DSCP map to map CoS values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic.

Beginning in privileged EXEC mode, follow these steps to modify the CoS-to-DSCP map. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos map cos-dscp <i>dscp1...dscp8</i> | Modifies the CoS-to-DSCP map. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Example: Device(config)# mls qos map cos-dscp 10 15 20 25 30 35 40 45 | For <i>dscp1...dscp8</i> , enter eight DSCP values that correspond to CoS values 0 to 7. Separate each DSCP value with a space. The DSCP range is 0 to 63. Note To return to the default map, use the no mls qos cos-dscp global configuration command. |
| Step 3 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 4 | show mls qos maps cos-dscp Example: Device# show mls qos maps cos-dscp | Verifies your entries. |
| Step 5 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring the IP-Precedence-to-DSCP Map

You use the IP-precedence-to-DSCP map to map IP precedence values in incoming packets to a DSCP value that QoS uses internally to represent the priority of the traffic.

Beginning in privileged EXEC mode, follow these steps to modify the IP-precedence-to-DSCP map. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos map ip-prec-dscp dscp1...dscp8 Example: | Modifies the IP-precedence-to-DSCP map. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>Device(config)# mls qos map ip-prec-dscp 10 15 20 25 30 35 40 45</pre> | <p>For <i>dscp1...dscp8</i>, enter eight DSCP values that correspond to the IP precedence values 0 to 7. Separate each DSCP value with a space.</p> <p>The DSCP range is 0 to 63.</p> <p>Note To return to the default map, use the no mls qos ip-prec-dscp global configuration command.</p> |
| Step 3 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | <p>show mls qos maps ip-prec-dscp</p> <p>Example:</p> <pre>Device# show mls qos maps ip-prec-dscp</pre> | Verifies your entries. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring the Policed-DSCP Map

You use the policed-DSCP map to mark down a DSCP value to a new value as the result of a policing and marking action.

The default policed-DSCP map is a null map, which maps an incoming DSCP value to the same DSCP value.

Beginning in privileged EXEC mode, follow these steps to modify the policed-DSCP map. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | <p>mls qos map policed-dscp <i>dscp-list</i> to <i>mark-down-dscp</i></p> | Modifies the policed-DSCP map. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <p>Example:</p> <pre>Device(config)# mls qos map policed-dscp 50 51 52 53 54 55 56 57 to 0</pre> | <ul style="list-style-type: none"> For <i>dscp-list</i>, enter up to eight DSCP values separated by spaces. Then enter the to keyword. For <i>mark-down-dscp</i>, enter the corresponding policed (marked down) DSCP value. <p>Note To return to the default map, use the no mls qos policed-dscp global configuration command.</p> |
| Step 3 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | <p>show mls qos maps policed-dscp</p> <p>Example:</p> <pre>Device(config)# show mls qos maps policed-dscp</pre> | Verifies your entries. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device#</pre> | (Optional) Saves your entries in the configuration file. |

Configuring the DSCP-to-CoS Map

You use the DSCP-to-CoS map to generate a CoS value, which is used to select one of the four egress queues.

Beginning in privileged EXEC mode, follow these steps to modify the DSCP-to-CoS map. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | <p>mls qos map dscp-cos <i>dscp-list</i> to <i>cos</i></p> <p>Example:</p> | Modifies the DSCP-to-CoS map. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>Device# mls qos map dscp-cos 0 8 16 24 32 40 48 50 to 0</pre> | <ul style="list-style-type: none"> For <i>dscp-list</i>, enter up to eight DSCP values separated by spaces. Then enter the to keyword. For <i>cos</i>, enter the CoS value to which the DSCP values correspond. <p>The DSCP range is 0 to 63; the CoS range is 0 to 7.</p> <p>Note To return to the default map, use the no mls qos dscp-cos global configuration command.</p> |
| Step 3 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | <p>show mls qos maps dscp-to-cos</p> <p>Example:</p> <pre>Device# show mls qos maps dscp-to-cos</pre> | Verifies your entries. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring the DSCP-to-DSCP-Mutation Map

If two QoS domains have different DSCP definitions, use the DSCP-to-DSCP-mutation map to translate one set of DSCP values to match the definition of another domain. You apply the DSCP-to-DSCP-mutation map to the receiving port (ingress mutation) at the boundary of a QoS administrative domain.

With ingress mutation, the new DSCP value overwrites the one in the packet, and QoS applies the new value to the packet. The sends the packet out the port with the new DSCP value.

You can configure multiple DSCP-to-DSCP-mutation maps on an ingress port. The default DSCP-to-DSCP-mutation map is a null map, which maps an incoming DSCP value to the same DSCP value.

Beginning in privileged EXEC mode, follow these steps to modify the DSCP-to-DSCP-mutation map. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | mls qos map dscp-mutation <i>dscp-mutation-name in-dscp to out-dscp</i> Example: Device (config)# <code>mls qos map dscp-mutation</code> <code>mutation1 1 2 3 4 5 6 7 to 0</code> | Modifies the DSCP-to-DSCP-mutation map. <ul style="list-style-type: none"> • For <i>dscp-mutation-name</i>, enter the mutation map name. You can create more than one map by specifying a new name. • For <i>in-dscp</i>, enter up to eight DSCP values separated by spaces. Then enter the to keyword. • For <i>out-dscp</i>, enter a single DSCP value. The DSCP range is 0 to 63. Note To return to the default map, use the no mls qos dscp-mutation <i>dscp-mutation-name</i> global configuration command. |
| Step 3 | interface interface-id Example: Device (config)# <code>interface</code> <code>gigabitethernet1/0/1</code> | Specifies the port to which to attach the map, and enters interface configuration mode. Valid interfaces include physical ports. |
| Step 4 | mls qos trust dscp Example: Device (config-if)# <code>mls qos trust dscp</code> | Configures the ingress port as a DSCP-trusted port. By default, the port is not trusted. |
| Step 5 | mls qos dscp-mutation <i>dscp-mutation-name</i> Example: Device (config-if)# <code>mls qos dscp-mutation</code> <code>mutation1</code> | Applies the map to the specified ingress DSCP-trusted port. For <i>dscp-mutation-name</i> , enter the mutation map name specified in Step 2. |
| Step 6 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | <code>Device(config-if)# end</code> | |
| Step 7 | show mls qos maps dscp-mutation Example: <code>Device# show mls qos maps dscp-mutation</code> | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: <code>Device# copy-running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Configuring Ingress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you might need to perform all of the tasks in the next modules. You need to make decisions about these characteristics:

- Which packets are assigned (by DSCP or CoS value) to each queue?
- What drop percentage thresholds apply to each queue, and which CoS or DSCP values map to each threshold?
- How much of the available buffer space is allocated between the queues?
- How much of the available bandwidth is allocated between the queues?
- Is there traffic (such as voice) that should be given high priority?

Configuration Guidelines

Follow these guidelines when the expedite queue is enabled or the egress queues are serviced based on their SRR weights:

- If the egress expedite queue is enabled, it overrides the SRR shaped and shared weights for queue 1.
- If the egress expedite queue is disabled and the SRR shaped and shared weights are configured, the shaped mode overrides the shared mode for queue 1, and SRR services this queue in shaped mode.
- If the egress expedite queue is disabled and the SRR shaped weights are not configured, SRR services this queue in shared mode.

Mapping DSCP or CoS Values to an Ingress Queue and Setting WTD Thresholds

You can prioritize traffic by placing packets with particular DSCPs or CoSs into certain queues and adjusting the queue thresholds so that packets with lower priorities are dropped.

Beginning in privileged EXEC mode, follow these steps to map DSCP or CoS values to an ingress queue and to set WTD thresholds. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | Use one of the following: <ul style="list-style-type: none"> • mls qos srr-queue input dscp-map queue <i>queue-id</i> threshold <i>threshold-id</i> <i>dscp1...dscp8</i> • mls qos srr-queue input cos-map queue <i>queue-id</i> threshold <i>threshold-id</i> <i>cos1...cos8</i> Example: Device(config)# mls qos srr-queue input dscp-map queue 1 threshold 2 20 21 22 23 24 25 26 | Maps DSCP or CoS values to an ingress queue and to a threshold ID. By default, DSCP values 0–39 and 48–63 are mapped to queue 1 and threshold 1. DSCP values 40–47 are mapped to queue 2 and threshold 1. By default, CoS values 0–4, 6, and 7 are mapped to queue 1 and threshold 1. CoS value 5 is mapped to queue 2 and threshold 1. <ul style="list-style-type: none"> • For <i>queue-id</i>, the range is 1 to 2. • For <i>threshold-id</i>, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state. • For <i>dscp1...dscp8</i>, enter up to eight values, and separate each value with a space. The range is 0 to 63. • For <i>cos1...cos8</i>, enter up to eight values, and separate each value with a space. The range is 0 to 7. |
| Step 3 | mls qos srr-queue input threshold <i>queue-id</i> <i>threshold-percentage1</i> <i>threshold-percentage2</i> Example: Device(config)# mls qos srr-queue input threshold 1 50 70 | Assigns the two WTD threshold percentages for (threshold 1 and 2) to an ingress queue. The default, both thresholds are set to 100 percent. <ul style="list-style-type: none"> • For <i>queue-id</i>, the range is 1 to 2. • For <i>threshold-percentage1</i> <i>threshold-percentage2</i>, the range is 1 to 100. Separate each value with a space. Each threshold value is a percentage of the total number of queue descriptors allocated for the queue. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos maps Example: Device# show mls qos maps | Verifies your entries. The DSCP input queue threshold map appears as a matrix. The d1 column specifies the most-significant digit of the DSCP number; the d2 row specifies the least-significant digit in the DSCP number. The intersection of the d1 and the d2 values provides the queue ID and threshold ID; for example, queue 2 and threshold 1 (02-01). The CoS input queue threshold map shows the CoS value in the top row and the corresponding queue ID and threshold ID in the second row; for example, queue 2 and threshold 2 (2-2). |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. To return to the default CoS input queue threshold map or the default DSCP input queue threshold map, use the no mls qos srr-queue input cos-map or the no mls qos srr-queue input dscp-map global configuration command. To return to the default WTD threshold percentages, use the no mls qos srr-queue input threshold queue-id global configuration command |

Allocating Buffer Space Between the Ingress Queues

You define the ratio (allocate the amount of space) with which to divide the ingress buffers between the two queues. The buffer and the bandwidth allocation control how much data can be buffered before packets are dropped.

Beginning in privileged EXEC mode, follow these steps to allocate the buffers between the ingress queues. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|-----------------------------------|
| Step 1 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device# <code>configure terminal</code> | |
| Step 2 | <p>mls qos srr-queue input buffers <i>percentage1 percentage2</i></p> <p>Example:</p> <pre>Device(config)# mls qos srr-queue input buffers 60 40</pre> | <p>Allocates the buffers between the ingress queues</p> <p>By default 90 percent of the buffers are allocated to queue 1, and 10 percent of the buffers are allocated to queue 2.</p> <p>For <i>percentage1 percentage2</i>, the range is 0 to 100. Separate each value with a space.</p> <p>You should allocate the buffers so that the queues can handle any incoming bursty traffic.</p> |
| Step 3 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 4 | <p>Use one of the following:</p> <ul style="list-style-type: none"> • show mls qos interface buffer • show mls qos input-queue <p>Example:</p> <pre>Device# show mls qos interface buffer</pre> <p>or</p> <pre>Device# show mls qos input-queue</pre> | Verifies your entries. |
| Step 5 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | <p>(Optional) Saves your entries in the configuration file.</p> <p>To return to the default setting, use the no mls qos srr-queue input buffers global configuration command.</p> |

Allocating Bandwidth Between the Ingress Queues

You need to specify how much of the available bandwidth is allocated between the ingress queues. The ratio of the weights is the ratio of the frequency in which the SRR scheduler sends packets from each queue. The bandwidth and the buffer allocation control how much data can be buffered before packets are dropped. On ingress queues, SRR operates only in shared mode.

Note SRR bandwidth limit works in both mls qos enabled and disabled states.

Beginning in privileged EXEC mode, follow these steps to allocate bandwidth between the ingress queues. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos srr-queue input bandwidth weight1 weight2 Example: Device(config)# mls qos srr-queue input bandwidth 25 75 | Assigns shared round robin weights to the ingress queues. The default setting for <i>weight1</i> and <i>weight2</i> is 4 (1/2 of the bandwidth is equally shared between the two queues). For <i>weight1</i> and <i>weight2</i> , the range is 1 to 100. Separate each value with a space. SRR services the priority queue for its configured weight as specified by the bandwidth keyword in the mls qos srr-queue input priority-queue queue-id bandwidth weight global configuration command. Then, SRR shares the remaining bandwidth with both ingress queues and services them as specified by the weights configured with the mls qos srr-queue input bandwidth weight1 weight2 global configuration command. |
| Step 3 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 4 | Use one of the following: <ul style="list-style-type: none"> • show mls qos interface queueing • show mls qos input-queue Example: Device# show mls qos interface queueing or Device# show mls qos input-queue | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. To return to the default setting, use the no mls qos srr-queue input bandwidth global configuration command. |

Configuring Egress Queue Characteristics

Depending on the complexity of your network and your QoS solution, you might need to perform all of the tasks in the following modules. You need to make decisions about these characteristics:

- Which packets are mapped by DSCP or CoS value to each queue and threshold ID?
- What drop percentage thresholds apply to the queue-set (four egress queues per port), and how much reserved and maximum memory is needed for the traffic type?
- How much of the fixed buffer space is allocated to the queue-set?
- Does the bandwidth of the port need to be rate limited?
- How often should the egress queues be serviced and which technique (shaped, shared, or both) should be used?

Configuration Guidelines

Follow these guidelines when the expedite queue is enabled or the egress queues are serviced based on their SRR weights:

- If the egress expedite queue is enabled, it overrides the SRR shaped and shared weights for queue 1.
- If the egress expedite queue is disabled and the SRR shaped and shared weights are configured, the shaped mode overrides the shared mode for queue 1, and SRR services this queue in shaped mode.
- If the egress expedite queue is disabled and the SRR shaped weights are not configured, SRR services this queue in shared mode.

Allocating Buffer Space to and Setting WTD Thresholds for an Egress Queue-Set

You can guarantee the availability of buffers, set WTD thresholds, and configure the maximum allocation for a queue-set by using the **mls qos queue-set output *qset-id* threshold *queue-id* drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold** global configuration command.

Each threshold value is a percentage of the queue's allocated buffers, which you specify by using the **mls qos queue-set output *qset-id* buffers *allocation1* ... *allocation4*** global configuration command. The queues use WTD to support distinct drop percentages for different traffic classes.

Note The switch supports 4 egress queues by default, although there is an option to enable a total of 8 egress queues. Use the **mls qos srr-queue output queues 8** global configuration command to enable all 8 egress queues. Once 8 egress queues are enabled, you are able to configure thresholds, buffers, bandwidth share weights, and bandwidth shape weights for all 8 queues. The 8 egress queue configuration is only supported on a standalone switch.

Note The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to configure the memory allocation and to drop thresholds for a queue-set. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos srr-queue output queues 8 Example: Device(config)# mls qos srr-queue output queues 8 | (Optional) The switch supports 4 egress queues by default, although you can enable a total of 8 egress queues. Use the optional mls qos srr-queue output queues 8 command to enable the additional 4 egress queues. Once 8 queue support is enabled, you can then proceed to configure the additional 4 queues. Any existing egress queue configuration commands are then modified to support the additional queue parameters. Note The option to enable 8 queues is only available on a standalone switch. |
| Step 3 | mls qos queue-set output <i>qset-id</i> buffers <i>allocation1</i> ... <i>allocation8</i> Example: Device(config)# mls qos queue-set output 2 buffers 40 20 20 20 10 10 10 10 | Allocates buffers to a queue set. By default, all allocation values are equally mapped among the four queues (25, 25, 25, 25). Each queue has 1/4 of the buffer space. When eight egress queues are configured, then by default 30 percent of the total buffer space is allocated to queue 2 and 10 percent (each) to queues 1,3,4,5,6,7, and 8. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>If you enabled 8 egress queues as described in Step 2 above, then the following applies:</p> <ul style="list-style-type: none"> • For <i>qset-id</i>, enter the ID of the queue set. The range is 1 to 2. Each port belongs to a queue set, which defines all the characteristics of the four egress queues per port. • For <i>allocation1 ... allocation8</i>, specify eight percentages, one for each queue in the queue set. For <i>allocation1</i>, <i>allocation3</i>, and <i>allocation4</i> to <i>allocation8</i>, the range is 0 to 99. For <i>allocation2</i>, the range is 1 to 100 (including the CPU buffer). <p>Allocate buffers according to the importance of the traffic; for example, give a large percentage of the buffer to the queue with the highest-priority traffic.</p> <p>Note To return to the default setting, use the no mls qos queue-set output <i>qset-id</i> buffers global configuration command.</p> |
| Step 4 | <p>mls qos queue-set output <i>qset-id</i> threshold <i>queue-id</i> drop-threshold1 drop-threshold2 reserved-threshold maximum-threshold</p> <p>Example:</p> <pre>Device(config)# mls qos queue-set output 2 threshold 2 40 60 100 200</pre> | <p>Configures the WTD thresholds, guarantee the availability of buffers, and configure the maximum memory allocation for the queue-set (four egress queues per port).</p> <p>By default, the WTD thresholds for queues 1, 3, and 4 are set to 100 percent. The thresholds for queue 2 are set to 200 percent. The reserved thresholds for queues 1, 2, 3, and 4 are set to 50 percent. The maximum thresholds for all queues are set to 400 percent by default.</p> <p>If you enabled 8 egress queues as described in Step 2 above, then the following applies:</p> <ul style="list-style-type: none"> • For <i>qset-id</i>, enter the ID of the queue-set specified in Step 2. The range is 1 to 2. • For <i>queue-id</i>, enter the specific queue in the queue set on which the command is performed. The queue-id range is 1-4 by default and 1-8 when 8 queues are enabled. • For <i>drop-threshold1 drop-threshold2</i>, specify the two WTD thresholds expressed as a percentage of the queue's allocated memory. The range is 1 to 3200 percent. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <ul style="list-style-type: none"> For <i>reserved-threshold</i>, enter the amount of memory to be guaranteed (reserved) for the queue expressed as a percentage of the allocated memory. The range is 1 to 100 percent. For <i>maximum-threshold</i>, enable a queue in the full condition to obtain more buffers than are reserved for it. This is the maximum memory the queue can have before the packets are dropped if the common pool is not empty. The range is 1 to 3200 percent. <p>Note To return to the default WTD threshold percentages, use the no mls qos queue-set output <i>qset-id</i> threshold [<i>queue-id</i>] global configuration command.</p> |
| Step 5 | interface <i>interface-id</i> Example: <pre>Device(config)# interface gigabitethernet1/0/1</pre> | Specifies the port of the outbound traffic, and enter interface configuration mode. |
| Step 6 | queue-set <i>qset-id</i> Example: <pre>Device(config-id)# queue-set 2</pre> | Maps the port to a queue-set. For <i>qset-id</i> , enter the ID of the queue-set specified in Step 2. The range is 1 to 2. The default is 1. |
| Step 7 | end Example: <pre>Device(config-id)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | show mls qos interface [<i>interface-id</i>] buffers Example: <pre>Device# show mls qos interface buffers</pre> | Verifies your entries. |
| Step 9 | copy running-config startup-config Example: <pre>Device# copy-running-config</pre> | (Optional) Saves your entries in the configuration file. To return to the default setting, use the no mls qos queue-set output <i>qset-id</i> buffers global |

| | Command or Action | Purpose |
|--|-----------------------------|--|
| | <code>startup-config</code> | configuration command. To return to the default WTD threshold percentages, use the no mls qos queue-set output <i>qset-id</i> threshold [<i>queue-id</i>] global configuration command. |

Mapping DSCP or CoS Values to an Egress Queue and to a Threshold ID

You can prioritize traffic by placing packets with particular DSCPs or costs of service into certain queues and adjusting the queue thresholds so that packets with lower priorities are dropped.

Note The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to map DSCP or CoS values to an egress queue and to a threshold ID. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | Use one of the following: <ul style="list-style-type: none"> • <code>mls qos srr-queue output dscp-map queue <i>queue-id</i> threshold <i>threshold-id</i> <i>dscp1...dscp8</i></code> • <code>mls qos srr-queue output cos-map queue <i>queue-id</i> threshold <i>threshold-id</i> <i>cos1...cos8</i></code> Example: Device(config)# <code>mls qos srr-queue output dscp-map queue 1 threshold 2 10 11</code> | Maps DSCP or CoS values to an egress queue and to a threshold ID. By default, DSCP values 0–15 are mapped to queue 2 and threshold 1. DSCP values 16–31 are mapped to queue 3 and threshold 1. DSCP values 32–39 and 48–63 are mapped to queue 4 and threshold 1. DSCP values 40–47 are mapped to queue 1 and threshold 1. By default, CoS values 0 and 1 are mapped to queue 2 and threshold 1. CoS values 2 and 3 are mapped to queue 3 and threshold 1. CoS values 4, 6, and 7 are mapped to queue 4 and threshold 1. CoS value 5 is mapped to queue 1 and threshold 1. <ul style="list-style-type: none"> • For <i>queue-id</i>, the range is 1 to 4. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <p>Note If you enabled 8 egress queues using the mls qos srr-queue output queues 8 global configuration command, then the <i>queue-id</i> range would be from 1 to 8.</p> <ul style="list-style-type: none"> • For <i>threshold-id</i>, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state. • For <i>dscp1...dscp8</i>, enter up to eight values, and separate each value with a space. The range is 0 to 63. • For <i>cos1...cos8</i>, enter up to eight values, and separate each value with a space. The range is 0 to 7. <p>Note To return to the default DSCP output queue threshold map or the default CoS output queue threshold map, use the no mls qos srr-queue output dscp-map or the no mls qos srr-queue output cos-map global configuration command.</p> |
| Step 3 | <p>mls qos srr-queue output cos-map queue <i>queue-id</i> threshold <i>threshold-id</i> <i>cos1...cos8</i></p> <p>Example:</p> <pre>Device(config)# mls qos srr-queue output cos-map queue 3 threshold 1 2 3</pre> | <p>Maps CoS values to an egress queue and to a threshold ID.</p> <p>By default, CoS values 0 and 1 are mapped to queue 2 and threshold 1. CoS values 2 and 3 are mapped to queue 3 and threshold 1. CoS values 4, 6, and 7 are mapped to queue 4 and threshold 1. CoS value 5 is mapped to queue 1 and threshold 1.</p> <ul style="list-style-type: none"> • For <i>queue-id</i>, the range is 1 to 4. • For <i>threshold-id</i>, the range is 1 to 3. The drop-threshold percentage for threshold 3 is predefined. It is set to the queue-full state. • For <i>cos1...cos8</i>, enter up to eight values, and separate each value with a space. The range is 0 to 7. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note To return to the default CoS output queue threshold map, use the no mls qos srr-queue output cos-map global configuration command. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos maps Example: Device# show mls qos maps | Verifies your entries. The DSCP output queue threshold map appears as a matrix. The d1 column specifies the most-significant digit of the DSCP number; the d2 row specifies the least-significant digit in the DSCP number. The intersection of the d1 and the d2 values provides the queue ID and threshold ID; for example, queue 2 and threshold 1 (02-01). The CoS output queue threshold map shows the CoS value in the top row and the corresponding queue ID and threshold ID in the second row; for example, queue 2 and threshold 2 (2-2). |
| Step 6 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. To return to the default DSCP output queue threshold map or the default CoS output queue threshold map, use the no mls qos srr-queue output dscp-map or the no mls qos srr-queue output cos-map global configuration command. |

Configuring SRR Shaped Weights on Egress Queues

You can specify how much of the available bandwidth is allocated to each queue. The ratio of the weights is the ratio of frequency in which the SRR scheduler sends packets from each queue.

You can configure the egress queues for shaped or shared weights, or both. Use shaping to smooth bursty traffic or to provide a smoother output over time.

Beginning in privileged EXEC mode, follow these steps to assign the shaped weights and to enable bandwidth shaping on the four egress queues mapped to a port. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id Example: Device(config)# interface gigabitethernet2/0/1 | Specifies the port of the outbound traffic, and enters interface configuration mode. |
| Step 3 | srr-queue bandwidth shape weight1 weight2 weight3 weight4 Example: Device(config-if)# srr-queue bandwidth shape 8 0 0 0 | <p>Assigns SRR weights to the egress queues. By default, weight1 is set to 25; weight2, weight3, and weight4 are set to 0, and these queues are in shared mode.</p> <p>For <i>weight1 weight2 weight3 weight4</i>, enter the weights to control the percentage of the port that is shaped. The inverse ratio (1/weight) controls the shaping bandwidth for this queue. Separate each value with a space. The range is 0 to 65535.</p> <p>If you configure a weight of 0, the corresponding queue operates in shared mode. The weight specified with the srr-queue bandwidth shape command is ignored, and the weights specified with the srr-queue bandwidth share interface configuration command for a queue come into effect. When configuring queues in the same queue-set for both shaping and sharing, make sure that you configure the lowest number queue for shaping. The shaped mode overrides the shared mode.</p> <p>To return to the default setting, use the no srr-queue bandwidth shape interface configuration command.</p> <p>Note If you enabled 8 egress queues using the mls qos srr-queue output queues 8 global configuration command, then you would be able to assign SRR weights to a total of 8 queues.</p> |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 4 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface <i>interface-id</i> queuing Example: Device# show mls qos interface interface-id queuing | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. To return to the default setting, use the no srr-queue bandwidth shape interface configuration command. |

Configuring SRR Shared Weights on Egress Queues

In shared mode, the queues share the bandwidth among them according to the configured weights. The bandwidth is guaranteed at this level but not limited to it. For example, if a queue empties and does not require a share of the link, the remaining queues can expand into the unused bandwidth and share it among them. With sharing, the ratio of the weights controls the frequency of dequeuing; the absolute values are meaningless.

Note The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to assign the shared weights and to enable bandwidth sharing on the four egress queues mapped to a port. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device (config) # interface | Specifies the port of the outbound traffic, and enters interface configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <code>gigabitethernet2/0/1</code> | |
| Step 3 | <p>srr-queue bandwidth share <i>weight1 weight2 weight3 weight4</i></p> <p>Example:</p> <pre>Device(config-id)# srr-queue bandwidth share 1 2 3 4</pre> | <p>Assigns SRR weights to the egress queues. By default, all four weights are 25 (1/4 of the bandwidth is allocated to each queue).</p> <p>For <i>weight1 weight2 weight3 weight4</i>, enter the weights to control the ratio of the frequency in which the SRR scheduler sends packets. Separate each value with a space. The range is 1 to 255.</p> <p>To return to the default setting, use the no srr-queue bandwidth share interface configuration command.</p> <p>Note If you enabled 8 egress queues using the mls qos srr-queue output queues 8 global configuration command, then you would be able to assign SRR weights to a total of 8 queues.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config-id)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>show mls qos interface <i>interface-id queuing</i></p> <p>Example:</p> <pre>Device# show mls qos interface interface_id queuing</pre> | Verifies your entries. |
| Step 6 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy-running-config startup-config</pre> | <p>(Optional) Saves your entries in the configuration file.</p> <p>To return to the default setting, use the no srr-queue bandwidth share interface configuration command.</p> |

Configuring the Egress Expedite Queue

You can ensure that certain packets have priority over all others by queuing them in the egress expedite queue. SRR services this queue until it is empty before servicing the other queues.

Beginning in privileged EXEC mode, follow these steps to enable the egress expedite queue. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | mls qos Example: Device(config)# mls qos | Enables QoS on a switch. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1 | Specifies the egress port, and enters interface configuration mode. |
| Step 4 | priority-queue out Example: Device(config-if)# priority-queue out | <p>Enables the egress expedite queue, which is disabled by default.</p> <p>When you configure this command, the SRR weight and queue size ratios are affected because there is one fewer queue participating in SRR. This means that <i>weight1</i> in the srr-queue bandwidth shape or the srr-queue bandwidth share command is ignored (not used in the ratio calculation).</p> <p>Note To disable the egress expedite queue, use the no priority-queue out interface configuration command.</p> |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 7 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. To disable the egress expedite queue, use the no priority-queue out interface configuration command. |

Limiting the Bandwidth on an Egress Interface

You can limit the bandwidth on an egress port. For example, if a customer pays only for a small percentage of a high-speed link, you can limit the bandwidth to that amount.

Note The egress queue default settings are suitable for most situations. You should change them only when you have a thorough understanding of the egress queues and if these settings do not meet your QoS solution.

Beginning in privileged EXEC mode, follow these steps to limit the bandwidth on an egress port. This procedure is optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: <pre>Device(config)# interface gigabitethernet2/0/1</pre> | Specifies the port to be rate-limited, and enters interface configuration mode. |
| Step 3 | srr-queue bandwidth limit <i>weight1</i> Example: <pre>Device(config-if)# srr-queue bandwidth limit 80</pre> | Specifies the percentage of the port speed to which the port should be limited. The range is 10 to 90. By default, the port is not rate-limited and is set to 100 percent. Note To return to the default setting, use the no srr-queue bandwidth limit interface configuration command. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | end Example: Device (config-if) # end | Returns to privileged EXEC mode. |
| Step 5 | show mls qos interface <i>[interface-id]</i> queueing Example: Device# show mls qos interface interface_id queueing | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy-running-config startup-config | (Optional) Saves your entries in the configuration file. To return to the default setting, use the no srr-queue bandwidth limit interface configuration command. |

Monitoring Standard QoS

Table 71: Commands for Monitoring Standard QoS on the Switch

| Command | Description |
|--|--|
| show class-map <i>[class-map-name]</i> | Displays QoS class maps, which define the match criteria traffic. |
| show mls qos | Displays global QoS configuration information. |
| show mls qos aggregate-policer <i>[aggregate-policer-name]</i> | Displays the aggregate policer configuration. |
| show mls qos interface <i>[interface-id]</i> [buffers policers queueing statistics] | Displays QoS information at the port level, including the allocation, which ports have configured policers, the queue strategy, and the ingress and egress statistics. |
| show mls qos maps [cos-dscp cos-output-q dscp-cos dscp-mutation <i>dscp-mutation-name</i> dscp-output-q ip-prec-dscp policed-dscp] | Displays QoS mapping information. |
| show mls qos queue-set <i>[qset-id]</i> | Displays QoS settings for the egress queues. |

| Command | Description |
|---|---|
| <code>show policy-map [policy-map-name [class class-map-name]]</code> | Displays QoS policy maps, which define classification of incoming traffic. Do not use the <code>show policy-map interface</code> privileged command to display classification information for interfaces. The <code>control-plane</code> and <code>interface</code> keywords are not supported. The statistics shown in the display should be ignored. |
| <code>show running-config include rewrite</code> | Displays the DSCP transparency setting. |

Configuration Examples for QoS

Example: Configuring Port to the DSCP-Trusted State and Modifying the DSCP-to-DSCP-Mutation Map

This example shows how to configure a port to the DSCP-trusted state and to modify the DSCP-to-DSCP-mutation map (named *gi1/0/2-mutation*) so that incoming DSCP values 10 to 13 are mapped to DSCP 30:

```
Device(config)# mls qos map dscp-mutation gigabitethernet1/0/2-mutation
10 11 12 13 to 30
Device(config)# interface gigabitethernet1/0/2
Device(config-if)# mls qos trust dscp
Device(config-if)# mls qos dscp-mutation gigabitethernet1/0/2-mutation
Device(config-if)# end
```

Examples: Classifying Traffic by Using ACLs

This example shows how to allow access for only those hosts on the three specified networks. The wildcard bits apply to the host portions of the network addresses. Any host with a source address that does not match the access list statements is rejected.

```
Device(config)# access-list 1 permit 192.5.255.0 0.0.0.255
Device(config)# access-list 1 permit 128.88.0.0 0.0.255.255
Device(config)# access-list 1 permit 36.0.0.0 0.0.0.255
! (Note: all other access implicitly denied)
```

This example shows how to create an ACL that permits IP traffic from any source to any destination that has the DSCP value set to 32:

```
Device(config)# access-list 100 permit ip any any dscp 32
```

This example shows how to create an ACL that permits IP traffic from a source host at 10.1.1.1 to a destination host at 10.1.1.2 with a precedence value of 5:

```
Device(config)# access-list 100 permit ip host 10.1.1.1 host 10.1.1.2 precedence 5
```

This example shows how to create an ACL that permits PIM traffic from any source to a destination group address of 224.0.0.2 with a DSCP set to 32:

```
Device(config)# access-list 102 permit pim any 224.0.0.2 dscp 32
```

This example shows how to create an ACL that permits IPv6 traffic from any source to any destination that has the DSCP value set to 32:

```
Device(config)# ipv6 access-list 100 permit ip any any dscp 32
```

This example shows how to create an ACL that permits IPv6 traffic from a source host at 10.1.1.1 to a destination host at 10.1.1.2 with a precedence value of 5:

```
Device(config)# ipv6 access-list ipv6_Name_ACL permit ip host 10::1 host 10.1.1.2
precedence 5
```

This example shows how to create a Layer 2 MAC ACL with two permit statements. The first statement allows traffic from the host with MAC address 0001.0000.0001 to the host with MAC address 0002.0000.0001. The second statement allows only Ethertype XNS-IDP traffic from the host with MAC address 0001.0000.0002 to the host with MAC address 0002.0000.0002.

```
Device(config)# mac access-list extended maclist1
Device(config-ext-macl)# permit 0001.0000.0001 0.0.0 0002.0000.0001 0.0.0
Device(config-ext-macl)# permit 0001.0000.0002 0.0.0 0002.0000.0002 0.0.0 xns-idp
! (Note: all other access implicitly denied)
```

Examples: Classifying Traffic by Using Class Maps

This example shows how to configure the class map called *class1*. The *class1* has one match criterion, which is access list 103. It permits traffic from any host to any destination that matches a DSCP value of 10.

```
Device(config)# access-list 103 permit ip any any dscp 10
Device(config)# class-map class1
Device(config-cmap)# match access-group 103
Device(config-cmap)# end
Device#
```

This example shows how to create a class map called *class2*, which matches incoming traffic with DSCP values of 10, 11, and 12.

```
Device(config)# class-map class2
Device(config-cmap)# match ip dscp 10 11 12
Device(config-cmap)# end
Device#
```

This example shows how to create a class map called *class3*, which matches incoming traffic with IP-precedence values of 5, 6, and 7:

```

Device(config)# class-map class3
Device(config-cmap)# match ip precedence 5 6 7
Device(config-cmap)# end
Device#

```

This example shows how to configure a class map to match IP DSCP and IPv6:

```

Device(config)# Class-map cm-1
Device(config-cmap)# match ip dscp 10
Device(config-cmap)# match protocol ipv6
Device(config-cmap)# exit
Device(config)# Class-map cm-2
Device(config-cmap)# match ip dscp 20
Device(config-cmap)# match protocol ip
Device(config-cmap)# exit
Device(config)# Policy-map pml
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# set dscp 6
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface G1/0/1
Device(config-if)# service-policy input pml

```

This example shows how to configure a class map that applies to both IPv4 and IPv6 traffic:

```

Device(config)# ip access-list 101 permit ip any any
Device(config)# ipv6 access-list ipv6-any permit ip any any
Device(config)# Class-map cm-1
Device(config-cmap)# match access-group 101
Device(config-cmap)# exit
Device(config)# class-map cm-2
Device(config-cmap)# match access-group name ipv6-any
Device(config-cmap)# exit
Device(config)# Policy-map pml
Device(config-pmap)# class cm-1
Device(config-pmap-c)# set dscp 4
Device(config-pmap-c)# exit
Device(config-pmap)# class cm-2
Device(config-pmap-c)# set dscp 6
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface G0/1
Device(config-if)# switch mode access
Device(config-if)# service-policy input pml

```

Examples: Classifying, Policing, and Marking Traffic on Physical Ports Using Policy Maps

This example shows how to create a policy map and attach it to an ingress port. In the configuration, the IP standard ACL permits traffic from network 10.1.0.0. For traffic matching this classification, the DSCP value

in the incoming packet is trusted. If the matched traffic exceeds an average traffic rate of 48000 b/s and a normal burst size of 8000 bytes, its DSCP is marked down (based on the policed-DSCP map) and sent:

```
Device(config)# access-list 1 permit 10.1.0.0 0.0.255.255
Device(config)# class-map ipclass1
Device(config-cmap)# match access-group 1
Device(config-cmap)# exit
Device(config)# policy-map flow1t
Device(config-pmap)# class ipclass1
Device(config-pmap-c)# trust dscp
Device(config-pmap-c)# police 1000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# service-policy input flow1t
```

This example shows how to create a Layer 2 MAC ACL with two permit statements and attach it to an ingress port. The first permit statement allows traffic from the host with MAC address 0001.0000.0001 destined for the host with MAC address 0002.0000.0001. The second permit statement allows only Ethernet XNS-IDP traffic from the host with MAC address 0001.0000.0002 destined for the host with MAC address 0002.0000.0002.

```
Device(config)# mac access-list extended maclist1
Device(config-ext-mac)# permit 0001.0000.0001 0.0.0 0002.0000.0001 0.0.0
Device(config-ext-mac)# permit 0001.0000.0002 0.0.0 0002.0000.0002 0.0.0 xns-idp
Device(config-ext-mac)# exit
Device(config)# mac access-list extended maclist2
Device(config-ext-mac)# permit 0001.0000.0003 0.0.0 0002.0000.0003 0.0.0
Device(config-ext-mac)# permit 0001.0000.0004 0.0.0 0002.0000.0004 0.0.0 aarp
Device(config-ext-mac)# exit
Device(config)# class-map macclass1
Device(config-cmap)# match access-group maclist1
Device(config-cmap)# exit
Device(config)# policy-map macpolicy1
Device(config-pmap)# class macclass1
Device(config-pmap-c)# set dscp 63
Device(config-pmap-c)# exit
Device(config-pmap)# class macclass2 maclist2
Device(config-pmap-c)# set dscp 45
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# mls qos trust cos
Device(config-if)# service-policy input macpolicy1
```

This example shows how to create a class map that applies to both IPv4 and IPv6 traffic with the default class applied to unclassified traffic:

```
Device(config)# ip access-list 101 permit ip any any
Device(config)# ipv6 access-list ipv6-any permit ip any any
Device(config)# class-map cm-1
Device(config-cmap)# match access-group 101
Device(config-cmap)# exit
Device(config)# class-map cm-2
Device(config-cmap)# match access-group name ipv6-any
Device(config-cmap)# exit
Device(config)# policy-map pm1
```

```

Device(config-pmap) # class cm-1
Device(config-pmap-c) # set dscp 4
Device(config-pmap-c) # exit
Device(config-pmap) # class cm-2
Device(config-pmap-c) # set dscp 6
Device(config-pmap-c) # exit
Device(config-pmap) # class class-default
Device(config-pmap-c) # set dscp 10
Device(config-pmap-c) # exit
Device(config-pmap) # exit
Device(config) # interface G0/1
Device(config-if) # switch mode access
Device(config-if) # service-policy input pml

```

Examples: Classifying, Policing, and Marking Traffic by Using Aggregate Policers

This example shows how to create an aggregate policer and attach it to multiple classes within a policy map. In the configuration, the IP ACLs permit traffic from network 10.1.0.0 and from host 11.3.1.1. For traffic coming from network 10.1.0.0, the DSCP in the incoming packets is trusted. For traffic coming from host 11.3.1.1, the DSCP in the packet is changed to 56. The traffic rate from the 10.1.0.0 network and from host 11.3.1.1 is policed. If the traffic exceeds an average rate of 48000 b/s and a normal burst size of 8000 bytes, its DSCP is marked down (based on the policed-DSCP map) and sent. The policy map is attached to an ingress port.

```

Device(config) # access-list 1 permit 10.1.0.0 0.0.255.255
Device(config) # access-list 2 permit 11.3.1.1
Device(config) # mls qos aggregate-police transmit1 48000 8000 exceed-action
policed-dscp-transmit
Device(config) # class-map ipclass1
Device(config-cmap) # match access-group 1
Device(config-cmap) # exit
Device(config) # class-map ipclass2
Device(config-cmap) # match access-group 2
Device(config-cmap) # exit
Device(config) # policy-map aggflow1
Device(config-pmap) # class ipclass1
Device(config-pmap-c) # trust dscp
Device(config-pmap-c) # police aggregate transmit1
Device(config-pmap-c) # exit
Device(config-pmap) # class ipclass2
Device(config-pmap-c) # set dscp 56
Device(config-pmap-c) # police aggregate transmit1
Device(config-pmap-c) # exit
Device(config-pmap) # class class-default
Device(config-pmap-c) # set dscp 10
Device(config-pmap-c) # exit
Device(config-pmap) # exit
Device(config) # interface gigabitethernet2/0/1
Device(config-if) # service-policy input aggflow1
Device(config-if) # exit

```

Examples: Configuring DSCP Maps

This example shows how to modify and display the CoS-to-DSCP map:

```
Device(config)# mls qos map cos-dscp 10 15 20 25 30 35 40 45
Device(config)# end
Device# show mls qos maps cos-dscp

Cos-dscp map:
  cos:   0  1  2  3  4  5  6  7
-----
  dscp:  10 15 20 25 30 35 40 45
```

This example shows how to modify and display the IP-precedence-to-DSCP map:

```
Device(config)# mls qos map ip-prec-dscp 10 15 20 25 30 35 40 45
Device(config)# end
Device# show mls qos maps ip-prec-dscp

IpPrecedence-dscp map:
  ipprec:  0  1  2  3  4  5  6  7
-----
  dscp:   10 15 20 25 30 35 40 45
```

This example shows how to map DSCP 50 to 57 to a marked-down DSCP value of 0:

```
Device(config)# mls qos map policed-dscp 50 51 52 53 54 55 56 57 to 0
Device(config)# end
Device# show mls qos maps policed-dscp

Policed-dscp map:
  d1 : d2 0  1  2  3  4  5  6  7  8  9
-----
  0 :   00 01 02 03 04 05 06 07 08 09
  1 :   10 11 12 13 14 15 16 17 18 19
  2 :   20 21 22 23 24 25 26 27 28 29
  3 :   30 31 32 33 34 35 36 37 38 39
  4 :   40 41 42 43 44 45 46 47 48 49
  5 :   00 00 00 00 00 00 00 00 58 59
  6 :   60 61 62 63
```

Note In this policed-DSCP map, the marked-down DSCP values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the original DSCP; the d2 row specifies the least-significant digit of the original DSCP. The intersection of the d1 and d2 values provides the marked-down value. For example, an original DSCP value of 53 corresponds to a marked-down DSCP value of 0.

This example shows how to map DSCP values 0, 8, 16, 24, 32, 40, 48, and 50 to CoS value 0 and to display the map:

```
Device(config)# mls qos map dscp-cos 0 8 16 24 32 40 48 50 to 0
Device(config)# end
Device# show mls qos maps dscp-cos

Dscp-cos map:
  d1 : d2 0  1  2  3  4  5  6  7  8  9
```

```

-----
0 : 00 00 00 00 00 00 00 00 00 01
1 : 01 01 01 01 01 01 00 02 02 02
2 : 02 02 02 02 00 03 03 03 03 03
3 : 03 03 00 04 04 04 04 04 04 04
4 : 00 05 05 05 05 05 05 05 00 06
5 : 00 06 06 06 06 06 07 07 07 07
6 : 07 07 07 07

```

Note In the above DSCP-to-CoS map, the CoS values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the DSCP; the d2 row specifies the least-significant digit of the DSCP. The intersection of the d1 and d2 values provides the CoS value. For example, in the DSCP-to-CoS map, a DSCP value of 08 corresponds to a CoS value of 0.

This example shows how to define the DSCP-to-DSCP-mutation map. All the entries that are not explicitly configured are not modified (remains as specified in the null map):

```

Device(config)# mls qos map dscp-mutation mutation1 1 2 3 4 5 6 7 to 0
Device(config)# mls qos map dscp-mutation mutation1 8 9 10 11 12 13 to 10
Device(config)# mls qos map dscp-mutation mutation1 20 21 22 to 20
Device(config)# mls qos map dscp-mutation mutation1 30 31 32 33 34 to 30
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# mls qos trust dscp
Device(config-if)# mls qos dscp-mutation mutation1
Device(config-if)# end
Device# show mls qos maps dscp-mutation mutation1
Dscp-dscp mutation map:
  mutation1:
    d1 : d2 0  1  2  3  4  5  6  7  8  9
-----
0 : 00 00 00 00 00 00 00 00 00 10 10
1 : 10 10 10 10 14 15 16 17 18 19
2 : 20 20 20 23 24 25 26 27 28 29
3 : 30 30 30 30 30 35 36 37 38 39
4 : 40 41 42 43 44 45 46 47 48 49
5 : 50 51 52 53 54 55 56 57 58 59
6 : 60 61 62 63

```

Note In the above DSCP-to-DSCP-mutation map, the mutated values are shown in the body of the matrix. The d1 column specifies the most-significant digit of the original DSCP; the d2 row specifies the least-significant digit of the original DSCP. The intersection of the d1 and d2 values provides the mutated value. For example, a DSCP value of 12 corresponds to a mutated value of 10.

Examples: Configuring Ingress Queue Characteristics

This example shows how to map DSCP values 0 to 6 to ingress queue 1 and to threshold 1 with a drop threshold of 50 percent. It maps DSCP values 20 to 26 to ingress queue 1 and to threshold 2 with a drop threshold of 70 percent:

```
Device(config)# mls qos srr-queue input dscp-map queue 1 threshold 1 0 1 2 3 4 5 6
```

```
Device(config)# mls qos srr-queue input dscp-map queue 1 threshold 2 20 21 22 23 24
25 26
Device(config)# mls qos srr-queue input threshold 1 50 70
```

In this example, the DSCP values (0 to 6) are assigned the WTD threshold of 50 percent and will be dropped sooner than the DSCP values (20 to 26) assigned to the WTD threshold of 70 percent.

This example shows how to allocate 60 percent of the buffer space to ingress queue 1 and 40 percent of the buffer space to ingress queue 2:

```
Device(config)# mls qos srr-queue input buffers 60 40
```

This example shows how to assign the ingress bandwidth to the queues. Priority queuing is disabled, and the shared bandwidth ratio allocated to queue 1 is 25/(25+75) and to queue 2 is 75/(25+75):

```
Device(config)# mls qos srr-queue input priority-queue 2 bandwidth 0
Device(config)# mls qos srr-queue input bandwidth 25 75
```

This example shows how to assign the ingress bandwidths to the queues. Queue 1 is the priority queue with 10 percent of the bandwidth allocated to it. The bandwidth ratios allocated to queues 1 and 2 is 4/(4+4). SRR services queue 1 (the priority queue) first for its configured 10 percent bandwidth. Then SRR equally shares the remaining 90 percent of the bandwidth between queues 1 and 2 by allocating 45 percent to each queue:

```
Device(config)# mls qos srr-queue input priority-queue 1 bandwidth 10
Device(config)# mls qos srr-queue input bandwidth 4 4
```

Examples: Configuring Egress Queue Characteristics

This example shows how to map DSCP values 10 and 11 to egress queue 1 and to threshold 2:

```
Device(config)# mls qos srr-queue output dscp-map queue 1 threshold 2 10 11
```

This example shows how to configure bandwidth shaping on queue 1. Because the weight ratios for queues 2, 3, and 4 are set to 0, these queues operate in shared mode. The bandwidth weight for queue 1 is 1/8, which is 12.5 percent:

```
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth shape 8 0 0 0
```

This example shows how to configure the weight ratio of the SRR scheduler running on an egress port. Four queues are used, and the bandwidth ratio allocated for each queue in shared mode is 1/(1+2+3+4), 2/(1+2+3+4), 3/(1+2+3+4), and 4/(1+2+3+4), which is 10 percent, 20 percent, 30 percent, and 40 percent for queues 1, 2, 3, and 4. This means that queue 4 has four times the bandwidth of queue 1, twice the bandwidth of queue 2, and one-and-a-third times the bandwidth of queue 3.

```
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth share 1 2 3 4
```

This example shows how to enable the egress expedite queue when the SRR weights are configured. The egress expedite queue overrides the configured SRR weights.

```
Device(config)# interface gigabitethernet1/0/1
Device(config-if)# srr-queue bandwidth shape 25 0 0 0
Device(config-if)# srr-queue bandwidth share 30 20 25 25
Device(config-if)# priority-queue out
Device(config-if)# end
```

This example shows how to limit the bandwidth on a port to 80 percent:

```
Device(config)# interface gigabitethernet2/0/1
Device(config-if)# srr-queue bandwidth limit 80
```

When you configure this command to 80 percent, the port is idle 20 percent of the time. The line rate drops to 80 percent of the connected speed, which is 800 Mb/s. These values are not exact because the hardware adjusts the line rate in increments of six.

Where to Go Next

Review the auto-QoS documentation to see if you can use these automated capabilities for your QoS configuration.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Auto-QoS

Before configuring standard QoS or auto-QoS, you must have a thorough understanding of these items:

- The types of applications used and the traffic patterns on your network.
- Traffic characteristics and needs of your network. Is the traffic bursty? Do you need to reserve bandwidth for voice and video streams?
- Bandwidth requirements and speed of the network.
- Location of congestion points in the network.

Restrictions for Auto-QoS

The following are restrictions for automatic QoS (auto-QoS):

- Auto-QoS (and enhanced auto-QoS) is not supported on switches running the LAN Lite image.

Information about Configuring Auto-QoS

Auto-QoS Overview

You can use the auto-QoS feature to simplify the deployment of QoS features. Auto-QoS determines the network design and enables QoS configurations so that the switch can prioritize different traffic flows. It uses the egress queues instead of using the default (disabled) QoS behavior. The switch offers best-effort service to each packet, regardless of the packet contents or size, and sends it from a single queue.

When you enable auto-QoS, it automatically classifies traffic based on the traffic type and ingress packet label. The switch uses the classification results to choose the appropriate egress queue.

You can use auto-QoS commands to identify ports connected to the following Cisco devices:

- Cisco IP Phones
- Devices running the Cisco SoftPhone application
- Cisco TelePresence
- Cisco IP Camera
- Cisco digital media player

You also use the auto-QoS commands to identify ports that receive trusted traffic through an uplink. Auto-QoS then performs these functions:

- Detects the presence or absence of auto-QoS devices through conditional trusted interfaces.
- Configures QoS classification
- Configures egress queues

Auto-QoS Compact Overview

When you enter an auto-QoS command, the switch displays all the generated commands as if the commands were entered from the CLI. You can use the auto-QoS compact feature to hide the auto-QoS generated commands from the running configuration. This would make it easier to comprehend the running-configuration and also help to increase efficient usage of memory.

Generated Auto-QoS Configuration

By default, auto-QoS is disabled on all ports. Packets are not modified--the CoS, DSCP and IP precedence values in the packet are not changed.

When you enable the auto-QoS feature on the first port of the interface:

- Ingress packet label is used to categorize traffic, to assign packet labels, and to configure the ingress and egress queues.
- QoS is globally enabled (**mls qos** global configuration command), and other global configuration commands are automatically generated. (See [Examples: Global Auto-QoS Configuration, on page 585](#)).
- Switch enables the trusted boundary feature and uses the Cisco Discovery Protocol (CDP) to detect the presence of a supported device.
- Policing is used to determine whether a packet is in or out of profile and specifies the action on the packet.

VoIP Device Specifics

The following activities occur when you issue these auto-QoS commands on a port:

- When you enter the **auto qos voip cisco-phone** command on a port at the network edge connected to a Cisco IP Phone, the switch enables the trusted boundary feature. If the packet does not have a DSCP value of 24, 26, or 46 or is out of profile, the switch changes the DSCP value to 0. When there is no Cisco IP Phone, the ingress classification is set to not trust the QoS label in the packet. The policing is applied to the traffic matching the policy-map classification before the switch enables the trust boundary feature.
- When you enter the **auto qos voip cisco-softphone** interface configuration command on a port at the network edge that is connected to a device running the Cisco SoftPhone, the switch uses policing to determine whether a packet is in or out of profile and to specify the action on the packet. If the packet does not have a DSCP value of 24, 26, or 46 or is out of profile, the switch changes the DSCP value to 0.
- When you enter the **auto qos voip trust** interface configuration command on a port connected to the network interior, the switch trusts the CoS value for nonrouted ports or the DSCP value for routed ports in ingress packets (the assumption is that traffic has already been classified by other edge devices).

Table 72: Traffic Types, Packet Labels, and Queues

| | VoIP Data Traffic | VoIP Control Traffic | Routing Protocol Traffic | STP BPDU Traffic | Real-Time Video Traffic | All Other Traffic |
|--------------------------|-------------------|----------------------|--------------------------|------------------|-------------------------|-------------------|
| DSCP value | 46 | 24, 26 | 48 | 56 | 34 | – |
| CoS value | 5 | 3 | 6 | 7 | 3 | – |
| CoS-to-Ingress queue map | 4, 5 (queue 2) | | | | | 0, 1, 2, 3, 6, 7 |
| CoS-to-Egress queue map | 4, 5 (queue 1) | 2, 3, 6, 7 (queue 2) | | | 0 (queue 3) | 2 (queue 3) |

The switch configures ingress queues on the port according to the settings in the following table. This table shows the generated auto-QoS configuration for the ingress queues.

Table 73: Auto-QoS Configuration for the Ingress Queues

| Ingress Queue | Queue Number | CoS-to-Queue Map | Queue Weight (Bandwidth) | Queue Size for Gigabit-Ports |
|---------------|--------------|------------------|--------------------------|------------------------------|
| SRR shared | 1 | 0, 1, 2, 3, 6, 7 | 70 percent | 90 percent |
| Priority | 2 | 4, 5 | 30 percent | 10 percent |

The switch configures egress queues on the port according to the settings in the following table. This table shows the generated auto-QoS configuration for the egress queues.

Table 74: Auto-QoS Configuration for the Egress Queues

| Egress Queue | Queue Number | Queue Weight (Bandwidth) | Queue Size for Gigabit-Ports |
|--------------|--------------|--------------------------|------------------------------|
| Priority | 1 | up to 100 percent | 25 percent |
| SRR shared | 2 | 10 percent | 25 percent |
| SRR shared | 3 | 60 percent | 25 percent |
| SRR shared | 4 | 20 percent | 25 percent |

- When you enable auto-QoS by using the **auto qos voip cisco-phone**, the **auto qos voip cisco-softphone**, or the **auto qos voip trust** interface configuration command, the switch automatically generates a QoS configuration based on the traffic type and ingress packet label and applies the commands listed in [Examples: Global Auto-QoS Configuration, on page 585](#) to the port.

Enhanced Auto-QoS for Video, Trust, and Classification

Auto-QoS is enhanced to support video. Automatic configurations are generated that classify and trust traffic from Cisco TelePresence systems and Cisco IP cameras.

Auto-QoS Configuration Migration

Auto-QoS configuration migration from legacy auto-QoS to enhanced auto-QoS occurs when:

- A switch is booted with a 12.2(55)SE image and QoS is not enabled.
 - Any video or voice trust configuration on the interface automatically generates enhanced auto-QoS commands.
- A switch is enabled with QoS, these guidelines take effect:
 - If you configure the interface for conditional trust on a voice device, only the legacy auto-QoS VoIP configuration is generated.

- If you configure the interface for conditional trust on a video device, the enhanced auto-QoS configuration is generated.
- If you configure the interface with classification or conditional trust based on the new interface auto-QoS commands, enhanced auto-QoS configuration is generated.
- Auto-QoS migration happens after a new device is connected when the **auto qos srnd4** global configuration command is enabled.

Note If an interface previously configured with legacy auto-QoS migrates to enhanced auto-QoS, voice commands and configuration are updated to match the new global QoS commands.

Auto-QoS configuration migration from enhanced auto-QoS to legacy auto-QoS can occur only when you disable all existing auto-QoS configurations from the interface.

Auto-QoS Configuration Guidelines

Before configuring auto-QoS, you should be aware of this information:

- After auto-QoS is enabled, do not modify a policy map that includes *AutoQoS* in its name. If you need to modify the policy map, make a copy of it, and change the copied policy map. To use this new policy map instead of the generated one, remove the generated policy map from the interface, and apply the new policy map to the interface.
- To take advantage of the auto-QoS defaults, you should enable auto-QoS before you configure other QoS commands. If necessary, you can fine-tune the QoS configuration, but we recommend that you do so only after the auto-QoS configuration is completed.
- You can enable auto-QoS on static, dynamic-access, voice VLAN access, and trunk ports.
- By default, the CDP is enabled on all ports. For auto-QoS to function properly, do not disable CDP.

Auto-QoS VoIP Considerations

Before configuring auto-QoS for VoIP, you should be aware of this information:

- Auto-QoS configures the switch for VoIP with Cisco IP Phones on nonrouted and routed ports. Auto-QoS also configures the switch for VoIP with devices running the Cisco SoftPhone application.

Note When a device running Cisco SoftPhone is connected to a nonrouted or routed port, the switch supports only one Cisco SoftPhone application per port.

- When enabling auto-QoS with a Cisco IP Phone on a routed port, you must assign a static IP address to the IP phone.
- This release supports only Cisco IP SoftPhone Version 1.3(3) or later.
- Connected devices must use Cisco Call Manager Version 4 or later.

Auto-QoS Enhanced Considerations

Auto-QoS is enhanced to support video. Automatic configurations are generated that classify and trust traffic from Cisco TelePresence systems and Cisco IP cameras.

Before configuring auto-QoS enhanced, you should be aware of this information:

- The **auto qos srnd4** global configuration command is generated as a result of enhanced auto-QoS configuration.

Effects of Auto-QoS on Running Configuration

When auto-QoS is enabled, the **auto qos** interface configuration commands and the generated global configuration are added to the running configuration.

The switch applies the auto-QoS-generated commands as if the commands were entered from the CLI. An existing user configuration can cause the application of the generated commands to fail or to be overridden by the generated commands. These actions may occur without warning. If all the generated commands are successfully applied, any user-entered configuration that was not overridden remains in the running configuration. Any user-entered configuration that was overridden can be retrieved by reloading the switch without saving the current configuration to memory. If the generated commands are not applied, the previous running configuration is restored.

Effects of Auto-QoS Compact on Running Configuration

If auto-QoS compact is enabled:

- Only the auto-QoS commands entered from the CLI are displayed in running-config.
- The generated global and interface configurations are hidden.
- When you save the configuration, only the auto-qos commands you have entered are saved (and not the hidden configuration).
- When you reload the switch, the system detects and re-executes the saved auto-QoS commands and the AutoQoS SRND4.0 compliant config-set is generated .

Note Do not make changes to the auto-QoS-generated commands when auto-QoS compact is enabled, because user-modifications are overridden when the switch reloads.

When auto-qos global compact is enabled:

- **show derived-config** command can be used to view hidden AQC derived commands.
- AQC commands will not be stored to memory. They will be regenerated every time the switch is reloaded.
- When compaction is enabled, auto-qos generated commands should not be modified .
- If the interface is configured with auto-QoS and if AQC needs to be disabled, auto-qos should be disabled at interface level first.

How to Configure Auto-QoS

Configuring Auto-QoS

Enabling Auto-QoS

For optimum QoS performance, enable auto-QoS on all the devices in your network.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface interface-id Example: Device(config)# interface gigabitethernet 3/0/1 | Specifies the port that is connected to a video device or the uplink port that is connected to another trusted switch or router in the network interior, and enters interface configuration mode. |
| Step 3 | Use one of the following: <ul style="list-style-type: none"> • auto qos voip {cisco-phone cisco-softphone trust} • auto qos video {cts ip-camera media-player} • auto qos classify [police] • auto qos trust {cos dscp} Example: Device(config-if)# auto qos trust dscp | Enables auto-QoS for VoIP. <ul style="list-style-type: none"> • cisco-phone—If the port is connected to a Cisco IP Phone, the QoS labels of incoming packets are trusted only when the telephone is detected. • cisco-softphone—The port is connected to device running the Cisco SoftPhone feature. • trust—The uplink port is connected to a trusted switch or router, and the VoIP traffic classification in the ingress packet is trusted. Enables auto-QoS for a video device. <ul style="list-style-type: none"> • cts—A port connected to a Cisco Telepresence system. • ip-camera—A port connected to a Cisco video surveillance camera. • media-player—A port connected to a CDP-capable Cisco digital media player. |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <p>QoS labels of incoming packets are trusted only when the system is detected.</p> <p>Enables auto-QoS for classification.</p> <ul style="list-style-type: none"> • police—Policing is set up by defining the QoS policy maps and applying them to ports (port-based QoS). <p>Enables auto-QoS for trusted interfaces.</p> <ul style="list-style-type: none"> • cos—Class of service. • dscp—Differentiated Services Code Point. • <cr>—Trust interface. <p>Note To view a list of commands that are automatically generated by issuing one of the auto-QoS commands listed here, you need to be in debug mode. Refer to the <i>Catalyst 2960-X Switch QoS Command Reference Guide, Cisco IOS Release 15.0(2)EX</i> for examples of how to run the appropriate debug command to view a list of these commands.</p> |
| Step 4 | <p>exit</p> <p>Example:</p> <pre>Device(config-if)# exit</pre> | Returns to global configuration mode. |
| Step 5 | <p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# interface gigabitethernet 2/0/1</pre> | Specifies the switch port identified as connected to a trusted switch or router, and enters interface configuration mode. |
| Step 6 | <p>auto qos trust</p> <p>Example:</p> <pre>Device(config-if)# auto qos trust</pre> | Enables auto-QoS on the port, and specifies that the port is connected to a trusted router or switch. |
| Step 7 | <p>end</p> <p>Example:</p> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config-if)# end | |
| Step 8 | show auto qos interface <i>interface-id</i> Example: Device# show auto qos interface gigabitethernet 2/0/1 | Verifies your entries. This command displays the auto-QoS command on the interface on which auto-QoS was enabled. You can use the show running-config privileged EXEC command to display the auto-QoS configuration and the user modifications. |

Enabling Auto-Qos Compact

To enable auto-Qos compact, enter this command:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | auto qos global compact Example: Device(config)# auto qos global compact | Enables auto-Qos compact and generates (hidden) the global configurations for auto-QoS. You can then enter the auto-QoS command you want to configure in the interface configuration mode and the interface commands that the system generates are also hidden. To display the auto-QoS configuration that has been applied, use these the privileged EXEC commands: <ul style="list-style-type: none"> • show derived-config • show policy-map • show access-list • show class-map • show table-map • show auto-qos • show policy-map interface • show ip access-lists These commands will have keyword "AutoQos-". |

What to do next

To disable auto-QoS compact, remove auto-QoS instances from all interfaces by entering the **no** form of the corresponding auto-QoS commands and then enter the **no auto qos global compact** global configuration command.

Troubleshooting Auto-QoS

To troubleshoot auto-QoS, use the **debug auto qos** privileged EXEC command. For more information, see the **debug auto qos** command in the command reference for this release.

To disable auto-QoS on a port, use the **no** form of the **auto qos** command interface configuration command, such as **no auto qos voip**. Only the auto-QoS-generated interface configuration commands for this port are removed. If this is the last port on which auto-QoS is enabled and you enter the **no auto qos voip** command, auto-QoS is considered disabled even though the auto-QoS-generated global configuration commands remain (to avoid disrupting traffic on other ports affected by the global configuration).

Monitoring Auto-QoS

Table 75: Commands for Monitoring Auto-QoS

| Command | Description |
|--|---|
| show auto qos [interface <i>interface-type</i>] | Displays the initial auto-QoS configuration. You can compare the show auto qos and the s to identify the user-defined QoS settings. |
| show mls qos [aggregate policer interface maps queue-set stack-port stack-qset] | Displays information about the QoS configura |
| show mls qos aggregate policer <i>policer_name</i> | Displays information about the QoS aggrega affected by auto-QoS. |
| show mls qos interface [<i>interface-type</i> buffers policers queueing statistics] | Displays information about the QoS interfac by auto-QoS. |
| show mls qos maps [cos-dscp cos-output-q dscp-cos dscp-mutation dscp-output-q ip-prec-dscp policed-dscp] | Displays information about the QoS maps co auto-QoS. |
| show mls qos queue-set <i>queue-set ID</i> | Displays information about the QoS queue-s by auto-QoS. |
| show mls qos stack-port buffers | Displays information about the QoS stack po affected by auto-QoS. |
| show mls qos stack-qset | Displays information about the QoS stack qu affected by auto-QoS. |
| show running-config | Displays information about the QoS configura You can compare the show auto qos and the s to identify the user-defined QoS settings. |

Configuration Examples for Auto-QoS

Examples: Global Auto-QoS Configuration

The following table describes the automatically generated commands for auto-QoS and enhanced auto-QoS by the switch.

Table 76: Generated Auto-QoS Configuration

| Description | Automatically Generated Command {voip} | Enhanced |
|---|---|---|
| The switch automatically enables standard QoS and configures the CoS-to-DSCP map (maps CoS values in incoming packets to a DSCP value). | <pre>Device(config)# mls qos Device(config)# mls qos map cos-dscp 0 8 16 26 32 46 48 56</pre> | <pre>Device (c Device (c 0 8 16 2</pre> |
| The switch automatically maps CoS values to an egress queue and to a threshold ID. | <pre>Device(config)# no mls qos srr-queue output cos-map Device(config)# mls qos srr-queue output cos-map queue 1 threshold 3 5 Device(config)# mls qos srr-queue output cos-map queue 2 threshold 3 3 6 7 Device(config)# mls qos srr-queue output cos-map queue 3 threshold 3 2 4 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 2 1 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 3 0</pre> | <pre>Device (c output c Device (c output c Device (c output c Device (c output c Device (c output c Device (c output c Device (c output c</pre> |

| Description | Automatically Generated Command {voip} | Enhanced Au |
|--|---|---|
| <p>The switch automatically maps DSCP values to an egress queue and to a threshold ID.</p> | <pre> Device(config)# no mls qos srr-queue output dscp-map Device(config)# mls qos srr-queue output dscp-map queue 1 threshold 3 40 41 42 43 44 45 46 47 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 24 25 26 27 28 29 30 31 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 48 49 50 51 52 53 54 55 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 56 57 58 59 60 61 62 63 Device(config)# mls qos srr-queue output dscp-map queue 3 threshold 3 16 17 18 19 20 21 22 23 Device(config)# mls qos srr-queue output dscp-map queue 3 threshold 3 32 33 34 35 36 37 38 39 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 1 8 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 2 9 10 11 12 13 14 15 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 3 0 1 2 3 4 5 6 7 </pre> | <pre> Device(confi output dscp Device(confi output dscp 33 40 41 42 Device(confi output dscp 17 18 19 20 Device(confi output dscp 27 28 29 30 Device(confi output dscp Device(confi output dscp 49 50 51 52 Device(confi output dscp 58 59 60 61 Device(confi output dscp 1 2 3 4 5 6 Device(confi output dscp 9 11 13 15 Device(confi output dscp 12 14 </pre> |

| Description | Automatically Generated Command {voip} | Enhanced |
|---|---|--|
| The switch automatically configures the egress queue buffer sizes. It configures the bandwidth and the SRR mode (shaped or shared) on the egress queues mapped to the port. | <pre> Device(config)# mls qos queue-set output 1 threshold 1 138 138 92 138 Device(config)# mls qos queue-set output 1 threshold 2 138 138 92 400 Device(config)# mls qos queue-set output 1 threshold 3 36 77 100 318 Device(config)# mls qos queue-set output 1 threshold 4 20 50 67 400 Device(config)# mls qos queue-set output 2 threshold 1 149 149 100 149 Device(config)# mls qos queue-set output 2 threshold 2 118 118 100 235 Device(config)# mls qos queue-set output 2 threshold 3 41 68 100 272 Device(config)# mls qos queue-set output 2 threshold 4 42 72 100 242 Device(config)# mls qos queue-set output 1 buffers 10 10 26 54 Device(config)# mls qos queue-set output 2 buffers 16 6 17 61 Device(config-if)# priority-queue out Device(config-if)# srr-queue bandwidth share 10 10 60 20 </pre> | <pre> Device (c output 1 Device (c output 1 Device (c output 1 Device (c output 1 Device (c output 1 Device (c output 1 </pre> |

Examples: Auto-QoS Generated Configuration for VoIP Devices

The following table describes the automatically generated commands for auto-QoS for VoIP devices by the switch.

Table 77: Generated Auto-QoS Configuration for VoIP Devices

| Description | Automatically Generated Command (VoIP) |
|---|---|
| The switch automatically enables standard QoS and configures the CoS-to-DSCP map (maps CoS values in incoming packets to a DSCP value). | <pre> Device(config)# mls qos Device(config)# mls qos map cos-dscp 0 8 16 26 32 46 48 56 </pre> |
| The switch automatically maps CoS values to an egress queue and to a threshold ID. | <pre> Device(config)# no mls qos srr-queue output cos-map Device(config)# mls qos srr-queue output cos-map queue 1 threshold 3 5 Device(config)# mls qos srr-queue output cos-map queue 2 threshold 3 3 6 7 Device(config)# mls qos srr-queue output cos-map queue 3 threshold 3 2 4 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 2 1 Device(config)# mls qos srr-queue output cos-map queue 4 threshold 3 0 </pre> |

| Description | Automatically Generated Command (VoIP) |
|---|---|
| The switch automatically maps DSCP values to an egress queue and to a threshold ID. | <pre> Device(config)# no mls qos srr-queue output dscp-map Device(config)# mls qos srr-queue output dscp-map queue 1 threshold 3 40 41 42 43 44 45 46 47 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 24 25 26 27 28 29 30 31 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 48 49 50 51 52 53 54 55 Device(config)# mls qos srr-queue output dscp-map queue 2 threshold 3 56 57 58 59 60 61 62 63 Device(config)# mls qos srr-queue output dscp-map queue 3 threshold 3 16 17 18 19 20 21 22 23 Device(config)# mls qos srr-queue output dscp-map queue 3 threshold 3 32 33 34 35 36 37 38 39 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 1 8 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 2 9 10 11 12 13 14 15 Device(config)# mls qos srr-queue output dscp-map queue 4 threshold 3 0 1 2 3 4 5 6 7 </pre> |
| The switch automatically configures the egress queue buffer sizes. It configures the bandwidth and the SRR mode (shaped or shared) on the egress queues mapped to the port. | <pre> SwitchDeviceconfig)# mls qos queue-set output 1 threshold 1 138 138 92 138 Device(config)# mls qos queue-set output 1 threshold 2 138 138 92 400 Device(config)# mls qos queue-set output 1 threshold 3 36 77 100 318 Device(config)# mls qos queue-set output 1 threshold 4 20 50 67 400 Device(config)# mls qos queue-set output 2 threshold 1 149 149 100 149 Device(config)# mls qos queue-set output 2 threshold 2 118 118 100 235 Device(config)# mls qos queue-set output 2 threshold 3 41 68 100 272 Device(config)# mls qos queue-set output 2 threshold 4 42 72 100 242 Device(config)# mls qos queue-set output 1 buffers 10 10 26 54 Device(config)# mls qos queue-set output 2 buffers 16 6 17 61 Device(config-if)# priority-que out Device(config-if)# srr-queue bandwidth share 10 10 60 20 </pre> |

If you entered the **auto qos voip cisco-phone** command, the switch automatically enables the trusted boundary feature, which uses the CDP to detect the presence or absence of a Cisco IP Phone (as shown below).

```
Device(config-if)# mls qos trust device cisco-phone
```

If you entered the **auto qos voip cisco-softphone** command, the switch automatically creates class maps and policy maps (as shown below).

```
Device(config)# mls qos map policed-dscp 24 26 46 to 0
```

```

Device(config)# class-map match-all AutoQoS-VoIP-RTP-Trust
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AutoQoS-VoIP-Control-Trust
Device(config-cmap)# match ip dscp cs3 af31
Device(config)# policy-map AutoQoS-Police-SoftPhone
Device(config-pmap)# class AutoQoS-VoIP-RTP-Trust
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 320000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AutoQoS-VoIP-Control-Trust
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit

```

After creating the class maps and policy maps, the switch automatically applies the policy map called *AutoQoS-Police-SoftPhone* to an ingress interface on which auto-QoS with the Cisco SoftPhone feature is enabled (as shown below).

```
Device(config-if)# service-policy input AutoQoS-Police-SoftPhone
```

Examples: Auto-QoS Generated Configuration for VoIP Devices

If you entered the **auto qos voip cisco-phone** command, the switch automatically enables the trusted boundary feature, which uses the CDP to detect the presence or absence of a Cisco IP Phone.

```
Device(config-if)# mls qos trust device cisco-phone
```

If you entered the **auto qos voip cisco-softphone** command, the switch automatically creates class maps and policy maps.

```

Device(config)# mls qos map policed-dscp 24 26 46 to 0
Device(config)# class-map match-all AutoQoS-VoIP-RTP-Trust
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AutoQoS-VoIP-Control-Trust
Device(config-cmap)# match ip dscp cs3 af31
Device(config)# policy-map AutoQoS-Police-SoftPhone
Device(config-pmap)# class AutoQoS-VoIP-RTP-Trust
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 320000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AutoQoS-VoIP-Control-Trust
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit

```

After creating the class maps and policy maps, the switch automatically applies the policy map called *AutoQoS-Police-SoftPhone* to an ingress interface on which auto-QoS with the Cisco SoftPhone feature is enabled.

```
Device(config-if)# service-policy input AutoQoS-Police-SoftPhone
```

If you entered the **auto qos voip cisco-phone** command, the switch automatically creates class maps and policy maps.

```
Device(config-if)# mls qos trust device cisco-phone
```

If you entered the **auto qos voip cisco-softphone** command, the switch automatically creates class maps and policy maps.

```
Device(config)# mls qos map policed-dscp 24 26 46 to 0
Device(config)# class-map match-all AutoQoS-VoIP-RTP-Trust
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AutoQoS-VoIP-Control-Trust
Device(config-cmap)# match ip dscp cs3 af31
Device(config)# policy-map AutoQoS-Police-CiscoPhone
Device(config-pmap)# class AutoQoS-VoIP-RTP-Trust
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 320000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AutoQoS-VoIP-Control-Trust
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
```

After creating the class maps and policy maps, the switch automatically applies the policy map called *AutoQoS-Police-SoftPhone* to an ingress interface on which auto-QoS with the Cisco SoftPhone feature is enabled.

```
Device(config-if)# service-policy input AutoQoS-Police-SoftPhone
```

Examples: Auto-QoS Generated Configuration For Enhanced Video, Trust, and Classify Devices

If you entered the following enhanced auto-QoS commands, the switch configures a CoS-to-DSCP map (maps CoS values in incoming packets to a DSCP value):

- **auto qos video cts**
- **auto qos video ip-camera**
- **auto qos video media-player**
- **auto qos trust**
- **auto qos trust cos**
- **auto qos trust dscp**

The following command is initiated after entering one of the above auto-QoS commands:

```
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
```

Note No class maps and policy maps are configured.

If you entered the **auto qos classify** command, the switch automatically creates class maps and policy maps (as shown below).

```
Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
```

```

Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
Device(config)# class-map match-all AUTOQOS_MULTTIENHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTTIENHANCED-CONF
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_SIGNALING_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SIGNALING
Device(config)# class-map match-all AUTOQOS_BULK_DATA_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-BULK-DATA
Device(config)# class-map match-all AUTOQOS_SCAVANGER_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SCAVANGER
Device(config)# policy-map AUTOQOS-SRND4-CLASSIFY-POLICY
Device(config-pmap)# class AUTOQOS_MULTTIENHANCED_CONF_CLASS
Device(config-pmap-c)# set dscp af41
Device(config-pmap-c)# class AUTOQOS_BULK_DATA_CLASS
Device(config-pmap-c)# set dscp af11
Device(config-pmap-c)# class AUTOQOS_TRANSACTION_CLASS
Device(config-pmap-c)# set dscp af21
Device(config-pmap-c)# class AUTOQOS_SCAVANGER_CLASS
Device(config-pmap-c)# set dscp cs1
Device(config-pmap-c)# class AUTOQOS_SIGNALING_CLASS
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c)# set dscp default
;
Device(config-if)# service-policy input AUTOQOS-SRND4-CLASSIFY-POLICY

```

If you entered the **auto qos classify police** command, the switch automatically creates class maps and policy maps (as shown below).

```

Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
Device(config)# class-map match-all AUTOQOS_MULTTIENHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTTIENHANCED-CONF
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_SIGNALING_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SIGNALING
Device(config)# class-map match-all AUTOQOS_BULK_DATA_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-BULK-DATA
Device(config)# class-map match-all AUTOQOS_SCAVANGER_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SCAVANGER
Device(config)# policy-map AUTOQOS-SRND4-CLASSIFY-POLICE
Device(config-pmap)# class AUTOQOS_MULTTIENHANCED_CONF_CLASS
Device(config-pmap-c)# set dscp af41
Device(config-pmap-c)# police 5000000 8000 exceed-action drop
Device(config-pmap-c)# class AUTOQOS_BULK_DATA_CLASS
Device(config-pmap-c)# set dscp af11
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AUTOQOS_TRANSACTION_CLASS
Device(config-pmap-c)# set dscp af21
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap-c)# class AUTOQOS_SCAVANGER_CLASS
Device(config-pmap-c)# set dscp cs1
Device(config-pmap-c)# police 10000000 8000 exceed-action drop
Device(config-pmap-c)# class AUTOQOS_SIGNALING_CLASS
Device(config-pmap-c)# set dscp cs3

```

```

Device(config-pmap-c)# police 32000 8000 exceed-action drop
Device(config-pmap)# class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c)# set dscp default
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
;
Device(config-if)# service-policy input AUTOQOS-SRND4-CLASSIFY-POLICE-POLICY

```

This is the enhanced configuration for the **auto qos voip cisco-phone** command:

```

Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
Device(config)# class-map match-all AUTOQOS_VOIP_DATA_CLASS
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-cmap)# match ip dscp cs3
Device(config)# policy-map AUTOQOS-SRND4-CISCOPHONE-POLICY
Device(config-pmap)# class AUTOQOS_VOIP_DATA_CLASS
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 128000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c)# set dscp default
Device(config-pmap-c)# police 10000000 8000 exceed-action policed-dscp-transmit
;
Device(config-if)# service-policy input AUTOQOS-SRND4-CISCOPHONE-POLICY

```

This is the enhanced configuration for the **auto qos voip cisco-softphone** command:

```

Device(config)# mls qos map policed-dscp 0 10 18 24 26 46 to 8
Device(config)# mls qos map cos-dscp 0 8 16 24 32 46 48 56
Device(config)# class-map match-all AUTOQOS_MULTIENTHANCED_CONF_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-MULTIENTHANCED-CONF
Device(config)# class-map match-all AUTOQOS_VOIP_DATA_CLASS
Device(config-cmap)# match ip dscp ef
Device(config)# class-map match-all AUTOQOS_DEFAULT_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-DEFAULT
Device(config)# class-map match-all AUTOQOS_TRANSACTION_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-TRANSACTIONAL-DATA
Device(config)# class-map match-all AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-cmap)# match ip dscp cs3
Device(config)# class-map match-all AUTOQOS_SIGNALING_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SIGNALING
Device(config)# class-map match-all AUTOQOS_BULK_DATA_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-BULK-DATA
Device(config)# class-map match-all AUTOQOS_SCAVANGER_CLASS
Device(config-cmap)# match access-group name AUTOQOS-ACL-SCAVANGER

Device(config)# policy-map AUTOQOS-SRND4-SOFTPHONE-POLICY
Device(config-pmap)# class AUTOQOS_VOIP_DATA_CLASS
Device(config-pmap-c)# set dscp ef
Device(config-pmap-c)# police 128000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AUTOQOS_VOIP_SIGNAL_CLASS
Device(config-pmap-c)# set dscp cs3
Device(config-pmap-c)# police 32000 8000 exceed-action policed-dscp-transmit
Device(config-pmap)# class AUTOQOS_MULTIENTHANCED_CONF_CLASS
Device(config-pmap-c)# set dscp af41

```

```

Device(config-pmap-c) # police 5000000 8000 exceed-action drop
Device(config-pmap) # class AUTOQOS_BULK_DATA_CLASS
Device(config-pmap-c) # set dscp af11
Device(config-pmap-c) # police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap) # class AUTOQOS_TRANSACTION_CLASS
Device(config-pmap-c) # set dscp af21
Device(config-pmap-c) # police 10000000 8000 exceed-action policed-dscp-transmit
Device(config-pmap) # class AUTOQOS_SCAVANGER_CLASS
Device(config-pmap-c) # set dscp cs1
Device(config-pmap-c) # police 10000000 8000 exceed-action drop
Device(config-pmap) # class AUTOQOS_SIGNALING_CLASS
Device(config-pmap-c) # set dscp cs3
Device(config-pmap-c) # police 32000 8000 exceed-action drop
Device(config-pmap) # class AUTOQOS_DEFAULT_CLASS
Device(config-pmap-c) # set dscp default
;
Device(config-if) # service-policy input AUTOQOS-SRND4-SOFTPHONE-POLICY

```

auto qos global compact

The following is an example of the **auto qos global compact** command.

```

Device# configure terminal
Device(config)# auto qos global compact
Device(config)# interface GigabitEthernet1/2
Device(config-if)# auto qos voip cisco-phone

Device# show auto-qos

GigabitEthernet1/2
auto qos voip cisco-phone

Device# show running-config interface GigabitEthernet 1/0/2

interface GigabitEthernet1/0/2
auto qos voip cisco-phone
end

```

Where to Go Next for Auto-QoS

Review the QoS documentation if you require any specific QoS changes to your auto-QoS configuration.

Configuring Cisco IOS Configuration Engine

- [Prerequisites for Configuring the Configuration Engine, on page 597](#)
- [Restrictions for Configuring the Configuration Engine, on page 597](#)
- [Information About Configuring the Configuration Engine, on page 598](#)
- [How to Configure the Configuration Engine, on page 603](#)
- [Monitoring CNS Configurations, on page 614](#)
- [Additional References, on page 615](#)
- [Feature History and Information for the Configuration Engine, on page 616](#)

Prerequisites for Configuring the Configuration Engine

- Obtain the name of the configuration engine instance to which you are connecting.
- Because the CNS uses both the event bus and the configuration server to provide configurations to devices, you must define both ConfigID and Device ID for each configured device.
- All devices configured with the **cns config partial** global configuration command must access the event bus. The DeviceID, as originated on the device, must match the DeviceID of the corresponding device definition in the Cisco Configuration Engine. You must know the hostname of the event bus to which you are connecting.

Restrictions for Configuring the Configuration Engine

- Within the scope of a single instance of the configuration server, no two configured devices can share the same value for ConfigID.
- Within the scope of a single instance of the event bus, no two configured devices can share the same value for DeviceID.

Information About Configuring the Configuration Engine

Cisco Configuration Engine Software

The Cisco Configuration Engine is network management utility software that acts as a configuration service for automating the deployment and management of network devices and services. Each Cisco Configuration Engine manages a group of Cisco devices (devices and routers) and the services that they deliver, storing their configurations and delivering them as needed. The Cisco Configuration Engine automates initial configurations and configuration updates by generating device-specific configuration changes, sending them to the device, executing the configuration change, and logging the results.

The Cisco Configuration Engine supports standalone and server modes and has these Cisco Networking Services (CNS) components:

- Configuration service:
 - Web server
 - File manager
 - Namespace mapping server
- Event service (event gateway)
- Data service directory (data models and schema)

Note Support for Cisco Configuration Engine will be deprecated in future releases. Use the configuration described in [Cisco Plug and Play Feature Guide](#) .

In standalone mode, the Cisco Configuration Engine supports an embedded directory service. In this mode, no external directory or other data store is required. In server mode, the Cisco Configuration Engine supports the use of a user-defined external directory.

Figure 70: Cisco Configuration Engine Architectural Overview

Configuration Service

The Configuration Service is the core component of the Cisco Configuration Engine. It consists of a Configuration Server that works with Cisco IOS CNS agents on the device. The Configuration Service delivers device and service configurations to the device for initial configuration and mass reconfiguration by logical groups. Devices receive their initial configuration from the Configuration Service when they start up on the network for the first time.

The Configuration Service uses the CNS Event Service to send and receive configuration change events and to send success and failure notifications.

The Configuration Server is a web server that uses configuration templates and the device-specific configuration information stored in the embedded (standalone mode) or remote (server mode) directory.

Configuration templates are text files containing static configuration information in the form of CLI commands. In the templates, variables are specified by using Lightweight Directory Access Protocol (LDAP) URLs that reference the device-specific configuration information stored in a directory.

The Cisco IOS agent can perform a syntax check on received configuration files and publish events to show the success or failure of the syntax check. The configuration agent can either apply configurations immediately or delay the application until receipt of a synchronization event from the configuration server.

Event Service

The Cisco Configuration Engine uses the Event Service for receipt and generation of configuration events. The Event Service consists of an event agent and an event gateway. The event agent is on the device and facilitates the communication between the device and the event gateway on the Cisco Configuration Engine.

The Event Service is a highly capable publish-and-subscribe communication method. The Event Service uses subject-based addressing to send messages to their destinations. Subject-based addressing conventions define a simple, uniform namespace for messages and their destinations.

NameSpace Mapper

The Cisco Configuration Engine includes the NameSpace Mapper (NSM) that provides a lookup service for managing logical groups of devices based on application, device or group ID, and event.

Cisco IOS devices recognize only event subject-names that match those configured in Cisco IOS software; for example, `cisco.cns.config.load`. You can use the namespace mapping service to designate events by using any desired naming convention. When you have populated your data store with your subject names, NSM changes your event subject-name strings to those known by Cisco IOS.

For a subscriber, when given a unique device ID and event, the namespace mapping service returns a set of events to which to subscribe. Similarly, for a publisher, when given a unique group ID, device ID, and event, the mapping service returns a set of events on which to publish.

Cisco Networking Services IDs and Device Hostnames

The Cisco Configuration Engine assumes that a unique identifier is associated with each configured device. This unique identifier can take on multiple synonyms, where each synonym is unique within a particular namespace. The event service uses namespace content for subject-based addressing of messages.

The Cisco Configuration Engine intersects two namespaces, one for the event bus and the other for the configuration server. Within the scope of the configuration server namespace, the term *ConfigID* is the unique identifier for a device. Within the scope of the event bus namespace, the term *DeviceID* is the CNS unique identifier for a device.

ConfigID

Each configured device has a unique ConfigID, which serves as the key into the Cisco Configuration Engine directory for the corresponding set of device CLI attributes. The ConfigID defined on the device must match the ConfigID for the corresponding device definition on the Cisco Configuration Engine.

The ConfigID is fixed at startup time and cannot be changed until the device restarts, even if the device hostname is reconfigured.

DeviceID

Each configured device participating on the event bus has a unique DeviceID, which is analogous to the device source address so that the device can be targeted as a specific destination on the bus.

The origin of the DeviceID is defined by the Cisco IOS hostname of the device. However, the DeviceID variable and its usage reside within the event gateway adjacent to the device.

The logical Cisco IOS termination point on the event bus is embedded in the event gateway, which in turn functions as a proxy on behalf of the device. The event gateway represents the device and its corresponding DeviceID to the event bus.

The device declares its hostname to the event gateway immediately after the successful connection to the event gateway. The event gateway couples the DeviceID value to the Cisco IOS hostname each time this connection is established. The event gateway retains this DeviceID value for the duration of its connection to the device.

Hostname and DeviceID

The DeviceID is fixed at the time of the connection to the event gateway and does not change even when the device hostname is reconfigured.

When changing the device hostname on the device, the only way to refresh the DeviceID is to break the connection between the device and the event gateway. For instructions on refreshing DeviceIDs, see "Related Topics."

When the connection is reestablished, the device sends its modified hostname to the event gateway. The event gateway redefines the DeviceID to the new value.

Caution When using the Cisco Configuration Engine user interface, you must first set the DeviceID field to the hostname value that the device acquires *after*, not *before*, and you must reinitialize the configuration for your Cisco IOS CNS agent. Otherwise, subsequent partial configuration command operations may malfunction.

Hostname, DeviceID, and ConfigID

In standalone mode, when a hostname value is set for a device, the configuration server uses the hostname as the DeviceID when an event is sent on hostname. If the hostname has not been set, the event is sent on the `cn=<value>` of the device.

In server mode, the hostname is not used. In this mode, the unique DeviceID attribute is always used for sending an event on the bus. If this attribute is not set, you cannot update the device.

These and other associated attributes (tag value pairs) are set when you run **Setup** on the Cisco Configuration Engine.

Cisco IOS CNS Agents

The CNS event agent feature allows the device to publish and subscribe to events on the event bus and works with the Cisco IOS CNS agent. These agents, embedded in the device Cisco IOS software, allow the device to be connected and automatically configured.

Initial Configuration

When the device first comes up, it attempts to get an IP address by broadcasting a Dynamic Host Configuration Protocol (DHCP) request on the network. Assuming there is no DHCP server on the subnet, the distribution device acts as a DHCP relay agent and forwards the request to the DHCP server. Upon receiving the request, the DHCP server assigns an IP address to the new device and includes the Trivial File Transfer Protocol (TFTP) server Internet Protocol (IP) address, the path to the bootstrap configuration file, and the default gateway IP address in a unicast reply to the DHCP relay agent. The DHCP relay agent forwards the reply to the device.

The device automatically configures the assigned IP address on interface VLAN 1 (the default) and downloads the bootstrap configuration file from the TFTP server. Upon successful download of the bootstrap configuration file, the device loads the file in its running configuration.

The Cisco IOS CNS agents initiate communication with the Configuration Engine by using the appropriate ConfigID and EventID. The Configuration Engine maps the Config ID to a template and downloads the full configuration file to the device.

The following figure shows a sample network configuration for retrieving the initial bootstrap configuration file by using DHCP-based autoconfiguration.

Figure 71: Initial Configuration

Incremental (Partial) Configuration

After the network is running, new services can be added by using the Cisco IOS CNS agent. Incremental (partial) configurations can be sent to the device. The actual configuration can be sent as an event payload by way of the event gateway (push operation) or as a signal event that triggers the device to initiate a pull operation.

The device can check the syntax of the configuration before applying it. If the syntax is correct, the device applies the incremental configuration and publishes an event that signals success to the configuration server. If the device does not apply the incremental configuration, it publishes an event showing an error status. When the device has applied the incremental configuration, it can write it to nonvolatile random-access memory (NVRAM) or wait until signaled to do so.

Synchronized Configuration

When the device receives a configuration, it can defer application of the configuration upon receipt of a write-signal event. The write-signal event tells the device not to save the updated configuration into its NVRAM. The device uses the updated configuration as its running configuration. This ensures that the device configuration is synchronized with other network activities before saving the configuration in NVRAM for use at the next reboot.

Automated CNS Configuration

To enable automated CNS configuration of the device, you must first complete the prerequisites listed in this topic. When you complete them, power on the device. At the **setup** prompt, do nothing; the device begins the initial configuration. When the full configuration file is loaded on your device, you do not need to do anything else.

For more information on what happens during initial configuration, see "Related Topics."

Table 78: Prerequisites for Enabling Automatic Configuration

| Device | Required Configuration |
|---------------|---|
| Access device | Factory default (no configuration file) |

| Device | Required Configuration |
|--------------------------|--|
| Distribution device | <ul style="list-style-type: none"> • IP helper address • Enable DHCP relay agent² • IP routing (if used as default gateway) |
| DHCP server | <ul style="list-style-type: none"> • IP address assignment • TFTP server IP address • Path to bootstrap configuration file on the TFTP server • Default gateway IP address |
| TFTP server | <ul style="list-style-type: none"> • A bootstrap configuration file that includes the CNS configuration commands that enable the device to communicate with the Configuration Engine • The device configured to use either the device MAC address or the serial number (instead of the default hostname) to generate the ConfigID and EventID • The CNS event agent configured to push the configuration file to the device |
| CNS Configuration Engine | One or more templates for each type of device, with the ConfigID of the device mapped to the template. |

² A DHCP Relay is needed only when the DHCP Server is on a different subnet from the client.

How to Configure the Configuration Engine

Enabling the CNS Event Agent

Note You must enable the CNS event agent on the device before you enable the CNS configuration agent.

Follow these steps to enable the CNS event agent on the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|--------|---|--|
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | <p>cns event {hostname ip-address} [port-number] [keepalive seconds retry-count] [failover-time seconds] [reconnect-time time] backup]</p> <p>Example:</p> <pre>Device(config)# cns event 10.180.1.27 keepalive 120 10</pre> | <p>Enables the event agent, and enters the gateway parameters.</p> <ul style="list-style-type: none"> • For {hostname ip-address}, enter either the hostname or the IP address of the event gateway. • (Optional) For <i>port number</i>, enter the port number for the event gateway. The default port number is 11011. • (Optional) For keepalive seconds, enter how often the device sends keepalive messages. For <i>retry-count</i>, enter the number of unanswered keepalive messages that the device sends before the connection is terminated. The default for each is 0. • (Optional) For failover-time seconds, enter how long the device waits for the primary gateway route after the route to the backup gateway is established. • (Optional) For reconnect-time time, enter the maximum time interval that the device waits before trying to reconnect to the event gateway. • (Optional) Enter backup to show that this is the backup gateway. (If omitted, this is the primary gateway.) <p>Note Though visible in the command-line help string, the encrypt and the clock-timeout time keywords are not supported.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>show running-config</p> <p>Example:</p> | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>show running-config</code> | |
| Step 6 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

What to do next

To verify information about the event agent, use the **show cns event connections** command in privileged EXEC mode.

To disable the CNS event agent, use the **no cns event** { *ip-address* | *hostname* } global configuration command.

Enabling the Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent on the device.

Before you begin

You must enable the CNS event agent on the device before you enable this agent.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | cns config initial { <i>hostname</i> <i>ip-address</i> } [<i>port-number</i>] Example: Device(config)# <code>cns config initial 10.180.1.27 10</code> | Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> • For {<i>hostname</i> <i>ip-address</i>}, enter either the hostname or the IP address of the configuration server. • (Optional) For <i>port number</i>, enter the port number for the configuration server. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | This command enables the Cisco IOS CNS agent and initiates an initial configuration on the device. |
| Step 4 | cns config partial { <i>hostname</i> <i>ip-address</i> } [<i>port-number</i>] Example: Device(config)# cns config partial 10.180.1.27 10 | Enables the Cisco IOS CNS agent, and enters the configuration server parameters. <ul style="list-style-type: none"> • For {<i>hostname</i> <i>ip-address</i>}, enter either the hostname or the IP address of the configuration server. • (Optional) For <i>port number</i>, enter the port number for the configuration server. Enables the Cisco IOS CNS agent and initiates a partial configuration on the device. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |
| Step 8 | Start the Cisco IOS CNS agent on the device. | |

What to do next

You can now use the Cisco Configuration Engine to remotely send incremental configurations to the device.

Enabling an Initial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the CNS configuration agent and initiate an initial configuration on the device.

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Example: Device> enable | <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | cns template connect <i>name</i> Example: Device (config)# cns template connect template-dhcp | Enters CNS template connect configuration mode, and specifies the name of the CNS connect template. |
| Step 4 | cli <i>config-text</i> Example: Device (config-tmpl-conn)# cli ip address dhcp | Enters a command line for the CNS connect template. Repeat this step for each command line in the template. |
| Step 5 | Repeat Steps 3 to 4 to configure another CNS connect template. | |
| Step 6 | exit Example: Device (config)# exit | Returns to global configuration mode. |
| Step 7 | cns connect <i>name</i> [<i>retries number</i>] [<i>retry-interval seconds</i>] [<i>sleep seconds</i>] [<i>timeout seconds</i>] Example: Device (config)# cns connect dhcp | Enters CNS connect configuration mode, specifies the name of the CNS connect profile, and defines the profile parameters. The device uses the CNS connect profile to connect to the Configuration Engine. <ul style="list-style-type: none"> • Enter the <i>name</i> of the CNS connect profile. • (Optional) For retries number, enter the number of connection retries. The range is 1 to 30. The default is 3. • (Optional) For retry-interval seconds, enter the interval between successive connection attempts to the Configuration Engine. The range is 1 to 40 seconds. The default is 10 seconds. • (Optional) For sleep seconds, enter the amount of time before which the first |

| | Command or Action | Purpose |
|----------------|--|--|
| | | <p>connection attempt occurs. The range is 0 to 250 seconds. The default is 0.</p> <ul style="list-style-type: none"> • (Optional) For timeout seconds, enter the amount of time after which the connection attempts end. The range is 10 to 2000 seconds. The default is 120. |
| Step 8 | <p>discover {controller <i>controller-type</i> dlci [subinterface <i>subinterface-number</i>] interface [<i>interface-type</i>] line <i>line-type</i>}</p> <p>Example:</p> <pre>Device(config-cns-conn)# discover interface gigabitethernet</pre> | <p>Specifies the interface parameters in the CNS connect profile.</p> <ul style="list-style-type: none"> • For controller <i>controller-type</i>, enter the controller type. • For dlci, enter the active data-link connection identifiers (DLCIs). <p>(Optional) For subinterface <i>subinterface-number</i>, specify the point-to-point subinterface number that is used to search for active DLCIs.</p> <ul style="list-style-type: none"> • For interface [<i>interface-type</i>], enter the type of interface. • For line <i>line-type</i>, enter the line type. |
| Step 9 | <p>template <i>name</i> [... <i>name</i>]</p> <p>Example:</p> <pre>Device(config-cns-conn)# template template-dhcp</pre> | <p>Specifies the list of CNS connect templates in the CNS connect profile to be applied to the device configuration. You can specify more than one template.</p> |
| Step 10 | <p>Repeat Steps 8 to 9 to specify more interface parameters and CNS connect templates in the CNS connect profile.</p> | |
| Step 11 | <p>exit</p> <p>Example:</p> <pre>Device(config-cns-conn)# exit</pre> | <p>Returns to global configuration mode.</p> |
| Step 12 | <p>hostname <i>name</i></p> <p>Example:</p> <pre>Device(config)# hostname device1</pre> | <p>Enters the hostname for the device.</p> |
| Step 13 | <p>ip route <i>network-number</i></p> <p>Example:</p> <pre>RemoteDevice(config)# ip route</pre> | <p>(Optional) Establishes a static route to the Configuration Engine whose IP address is <i>network-number</i>.</p> |

| | Command or Action | Purpose |
|----------------|--|--|
| | 172.28.129.22 255.255.255.255 11.11.11.1 | |
| Step 14 | <p>cns id <i>interface num</i> {dns-reverse ipaddress mac-address} [event] [image]</p> <p>Example:</p> <pre>RemoteDevice(config)# cns id GigabitEthernet0/1 ipaddress</pre> | <p>(Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the cns id {hardware-serial hostname string string udi} [event] [image] command.</p> <ul style="list-style-type: none"> For <i>interface num</i>, enter the type of interface. For example, ethernet, group-async, loopback, or virtual-template. This setting specifies from which interface the IP or MAC address should be retrieved to define the unique ID. For {dns-reverse ipaddress mac-address}, enter dns-reverse to retrieve the hostname and assign it as the unique ID, enter ipaddress to use the IP address, or enter mac-address to use the MAC address as the unique ID. (Optional) Enter event to set the ID to be the event-id value used to identify the device. (Optional) Enter image to set the ID to be the image-id value used to identify the device. <p>Note If both the event and image keywords are omitted, the image-id value is used to identify the device.</p> |
| Step 15 | <p>cns id {hardware-serial hostname string string udi} [event] [image]</p> <p>Example:</p> <pre>RemoteDevice(config)# cns id hostname</pre> | <p>(Optional) Sets the unique EventID or ConfigID used by the Configuration Engine. If you enter this command, do not enter the cns id <i>interface num</i> {dns-reverse ipaddress mac-address} [event] [image] command.</p> <ul style="list-style-type: none"> For { hardware-serial hostname string string udi }, enter hardware-serial to set the device serial number as the unique ID, enter hostname (the default) to select the device hostname as the unique ID, enter an arbitrary text string for string string as the unique ID, or enter udi to set the unique device identifier (UDI) as the unique ID. |

| | Command or Action | Purpose |
|---------|---|---|
| Step 16 | <p>cns config initial {<i>hostname</i> <i>ip-address</i>} [<i>port-number</i>] [<i>event</i>] [no-persist] [page <i>page</i>] [source <i>ip-address</i>] [syntax-check]</p> <p>Example:</p> <pre>RemoteDevice(config)# cns config initial 10.1.1.1 no-persist</pre> | <p>Enables the Cisco IOS agent, and initiates an initial configuration.</p> <ul style="list-style-type: none"> For {<i>hostname</i> <i>ip-address</i>}, enter the hostname or the IP address of the configuration server. (Optional) For <i>port-number</i>, enter the port number of the configuration server. The default port number is 80. (Optional) Enable event for configuration success, failure, or warning messages when the configuration is finished. (Optional) Enable no-persist to suppress the automatic writing to NVRAM of the configuration pulled as a result of entering the cns config initial global configuration command. If the no-persist keyword is not entered, using the cns config initial command causes the resultant configuration to be automatically written to NVRAM. (Optional) For page <i>page</i>, enter the web page of the initial configuration. The default is /Config/config/asp. (Optional) Enter source <i>ip-address</i> to use for source IP address. (Optional) Enable syntax-check to check the syntax when this parameter is entered. <p>Note Though visible in the command-line help string, the encrypt, status url, and inventory keywords are not supported.</p> |
| Step 17 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 18 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 19 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

What to do next

To verify information about the configuration agent, use the **show cns config connections** command in privileged EXEC mode.

To disable the CNS Cisco IOS agent, use the **no cns config initial** { *ip-address* | *hostname* } global configuration command.

Refreshing DeviceIDs

Follow these steps to refresh a DeviceID when changing the hostname on the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show cns config connections Example: <pre>Device# show cns config connections</pre> | Displays whether the CNS event agent is connecting to the gateway, connected, or active, and the gateway used by the event agent, its IP address and port number. |
| Step 3 | Make sure that the CNS event agent is properly connected to the event gateway. | Examine the output of show cns config connections for the following: <ul style="list-style-type: none"> • Connection is active. • Connection is using the currently configured device hostname. The DeviceID will be refreshed to correspond to the new hostname configuration using these instructions. |
| Step 4 | show cns event connections Example: <pre>Device# show cns event connections</pre> | Displays the event connection information for your device. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 5 | Record from the output of Step 4 the information for the currently connected connection listed below. You will be using the IP address and port number in subsequent steps of these instructions. | |
| Step 6 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 7 | no cns event ip-address port-number Example: Device(config)# <code>no cns event 172.28.129.22 2012</code> | Specifies the IP address and port number that you recorded in Step 5 in this command. This command breaks the connection between the device and the event gateway. It is necessary to first break, then reestablish, this connection to refresh the DeviceID. |
| Step 8 | cns event ip-address port-number Example: Device(config)# <code>cns event 172.28.129.22 2012</code> | Specifies the IP address and port number that you recorded in Step 5 in this command. This command reestablishes the connection between the device and the event gateway. |
| Step 9 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 10 | Make sure that you have reestablished the connection between the device and the event connection by examining the output from show cns event connections . | |
| Step 11 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 12 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Enabling a Partial Configuration for Cisco IOS CNS Agent

Follow these steps to enable the Cisco IOS CNS agent and to initiate a partial configuration on the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | cns config partial <i>{ip-address hostname}</i> <i>[port-number] [source ip-address]</i> Example: Device(config)# cns config partial 172.28.129.22 2013 | Enables the configuration agent, and initiates a partial configuration. <ul style="list-style-type: none"> • For <i>{ip-address hostname}</i>, enter the IP address or the hostname of the configuration server. • (Optional) For <i>port-number</i>, enter the port number of the configuration server. The default port number is 80. • (Optional) Enter source ip-address to use for the source IP address. <p>Note Though visible in the command-line help string, the encrypt keyword is not supported.</p> |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

What to do next

To verify information about the configuration agent, use either the **show cns config stats** or the **show cns config outstanding** command in privileged EXEC mode.

To disable the Cisco IOS agent, use the **no cns config partial** { *ip-address* | *hostname* } global configuration command. To cancel a partial configuration, use the **cns config cancel** global configuration command.

Monitoring CNS Configurations

Table 79: CNS show Commands

| Command | Purpose |
|--|--|
| show cns config connections Device# <code>show cns config connections</code> | Displays the status of the CNS Cisco IOS CNS agent connections. |
| show cns config outstanding Device# <code>show cns config outstanding</code> | Displays information about incremental (partial) CNS configurations that have started but are not yet completed. |
| show cns config stats Device# <code>show cns config stats</code> | Displays statistics about the Cisco IOS CNS agent. |
| show cns event connections Device# <code>show cns event connections</code> | Displays the status of the CNS event agent connections. |
| show cns event gateway Device# <code>show cns event gateway</code> | Displays the event gateway information for your device. |
| show cns event stats Device# <code>show cns event stats</code> | Displays statistics about the CNS event agent. |
| show cns event subject Device# <code>show cns event subject</code> | Displays a list of event agent subjects that are subscribed to by applications. |

CHAPTER 31

Configuring the Cisco Discovery Protocol

Cisco Discovery Protocol is a Layer 2, media-independent, and network-independent protocol that runs on Cisco devices and enables networking applications to learn about directly connected devices nearby. This protocol facilitates the management of Cisco devices by discovering these devices, determining how they are configured, and allowing systems using different network-layer protocols to learn about each other.

This module describes Cisco Discovery Protocol Version 2 and how it functions with SNMP.

Information About CDP

Cisco Discovery Protocol Overview

Cisco Discovery Protocol is a device discovery protocol that runs over Layer 2 (the data-link layer) on all Cisco-manufactured devices (routers, bridges, access servers, controllers, and switches) and allows network management applications to discover Cisco devices that are neighbors of already known devices. With Cisco Discovery Protocol, network management applications can learn the device type and the SNMP agent address of neighboring devices running lower-layer, transparent protocols. This feature enables applications to send SNMP queries to neighboring devices.

Cisco Discovery Protocol runs on all media that support Subnetwork Access Protocol (SNAP). Because Cisco Discovery Protocol runs over the data-link layer only, two systems that support different network-layer protocols can learn about each other.

Each Cisco Discovery Protocol-configured device sends periodic messages to a multicast address, advertising at least one address at which it can receive SNMP messages. The advertisements also contain time-to-live, or holdtime information, which is the length of time a receiving device holds Cisco Discovery Protocol information before discarding it. Each device also listens to the messages sent by other devices to learn about neighboring devices.

On the device, Cisco Discovery Protocol enables Network Assistant to display a graphical view of the network. The device uses Cisco Discovery Protocol to find cluster candidates and maintain information about cluster members and other devices up to three cluster-enabled devices away from the command device by default.

- Cisco Discovery Protocol identifies connected endpoints that communicate directly with the device.
- To prevent duplicate reports of neighboring devices, only one wired device reports the location information.
- The wired device and the endpoints both send and receive location information.

CDP and Stacks

A device stack appears as a single device in the network. Therefore, CDP discovers the device stack, not the individual stack members. The device stack sends CDP messages to neighboring network devices when there are changes to the device stack membership, such as stack members being added or removed.

Default Cisco Discovery Protocol Configuration

This table shows the default Cisco Discovery Protocol configuration.

| Feature | Default Setting |
|--|-----------------|
| Cisco Discovery Protocol global state | Enabled |
| Cisco Discovery Protocol interface state | Enabled |
| Cisco Discovery Protocol timer (packet update frequency) | 60 seconds |
| Cisco Discovery Protocol holdtime (before discarding) | 180 seconds |
| Cisco Discovery Protocol Version-2 advertisements | Enabled |

How to Configure CDP

Configuring Cisco Discovery Protocol Characteristics

You can configure these Cisco Discovery Protocol characteristics:

- Frequency of Cisco Discovery Protocol updates
- Amount of time to hold the information before discarding it
- Whether or not to send Version 2 advertisements

Note Steps 3 through 5 are all optional and can be performed in any order.

Follow these steps to configure the Cisco Discovery Protocol characteristics.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | cdp timer <i>seconds</i> Example: Device(config)# cdp timer 20 | (Optional) Sets the transmission frequency of Cisco Discovery Protocol updates in seconds. The range is 5 to 254; the default is 60 seconds. |
| Step 4 | cdp holdtime <i>seconds</i> Example: Device(config)# cdp holdtime 60 | (Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it. The range is 10 to 255 seconds; the default is 180 seconds. |
| Step 5 | cdp advertise-v2 Example: Device(config)# cdp advertise-v2 | (Optional) Configures Cisco Discovery Protocol to send Version 2 advertisements. This is the default state. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

What to do next

Use the **no** form of the Cisco Discovery Protocol commands to return to the default settings.

Disabling Cisco Discovery Protocol

Cisco Discovery Protocol is enabled by default.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Follow these steps to disable the Cisco Discovery Protocol device discovery capability.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no cdp run Example: Device(config)# no cdp run | Disables Cisco Discovery Protocol. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|-----------------------------|---------|
| | <code>startup-config</code> | |

What to do next

You must reenable Cisco Discovery Protocol to use it.

Enabling Cisco Discovery Protocol

Cisco Discovery Protocol is enabled by default.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Follow these steps to enable Cisco Discovery Protocol when it has been disabled.

Before you begin

Cisco Discovery Protocol must be disabled, or it cannot be enabled.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | cdp run Example: Device(config)# <code>cdp run</code> | Enables Cisco Discovery Protocol if it has been disabled. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

What to do next

Use the **show run all** command to show that Cisco Discovery Protocol has been enabled. If you enter only **show run**, the enabling of Cisco Discovery Protocol may not be displayed.

Disabling Cisco Discovery Protocol on an Interface

Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note Cisco Discovery Protocol bypass is not supported and may cause a port go into err-disabled state.

Follow these steps to disable Cisco Discovery Protocol on a port.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# <code>configure terminal</code> | |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# <code>interface gigabitethernet 1/0/1</code> | Specifies the interface on which you are disabling Cisco Discovery Protocol, and enters interface configuration mode. |
| Step 4 | no cdp enable Example: Device(config-if)# <code>no cdp enable</code> | Disables Cisco Discovery Protocol on the interface specified in Step 3. |
| Step 5 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Enabling Cisco Discovery Protocol on an Interface

Cisco Discovery Protocol is enabled by default on all supported interfaces to send and to receive Cisco Discovery Protocol information.

Note Device clusters and other Cisco devices (such as Cisco IP Phones) regularly exchange Cisco Discovery Protocol messages. Disabling Cisco Discovery Protocol can interrupt cluster discovery and device connectivity.

Note Cisco Discovery Protocol bypass is not supported and may cause a port go into err-disabled state.

Follow these steps to enable Cisco Discovery Protocol on a port on which it has been disabled.

Before you begin

Cisco Discovery Protocol must be disabled on the port that you are trying to Cisco Discovery Protocol enable on, or it cannot be enabled.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet1/0/1 | Specifies the interface on which you are enabling Cisco Discovery Protocol, and enters interface configuration mode. |
| Step 4 | cdp enable Example: Device(config-if)# cdp enable | Enables Cisco Discovery Protocol on a disabled interface. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring and Maintaining Cisco Discovery Protocol

Table 80: Commands for Displaying Cisco Discovery Protocol Information

| Command | Description |
|---|---|
| clear cdp counters | Resets the traffic counters to zero. |
| clear cdp table | Deletes the Cisco Discovery Protocol table of information about |
| show cdp | Displays global information, such as frequency of transmissions and for packets being sent. |
| show cdp entry <i>entry-name</i> [version] [protocol] | Displays information about a specific neighbor. You can enter an asterisk (*) to display all Cisco Discovery Protocol or you can enter the name of the neighbor about which you want You can also limit the display to information about the protocols of specified neighbor or information about the version of software on device. |
| show cdp interface [<i>interface-id</i>] | Displays information about interfaces where Cisco Discovery Protocol You can limit the display to the interface about which you want i |
| show cdp neighbors [<i>interface-id</i>] [<i>detail</i>] | Displays information about neighbors, including device type, inter number, holdtime settings, capabilities, platform, and port ID. You can limit the display to neighbors of a specific interface or e display to provide more detailed information. |
| show cdp traffic | Displays Cisco Discovery Protocol counters, including the number sent and received and checksum errors. |

Prerequisites for SNMP

Supported SNMP Versions

This software release supports the following SNMP versions:

- **SNMPv1**—The Simple Network Management Protocol, a Full Internet Standard, defined in RFC 1157.
- **SNMPv2C** replaces the Party-based Administrative and Security Framework of SNMPv2Classic with the community-string-based Administrative Framework of SNMPv2C while retaining the bulk retrieval and improved error handling of SNMPv2Classic. It has these features:
 - **SNMPv2**—Version 2 of the Simple Network Management Protocol, a Draft Internet Standard, defined in RFCs 1902 through 1907.
 - **SNMPv2C**—The community-string-based Administrative Framework for SNMPv2, an Experimental Internet Protocol defined in RFC 1901.
- **SNMPv3**—Version 3 of the SNMP is an interoperable standards-based protocol defined in RFCs 2273 to 2275. SNMPv3 provides secure access to devices by authenticating and encrypting packets over the network and includes these security features:
 - **Message integrity**—Ensures that a packet was not tampered with in transit.
 - **Authentication**—Determines that the message is from a valid source.

- Encryption—Mixes the contents of a package to prevent it from being read by an unauthorized source.

Note To select encryption, enter the **priv** keyword.

Both SNMPv1 and SNMPv2C use a community-based form of security. The community of managers able to access the agent's MIB is defined by an IP address access control list and password.

SNMPv2C includes a bulk retrieval function and more detailed error message reporting to management stations. The bulk retrieval function retrieves tables and large quantities of information, minimizing the number of round-trips required. The SNMPv2C improved error-handling includes expanded error codes that distinguish different kinds of error conditions; these conditions are reported through a single error code in SNMPv1. Error return codes in SNMPv2C report the error type.

SNMPv3 provides for both security models and security levels. A security model is an authentication strategy set up for a user and the group within which the user resides. A security level is the permitted level of security within a security model. A combination of the security level and the security model determine which security method is used when handling an SNMP packet. Available security models are SNMPv1, SNMPv2C, and SNMPv3.

The following table identifies characteristics and compares different combinations of security models and levels:

Table 81: SNMP Security Models and Levels

| Model | Level | Authentication | Encryption | Result |
|---------|--------------|---|------------|---|
| SNMPv1 | noAuthNoPriv | Community string | No | Uses a community string match for authentication. |
| SNMPv2C | noAuthNoPriv | Community string | No | Uses a community string match for authentication. |
| SNMPv3 | noAuthNoPriv | Username | No | Uses a username match for authentication. |
| SNMPv3 | authNoPriv | Message Digest 5 (MD5) or Secure Hash Algorithm (SHA) | No | Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms. |

| Model | Level | Authentication | Encryption | Result |
|--------|----------|----------------|--|---|
| SNMPv3 | authPriv | MD5 or SHA | Data Encryption Standard (DES) or Advanced Encryption Standard (AES) | <p>Provides authentication based on the HMAC-MD5 or HMAC-SHA algorithms.</p> <p>Allows specifying the User-based Security Model (USM) with these encryption algorithms:</p> <ul style="list-style-type: none"> • DES 56-bit encryption in addition to authentication based on the CBC-DES (DES-56) standard. • 3DES 168-bit encryption • AES 128-bit, 192-bit, or 256-bit encryption |

You must configure the SNMP agent to use the SNMP version supported by the management station. Because an agent can communicate with multiple managers, you can configure the software to support communications using SNMPv1, SNMPv2C, or SNMPv3.

Restrictions for SNMP

Version Restrictions

- SNMPv1 does not support informs.

Information About SNMP

SNMP Overview

SNMP is an application-layer protocol that provides a message format for communication between managers and agents. The SNMP system consists of an SNMP manager, an SNMP agent, and a management information

base (MIB). The SNMP manager can be part of a network management system (NMS) such as Cisco Prime Infrastructure. The agent and MIB reside on the device. To configure SNMP on the device, you define the relationship between the manager and the agent.

The SNMP agent contains MIB variables whose values the SNMP manager can request or change. A manager can get a value from an agent or store a value into the agent. The agent gathers data from the MIB, the repository for information about device parameters and network data. The agent can also respond to a manager's requests to get or set data.

An agent can send unsolicited traps to the manager. Traps are messages alerting the SNMP manager to a condition on the network. Traps can mean improper user authentication, restarts, link status (up or down), MAC address tracking, closing of a TCP connection, loss of connection to a neighbor, or other significant events.

SNMP Manager Functions

The SNMP manager uses information in the MIB to perform the operations described in the following table:

Table 82: SNMP Operations

| Operation | Description |
|-------------------------------|---|
| get-request | Retrieves a value from a specific variable. |
| get-next-request | Retrieves a value from a variable within a table. ³ |
| get-bulk-request ⁴ | Retrieves large blocks of data, such as multiple rows in a table, that would otherwise require the transmission of many small blocks of data. |
| get-response | Replies to a get-request, get-next-request, and set-request sent by an NMS. |
| set-request | Stores a value in a specific variable. |
| trap | An unsolicited message sent by an SNMP agent to an SNMP manager when some event has occurred. |

³ With this operation, an SNMP manager does not need to know the exact variable name. A sequential search is performed to find the needed variable from within a table.

⁴ The get-bulk command only works with SNMPv2 or later.

SNMP Agent Functions

The SNMP agent responds to SNMP manager requests as follows:

- Get a MIB variable—The SNMP agent begins this function in response to a request from the NMS. The agent retrieves the value of the requested MIB variable and responds to the NMS with that value.
- Set a MIB variable—The SNMP agent begins this function in response to a message from the NMS. The SNMP agent changes the value of the MIB variable to the value requested by the NMS.

The SNMP agent also sends unsolicited trap messages to notify an NMS that a significant event has occurred on the agent. Examples of trap conditions include, but are not limited to, when a port or module goes up or down, when spanning-tree topology changes occur, and when authentication failures occur.

SNMP Community Strings

SNMP community strings authenticate access to MIB objects and function as embedded passwords. In order for the NMS to access the device, the community string definitions on the NMS must match at least one of the three community string definitions on the device.

A community string can have one of the following attributes:

- Read-only (RO)—Gives all objects in the MIB except the community strings read access to authorized management stations, but does not allow write access.
- Read-write (RW)—Gives all objects in the MIB read and write access to authorized management stations, but does not allow access to the community strings.
- When a cluster is created, the command device manages the exchange of messages among member devices and the SNMP application. The Network Assistant software appends the member device number (@esN, where N is the device number) to the first configured RW and RO community strings on the command device and propagates them to the member devices.

SNMP MIB Variables Access

An example of an NMS is the Cisco Prime Infrastructure network management software. Cisco Prime Infrastructure software uses the device MIB variables to set device variables and to poll devices on the network for specific information. The results of a poll can be displayed as a graph and analyzed to troubleshoot internetworking problems, increase network performance, verify the configuration of devices, monitor traffic loads, and more.

As shown in the figure, the SNMP agent gathers data from the MIB. The agent can send traps, or notification of certain events, to the SNMP manager, which receives and processes the traps. Traps alert the SNMP manager to a condition on the network such as improper user authentication, restarts, link status (up or down), MAC address tracking, and so forth. The SNMP agent also responds to MIB-related queries sent by the SNMP manager in *get-request*, *get-next-request*, and *set-request* format.

Figure 72: SNMP Network

SNMP Notifications

SNMP allows the device to send notifications to SNMP managers when particular events occur. SNMP notifications can be sent as traps or inform requests. In command syntax, unless there is an option in the command to select either traps or informs, the keyword `traps` refers to either traps or informs, or both. Use the `snmp-server host` command to specify whether to send SNMP notifications as traps or informs.

Note SNMPv1 does not support informs.

Traps are unreliable because the receiver does not send an acknowledgment when it receives a trap, and the sender cannot determine if the trap was received. When an SNMP manager receives an inform request, it acknowledges the message with an SNMP response protocol data unit (PDU). If the sender does not receive a response, the inform request can be sent again. Because they can be resent, informs are more likely than traps to reach their intended destination.

The characteristics that make informs more reliable than traps also consume more resources in the device and in the network. Unlike a trap, which is discarded as soon as it is sent, an inform request is held in memory until a response is received or the request times out. Traps are sent only once, but an inform might be resent or retried several times. The retries increase traffic and contribute to a higher overhead on the network. Therefore, traps and informs require a trade-off between reliability and resources. If it is important that the SNMP manager receive every notification, use inform requests. If traffic on the network or memory in the device is a concern and notification is not required, use traps.

SNMP ifIndex MIB Object Values

In an NMS, the IF-MIB generates and assigns an interface index (ifIndex) object value that is a unique number greater than zero to identify a physical or a logical interface. When the device reboots or the device software is upgraded, the device uses this same value for the interface. For example, if the device assigns a port 2 an ifIndex value of 10003, this value is the same after the device reboots.

The device uses one of the values in the following table to assign an ifIndex value to an interface:

Table 83: ifIndex Values

| Interface Type | ifIndex Range |
|---|---------------|
| SVI ⁵ | 1–4999 |
| EtherChannel | 5001–5048 |
| Tunnel | 5078–5142 |
| Physical (such as Gigabit Ethernet or SFP ⁶ -module interfaces) based on type and port numbers | 10000–14500 |
| Null | 14501 |
| Loopback and Tunnel | 24567+ |

⁵ SVI = switch virtual interface

⁶ SFP = small form-factor pluggable

Default SNMP Configuration

| Feature | Default Setting |
|--------------------|---|
| SNMP agent | Disabled ⁷ . |
| SNMP trap receiver | None configured. |
| SNMP traps | None enabled except the trap for TCP connections (tty). |
| SNMP version | If no version keyword is present, the default is Version 1. |

| Feature | Default Setting |
|------------------------|---|
| SNMPv3 authentication | If no keyword is entered, the default is the noauth (noAuthNoPriv) security level. |
| SNMP notification type | If no type is specified, all notifications are sent. |

⁷ This is the default when the device starts and the startup configuration does not have any **snmp-server** global configuration commands.

SNMP Configuration Guidelines

If the device starts and the device startup configuration has at least one **snmp-server** global configuration command, the SNMP agent is enabled.

An SNMP *group* is a table that maps SNMP users to SNMP views. An SNMP *user* is a member of an SNMP group. An SNMP *host* is the recipient of an SNMP trap operation. An SNMP *engine ID* is a name for the local or remote SNMP engine.

When configuring SNMP, follow these guidelines:

- When configuring an SNMP group, do not specify a notify view. The **snmp-server host** global configuration command auto-generates a notify view for the user and then adds it to the group associated with that user. Modifying the group's notify view affects all users associated with that group.
- To configure a remote user, specify the IP address or port number for the remote SNMP agent of the device where the user resides.
- Before you configure remote users for a particular agent, configure the SNMP engine ID, using the **snmp-server engineID** global configuration command with the **remote** option. The remote agent's SNMP engine ID and user password are used to compute the authentication and privacy digests. If you do not configure the remote engine ID first, the configuration command fails.
- When configuring SNMP informs, you need to configure the SNMP engine ID for the remote agent in the SNMP database before you can send proxy requests or informs to it.
- If a local user is not associated with a remote host, the device does not send informs for the **auth** (authNoPriv) and the **priv** (authPriv) authentication levels.
- Changing the value of the SNMP engine ID has significant results. A user's password (entered on the command line) is converted to an MD5 or SHA security digest based on the password and the local engine ID. The command-line password is then destroyed, as required by RFC 2274. Because of this deletion, if the value of the engine ID changes, the security digests of SNMPv3 users become invalid, and you need to reconfigure SNMP users by using the **snmp-server user username** global configuration command. Similar restrictions require the reconfiguration of community strings when the engine ID changes.

How to Configure SNMP

Disabling the SNMP Agent

The **no snmp-server** global configuration command disables all running versions (Version 1, Version 2C, and Version 3) of the SNMP agent on the device. You reenables all versions of the SNMP agent by the first **snmp-server** global configuration command that you enter. There is no Cisco IOS command specifically designated for enabling SNMP.

Follow these steps to disable the SNMP agent.

Before you begin

The SNMP Agent must be enabled before it can be disabled. The SNMP agent is enabled by the first **snmp-server** global configuration command entered on the device.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no snmp-server Example: Device(config)# no snmp-server | Disables the SNMP agent operation. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring Community Strings

You use the SNMP community string to define the relationship between the SNMP manager and the agent. The community string acts like a password to permit access to the agent on the device. Optionally, you can specify one or more of these characteristics associated with the string:

- An access list of IP addresses of the SNMP managers that are permitted to use the community string to gain access to the agent
- A MIB view, which defines the subset of all MIB objects accessible to the given community
- Read and write or read-only permission for the MIB objects accessible to the community

Follow these steps to configure a community string on the device.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | snmp-server community <i>string</i> [view <i>view-name</i>] [ro rw] [<i>access-list-number</i>] Example: <pre>Device(config)# snmp-server community comaccess ro 4</pre> | Configures the community string. <p>Note The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <ul style="list-style-type: none"> • For <i>string</i>, specify a string that acts like a password and permits access to the SNMP protocol. You can configure one or more community strings of any length. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> • (Optional) For view, specify the view record accessible to the community. • (Optional) Specify either read-only (ro) if you want authorized management stations to retrieve MIB objects, or specify read-write (rw) if you want authorized management stations to retrieve and modify MIB objects. By default, the community string permits read-only access to all objects. • (Optional) For <i>access-list-number</i>, enter an IP standard access list numbered from 1 to 99 and 1300 to 1999. |
| Step 4 | <p>access-list <i>access-list-number</i> {deny permit} <i>source</i> [<i>source-wildcard</i>]</p> <p>Example:</p> <pre>Device(config)# access-list 4 deny any</pre> | <p>(Optional) If you specified an IP standard access list number in Step 3, then create the list, repeating the command as many times as necessary.</p> <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the access list number specified in Step 3. • The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched. • For <i>source</i>, enter the IP address of the SNMP managers that are permitted to use the community string to gain access to the agent. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits in dotted decimal notation to be applied to the source. Place ones in the bit positions that you want to ignore. <p>Recall that the access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <p>show running-config</p> <p>Example:</p> | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>show running-config</code> | |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

What to do next

To disable access for an SNMP community, set the community string for that community to the null string (do not enter a value for the community string).

To remove a specific community string, use the **no snmp-server** community string global configuration command.

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Configuring SNMP Groups and Users

You can specify an identification name (engine ID) for the local or remote SNMP server engine on the device. You can configure an SNMP server group that maps SNMP users to SNMP views, and you can add new users to the SNMP group.

Follow these steps to configure SNMP groups and users on the device.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | snmp-server engineID { local <i>engineid-string</i> remote <i>ip-address</i> [udp-port <i>port-number</i>] <i>engineid-string</i> } Example: | Configures a name for either the local or remote copy of SNMP. <ul style="list-style-type: none"> • The <i>engineid-string</i> is a 24-character ID string with the name of the copy of SNMP. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>Device(config)# snmp-server engineID local 1234</pre> | <p>You need not specify the entire 24-character engine ID if it has trailing zeros. Specify only the portion of the engine ID up to the point where only zeros remain in the value. The Step Example configures an engine ID of 123400000000000000000000.</p> <ul style="list-style-type: none"> If you select remote, specify the <i>ip-address</i> of the device that contains the remote copy of SNMP and the optional User Datagram Protocol (UDP) port on the remote device. The default is 162. |
| Step 4 | <p>snmp-server group <i>group-name</i> {v1 v2c v3 {auth noauth priv}} [read <i>readview</i>] [write <i>writeview</i>] [notify <i>notifyview</i>] [access <i>access-list</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server group public v2c access lmnop</pre> | <p>Configures a new SNMP group on the remote device.</p> <p>For <i>group-name</i>, specify the name of the group.</p> <p>Specify one of the following security models:</p> <ul style="list-style-type: none"> v1 is the least secure of the possible security models. v2c is the second least secure model. It allows transmission of informs and integers twice the normal width. v3, the most secure, requires you to select one of the following authentication levels: <ul style="list-style-type: none"> auth—Enables the Message Digest 5 (MD5) and the Secure Hash Algorithm (SHA) packet authentication. noauth—Enables the noAuthNoPriv security level. This is the default if no keyword is specified. priv—Enables Data Encryption Standard (DES) packet encryption (also called privacy). <p>(Optional) Enter read <i>readview</i> with a string (not to exceed 64 characters) that is the name of the view in which you can only view the contents of the agent.</p> <p>(Optional) Enter write <i>writeview</i> with a string (not to exceed 64 characters) that is the name of the view in which you enter data and configure the contents of the agent.</p> |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <p>(Optional) Enter notify <i>notifyview</i> with a string (not to exceed 64 characters) that is the name of the view in which you specify a notify, inform, or trap.</p> <p>(Optional) Enter access <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list.</p> |
| Step 5 | <p>snmp-server user <i>username group-name</i> { remote <i>host</i> [udp-port <i>port</i>] } { v1 [access <i>access-list</i>] v2c [access <i>access-list</i>] v3 [encrypted] [access <i>access-list</i>] [auth { md5 sha } <i>auth-password</i>] } [priv { des 3des aes { 128 192 256 } } <i>priv-password</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server user Pat public v2c</pre> | <p>Adds a new user for an SNMP group.</p> <p>The <i>username</i> is the name of the user on the host that connects to the agent.</p> <p>The <i>group-name</i> is the name of the group to which the user is associated.</p> <p>Enter remote to specify a remote SNMP entity to which the user belongs and the hostname or IP address of that entity with the optional UDP port number. The default is 162.</p> <p>Enter the SNMP version number (v1, v2c, or v3). If you enter v3, you have these additional options:</p> <ul style="list-style-type: none"> • encrypted specifies that the password appears in encrypted format. This keyword is available only when the v3 keyword is specified. • auth is an authentication level setting session that can be either the HMAC-MD5-96 (md5) or the HMAC-SHA-96 (sha) authentication level and requires a password string <i>auth-password</i> (not to exceed 64 characters). <p>If you enter v3 you can also configure a private (priv) encryption algorithm and password string <i>priv-password</i> using the following keywords (not to exceed 64 characters):</p> <ul style="list-style-type: none"> • priv specifies the User-based Security Model (USM). • des specifies the use of the 56-bit DES algorithm. • 3des specifies the use of the 168-bit DES algorithm. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> aes specifies the use of the DES algorithm. You must select either 128-bit, 192-bit, or 256-bit encryption. (Optional) Enter access <i>access-list</i> with a string (not to exceed 64 characters) that is the name of the access list. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring SNMP Notifications

A trap manager is a management station that receives and processes traps. Traps are system alerts that the device generates when certain events occur. By default, no trap manager is defined, and no traps are sent. Devices running this Cisco IOS release can have an unlimited number of trap managers.

Note Many commands use the word **traps** in the command syntax. Unless there is an option in the command to select either traps or informs, the keyword **traps** refers to traps, informs, or both. Use the **snmp-server host** global configuration command to specify whether to send SNMP notifications as traps or informs.

You can use the **snmp-server host** global configuration command for a specific host to receive the notification types listed in the following table. You can enable any or all of these traps and configure a trap manager to receive them.

Table 84: Device Notification Types

| Notification Type Keyword | Description |
|---------------------------|--|
| bridge | Generates STP bridge MIB traps. |
| cluster | Generates a trap when the cluster configuration changes. |

| Notification Type Keyword | Description |
|---------------------------|--|
| config | Generates a trap for SNMP configuration changes. |
| copy-config | Generates a trap for SNMP copy configuration changes. |
| cpu threshold | Allow CPU-related traps. |
| entity | Generates a trap for SNMP entity changes. |
| envmon | Generates environmental monitor traps. You can enable any or all of these environmental traps: fan, shutdown, status, supply, temperature. |
| errdisable | Generates a trap for a port VLAN errdisabled. You can also set a maximum trap rate per minute. The range is from 0 to 10000; the default is 0, which means there is no rate limit. |
| flash | Generates SNMP FLASH notifications. In a device stack, you can optionally enable notification for flash insertion or removal, which would cause a trap to be issued whenever a device in the stack is removed or inserted (physical removal, power cycle, or reload). |
| fru-ctrl | Generates entity field-replaceable unit (FRU) control traps. In the device stack, this trap refers to the insertion or removal of a device in the stack. |
| hsrp | Generates a trap for Hot Standby Router Protocol (HSRP) changes. |
| ipmulticast | Generates a trap for IP multicast routing changes. |
| ipsla | Generates a trap for the SNMP IP Service Level Agreements (SLAs). |
| mac-notification | Generates a trap for MAC address notifications. |
| msdp | Generates a trap for Multicast Source Discovery Protocol (MSDP) changes. |
| ospf | Generates a trap for Open Shortest Path First (OSPF) changes. You can enable any or all of these traps: Cisco specific, errors, link-state advertisement, rate limit, retransmit, and state changes. |
| pim | Generates a trap for Protocol-Independent Multicast (PIM) changes. You can enable any or all of these traps: invalid PIM messages, neighbor changes, and rendezvous point (RP)-mapping changes. |
| port-security | <p>Generates SNMP port security traps. You can also set a maximum trap rate per second. The range is from 0 to 1000; the default is 0, which means that there is no rate limit.</p> <p>Note When you configure a trap by using the notification type port-security, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> snmp-server enable traps port-security snmp-server enable traps port-security trap-rate <i>rate</i> |

| Notification Type Keyword | Description |
|---------------------------|--|
| snmp | Generates a trap for SNMP-type notifications for authentication, cold start, warm start, link up or link down. |
| storm-control | Generates a trap for SNMP storm-control. You can also set a maximum trap rate per minute. The range is from 0 to 1000; the default is 0 (no limit is imposed; a trap is sent at every occurrence). |
| stpx | Generates SNMP STP Extended MIB traps. |
| syslog | Generates SNMP syslog traps. |
| tty | Generates a trap for TCP connections. This trap is enabled by default. |
| vlan-membership | Generates a trap for SNMP VLAN membership changes. |
| vlancreate | Generates SNMP VLAN created traps. |
| vlandelete | Generates SNMP VLAN deleted traps. |
| vtp | Generates a trap for VLAN Trunking Protocol (VTP) changes. |

Follow these steps to configure the device to send traps or informs to a host.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | snmp-server engineID remote ip-address engineid-string Example: Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b | Specifies the engine ID for the remote host. |
| Step 4 | snmp-server user username group-name { remote host [udp-port port] } { v1 [access access-list] v2c [access access-list] v3 | Configures an SNMP user to be associated with the remote host created in Step 3. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <p>[encrypted] [access <i>access-list</i>] [auth {md5 sha} <i>auth-password</i>] }</p> <p>Example:</p> <pre>Device(config)# snmp-server user Pat public v2c</pre> | <p>Note You cannot configure a remote user for an address without first configuring the engine ID for the remote host. Otherwise, you receive an error message, and the command is not executed.</p> |
| Step 5 | <p>snmp-server group <i>group-name</i> {v1 v2c v3 {auth noauth priv}} [read <i>readview</i>] [write <i>writeview</i>] [notify <i>notifyview</i>] [access <i>access-list</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server group public v2c access lmnop</pre> | <p>Configures an SNMP group.</p> |
| Step 6 | <p>snmp-server host <i>host-addr</i> [informs traps] [version {1 2c 3 {auth noauth priv}}] <i>community-string</i> [<i>notification-type</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server host 203.0.113.1 comaccess snmp</pre> | <p>Specifies the recipient of an SNMP trap operation.</p> <p>For <i>host-addr</i>, specify the name or Internet address of the host (the targeted recipient).</p> <p>(Optional) Specify traps (the default) to send SNMP traps to the host.</p> <p>(Optional) Specify informs to send SNMP informs to the host.</p> <p>(Optional) Specify the SNMP version (1, 2c, or 3). SNMPv1 does not support informs.</p> <p>(Optional) For Version 3, select authentication level auth, noauth, or priv.</p> <p>Note The priv keyword is available only when the cryptographic software image is installed.</p> <p>For <i>community-string</i>, when version 1 or version 2c is specified, enter the password-like community string sent with the notification operation. When version 3 is specified, enter the SNMPv3 username.</p> <p>The @ symbol is used for delimiting the context information. Avoid using the @ symbol as part of the SNMP community string when configuring this command.</p> <p>(Optional) For <i>notification-type</i>, use the keywords listed in the table above. If no type is specified, all notifications are sent.</p> |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 7 | <p>snmp-server enable traps <i>notification-types</i></p> <p>Example:</p> <pre>Device(config)# snmp-server enable traps snmp</pre> | <p>Enables the device to send traps or informs and specifies the type of notifications to be sent. For a list of notification types, see the table above, or enter snmp-server enable traps ?</p> <p>To enable multiple types of traps, you must enter a separate snmp-server enable traps command for each trap type.</p> <p>Note When you configure a trap by using the notification type port-security, configure the port security trap first, and then configure the port security trap rate:</p> <ol style="list-style-type: none"> a. snmp-server enable traps port-security b. snmp-server enable traps port-security trap-rate rate |
| Step 8 | <p>snmp-server trap-source <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# snmp-server trap-source gigabitethernet 1/0/1</pre> | <p>(Optional) Specifies the source interface, which provides the IP address for the trap message. This command also sets the source IP address for informs.</p> |
| Step 9 | <p>snmp-server queue-length <i>length</i></p> <p>Example:</p> <pre>Device(config)# snmp-server queue-length 20</pre> | <p>(Optional) Establishes the message queue length for each trap host. The range is 1 to 5000; the default is 10.</p> |
| Step 10 | <p>snmp-server trap-timeout <i>seconds</i></p> <p>Example:</p> <pre>Device(config)# snmp-server trap-timeout 60</pre> | <p>(Optional) Defines how often to resend trap messages. The range is 1 to 1000; the default is 30 seconds.</p> |
| Step 11 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | <p>Returns to privileged EXEC mode.</p> |
| Step 12 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | <p>Verifies your entries.</p> |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 13 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

What to do next

The **snmp-server host** command specifies which hosts receive the notifications. The **snmp-server enable traps** command globally enables the method for the specified notification (for traps and informs). To enable a host to receive an inform, you must configure an **snmp-server host informs** command for the host and globally enable informs by using the **snmp-server enable traps** command.

To remove the specified host from receiving traps, use the **no snmp-server host** *host* global configuration command. The **no snmp-server host** command with no keywords disables traps, but not informs, to the host. To disable informs, use the **no snmp-server host informs** global configuration command. To disable a specific trap type, use the **no snmp-server enable traps** *notification-types* global configuration command.

Setting the Agent Contact and Location Information

Follow these steps to set the system contact and location of the SNMP agent so that these descriptions can be accessed through the configuration file.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | snmp-server contact <i>text</i> Example: <pre>Device(config)# snmp-server contact Dial System Operator at beeper 21555</pre> | Sets the system contact string. |
| Step 4 | snmp-server location <i>text</i> Example: | Sets the system location string. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device (config)# snmp-server location Building 3/Room 222 | |
| Step 5 | end Example: Device (config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Limiting TFTP Servers Used Through SNMP

Follow these steps to limit the TFTP servers used for saving and loading configuration files through SNMP to the servers specified in an access list.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | snmp-server tftp-server-list <i>access-list-number</i> Example: Device (config)# snmp-server tftp-server-list 44 | Limits the TFTP servers used for configuration file copies through SNMP to the servers in the access list. For <i>access-list-number</i> , enter an IP standard access list numbered from 1 to 99 and 1300 to 1999. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | <p>access-list <i>access-list-number</i> { deny permit } <i>source</i> [<i>source-wildcard</i>]</p> <p>Example:</p> <pre>Device(config)# access-list 44 permit 10.1.1.2</pre> | <p>Creates a standard access list, repeating the command as many times as necessary.</p> <p>For <i>access-list-number</i>, enter the access list number specified in Step 3.</p> <p>The deny keyword denies access if the conditions are matched. The permit keyword permits access if the conditions are matched.</p> <p>For <i>source</i>, enter the IP address of the TFTP servers that can access the device.</p> <p>(Optional) For <i>source-wildcard</i>, enter the wildcard bits, in dotted decimal notation, to be applied to the source. Place ones in the bit positions that you want to ignore.</p> <p>The access list is always terminated by an implicit deny statement for everything.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Monitoring SNMP Status

To display SNMP input and output statistics, including the number of illegal community string entries, errors, and requested variables, use the **show snmp** privileged EXEC command. You also can use the other privileged EXEC commands listed in the table to display SNMP information.

Table 85: Commands for Displaying SNMP Information

| Command | Purpose |
|------------------|---------------------------|
| show snmp | Displays SNMP statistics. |

| Command | Purpose |
|---------------------------|---|
| | Displays information on the local SNMP engine and all remote engines that have been configured on the device. |
| show snmp group | Displays information on each SNMP group on the network. |
| show snmp pending | Displays information on pending SNMP requests. |
| show snmp sessions | Displays information on the current SNMP sessions. |
| show snmp user | Displays information on each SNMP user name in the SNMP users table. Note You must use this command to display SNMPv3 configuration information for auth noauth priv mode. This information is displayed in the show running-config output. |

SNMP Examples

This example shows how to enable all versions of SNMP. The configuration permits any SNMP manager to access all objects with read-only permissions using the community string *public*. This configuration does not cause the device to send any traps.

```
Device(config)# snmp-server community public
```

This example shows how to permit any SNMP manager to access all objects with read-only permission using the community string *public*. The device also sends VTP traps to the hosts 192.180.1.111 and 192.180.1.33 using SNMPv1 and to the host 192.180.1.27 using SNMPv2C. The community string *public* is sent with the traps.

```
Device(config)# snmp-server community public
Device(config)# snmp-server enable traps vtp
Device(config)# snmp-server host 192.180.1.27 version 2c public
Device(config)# snmp-server host 192.180.1.111 version 1 public
Device(config)# snmp-server host 192.180.1.33 public
```

This example shows how to allow read-only access for all objects to members of access list 4 that use the *comaccess* community string. No other SNMP managers have access to any objects. SNMP Authentication Failure traps are sent by SNMPv2C to the host *cisco.com* using the community string *public*.

```
Device(config)# snmp-server community comaccess ro 4
Device(config)# snmp-server enable traps snmp authentication
Device(config)# snmp-server host cisco.com version 2c public
```

This example shows how to send Entity MIB traps to the host *cisco.com*. The community string is restricted. The first line enables the device to send Entity MIB traps in addition to any traps previously enabled. The second line specifies the destination of these traps and overwrites any previous **snmp-server** host commands for the host *cisco.com*.

```
Device(config)# snmp-server enable traps entity
Device(config)# snmp-server host cisco.com restricted entity
```

This example shows how to enable the device to send all traps to the host *myhost.cisco.com* using the community string *public*:

```
Device(config)# snmp-server enable traps
Device(config)# snmp-server host myhost.cisco.com public
```

This example shows how to associate a user with a remote host and to send **auth** (authNoPriv) authentication-level informs when the user enters global configuration mode:

```
Device(config)# snmp-server engineID remote 192.180.1.27 00000063000100a1c0b4011b
Device(config)# snmp-server group authgroup v3 auth
Device(config)# snmp-server user authuser authgroup remote 192.180.1.27 v3 auth md5 mypassword
Device(config)# snmp-server user authuser authgroup v3 auth md5 mypassword
Device(config)# snmp-server host 192.180.1.27 informs version 3 auth authuser config
Device(config)# snmp-server enable traps
Device(config)# snmp-server inform retries 0
```

CHAPTER 33

Configuring SPAN and RSPAN

- [Prerequisites for SPAN and RSPAN, on page 651](#)
- [Restrictions for SPAN and RSPAN, on page 651](#)
- [Information About SPAN and RSPAN, on page 653](#)
- [How to Configure SPAN and RSPAN, on page 662](#)
- [Monitoring SPAN and RSPAN Operations, on page 678](#)
- [SPAN and RSPAN Configuration Examples, on page 679](#)
- [Additional References, on page 681](#)
- [Feature History and Information for SPAN and RSPAN, on page 682](#)

Prerequisites for SPAN and RSPAN

SPAN

- You can limit SPAN traffic to specific VLANs by using the **filter vlan** keyword. If a trunk port is being monitored, only traffic on the VLANs specified with this keyword is monitored. By default, all VLANs are monitored on a trunk port.

RSPAN

- We recommend that you configure an RSPAN VLAN before you configure an RSPAN source or a destination session.

Restrictions for SPAN and RSPAN

SPAN

The restrictions for SPAN are as follows:

- On each device, you can configure 66 sessions. A maximum of 7 source sessions can be configured and the remaining sessions can be configured as RSPAN destinations sessions. A source session is either a local SPAN session or an RSPAN source session.
- For SPAN sources, you can monitor traffic for a single port or VLAN or a series or range of ports or VLANs for each session. You cannot mix source ports and source VLANs within a single SPAN session.

- The destination port cannot be a source port; a source port cannot be a destination port.
- You cannot have two SPAN sessions using the same destination port.
- When you configure a device port as a SPAN destination port, it is no longer a normal device port; only monitored traffic passes through the SPAN destination port.
- Entering SPAN configuration commands does not remove previously configured SPAN parameters. You must enter the **no monitor session** {*session_number* | **all** | **local** | **remote**} global configuration command to delete configured SPAN parameters.
- For local SPAN, outgoing packets through the SPAN destination port carry the original encapsulation headers—untagged, ISL, or IEEE 802.1Q—if the **encapsulation replicate** keywords are specified. If the keywords are not specified, the packets are sent in native form.
- You can configure a disabled port to be a source or destination port, but the SPAN function does not start until the destination port and at least one source port or source VLAN are enabled.
- You cannot mix source VLANs and filter VLANs within a single SPAN session.

Traffic monitoring in a SPAN session has the following restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- Wireshark does not capture egress packets when egress span is active.
- The device supports up to four local SPAN or RSPAN source sessions. However if this switch is stacked with Catalyst 2960-S switches, you are limited to 2 local SPAN or RSPAN source sessions.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
 - An RSPAN source session cannot have a local destination port.
 - An RSPAN destination session cannot have a local source port.
 - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

RSPAN

The restrictions for RSPAN are as follows:

- RSPAN does not support BPDU packet monitoring or other Layer 2 device protocols.
- The RSPAN VLAN is configured only on trunk ports and not on access ports. To avoid unwanted traffic in RSPAN VLANs, make sure that the VLAN remote-span feature is supported in all the participating devices.
- RSPAN VLANs are included as sources for port-based RSPAN sessions when source trunk ports have active RSPAN VLANs. RSPAN VLANs can also be sources in SPAN sessions. However, since the device does not monitor spanned traffic, it does not support egress spanning of packets on any RSPAN VLAN identified as the destination of an RSPAN source session on the device.
- CDP packets are not forwarded in RSPAN configured VLAN due to limitation in hardware. The workaround is to disable CDP on all the interfaces carrying RSPAN VLAN on the devices connected to the switch.
- If you enable VTP and VTP pruning, RSPAN traffic is pruned in the trunks to prevent the unwanted flooding of RSPAN traffic across the network for VLAN IDs that are lower than 1005.
- To use RSPAN, the switch must be running the LAN Base image.

Information About SPAN and RSPAN

SPAN and RSPAN

You can analyze network traffic passing through ports or VLANs by using SPAN or RSPAN to send a copy of the traffic to another port on the device or on another device that has been connected to a network analyzer or other monitoring or security device. SPAN copies (or mirrors) traffic received or sent (or both) on source ports or source VLANs to a destination port for analysis. SPAN does not affect the switching of network traffic on the source ports or VLANs. You must dedicate the destination port for SPAN use. Except for traffic that is required for the SPAN or RSPAN session, destination ports do not receive or forward traffic.

Only traffic that enters or leaves source ports or traffic that enters or leaves source VLANs can be monitored by using SPAN; traffic routed to a source VLAN cannot be monitored. For example, if incoming traffic is being monitored, traffic that gets routed from another VLAN to the source VLAN cannot be monitored; however, traffic that is received on the source VLAN and routed to another VLAN can be monitored.

You can use the SPAN or RSPAN destination port to inject traffic from a network security device. For example, if you connect a Cisco Intrusion Detection System (IDS) sensor appliance to a destination port, the IDS device can send TCP reset packets to close down the TCP session of a suspected attacker.

Local SPAN

Local SPAN supports a SPAN session entirely within one device; all source ports or source VLANs and destination ports are in the same device or device stack. Local SPAN copies traffic from one or more source ports in any VLAN or from one or more VLANs to a destination port for analysis.

Figure 73: Example of Local SPAN Configuration on a Single Device

All traffic on port 5 (the source port) is mirrored to port 10 (the destination port). A network analyzer on port 10 receives all network traffic from port 5 without being physically attached to port

Figure 74: Example of Local SPAN Configuration on a Device Stack

This is an example of a local SPAN in a device stack, where the source and destination ports reside on different stack members.

Remote SPAN

RSPAN supports source ports, source VLANs, and destination ports on different devices (or different device stacks), enabling remote monitoring of multiple devices across your network.

Figure 75: Example of RSPAN Configuration

The figure below shows source ports on Device A and Device B. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session in all participating devices.

The RSPAN traffic from the source ports or VLANs is copied into the RSPAN VLAN and forwarded over trunk ports carrying the RSPAN VLAN to a destination session monitoring the RSPAN VLAN. Each RSPAN source device must have either ports or VLANs as RSPAN sources. The destination is always a physical port,

as shown on Device C in the figure.

SPAN and RSPAN Concepts and Terminology

SPAN Sessions

SPAN sessions (local or remote) allow you to monitor traffic on one or more ports, or one or more VLANs, and send the monitored traffic to one or more destination ports.

A local SPAN session is an association of a destination port with source ports or source VLANs, all on a single network device. Local SPAN does not have separate source and destination sessions. Local SPAN sessions gather a set of ingress and egress packets specified by the user and form them into a stream of SPAN data, which is directed to the destination port.

RSPAN consists of at least one RSPAN source session, an RSPAN VLAN, and at least one RSPAN destination session. You separately configure RSPAN source sessions and RSPAN destination sessions on different network devices. To configure an RSPAN source session on a device, you associate a set of source ports or source VLANs with an RSPAN VLAN. The output of this session is the stream of SPAN packets that are sent to the RSPAN VLAN. To configure an RSPAN destination session on another device, you associate the destination port with the RSPAN VLAN. The destination session collects all RSPAN VLAN traffic and sends it out the RSPAN destination port.

An RSPAN source session is very similar to a local SPAN session, except for where the packet stream is directed. In an RSPAN source session, SPAN packets are relabeled with the RSPAN VLAN ID and directed over normal trunk ports to the destination device.

An RSPAN destination session takes all packets received on the RSPAN VLAN, strips off the VLAN tagging, and presents them on the destination port. The session presents a copy of all RSPAN VLAN packets (except Layer 2 control packets) to the user for analysis.

More than one source session and more than one destination session can be active in the same RSPAN VLAN. Intermediate devices also can separate the RSPAN source and destination sessions. These devices are unable to run RSPAN, but they must respond to the requirements of the RSPAN VLAN.

Traffic monitoring in a SPAN session has these restrictions:

- Sources can be ports or VLANs, but you cannot mix source ports and source VLANs in the same session.
- You can run both a local SPAN and an RSPAN source session in the same device or device stack. The device or device stack supports a total of 66 source and RSPAN destination sessions.
- You can configure two separate SPAN or RSPAN source sessions with separate or overlapping sets of SPAN source ports and VLANs. Both switched and routed ports can be configured as SPAN sources and destinations.
- You can have multiple destination ports in a SPAN session, but no more than 64 destination ports per device stack.
- SPAN sessions do not interfere with the normal operation of the device. However, an oversubscribed SPAN destination, for example, a 10-Mb/s port monitoring a 100-Mb/s port, can result in dropped or lost packets.
- When SPAN or RSPAN is enabled, each packet being monitored is sent twice, once as normal traffic and once as a monitored packet. Therefore monitoring a large number of ports or VLANs could potentially generate large amounts of network traffic.
- You can configure SPAN sessions on disabled ports; however, a SPAN session does not become active unless you enable the destination port and at least one source port or VLAN for that session.
- The device does not support a combination of local SPAN and RSPAN in a single session.
 - An RSPAN source session cannot have a local destination port.
 - An RSPAN destination session cannot have a local source port.
 - An RSPAN destination session and an RSPAN source session that are using the same RSPAN VLAN cannot run on the same device or device stack.

Monitored Traffic

SPAN sessions can monitor these traffic types:

- Receive (Rx) SPAN—Receive (or ingress) SPAN monitors as much as possible all of the packets received by the source interface or VLAN before any modification or processing is performed by the device. A copy of each packet received by the source is sent to the destination port for that SPAN session.

Packets that are modified because of routing or Quality of Service (QoS)—for example, modified Differentiated Services Code Point (DSCP)—are copied before modification.

Features that can cause a packet to be dropped during receive processing have no effect on ingress SPAN; the destination port receives a copy of the packet even if the actual incoming packet is dropped. These features include IP standard and extended input Access Control Lists (ACLs), ingress QoS policing, VLAN ACLs, and egress QoS policing.

- **Transmit (Tx) SPAN**—Transmit (or egress) SPAN monitors as much as possible all of the packets sent by the source interface after all modification and processing is performed by the device. A copy of each packet sent by the source is sent to the destination port for that SPAN session. The copy is provided after the packet is modified.

Packets that are modified because of routing (for example, with modified time-to-live (TTL), MAC address, or QoS values) are duplicated (with the modifications) at the destination port.

Features that can cause a packet to be dropped during transmit processing also affect the duplicated copy for SPAN. These features include IP standard and extended output ACLs and egress QoS policing.

- **Both**—In a SPAN session, you can also monitor a port or VLAN for both received and sent packets. This is the default.

The default configuration for local SPAN session ports is to send all packets untagged. SPAN also does not normally monitor bridge protocol data unit (BPDU) packets and Layer 2 protocols, such as Cisco Discovery Protocol (CDP), VLAN Trunk Protocol (VTP), Dynamic Trunking Protocol (DTP), Spanning Tree Protocol (STP), and Port Aggregation Protocol (PAgP). However, when you enter the **encapsulation replicate** keywords when configuring a destination port, these changes occur:

- Packets are sent on the destination port with the same encapsulation (untagged or IEEE 802.1Q) that they had on the source port.
- Packets of all types, including BPDU and Layer 2 protocol packets, are monitored.

Therefore, a local SPAN session with **encapsulation replicate** enabled can have a mixture of untagged and IEEE 802.1Q tagged packets appear on the destination port.

Device congestion can cause packets to be dropped at ingress source ports, egress source ports, or SPAN destination ports. In general, these characteristics are independent of one another. For example:

- A packet might be forwarded normally but dropped from monitoring due to an oversubscribed SPAN destination port.
- An ingress packet might be dropped from normal forwarding, but still appear on the SPAN destination port.
- An egress packet dropped because of device congestion is also dropped from egress SPAN.

In some SPAN configurations, multiple copies of the same source packet are sent to the SPAN destination port. For example, a bidirectional (both Rx and Tx) SPAN session is configured for the Rx monitor on port A and Tx monitor on port B. If a packet enters the device through port A and is switched to port B, both incoming and outgoing packets are sent to the destination port. Both packets are the same unless a Layer 3 rewrite occurs, in which case the packets are different because of the packet modification.

Source Ports

A source port (also called a monitored port) is a switched or routed port that you monitor for network traffic analysis.

In a local SPAN session or RSPAN source session, you can monitor source ports or VLANs for traffic in one or both directions.

The device supports any number of source ports (up to the maximum number of available ports on the device) and any number of source VLANs (up to the maximum number of VLANs supported).

However, the device supports a maximum of four sessions (two sessions if device is in a stack with Catalyst 2960-S switches) (local or RSPAN) with source ports or VLANs. You cannot mix ports and VLANs in a single session.

A source port has these characteristics:

- It can be monitored in multiple SPAN sessions.
- Each source port can be configured with a direction (ingress, egress, or both) to monitor.
- It can be any port type (for example, EtherChannel, Gigabit Ethernet, and so forth).
- For EtherChannel sources, you can monitor traffic for the entire EtherChannel or individually on a physical port as it participates in the port channel.
- It can be an access port, trunk port, routed port, or voice VLAN port.
- It cannot be a destination port.
- Source ports can be in the same or different VLANs.
- You can monitor multiple source ports in a single session.

Source VLANs

VLAN-based SPAN (VSPAN) is the monitoring of the network traffic in one or more VLANs. The SPAN or RSPAN source interface in VSPAN is a VLAN ID, and traffic is monitored on all the ports for that VLAN.

VSPAN has these characteristics:

- All active ports in the source VLAN are included as source ports and can be monitored in either or both directions.
- On a given port, only traffic on the monitored VLAN is sent to the destination port.
- If a destination port belongs to a source VLAN, it is excluded from the source list and is not monitored.
- If ports are added to or removed from the source VLANs, the traffic on the source VLAN received by those ports is added to or removed from the sources being monitored.
- You cannot use filter VLANs in the same session with VLAN sources.
- You can monitor only Ethernet VLANs.

VLAN Filtering

When you monitor a trunk port as a source port, by default, all VLANs active on the trunk are monitored. You can limit SPAN traffic monitoring on trunk source ports to specific VLANs by using VLAN filtering.

- VLAN filtering applies only to trunk ports or to voice VLAN ports.
- VLAN filtering applies only to port-based sessions and is not allowed in sessions with VLAN sources.
- When a VLAN filter list is specified, only those VLANs in the list are monitored on trunk ports or on voice VLAN access ports.
- SPAN traffic coming from other port types is not affected by VLAN filtering; that is, all VLANs are allowed on other ports.

- VLAN filtering affects only traffic forwarded to the destination SPAN port and does not affect the switching of normal traffic.

Destination Port

Each local SPAN session or RSPAN destination session must have a destination port (also called a monitoring port) that receives a copy of traffic from the source ports or VLANs and sends the SPAN packets to the user, usually a network analyzer.

A destination port has these characteristics:

- For a local SPAN session, the destination port must reside on the same device or device stack as the source port. For an RSPAN session, it is located on the device containing the RSPAN destination session. There is no destination port on a device or device stack running only an RSPAN source session.
- When a port is configured as a SPAN destination port, the configuration overwrites the original port configuration. When the SPAN destination configuration is removed, the port reverts to its previous configuration. If a configuration change is made to the port while it is acting as a SPAN destination port, the change does not take effect until the SPAN destination configuration had been removed.

Note When QoS is configured on the SPAN destination port, QoS takes effect immediately.

- If the port was in an EtherChannel group, it is removed from the group while it is a destination port. If it was a routed port, it is no longer a routed port.
- It can be any Ethernet physical port.
- It cannot be a secure port.
- It cannot be a source port.
- It can participate in only one SPAN session at a time (a destination port in one SPAN session cannot be a destination port for a second SPAN session).
- When it is active, incoming traffic is disabled. The port does not transmit any traffic except that required for the SPAN session. Incoming traffic is never learned or forwarded on a destination port.
- If ingress traffic forwarding is enabled for a network security device, the destination port forwards traffic at Layer 2.
- It does not participate in any of the Layer 2 protocols (STP, VTP, CDP, DTP, PagP).
- A destination port that belongs to a source VLAN of any SPAN session is excluded from the source list and is not monitored.
- The maximum number of destination ports in a device or device stack is 64.

Local SPAN and RSPAN destination ports function differently with VLAN tagging and encapsulation:

- For local SPAN, if the **encapsulation replicate** keywords are specified for the destination port, these packets appear with the original encapsulation (untagged, ISL, or IEEE 802.1Q). If these keywords are not specified, packets appear in the untagged format. Therefore, the output of a local SPAN session with **encapsulation replicate** enabled can contain a mixture of untagged, ISL, or IEEE 802.1Q-tagged packets.

- For RSPAN, the original VLAN ID is lost because it is overwritten by the RSPAN VLAN identification. Therefore, all packets appear on the destination port as untagged.

RSPAN VLAN

The RSPAN VLAN carries SPAN traffic between RSPAN source and destination sessions. RSPAN VLAN has these special characteristics:

- All traffic in the RSPAN VLAN is always flooded.
- No MAC address learning occurs on the RSPAN VLAN.
- RSPAN VLAN traffic only flows on trunk ports.
- RSPAN VLANs must be configured in VLAN configuration mode by using the **remote-span** VLAN configuration mode command.
- STP can run on RSPAN VLAN trunks but not on SPAN destination ports.
- An RSPAN VLAN cannot be a private-VLAN primary or secondary VLAN.

For VLANs 1 to 1005 that are visible to VLAN Trunking Protocol (VTP), the VLAN ID and its associated RSPAN characteristic are propagated by VTP. If you assign an RSPAN VLAN ID in the extended VLAN range (1006 to 4094), you must manually configure all intermediate devices.

It is normal to have multiple RSPAN VLANs in a network at the same time with each RSPAN VLAN defining a network-wide RSPAN session. That is, multiple RSPAN source sessions anywhere in the network can contribute packets to the RSPAN session. It is also possible to have multiple RSPAN destination sessions throughout the network, monitoring the same RSPAN VLAN and presenting traffic to the user. The RSPAN VLAN ID separates the sessions.

SPAN and RSPAN Interaction with Other Features

SPAN interacts with these features:

- Routing—SPAN does not monitor routed traffic. VSPAN only monitors traffic that enters or exits the device, not traffic that is routed between VLANs. For example, if a VLAN is being Rx-monitored and the device routes traffic from another VLAN to the monitored VLAN, that traffic is not monitored and not received on the SPAN destination port.
- STP—A destination port does not participate in STP while its SPAN or RSPAN session is active. The destination port can participate in STP after the SPAN or RSPAN session is disabled. On a source port, SPAN does not affect the STP status. STP can be active on trunk ports carrying an RSPAN VLAN.
- CDP—A SPAN destination port does not participate in CDP while the SPAN session is active. After the SPAN session is disabled, the port again participates in CDP.
- VTP—You can use VTP to prune an RSPAN VLAN between devices.
- VLAN and trunking—You can modify VLAN membership or trunk settings for source or destination ports at any time. However, changes in VLAN membership or trunk settings for a destination port do not take effect until you remove the SPAN destination configuration. Changes in VLAN membership or trunk settings for a source port immediately take effect, and the respective SPAN sessions automatically adjust accordingly.
- EtherChannel—You can configure an EtherChannel group as a source port a SPAN destination port. When a group is configured as a SPAN source, the entire group is monitored.

If a physical port is added to a monitored EtherChannel group, the new port is added to the SPAN source port list. If a port is removed from a monitored EtherChannel group, it is automatically removed from the source port list.

A physical port that belongs to an EtherChannel group can be configured as a SPAN source port and still be a part of the EtherChannel. In this case, data from the physical port is monitored as it participates in the EtherChannel. However, if a physical port that belongs to an EtherChannel group is configured as a SPAN destination, it is removed from the group. After the port is removed from the SPAN session, it rejoins the EtherChannel group. Ports removed from an EtherChannel group remain members of the group, but they are in the inactive or suspended state.

If a physical port that belongs to an EtherChannel group is a destination port and the EtherChannel group is a source, the port is removed from the EtherChannel group and from the list of monitored ports.

- Multicast traffic can be monitored. For egress and ingress port monitoring, only a single unedited packet is sent to the SPAN destination port. It does not reflect the number of times the multicast packet is sent.
- A private-VLAN port cannot be a SPAN destination port.
- A secure port cannot be a SPAN destination port.

For SPAN sessions, do not enable port security on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable port security on any ports with monitored egress.

- An IEEE 802.1x port can be a SPAN source port. You can enable IEEE 802.1x on a port that is a SPAN destination port; however, IEEE 802.1x is disabled until the port is removed as a SPAN destination.

For SPAN sessions, do not enable IEEE 802.1x on ports with monitored egress when ingress forwarding is enabled on the destination port. For RSPAN source sessions, do not enable IEEE 802.1x on any ports that are egress monitored.

SPAN and RSPAN and Device Stacks

Because the stack of devices represents one logical device, local SPAN source ports and destination ports can be in different devices in the stack. Therefore, the addition or deletion of devices in the stack can affect a local SPAN session, as well as an RSPAN source or destination session. An active session can become inactive when a device is removed from the stack or an inactive session can become active when a device is added to the stack.

Default SPAN and RSPAN Configuration

Table 86: Default SPAN and RSPAN Configuration

| Feature | Default Setting |
|---------------------------------------|---|
| SPAN state (SPAN and RSPAN) | Disabled. |
| Source port traffic to monitor | Both received and sent traffic (both). |
| Encapsulation type (destination port) | Native form (untagged packets). |
| Ingress forwarding (destination port) | Disabled. |

| Feature | Default Setting |
|----------------|--|
| VLAN filtering | On a trunk interface used as a source port, all VLANs are monitored. |
| RSPAN VLANs | None configured. |

Configuration Guidelines

SPAN Configuration Guidelines

- To remove a source or destination port or VLAN from the SPAN session, use the **no monitor session session_number source {interface interface-id | vlan vlan-id}** global configuration command or the **no monitor session session_number destination interface interface-id** global configuration command. For destination interfaces, the **encapsulation** options are ignored with the **no** form of the command.
- To monitor all VLANs on the trunk port, use the **no monitor session session_number filter** global configuration command.

RSPAN Configuration Guidelines

- All the SPAN configuration guidelines apply to RSPAN.
- As RSPAN VLANs have special properties, you should reserve a few VLANs across your network for use as RSPAN VLANs; do not assign access ports to these VLANs.
- You can apply an output ACL to RSPAN traffic to selectively filter or monitor specific packets. Specify these ACLs on the RSPAN VLAN in the RSPAN source devices.
- For RSPAN configuration, you can distribute the source ports and the destination ports across multiple devices in your network.
- Access ports (including voice VLAN ports) on the RSPAN VLAN are put in the inactive state.
- You can configure any VLAN as an RSPAN VLAN as long as these conditions are met:
 - The same RSPAN VLAN is used for an RSPAN session in all the devices.
 - All participating devices support RSPAN.

How to Configure SPAN and RSPAN

Creating a Local SPAN Session

Follow these steps to create a SPAN session and specify the source (monitored) ports or VLANs and the destination (monitoring) ports.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | no monitor session { <i>session_number</i> all local remote } Example: <pre>Device(config)# no monitor session all</pre> | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 4. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | monitor session <i>session_number</i> source { interface <i>interface-id</i> / vlan <i>vlan-id</i> } [, -] [both rx tx] Example: <pre>Device(config)# monitor session 1 source interface gigabitethernet1/0/1</pre> | Specifies the SPAN session and the source port (monitored port). <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 4. • For <i>interface-id</i>, specify the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 6. • For <i>vlan-id</i>, specify the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). <p>Note A single session can include multiple sources (ports or VLANs) defined in a series of commands, but you cannot combine source ports and source VLANs in one session.</p> <ul style="list-style-type: none"> • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <p>the comma; enter a space before and after the hyphen.</p> <ul style="list-style-type: none"> • (Optional) both rx tx—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. <ul style="list-style-type: none"> • both—Monitors both received and sent traffic. • rx—Monitors received traffic. • tx—Monitors sent traffic. <p>Note You can use the monitor session <i>session_number</i> source command multiple times to configure multiple source ports.</p> |
| Step 5 | <p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [encapsulation replicate]}</p> <p>Example:</p> <pre>Device(config)# monitor session 1 destination interface gigabitethernet1/0/2 encapsulation replicate</pre> | <p>Specifies the SPAN session and the destination port (monitoring port). The port LED changes to amber when the configuration changes take effect. The LED returns to its original state(green) only after removing the SPAN destination configuration.</p> <p>Note For local SPAN, you must use the same session number for the source and destination interfaces.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. <p>(Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged).</p> |

| | Command or Action | Purpose |
|---------------|---|---|
| | | Note You can use monitor session session_number destination command multiple times to configure multiple destination ports. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Creating a Local SPAN Session and Configuring Incoming Traffic

Follow these steps to create a SPAN session, to specify the source ports or VLANs and the destination ports, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 3 | <p>no monitor session {<i>session_number</i> all local remote}</p> <p>Example:</p> <pre>Device(config)# no monitor session all</pre> | <p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 4. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | <p>monitor session <i>session_number</i> source {interface <i>interface-id</i> vlan <i>vlan-id</i>} [, -] [both rx tx]</p> <p>Example:</p> <pre>Device(config)# monitor session 2 source gigabitethernet0/1 rx</pre> | <p>Specifies the SPAN session and the source port (monitored port).</p> |
| Step 5 | <p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [encapsulation replicate[ingress {dot1q vlan <i>vlan-id</i> untagged vlan <i>vlan-id</i> vlan <i>vlan-id</i>}]}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 encapsulation replicate ingress dot1q vlan 6</pre> | <p>Specifies the SPAN session, the destination port, the packet encapsulation, and the ingress VLAN and encapsulation.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma or hyphen. • (Optional) encapsulation replicate—Specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). • ingress—Enables forwarding of incoming traffic on the destination port and to specify the encapsulation type. <ul style="list-style-type: none"> • dot1q vlan <i>vlan-id</i>—Accepts incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN. • untagged vlan <i>vlan-id</i> or vlan <i>vlan-id</i>—Accepts incoming packets |

| | Command or Action | Purpose |
|---------------|---|---|
| | | with untagged encapsulation type with the specified VLAN as the default VLAN. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Specifying VLANs to Filter

Follow these steps to limit SPAN source traffic to specific VLANs.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | no monitor session { <i>session_number</i> all local remote } Example: | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>Device(config)# no monitor session all</pre> | <ul style="list-style-type: none"> • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | <p>monitor session <i>session_number</i> source interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</pre> | <p>Specifies the characteristics of the source port (monitored port) and SPAN session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port. |
| Step 5 | <p>monitor session <i>session_number</i> filter vlan <i>vlan-id</i> [, -]</p> <p>Example:</p> <pre>Device(config)# monitor session 2 filter vlan 1 - 5 , 9</pre> | <p>Limits the SPAN source traffic to specific VLANs.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the session number specified in Step 4. • For <i>vlan-id</i>, the range is 1 to 4094. • (Optional) Use a comma (,) to specify a series of VLANs, or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen. |
| Step 6 | <p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [encapsulation replicate]}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/1</pre> | <p>Specifies the SPAN session and the destination port (monitoring port).</p> <ul style="list-style-type: none"> • For <i>session_number</i>, specify the session number entered in Step 4. • For <i>interface-id</i>, specify the destination port. The destination interface must be a physical port; it cannot be an EtherChannel, and it cannot be a VLAN. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) encapsulation replicate specifies that the destination interface replicates the source interface encapsulation method. If not selected, the default is to send packets in native form (untagged). |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 7 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 8 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring a VLAN as an RSPAN VLAN

Follow these steps to create a new VLAN, then configure it to be the RSPAN VLAN for the RSPAN session.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | vlan <i>vlan-id</i> Example: Device(config)# vlan 100 | Enters a VLAN ID to create a VLAN, or enters the VLAN ID of an existing VLAN, and enters VLAN configuration mode. The range is 2 to 1001 and 1006 to 4094. The RSPAN VLAN cannot be VLAN 1 (the default VLAN) or VLAN IDs 1002 through 1005 (reserved for Token Ring and FDDI VLANs). |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | remote-span Example: Device (config-vlan) # remote-span | Configures the VLAN as an RSPAN VLAN. |
| Step 5 | end Example: Device (config-vlan) # end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

What to do next

You must create the RSPAN VLAN in all devices that will participate in RSPAN. If the RSPAN VLAN-ID is in the normal range (lower than 1005) and VTP is enabled in the network, you can create the RSPAN VLAN in one device, and VTP propagates it to the other devices in the VTP domain. For extended-range VLANs (greater than 1005), you must configure RSPAN VLAN on both source and destination devices and any intermediate devices.

Use VTP pruning to get an efficient flow of RSPAN traffic, or manually delete the RSPAN VLAN from all trunks that do not need to carry the RSPAN traffic.

To remove the remote SPAN characteristic from a VLAN and convert it back to a normal VLAN, use the **no remote-span** VLAN configuration command.

To remove a source port or VLAN from the SPAN session, use the **no monitor session session_number source {interface interface-id | vlan vlan-id}** global configuration command. To remove the RSPAN VLAN from the session, use the **no monitor session session_number destination remote vlan vlan-id**.

Creating an RSPAN Source Session

Follow these steps to create and start an RSPAN source session and to specify the monitored source and the destination RSPAN VLAN.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | no monitor session { <i>session_number</i> all local remote } Example: <pre>Device(config)# no monitor session 1</pre> | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | monitor session <i>session_number</i> source { interface <i>interface-id</i> vlan <i>vlan-id</i> } [, -] [both rx tx] Example: <pre>Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx</pre> | Specifies the RSPAN session and the source port (monitored port). <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • Enter a source port or source VLAN for the RSPAN session: <ul style="list-style-type: none"> • For <i>interface-id</i>, specifies the source port to monitor. Valid interfaces include physical interfaces and port-channel logical interfaces (port-channel <i>port-channel-number</i>). Valid port-channel numbers are 1 to 48. • For <i>vlan-id</i>, specifies the source VLAN to monitor. The range is 1 to 4094 (excluding the RSPAN VLAN). A single session can include multiple sources (ports or VLANs), defined in a series of commands, but you cannot combine source ports and source VLANs in one session. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <ul style="list-style-type: none"> • (Optional) [, -]—Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • (Optional) both rx tx—Specifies the direction of traffic to monitor. If you do not specify a traffic direction, the source interface sends both sent and received traffic. <ul style="list-style-type: none"> • both—Monitors both received and sent traffic. • rx—Monitors received traffic. • tx—Monitors sent traffic. |
| Step 5 | monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i> Example: <pre>Device(config)# monitor session 1 destination remote vlan 100</pre> | Specifies the RSPAN session, the destination RSPAN VLAN, and the destination-port group. <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 4. • For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor. |
| Step 6 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Specifying VLANs to Filter

Follow these steps to configure the RSPAN source session to limit RSPAN source traffic to specific VLANs.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | no monitor session { <i>session_number</i> all local remote } Example: <pre>Device(config)# no monitor session 2</pre> | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | monitor session <i>session_number</i> source interface <i>interface-id</i> Example: <pre>Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx</pre> | Specifies the characteristics of the source port (monitored port) and SPAN session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>interface-id</i>, specify the source port to monitor. The interface specified must already be configured as a trunk port. |
| Step 5 | monitor session <i>session_number</i> filter vlan <i>vlan-id</i> [, -] Example: <pre>Device(config)# monitor session 2 filter vlan 1 - 5 , 9</pre> | Limits the SPAN source traffic to specific VLANs. <ul style="list-style-type: none"> • For <i>session_number</i>, enter the session number specified in step 4. • For <i>vlan-id</i>, the range is 1 to 4094. • (Optional) , - Use a comma (,) to specify a series of VLANs or use a hyphen (-) to specify a range of VLANs. Enter a space before and after the comma; enter a space before and after the hyphen. |
| Step 6 | monitor session <i>session_number</i> destination remote vlan <i>vlan-id</i> Example: | Specifies the RSPAN session and the destination remote VLAN (RSPAN VLAN). |

| | Command or Action | Purpose |
|---------------|---|--|
| | <pre>Device(config)# monitor session 2 destination remote vlan 902</pre> | <ul style="list-style-type: none"> For <i>session_number</i>, enter the session number specified in Step 4. For <i>vlan-id</i>, specify the RSPAN VLAN to carry the monitored traffic to the destination port. |
| Step 7 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 9 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Creating an RSPAN Destination Session

You configure an RSPAN destination session on a different device or device stack; that is, not the device or device stack on which the source session was configured.

Follow these steps to define the RSPAN VLAN on that device, to create an RSPAN destination session, and to specify the source RSPAN VLAN and the destination port.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | vlan <i>vlan-id</i> Example: Device (config) # vlan 901 | Specifies the VLAN ID of the RSPAN VLAN created from the source device, and enters VLAN configuration mode. If both devices are participating in VTP and the RSPAN VLAN ID is from 2 to 1005, Steps 3 through 5 are not required because the RSPAN VLAN ID is propagated through the VTP network. |
| Step 4 | remote-span Example: Device (config-vlan) # remote-span | Identifies the VLAN as the RSPAN VLAN. |
| Step 5 | exit Example: Device (config-vlan) # exit | Returns to global configuration mode. |
| Step 6 | no monitor session { <i>session_number</i> all local remote } Example: Device (config) # no monitor session 1 | Removes any existing SPAN configuration for the session. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 7 | monitor session <i>session_number</i> source remote vlan <i>vlan-id</i> Example: Device (config) # monitor session 1 source remote vlan 901 | Specifies the RSPAN session and the source RSPAN VLAN. <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor. |
| Step 8 | monitor session <i>session_number</i> destination interface <i>interface-id</i> Example: Device (config) # monitor session 1 destination interface gigabitethernet2/0/1 | Specifies the RSPAN session and the destination interface. <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 7. In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port. |

| | Command or Action | Purpose |
|----------------|---|---|
| | | <ul style="list-style-type: none"> For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface. Though visible in the command-line help string, encapsulation replicate is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged. |
| Step 9 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 10 | show running-config Example: <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 11 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Creating an RSPAN Destination Session and Configuring Incoming Traffic

Follow these steps to create an RSPAN destination session, to specify the source RSPAN VLAN and the destination port, and to enable incoming traffic on the destination port for a network security device (such as a Cisco IDS Sensor Appliance).

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device# <code>configure terminal</code> | |
| Step 3 | <p>no monitor session {<i>session_number</i> all local remote}</p> <p>Example:</p> <pre>Device(config)# no monitor session 2</pre> | <p>Removes any existing SPAN configuration for the session.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • all—Removes all SPAN sessions. • local—Removes all local sessions. • remote—Removes all remote SPAN sessions. |
| Step 4 | <p>monitor session <i>session_number</i> source remote vlan <i>vlan-id</i></p> <p>Example:</p> <pre>Device(config)# monitor session 2 source remote vlan 901</pre> | <p>Specifies the RSPAN session and the source RSPAN VLAN.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, the range is 1 to 66. • For <i>vlan-id</i>, specify the source RSPAN VLAN to monitor. |
| Step 5 | <p>monitor session <i>session_number</i> destination {interface <i>interface-id</i> [, -] [ingress {dot1q vlan <i>vlan-id</i> untagged vlan <i>vlan-id</i> vlan <i>vlan-id</i>}]}</p> <p>Example:</p> <pre>Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6</pre> | <p>Specifies the SPAN session, the destination port, the packet encapsulation, and the incoming VLAN and encapsulation.</p> <ul style="list-style-type: none"> • For <i>session_number</i>, enter the number defined in Step 5. • In an RSPAN destination session, you must use the same session number for the source RSPAN VLAN and the destination port. • For <i>interface-id</i>, specify the destination interface. The destination interface must be a physical interface. • Though visible in the command-line help string, encapsulation replicate is not supported for RSPAN. The original VLAN ID is overwritten by the RSPAN VLAN ID, and all packets appear on the destination port as untagged. • (Optional) [, -] Specifies a series or range of interfaces. Enter a space before and after the comma; enter a space before and after the hyphen. • Enter ingress with additional keywords to enable forwarding of incoming traffic on |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>the destination port and to specify the encapsulation type:</p> <ul style="list-style-type: none"> • dot1q vlan <i>vlan-id</i>—Forwards incoming packets with IEEE 802.1Q encapsulation with the specified VLAN as the default VLAN. • untagged vlan <i>vlan-id</i> or vlan <i>vlan-id</i>—Forwards incoming packets with untagged encapsulation type with the specified VLAN as the default VLAN. |
| Step 6 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 8 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Monitoring SPAN and RSPAN Operations

The following table describes the command used to display SPAN and RSPAN operations configuration and results to monitor operations:

Table 87: Monitoring SPAN and RSPAN Operations

| Command | Purpose |
|---------------------|---|
| show monitor | Displays the current SPAN, RSPAN configuration. |

SPAN and RSPAN Configuration Examples

Example: Configuring Local SPAN

This example shows how to set up SPAN session 1 for monitoring source port traffic to a destination port. First, any existing SPAN configuration for session 1 is deleted, and then bidirectional traffic is mirrored from source Gigabit Ethernet port 1 to destination Gigabit Ethernet port 2, retaining the encapsulation method.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1
Device(config)# monitor session 1 destination interface gigabitethernet1/0/2
encapsulation replicate
Device(config)# end
```

This example shows how to remove port 1 as a SPAN source for SPAN session 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1
Device(config)# end
```

This example shows how to disable received traffic monitoring on port 1, which was configured for bidirectional monitoring:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1 source interface gigabitethernet1/0/1 rx
```

The monitoring of traffic received on port 1 is disabled, but traffic sent from this port continues to be monitored.

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on all ports belonging to VLANs 1 through 3, and send it to destination Gigabit Ethernet port 2. The configuration is then modified to also monitor all traffic on all ports belonging to VLAN 10.

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source vlan 1 - 3 rx
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2
Device(config)# monitor session 2 source vlan 10
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor received traffic on Gigabit Ethernet source port 1, and send it to destination Gigabit Ethernet port 2 with the same egress encapsulation type as the source port, and to enable ingress forwarding with VLAN 6 as the default ingress VLAN:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source gigabitethernet0/1 rx
```

```
Device(config)# monitor session 2 destination interface gigabitethernet0/2 encapsulation
replicate ingress vlan 6
Device(config)# end
```

This example shows how to remove any existing configuration on SPAN session 2, configure SPAN session 2 to monitor traffic received on Gigabit Ethernet trunk port 2, and send traffic for only VLANs 1 through 5 and VLAN 9 to destination Gigabit Ethernet port 1:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination interface gigabitethernet1/0/1
Device(config)# end
```

Examples: Creating an RSPAN VLAN

This example shows how to create the RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# vlan 901
Device(config-vlan)# remote span
Device(config-vlan)# end
```

This example shows how to remove any existing RSPAN configuration for session 1, configure RSPAN session 1 to monitor multiple source interfaces, and configure the destination as RSPAN VLAN 901:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 1
Device(config)# monitor session 1 source interface gigabitethernet1/0/1 tx
Device(config)# monitor session 1 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 1 source interface port-channel 2
Device(config)# monitor session 1 destination remote vlan 901
Device(config)# end
```

This example shows how to remove any existing configuration on RSPAN session 2, configure RSPAN session 2 to monitor traffic received on trunk port 2, and send traffic for only VLANs 1 through 5 and 9 to destination RSPAN VLAN 902:

```
Device> enable
Device# configure terminal
Device(config)# no monitor session 2
Device(config)# monitor session 2 source interface gigabitethernet1/0/2 rx
Device(config)# monitor session 2 filter vlan 1 - 5 , 9
Device(config)# monitor session 2 destination remote vlan 902
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN and port 1 as the destination interface:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 1 source remote vlan 901
```

```
Device(config)# monitor session 1 destination interface gigabitethernet2/0/1
Device(config)# end
```

This example shows how to configure VLAN 901 as the source remote VLAN in RSPAN session 2, to configure Gigabit Ethernet source port 2 as the destination interface, and to enable forwarding of incoming traffic on the interface with VLAN 6 as the default receiving VLAN:

```
Device> enable
Device# configure terminal
Device(config)# monitor session 2 source remote vlan 901
Device(config)# monitor session 2 destination interface gigabitethernet1/0/2 ingress vlan 6
Device(config)# end
```

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About Configuring IP Unicast Routing

This module describes how to configure IP Version 4 (IPv4) unicast routing on the switch.

A switch stack operates and appears as a single router to the rest of the routers in the network. .

Note In addition to IPv4 traffic, you can also enable IP Version 6 (IPv6) unicast routing and configure interfaces to forward IPv6 traffic .

Information About IP Routing

In some network environments, VLANs are associated with individual networks or subnetworks. In an IP network, each subnetwork is mapped to an individual VLAN. Configuring VLANs helps control the size of the broadcast domain and keeps local traffic local. However, network devices in different VLANs cannot communicate with one another without a Layer 3 device (router) to route traffic between the VLAN, referred to as inter-VLAN routing. You configure one or more routers to route traffic to the appropriate destination VLAN.

Figure 76: Routing Topology Example

This figure shows a basic routing topology. Switch A is in VLAN 10, and Switch B is in VLAN 20. The router

has an interface in each VLAN.

When Host A in VLAN 10 needs to communicate with Host B in VLAN 10, it sends a packet addressed to that host. Switch A forwards the packet directly to Host B, without sending it to the router.

When Host A sends a packet to Host C in VLAN 20, Switch A forwards the packet to the router, which receives the traffic on the VLAN 10 interface. The router checks the routing table, finds the correct outgoing interface, and forwards the packet on the VLAN 20 interface to Switch B. Switch B receives the packet and forwards it to Host C.

Types of Routing

Routers and Layer 3 switches can route packets in these ways:

- By using default routing
- By using preprogrammed static routes for the traffic
- By dynamically calculating routes by using a routing protocol

The switch supports static routes and default routes. It does not support routing protocols.

IP Routing and Switch Stacks

A switch stack appears to the network as a single switch, regardless of which switch in the stack is connected to a routing peer.

The active switch performs these functions:

- It generates, maintains, and distributes the distributed Cisco Express Forwarding (dCEF) database to all stack members. The routes are programmed on all switches in the stack bases on this database.
- The MAC address of the active switch is used as the router MAC address for the whole stack, and all outside devices use this address to send IP packets to the stack.
- All IP packets that require software forwarding or processing go through the CPU of the active switch.

Stack members perform these functions:

- They act as routing standby switches, ready to take over in case they are elected as the new active switch if the active switch fails.
- They program the routes into hardware.

If a active switch fails, the stack detects that the active switch is down and elects one of the stack members to be the new active switch. During this period, except for a momentary interruption, the hardware continues to forward packets with no active protocols.

Upon election, the new active switch performs these functions:

- It starts generating, receiving, and processing routing updates.
- It builds routing tables, generates the CEF database, and distributes it to stack members.
- It uses its MAC address as the router MAC address. To notify its network peers of the new MAC address, it periodically (every few seconds for 5 minutes) sends a gratuitous ARP reply with the new router MAC address.

Note If you configure the persistent MAC address feature on the stack and the active switch changes, the stack MAC address does not change for the configured time period. If the previous active switch rejoins the stack as a member switch during that time period, the stack MAC address remains the MAC address of the previous active switch.

- It attempts to determine the reachability of every proxy ARP entry by sending an ARP request to the proxy ARP IP address and receiving an ARP reply. For each reachable proxy ARP IP address, it generates a gratuitous ARP reply with the new router MAC address. This process is repeated for 5 minutes after a new active switch election.

Caution Partitioning of the switch stack into two or more stacks might lead to undesirable behavior in the network.

If the switch is reloaded, then all the ports on that switch go down and there is a loss of traffic for the interfaces involved in routing.

Configuring IP Unicast Routing

By default, IP routing is disabled on the device. For detailed IP routing configuration information, see the *Cisco IOS IP Configuration Guide, Release 12.2* from the *Cisco.com* page under **Documentation > Cisco IOS Software Releases > 12.2 Mainline > Configuration Guides**.

In these procedures, the specified interface must be a device virtual interface (SVI)-a VLAN interface created by using the **interface vlan** *vlan_id* global configuration command and by default a Layer 3 interface. All Layer 3 interfaces on which routing will occur must have IP addresses assigned to them. See the *Assigning IP Addresses to SVIs* section.

Note The device supports 16 static routes (including user-configured routes and the default route) and any directly connected routes and default routes for the management interface. You can use the "lanbase-default" SDM template to configure the static routes. The device can have an IP address assigned to each SVI. Before enabling routing, enter the **sdm prefer lanbase-routing** global configuration command and reload the device.

Procedures for configuring routing:

- To support VLAN interfaces, create and configure VLANs on the device or switch stack, and assign VLAN membership to Layer 2 interfaces. For more information, see chapter: *Configuring VLANs*.
- Configure Layer 3 interfaces (SVIs).
- Enable IP routing on the device.
- Assign IP addresses to the Layer 3 interfaces.
- Configure static routes.

Enabling IP Unicast Routing

By default, the Device is in Layer 2 switching mode and IP routing is disabled. To use the Layer 3 capabilities of the Device, you must enable IP routing.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip routing Example: Device(config)# ip routing | Enables IP routing. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 5 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Assigning IP Addresses to SVIs

To configure IP routing, you need to assign IP addresses to Layer 3 network interfaces. This enables communication with the hosts of those interfaces that use IP. IP routing is disabled by default, and no IP addresses are assigned to SVIs.

An IP address identifies a location to which IP packets can be sent. Some IP addresses are reserved for special uses and cannot be used for host, subnet, or network addresses. RFC 1166, "Internet Numbers," contains the official description of IP addresses.

An interface can have one primary IP address. A mask identifies the bits that denote the network number in an IP address. When you use the mask to subnet a network, the mask is referred to as a subnet mask. To receive an assigned network number, contact your Internet service provider.

Follow these steps to assign an IP address and a network mask to an SVI:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | interface vlan <i>vlan-id</i> | Enters interface configuration mode, and specifies the Layer 3 VLAN to configure. |

| | Command or Action | Purpose |
|---------------|--|---|
| | | Note If the interface is still in Layer 2 mode (the default), you must enter a no switchport interface configuration command before entering the ip address interface configuration command. |
| Step 4 | ip address <i>ip-address subnet-mask</i> Example: Device(config-if)# ip address 10.1.5.1 255.255.255.0 | Configures the IP address and IP subnet mask. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show interfaces [<i>interface-id</i>] Example: Device# show interfaces gigabitethernet 1/0/1 | Verifies your entries. |
| Step 7 | show interfaces vlan [<i>vlan-id</i>] Example: Device# show interfaces vlan 4 | Verifies your entries. |
| Step 8 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Static Unicast Routes

Static unicast routes are user-defined routes that cause packets moving between a source and a destination to take a specified path. Static routes can be important if the router cannot build a route to a particular destination and are useful for specifying a gateway of last resort to which all unroutable packets are sent.

Follow these steps to configure a static route:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip route prefix mask <i>{address interface}</i> <i>[distance] vlan vlan-id</i> Example: Device(config)# ip route prefix mask gigabitethernet 1/0/4vlan 4 | Establish a static route. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip route Example: Device# show ip route | Displays the current state of the routing table to verify the configuration. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

What to do next

Use the **no ip route** *prefix mask {address| interface}* global configuration command to remove a static route. The device retains static routes until you remove them.

Monitoring and Maintaining the IP Network

You can remove all contents of a particular cache, table, or database. You can also display specific statistics.

Table 88: Commands to Clear IP Routes or Display Route Status

| Command | Purpose |
|---|--|
| show ip route [<i>address</i> [<i>mask</i>] [longer-prefixes]] | Displays the current state of the routing table. |
| show ip route summary | Displays the current state of the routing table in summary form. |
| show platform ip unicast | Displays platform-dependent IP unicast information. |

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for First Hop Security in IPv6

- You have configured the necessary IPv6 enabled SDM template.
- QoS should be enabled on the switch before configuring CoPP policies using **mls qos** command.

Restrictions for First Hop Security in IPv6

- The following restrictions apply when applying FHS policies to EtherChannel interfaces (Port Channels):
 - A physical port with an FHS policy attached cannot join an EtherChannel group.
 - An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.
- By default, a snooping policy has a security-level of guard. When such a snooping policy is configured on an access switch, external IPv6 Router Advertisement (RA) or Dynamic Host Configuration Protocol for IPv6 (DHCPv6) server packets are blocked, even though the uplink port facing the router or DHCP server/relay is configured as a trusted port. To allow IPv6 RA or DHCPv6 server messages, do the following:
 - Apply an IPv6 RA-guard policy (for RA) or IPv6 DHCP-guard policy (for DHCP server messages) on the uplink port.
 - Configure a snooping policy with a lower security-level, for example glean or inspect. However; configuring a lower security level is not recommended with such a snooping policy, because benefits of First Hop security features are not effective.
- The following restrictions apply for CoPP policies with IPv6 SISF-based device tracking policies due to limitation reported in [CSCvk32439](#):
 - CoPP policies are required to limit IPv6 NDP traffic when IPv6 SISF policies are configured on the switch.
 - After NDP CoPP policies are configured, limited traffic hits CPU. To accommodate the total end points connected, the number of NDP CoPP policies should be slightly more than the number of users connected to each switch in a stack. If you configure NDP CoPP policies less than the number of end points connected to the switch, the IP allocation to the end point is delayed but is not ignored completely.

Note For example, if a stack of 5 switches has approximately 300 users, the NDP CoPP policies should be more than 300.

- The DHCPv6 (server-to-client and client-to-server) CoPP policies are required only if Lightweight DHCPv6 Relay Agent (LDRA) is configured under IPv6 SISF-based device tracking policies on the switch.

Information about First Hop Security in IPv6

First Hop Security in IPv6 (FHS IPv6) is a set of IPv6 security features, the policies of which can be attached to a physical interface, an EtherChannel interface, or a VLAN. An IPv6 software policy database service stores and accesses these policies. When a policy is configured or modified, the attributes of the policy are stored or updated in the software policy database, then applied as was specified. The following IPv6 policies are currently supported:

- IPv6 Snooping Policy—IPv6 Snooping Policy acts as a container policy that enables most of the features available with FHS in IPv6.
- IPv6 FHS Binding Table Content—A database table of IPv6 neighbors connected to the switch is created from information sources such as Neighbor Discovery (ND) protocol snooping. This database, or binding, table is used by various IPv6 guard features (such as IPv6 ND Inspection) to validate the link-layer address (LLA), the IPv4 or IPv6 address, and prefix binding of the neighbors to prevent spoofing and redirect attacks.
- IPv6 Neighbor Discovery Inspection—IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables. IPv6 ND inspection analyzes neighbor discovery messages in order to build a trusted binding table database and IPv6 neighbor discovery messages that do not conform are dropped. An ND message is considered trustworthy if its IPv6-to-Media Access Control (MAC) mapping is verifiable.

This feature mitigates some of the inherent vulnerabilities of the ND mechanism, such as attacks on DAD, address resolution, router discovery, and the neighbor cache.

- IPv6 Router Advertisement Guard—The IPv6 Router Advertisement (RA) guard feature enables the network administrator to block or reject unwanted or rogue RA guard messages that arrive at the network switch platform. RAs are used by routers to announce themselves on the link. The RA Guard feature analyzes the RAs and filters out bogus RAs sent by unauthorized routers. In host mode, all router advertisement and router redirect messages are disallowed on the port. The RA guard feature compares configuration information on the Layer 2 device with the information found in the received RA frame. Once the Layer 2 device has validated the content of the RA frame and router redirect frame against the configuration, it forwards the RA to its unicast or multicast destination. If the RA frame content is not validated, the RA is dropped.
- IPv6 DHCP Guard—The IPv6 DHCP Guard feature blocks reply and advertisement messages that come from unauthorized DHCPv6 servers and relay agents. IPv6 DHCP guard can prevent forged messages from being entered in the binding table and block DHCPv6 server messages when they are received on ports that are not explicitly configured as facing a DHCPv6 server or DHCP relay. To use this feature, configure a policy and attach it to an interface or a VLAN. To debug DHCP guard packets, use the **debug ipv6 snooping dhcp-guard** privileged EXEC command.
- IPv6 Source Guard—Like IPv4 Source Guard, IPv6 Source Guard validates the source address or prefix to prevent source address spoofing.

A source guard programs the hardware to allow or deny traffic based on source or destination addresses. It deals exclusively with data packet traffic.

The IPv6 source guard feature provides the ability to use the IPv6 binding table to install ACLs to prevent a host from sending packets with an invalid IPv6 source address.

To debug source-guard packets, use the `debug ipv6 snooping source-guard` privileged EXEC command.

Note The IPv6 ACL feature is supported only in the ingress direction; it is not supported in the egress direction.

The following restrictions apply:

- An FHS policy cannot be attached to a physical port when it is a member of an EtherChannel group.

- When IPv6 source guard is enabled on a switch port, NDP or DHCP snooping must be enabled on the interface to which the switch port belongs. Otherwise, all data traffic from this port will be blocked.
- An IPv6 source guard policy cannot be attached to a VLAN. It is supported only at the interface level.
- When you configure IPv4 and IPv6 source guard together on an interface, it is recommended to use **ip verify source mac-check** instead of **ip verify source**. IPv4 connectivity on a given port might break due to two different filtering rules set — one for IPv4 (IP-filter) and the other for IPv6 (IP-MAC filter).
- You cannot use IPv6 Source Guard and Prefix Guard together. When you attach the policy to an interface, it should be "validate address" or "validate prefix" but not both.
- PVLAN and Source/Prefix Guard cannot be applied together.

For more information on IPv6 Source Guard, see the [IPv6 Source Guard](#) chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Prefix Guard—The IPv6 prefix guard feature works within the IPv6 source guard feature, to enable the device to deny traffic originated from non-topologically correct addresses. IPv6 prefix guard is often used when IPv6 prefixes are delegated to devices (for example, home gateways) using DHCP prefix delegation. The feature discovers ranges of addresses assigned to the link and blocks any traffic sourced with an address outside this range.

For more information on IPv6 Prefix Guard, see the [IPv6 Prefix Guard](#) chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Destination Guard—The IPv6 destination guard feature works with IPv6 neighbor discovery to ensure that the device performs address resolution only for those addresses that are known to be active on the link. It relies on the address glean functionality to populate all destinations active on the link into the binding table and then blocks resolutions before they happen when the destination is not found in the binding table.

Note IPv6 Destination Guard is recommended only on Layer 3. It is not recommended on Layer 2.

For more information about IPv6 Destination Guard, see the [IPv6 Destination Guard](#) chapter of the Cisco IOS IPv6 Configuration Guide Library on Cisco.com.

- IPv6 Neighbor Discovery Multicast Suppress—The IPv6 Neighbor Discovery multicast suppress feature is an IPv6 snooping feature that runs on a switch or a wireless controller and is used to reduce the amount of control traffic necessary for proper link operations.
- DHCPv6 Relay—Lightweight DHCPv6 Relay Agent—The DHCPv6 Relay—Lightweight DHCPv6 Relay Agent feature allows relay agent information to be inserted by an access node that performs a link-layer bridging (non-routing) function. Lightweight DHCPv6 Relay Agent (LDRA) functionality can be implemented in existing access nodes, such as DSL access multiplexers (DSLAMs) and Ethernet switches, that do not support IPv6 control or routing functions. LDRA is used to insert relay-agent options in DHCP version 6 (DHCPv6) message exchanges primarily to identify client-facing interfaces. LDRA functionality can be enabled on an interface and on a VLAN.

Note If an LDRA device is directly connected to a client, the interface must have the pool configuration to fetch the specific subnet or link information at the server side. In this case, if the LDRA device is present in different subnets or links, the server may not be able to fetch the correct subnet. You can now configure the pool name in the interface so as to choose the proper subnet or link for the client.

For more information about DHCPv6 Relay, See the [DHCPv6 Relay—Lightweight DHCPv6 Relay Agent](#) section of the IP Addressing: DHCP Configuration Guide, Cisco IOS Release 15.1SG.

How to Configure an IPv6 Snooping Policy

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Snooping Policy :

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters the global configuration mode. |
| Step 2 | ipv6 snooping policy <i>policy-name</i> Example: Device(config)# <code>ipv6 snooping policy example_policy</code> | Creates a snooping policy and enters IPv6 Snooping Policy Configuration mode. |
| Step 3 | <code>{[default] [device-role {node switch}] [limit address-count <i>value</i>] [no] [protocol {dhcp ndp}] [security-level {glean guard inspect}] [tracking {disable [stale-lifetime [<i>seconds</i> infinite]] enable [reachable-lifetime [<i>seconds</i> infinite]]}] [trusted-port]}</code> Example: Device (config-ipv6-snooping) # <code>security-level inspect</code> Example: Device (config-ipv6-snooping) # <code>trusted-port</code> | Enables data address glean, validates messages against various criteria, specifies the security level for messages. <ul style="list-style-type: none"> • (Optional) default—Sets all to default options. • (Optional) device-role {node switch}—Specifies the role of the device attached to the port. Default is node. • (Optional) limit address-count <i>value</i>—Limits the number of addresses allowed per target. • (Optional) no—Negates a command or sets it to defaults. • (Optional) protocol {dhcp ndp}—Specifies which protocol should be redirected to the snooping feature for analysis. The default, is dhcp and ndp. To |

| | Command or Action | Purpose |
|---------------|---|--|
| | | <p>change the default, use the no protocol command.</p> <ul style="list-style-type: none"> (Optional) security-level {glean guard inspect}—Specifies the level of security enforced by the feature. Default is guard. <ul style="list-style-type: none"> glean—Gleans addresses from messages and populates the binding table without any verification. guard—Gleans addresses and inspects messages. In addition, it rejects RA and DHCP server messages. This is the default option. inspect—Gleans addresses, validates messages for consistency and conformance, and enforces address ownership. (Optional) tracking {disable enable}—Overrides the default tracking behavior and specifies a tracking option. (Optional) trusted-port—Sets up a trusted port. It disables the guard on applicable targets. Bindings learned through a trusted port have preference over bindings learned through any other port. A trusted port is given preference in case of a collision while making an entry in the table. |
| Step 4 | end Example: Device(config-ipv6-snooping)# exit | Exits configuration modes to Privileged EXEC mode. |
| Step 5 | show ipv6 snooping policy <i>policy-name</i> Example: Device# show ipv6 snooping policy example_policy | Displays the snooping policy configuration. |

What to do next

Attach an IPv6 Snooping policy to interfaces or VLANs.

How to Attach an IPv6 Snooping Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an interface or VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface Interface_type <i>stack/module/port</i> Example: Device(config)# interface gigabitethernet 1/1/4 | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 3 | switchport Example: Device(config-if)# switchport | Note To configure Layer 2 parameters, if the interface is in Layer 3 mode, you must enter the switchport interface configuration command without any parameters to put the interface into Layer 2 mode. This shuts down the interface and then re-enables it, which might generate messages on the device to which the interface is connected. When you put an interface that is in Layer 3 mode into Layer 2 mode, the previous configuration information related to the affected interface might be lost, and the interface is returned to its default configuration. The command prompt displays as (config-if)# in Switchport configuration mode. |
| Step 4 | ipv6 snooping [attach-policy <i>policy_name</i> [vlan { <i>vlan_id</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> }] vlan { <i>vlan_id</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] Example: Device(config-if)# ipv6 snooping or Device(config-if)# ipv6 snooping attach-policy example_policy or Device(config-if)# ipv6 snooping vlan 111,112 | Attaches a custom ipv6 snooping policy to the interface or the specified VLANs on the interface. To attach the default policy to the interface, use the ipv6 snooping command without the attach-policy keyword. To attach the default policy to VLANs on the interface, use the ipv6 snooping vlan command. The default policy is, security-level guard , device-role node , protocol ndp and dhcp . |

| | Command or Action | Purpose |
|---------------|---|---|
| | <pre>or Device(config-if)# ipv6 snooping attach-policy example_policy vlan 111,112</pre> | |
| Step 5 | <p>do show running-config</p> <p>Example:</p> <pre>Device#(config-if)# do show running-config</pre> | Verifies that the policy is attached to the specified interface without exiting the interface configuration mode. |

How to Attach an IPv6 Snooping Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Snooping policy on an EtherChannel interface or VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters the global configuration mode. |
| Step 2 | <p>interface range <i>Interface_name</i></p> <p>Example:</p> <pre>Device(config)# interface range Po11</pre> | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode. Tip Enter the do show interfaces summary command for quick reference to interface names and types. |
| Step 3 | <p>ipv6 snooping [attach-policy <i>policy_name</i> [vlan {<i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all}] vlan [{<i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all}]]</p> <p>Example:</p> <pre>Device(config-if-range)# ipv6 snooping attach-policy example_policy or Device(config-if-range)# ipv6 snooping attach-policy example_policy vlan 222,223,224 or Device(config-if-range)#ipv6 snooping</pre> | Attaches the IPv6 Snooping policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |

| | Command or Action | Purpose |
|---------------|---|---|
| | <code>vlan 222, 223,224</code> | |
| Step 4 | do show running-config interface <i>portchannel_interface_name</i> Example: Device#(config-if-range)# do show running-config int po11 | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Configure the IPv6 Binding Table Content

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content :

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | [no] ipv6 neighbor binding [vlan vlan-id <i>{ipv6-address interface interface_type</i> <i>stack/module/port hw_address</i> [reachable-lifetimevalue [seconds default infinite] [tracking{ [default disable] [reachable-lifetimevalue [seconds default infinite] [enable [reachable-lifetimevalue <i>[seconds default infinite] [retry-interval</i> <i>{seconds default [reachable-lifetimevalue</i> <i>[seconds default infinite] }]</i> Example: Device(config)# ipv6 neighbor binding | Adds a static entry to the binding table database. |
| Step 3 | [no] ipv6 neighbor binding max-entries <i>number [mac-limit number port-limit number</i> <i>[mac-limit number] vlan-limit number [</i> <i>[mac-limit number] [port-limit number</i> <i>[mac-limitnumber]]]]</i> Example: Device(config)# ipv6 neighbor binding max-entries 30000 | Specifies the maximum number of entries that are allowed to be inserted in the binding table cache. |
| Step 4 | ipv6 neighbor binding logging Example: | Enables the logging of binding table main events. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device (config) # ipv6 neighbor binding logging | |
| Step 5 | exit Example: Device (config) # exit | Exits global configuration mode, and places the router in privileged EXEC mode. |
| Step 6 | show ipv6 neighbor binding Example: Device # show ipv6 neighbor binding | Displays contents of a binding table. |

How to Configure an IPv6 Neighbor Discovery Inspection Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 ND Inspection Policy:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device # configure terminal | Enters the global configuration mode. |
| Step 2 | [no]ipv6 nd inspection policy <i>policy-name</i> Example: Device (config) # ipv6 nd inspection policy example_policy | Specifies the ND inspection policy name and enters ND Inspection Policy configuration mode. |
| Step 3 | device-role {host monitor router switch} Example: Device (config-nd-inspection) # device-role switch | Specifies the role of the device attached to the port. The default is host . |
| Step 4 | drop-unsecure Example: Device (config-nd-inspection) # drop-unsecure | Drops messages with no or invalid options or an invalid signature. |
| Step 5 | limit address-count <i>value</i> Example: Device (config-nd-inspection) # limit address-count 1000 | Enter 1–10,000. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 6 | sec-level minimum <i>value</i> Example: Device(config-nd-inspection)# limit address-count 1000 | Specifies the minimum security level parameter value when Cryptographically Generated Address (CGA) options are used. |
| Step 7 | tracking { enable [reachable-lifetime { <i>value</i> infinite }] disable [stale-lifetime { <i>value</i> infinite }]} Example: Device(config-nd-inspection)# tracking disable stale-lifetime infinite | Overrides the default tracking policy on a port. |
| Step 8 | trusted-port Example: Device(config-nd-inspection)# trusted-port | Configures a port to become a trusted port. |
| Step 9 | validate source-mac Example: Device(config-nd-inspection)# validate source-mac | Checks the source media access control (MAC) address against the link-layer address. |
| Step 10 | no { device-role drop-unsecure limit address-count sec-level minimum tracking trusted-port validate source-mac } Example: Device(config-nd-inspection)# no validate source-mac | Remove the current configuration of a parameter with the no form of the command. |
| Step 11 | default { device-role drop-unsecure limit address-count sec-level minimum tracking trusted-port validate source-mac } Example: Device(config-nd-inspection)# default limit address-count | Restores configuration to the default values. |
| Step 12 | do show ipv6 nd inspection policy <i>policy_name</i> Example: Device(config-nd-inspection)# do show ipv6 nd inspection policy example_policy | Verifies the ND Inspection Configuration without exiting ND inspection configuration mode. |

How to Attach an IPv6 Neighbor Discovery Inspection Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 ND Inspection policy to an interface or VLANs on an interface :

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface Interface_type <i>stack/module/port</i> Example: Device(config)# interface gigabitethernet 1/1/4 | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 3 | ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }]] Example: Device(config-if)# ipv6 nd inspection attach-policy example_policy or Device(config-if)# ipv6 nd inspection attach-policy example_policy vlan 222,223,224 or Device(config-if)# ipv6 nd inspection vlan 222, 223,224 | Attaches the Neighbor Discovery Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |
| Step 4 | do show running-config Example: Device#(config-if)# do show running-config | Verifies that the policy is attached to the specified interface without exiting the interface configuration mode. |

How to Attach an IPv6 Neighbor Discovery Inspection Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Neighbor Discovery Inspection policy on an EtherChannel interface or VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters the global configuration mode. |
| Step 2 | interface range <i>Interface_name</i> Example: Device(config)# <code>interface Po11</code> | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode. Tip Enter the do show interfaces summary command for quick reference to interface names and types. |
| Step 3 | ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }]] Example: Device(config-if-range)# <code>ipv6 nd inspection attach-policy example_policy</code> or Device(config-if-range)# <code>ipv6 nd inspection attach-policy example_policy vlan 222,223,224</code> or Device(config-if-range)# <code>ipv6 nd inspection vlan 222, 223,224</code> | Attaches the ND Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |
| Step 4 | do show running-config interface <i>portchannel_interface_name</i> Example: Device#(config-if-range)# <code>do show running-config int po11</code> | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on a Device

To attach an IPV6 Neighbor Discovery Multicast Suppress policy on a device, complete the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal | Enters the global configuration mode. |
| Step 3 | ipv6 nd suppress policy <i>policy-name</i> | Defines the Neighbor Discovery suppress policy name and enters Neighbor Discovery suppress policy configuration mode. |
| Step 4 | mode dad-proxy | Enables Neighbor Discovery suppress in IPv6 DAD proxy mode. |
| Step 5 | mode full-proxy | Enables Neighbor Discovery suppress to proxy multicast and unicast Neighbor Solicitation messages. |
| Step 6 | mode mc-proxy | Enables Neighbor Discovery suppress to proxy multicast Neighbor Solicitation messages. |

How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy on an Interface

To attach an IPv6 Neighbor Discovery Multicast Suppress policy on an interface, complete the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal | Enters the global configuration mode. |
| Step 3 | Perform one of the following tasks: <ul style="list-style-type: none"> • interface <i>type number</i> • ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { add except none remove all} <i>vlan</i> [<i>vlan1</i>, <i>vlan2</i>, <i>vlan3</i>...]]] | Specifies an interface type and number, and places the device in interface configuration mode. Attaches the IPv6 Neighbor Discovery Multicast Policy to an interface or a VLAN. |

| | Command or Action | Purpose |
|---------------|--|--|
| | OR <ul style="list-style-type: none"> • vlan configuration <i>vlan-id</i> • ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { add except none remove all } <i>vlan</i> [<i>vlan1</i>, <i>vlan2</i>, <i>vlan3...</i>]]] | |
| Step 4 | exit | Exists the interface configuration mode. |

How to Attach an IPv6 Neighbor Discovery Multicast Suppress Policy to a Layer 2 EtherChannel Interface

To attach an IPv6 Neighbor Discovery Multicast Suppress policy on an EtherChannel interface, complete the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal | Enters the global configuration mode. |
| Step 3 | Perform one of the following tasks: <ul style="list-style-type: none"> • interface port-channel <i>port-channel-number</i> • ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { add except none remove all } <i>vlan</i> [<i>vlan1</i>, <i>vlan2</i>, <i>vlan3...</i>]]] OR <ul style="list-style-type: none"> • vlan configuration <i>vlan-id</i> • ipv6 nd inspection [attach-policy <i>policy_name</i> [vlan { add except none remove all } <i>vlan</i> [<i>vlan1</i>, <i>vlan2</i>, <i>vlan3...</i>]]] | Specifies an interface type and port number and places the switch in the port channel configuration mode. Attaches the IPv6 Neighbor Discovery Multicast Policy to an interface or a VLAN. |
| Step 4 | exit | Exists the interface configuration mode. |

How to Configure an IPv6 Router Advertisement Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 Router Advertisement policy :

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | [no]ipv6 nd rguard policy <i>policy-name</i> Example: Device(config)# ipv6 nd rguard policy example_policy | Specifies the RA Guard policy name and enters RA Guard Policy configuration mode. |
| Step 3 | [no]device-role {host monitor router switch} Example: Device(config-nd-raguard)# device-role switch | Specifies the role of the device attached to the port. The default is host . |
| Step 4 | [no]hop-limit {maximum minimum} <i>value</i> Example: Device(config-nd-raguard)# hop-limit maximum 33 | (1–255) Range for Maximum and Minimum Hop Limit values. Enables filtering of Router Advertisement messages by the Hop Limit value. A rogue RA message may have a low Hop Limit value (equivalent to the IPv4 Time to Live) that when accepted by the host, prevents the host from generating traffic to destinations beyond the rogue RA message generator. An RA message with an unspecified Hop Limit value is blocked. If not configured, this filter is disabled. Configure minimum to block RA messages with Hop Limit values lower than the value you specify. Configure maximum to block RA messages with Hop Limit values greater than the value you specify. |
| Step 5 | [no]managed-config-flag {off on} Example: Device(config-nd-raguard)# managed-config-flag on | Enables filtering of Router Advertisement messages by the Managed Address Configuration, or "M" flag field. A rogue RA message with an M field of 1 can cause a host to use a rogue DHCPv6 server. If not configured, this filter is disabled. |

| | Command or Action | Purpose |
|----------------|--|--|
| | | <p>On—Accepts and forwards RA messages with an M value of 1, blocks those with 0.</p> <p>Off—Accepts and forwards RA messages with an M value of 0, blocks those with 1.</p> |
| Step 6 | <p>[no]match {ipv6 access-list list ra prefix-list list}</p> <p>Example:</p> <pre>Device(config-nd-raguard)# match ipv6 access-list example_list</pre> | Matches a specified prefix list or access list. |
| Step 7 | <p>[no]other-config-flag {on off}</p> <p>Example:</p> <pre>Device(config-nd-raguard)# other-config-flag on</pre> | <p>Enables filtering of Router Advertisement messages by the Other Configuration, or "O" flag field. A rouge RA message with an O field of 1 can cause a host to use a rogue DHCPv6 server. If not configured, this filter is disabled.</p> <p>On—Accepts and forwards RA messages with an O value of 1, blocks those with 0.</p> <p>Off—Accepts and forwards RA messages with an O value of 0, blocks those with 1.</p> |
| Step 8 | <p>[no]router-preference maximum {high medium low}</p> <p>Example:</p> <pre>Device(config-nd-raguard)# router-preference maximum high</pre> | <p>Enables filtering of Router Advertisement messages by the Router Preference flag. If not configured, this filter is disabled.</p> <ul style="list-style-type: none"> • high—Accepts RA messages with the Router Preference set to high, medium, or low. • medium—Blocks RA messages with the Router Preference set to high. • low—Blocks RA messages with the Router Preference set to medium and high. |
| Step 9 | <p>[no]trusted-port</p> <p>Example:</p> <pre>Device(config-nd-raguard)# trusted-port</pre> | When configured as a trusted port, all attached devices are trusted, and no further message verification is performed. |
| Step 10 | <p>default {device-role hop-limit {maximum minimum} managed-config-flag match {ipv6 access-list ra prefix-list } other-config-flag router-preference maximum trusted-port}</p> <p>Example:</p> <pre>Device(config-nd-raguard)# default hop-limit</pre> | Restores a command to its default value. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 11 | do show ipv6 nd rguard policy <i>policy_name</i> Example: Device(config-nd-rguard)# do show ipv6 nd rguard policy example_policy | (Optional)—Displays the ND Guard Policy configuration without exiting the RA Guard policy configuration mode. |

How to Attach an IPv6 Router Advertisement Guard Policy to an Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement policy to an interface or to VLANs on the interface :

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface Interface_type <i>stack/module/port</i> Example: Device(config)# interface gigabitethernet 1/1/4 | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 3 | ipv6 nd rguard [attach-policy <i>policy_name</i> [vlan {<i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all}] vlan [{<i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all}] Example: Device(config-if)# ipv6 nd rguard attach-policy example_policy or Device(config-if)# ipv6 nd rguard attach-policy example_policy vlan 222,223,224 or Device(config-if)# ipv6 nd rguard vlan 222, 223,224 | Attaches the Neighbor Discovery Inspection policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |
| Step 4 | do show running-config Example: Device#(config-if)# do show running-config | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Attach an IPv6 Router Advertisement Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 Router Advertisement Guard Policy on an EtherChannel interface or VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface range <i>Interface_name</i> Example: Device(config)# interface Po11 | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode. Tip Enter the do show interfaces summary command for quick reference to interface names and types. |
| Step 3 | ipv6 nd rguard [attach-policy <i>policy_name</i> [vlan { <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }]] Example: Device(config-if-range)# ipv6 nd rguard attach-policy example_policy or Device(config-if-range)# ipv6 nd rguard attach-policy example_policy vlan 222,223,224 or Device(config-if-range)# ipv6 nd rguard vlan 222, 223,224 | Attaches the RA Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |
| Step 4 | do show running-config interface <i>portchannel_interface_name</i> Example: Device#(config-if-range)# do show running-config int po11 | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Configure an IPv6 DHCP Guard Policy

Beginning in privileged EXEC mode, follow these steps to configure an IPv6 DHCP (DHCPv6) Guard policy:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | [no]ipv6 dhcp guard policy <i>policy-name</i> Example: Device(config)# ipv6 dhcp guard policy example_policy | Specifies the DHCPv6 Guard policy name and enters DHCPv6 Guard Policy configuration mode. |
| Step 3 | [no]device-role {client server} Example: Device(config-dhcp-guard)# device-role server | (Optional) Filters out DHCPv6 replies and DHCPv6 advertisements on the port that are not from a device of the specified role. Default is client . <ul style="list-style-type: none"> • client—Default value, specifies that the attached device is a client. Server messages are dropped on this port. • server—Specifies that the attached device is a DHCPv6 server. Server messages are allowed on this port. |
| Step 4 | [no] match server access-list <i>ipv6-access-list-name</i> Example: <pre>;;Assume a preconfigured IPv6 Access List as follows: Device(config)# ipv6 access-list my_acls Device(config-ipv6-acl)# permit host FE80::A8BB:CFF:FE01:F700 any ;;configure DCHPv6 Guard to match approved access list. Device(config-dhcp-guard)# match server access-list my_acls</pre> | (Optional). Enables verification that the advertised DHCPv6 server or relay address is from an authorized server access list (The destination address in the access list is 'any'). If not configured, this check will be bypassed. An empty access list is treated as a permit all. |
| Step 5 | [no] match reply prefix-list <i>ipv6-prefix-list-name</i> Example: <pre>;;Assume a preconfigured IPv6 prefix list as follows:</pre> | (Optional) Enables verification of the advertised prefixes in DHCPv6 reply messages from the configured authorized prefix list. If not configured, this check will be bypassed. An empty prefix list is treated as a permit. |

| | Command or Action | Purpose |
|---------------|--|---|
| | <pre>Device(config)# ipv6 prefix-list my_prefix permit 2001:0DB8::/64 le 128 ;; Configure DHCPv6 Guard to match prefix Device(config-dhcp-guard)# match reply prefix-list my_prefix</pre> | |
| Step 6 | <p>[no]preference { <i>max limit</i> <i>min limit</i> }</p> <p>Example:</p> <pre>Device(config-dhcp-guard)# preference max 250 Device(config-dhcp-guard)#preference min 150</pre> | <p>Configure max and min when device-role is server to filter DHCPv6 server advertisements by the server preference value. The defaults permit all advertisements.</p> <p>max limit—(0 to 255) (Optional) Enables verification that the advertised preference (in preference option) is less than the specified limit. Default is 255. If not specified, this check will be bypassed.</p> <p>min limit—(0 to 255) (Optional) Enables verification that the advertised preference (in preference option) is greater than the specified limit. Default is 0. If not specified, this check will be bypassed.</p> |
| Step 7 | <p>[no] trusted-port</p> <p>Example:</p> <pre>Device(config-dhcp-guard)# trusted-port</pre> | <p>(Optional) trusted-port—Sets the port to a trusted mode. No further policing takes place on the port.</p> <p>Note If you configure a trusted port then the device-role option is not available.</p> |
| Step 8 | <p>default {device-role trusted-port}</p> <p>Example:</p> <pre>Device(config-dhcp-guard)# default device-role</pre> | <p>(Optional) default—Sets a command to its defaults.</p> |
| Step 9 | <p>do show ipv6 dhcp guard policy <i>policy_name</i></p> <p>Example:</p> <pre>Device(config-dhcp-guard)# do show ipv6 dhcp guard policy example_policy</pre> | <p>(Optional) Displays the configuration of the IPv6 DHCP guard policy without leaving the configuration submode. Omitting the <i>policy_name</i> variable displays all DHCPv6 policies.</p> |

Example of DHCPv6 Guard Configuration

```
enable
configure terminal
ipv6 access-list acl1
 permit host FE80::A8BB:CCFF:FE01:F700 any
ipv6 prefix-list abc permit 2001:0DB8::/64 le 128
ipv6 dhcp guard policy poll
 device-role server
 match server access-list acl1
```

```

match reply prefix-list abc
preference min 0
preference max 255
trusted-port
interface GigabitEthernet 0/2/0
switchport
ipv6 dhcp guard attach-policy poll vlan add 1
vlan 1
    ipv6 dhcp guard attach-policy poll
show ipv6 dhcp guard policy poll

```

How to Attach an IPv6 DHCP Guard Policy to an Interface or a VLAN on an Interface

Beginning in privileged EXEC mode, follow these steps to configure IPv6 Binding Table Content :

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface Interface_type <i>stack/module/port</i> Example: Device(config)# interface gigabitethernet 1/1/4 | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 3 | ipv6 dhcp guard [attach-policy <i>policy_name</i> [vlan { <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }]] Example: Device(config-if)# ipv6 dhcp guard attach-policy example_policy or Device(config-if)# ipv6 dhcp guard attach-policy example_policy vlan 222,223,224 or Device(config-if)# ipv6 dhcp guard vlan 222, 223,224 | Attaches the DHCP Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 4 | do show running-config interface Interface_type <i>stack/module/port</i> Example: Device#(config-if)# do show running-config gig 1/1/4 | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Attach an IPv6 DHCP Guard Policy to a Layer 2 EtherChannel Interface

Beginning in privileged EXEC mode, follow these steps to attach an IPv6 DHCP Guard policy on an EtherChannel interface or VLAN:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 2 | interface range <i>Interface_name</i> Example: Device(config)# interface Po11 | Specify the port-channel interface name assigned when the EtherChannel was created. Enters the interface range configuration mode. Tip Enter the do show interfaces summary command for quick reference to interface names and types. |
| Step 3 | ipv6 dhcp guard [attach-policy <i>policy_name</i> [vlan { <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }] vlan [{ <i>vlan_ids</i> add <i>vlan_ids</i> except <i>vlan_ids</i> none remove <i>vlan_ids</i> all }]] Example: Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy or Device(config-if-range)# ipv6 dhcp guard attach-policy example_policy vlan 222,223,224 or Device(config-if-range)# ipv6 dhcp guard vlan 222, 223,224 | Attaches the DHCP Guard policy to the interface or the specified VLANs on that interface. The default policy is attached if the attach-policy option is not used. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 4 | do show running-config interface <i>portchannel_interface_name</i> Example: Device#(config-if-range)# do show running-config int poll | Confirms that the policy is attached to the specified interface without exiting the configuration mode. |

How to Configure IPv6 Source Guard

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 3 | [no] ipv6 source-guard policy <i>policy_name</i> Example: Device(config)# ipv6 source-guard policy example_policy | Specifies the IPv6 Source Guard policy name and enters IPv6 Source Guard policy configuration mode. |
| Step 4 | [deny global-autoconf] [permit link-local] [default{...}] [exit] [no{...}] Example: Device(config-sisf-sourceguard)# deny global-autoconf | (Optional) Defines the IPv6 Source Guard policy. <ul style="list-style-type: none"> • deny global-autoconf—Denies data traffic from auto-configured global addresses. This is useful when all global addresses on a link are DHCP-assigned and the administrator wants to block hosts with self-configured addresses to send traffic. • permit link-local—Allows all data traffic that is sourced by a link-local address. <p>Note Trusted option under source guard policy is not supported.</p> |
| Step 5 | end Example: Device(config-sisf-sourceguard)# end | Exits out of IPv6 Source Guard policy configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | show ipv6 source-guard policy <i>policy_name</i> Example: Device# show ipv6 source-guard policy example_policy | Shows the policy configuration and all the interfaces where the policy is applied. |

What to do next

Apply the IPv6 Source Guard policy to an interface.

How to Attach an IPv6 Source Guard Policy to an Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 3 | interface <i>Interface_type stack/module/port</i> Example: Device(config)# interface gigabitethernet 1/1/4 | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 4 | ipv6 source-guard [attach-policy <policy_name>] Example: Device(config-if)# ipv6 source-guard attach-policy example_policy | Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used. |
| Step 5 | show ipv6 source-guard policy <i>policy_name</i> Example: Device#(config-if)# show ipv6 source-guard policy example_policy | Shows the policy configuration and all the interfaces where the policy is applied. |

How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters the global configuration mode. |
| Step 3 | interface port-channel <i>port-channel-number</i> Example: Device (config)# interface Po4 | Specifies an interface type and port number and places the switch in the port channel configuration mode. |
| Step 4 | ipv6 source-guard [attach-policy <i><policy_name></i>] Example: Device(config-if) # ipv6 source-guard attach-policy example_policy | Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used. |
| Step 5 | show ipv6 source-guard policy <i>policy_name</i> Example: Device(config-if) # show ipv6 source-guard policy example_policy | Shows the policy configuration and all the interfaces where the policy is applied. |

How to Configure IPv6 Prefix Guard

Note To allow routing protocol control packets sourced by a link-local address when prefix guard is applied, enable the permit link-local command in the source-guard policy configuration mode.

Procedure

| | Command or Action | Purpose |
|---------------|----------------------------------|--|
| Step 1 | enable Example: | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device> enable | |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | [no] ipv6 source-guard policy <i>source-guard-policy</i> Example: Device(config)# ipv6 source-guard policy my_snooping_policy | Defines an IPv6 source-guard policy name and enters switch integrated security features source-guard policy configuration mode. |
| Step 4 | [no] validate address Example: Device(config-sisf-sourceguard)# no validate address | Disables the validate address feature and enables the IPv6 prefix guard feature to be configured. |
| Step 5 | validate prefix Example: Device(config-sisf-sourceguard)# validate prefix | Enables IPv6 source guard to perform the IPv6 prefix-guard operation. |
| Step 6 | exit Example: Device(config-sisf-sourceguard)# exit | Exits switch integrated security features source-guard policy configuration mode and returns to privileged EXEC mode. |
| Step 7 | show ipv6 source-guard policy <i>[source-guard-policy]</i> Example: Device# show ipv6 source-guard policy policy1 | Displays the IPv6 source-guard policy configuration. |

How to Attach an IPv6 Prefix Guard Policy to an Interface

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters the global configuration mode. |
| Step 3 | interface <i>Interface_type stack/module/port</i> Example: Device (config)# <code>interface gigabitethernet 1/1/4</code> | Specifies an interface type and identifier; enters the interface configuration mode. |
| Step 4 | ipv6 source-guard attach-policy <i>policy_name</i> Example: Device (config-if)# <code>ipv6 source-guard attach-policy example_policy</code> | Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used. |
| Step 5 | show ipv6 source-guard policy <i>policy_name</i> Example: Device (config-if)# <code>show ipv6 source-guard policy example_policy</code> | Shows the policy configuration and all the interfaces where the policy is applied. |

How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters the global configuration mode. |
| Step 3 | interface port-channel <i>port-channel-number</i> Example: Device (config)# <code>interface Po4</code> | Specifies an interface type and port number and places the switch in the port channel configuration mode. |
| Step 4 | ipv6 source-guard [attach-policy <i><policy_name></i>] Example: Device (config-if)# <code>ipv6 source-guard attach-policy example_policy</code> | Attaches the IPv6 Source Guard policy to the interface. The default policy is attached if the attach-policy option is not used. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 5 | show ipv6 source-guard policy <i>policy_name</i> Example: Device(config-if)# show ipv6 source-guard policy example_policy | Shows the policy configuration and all the interfaces where the policy is applied. |

Configuration Examples for IPv6 First Hop Security

Examples: How to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface

The following example shows how to attach an IPv6 Source Guard Policy to a Layer 2 EtherChannel Interface:

```
Switch# configure terminal
Switch(config)# ipv6 source-guard policy POL
Switch(config-sisf-sourceguard) # validate address
switch(config-sisf-sourceguard)# exit
Switch(config)# interface Po4
Switch(config)# ipv6 snooping
Switch(config-if)# ipv6 source-guard attach-policy POL
Switch(config-if)# exit
switch(config)#
```

Examples: How to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface

The following example shows how to attach an IPv6 Prefix Guard Policy to a Layer 2 EtherChannel Interface:

```
Switch# configure terminal
Switch(config)# ipv6 source-guard policy POL
Switch (config-sisf-sourceguard)# no validate address
Switch((config-sisf-sourceguard)# validate prefix
Switch(config)# interface Po4
Switch(config-if)# ipv6 snooping
Switch(config-if)# ipv6 source-guard attach-policy POL
```

CHAPTER 36

Routing Information Protocol

RIP is a commonly used routing protocol in small to medium TCP/IP networks. Routing Information Protocol (RIP) is a stable protocol that uses a distance-vector algorithm to calculate routes.

This module describes how to configure RIP.

- [Prerequisites for RIP, on page 723](#)
- [Restrictions for RIP, on page 723](#)
- [Information About Routing Information Protocol, on page 723](#)
- [How to Configure Routing Information Protocol, on page 727](#)

Prerequisites for RIP

You must configure **ip routing** command before you configure RIP.

Restrictions for RIP

Routing Information Protocol (RIP) uses hop count as the metric to rate the value of different routes. The hop count is the number of devices that can be traversed in a route. A directly connected network has a metric of zero; an unreachable network has a metric of 16. This limited metric range makes RIP unsuitable for large networks.

Information About Routing Information Protocol

RIP Overview

The Routing Information Protocol (RIP) Version 1 uses broadcast UDP data packets, and RIPv2 uses multicast packets to exchange the routing information. Cisco software sends routing information updates every 30 seconds, which is termed advertising. If a device does not receive an update from another device for 180

seconds or more, the receiving device marks the routes served by the nonupdating device as unusable. If there is still no update after 240 seconds, the device removes all routing table entries for the nonupdating device.

A device that is running RIP can receive a default network via an update from another device that is running RIP, or the device can source the default network using RIP. In both cases, the default network is advertised through RIP to other RIP neighbors.

The Cisco implementation of RIP Version 2 (RIPv2) supports plain text and message digest algorithm 5 (MD5) authentication, route summarization, classless interdomain routing (CIDR), and variable-length subnet masks (VLSMs).

RIP Routing Updates

The Routing Information Protocol (RIP) sends routing-update messages at regular intervals and when the network topology changes. When a device receives a RIP routing update that includes changes to an entry, the device updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP devices maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the device immediately begins transmitting RIP routing updates to inform other network devices of the change. These updates are sent independently of the regularly scheduled updates that RIP devices send.

Authentication in RIP

The Cisco implementation of the Routing Information Protocol (RIP) Version 2 (RIPv2) supports authentication, key management, route summarization, classless interdomain routing (CIDR), and variable-length subnet masks (VLSMs).

By default, the software receives RIP Version 1 (RIPv1) and RIPv2 packets, but sends only RIPv1 packets. You can configure the software to receive and send only RIPv1 packets. Alternatively, you can configure the software to receive and send only RIPv2 packets. To override the default behavior, you can configure the RIP version that an interface sends. Similarly, you can also control how packets received from an interface are processed.

RIPv1 does not support authentication. If you are sending and receiving RIP v2 packets, you can enable RIP authentication on an interface.

The key chain determines the set of keys that can be used on the interface. Authentication, including default authentication, is performed on that interface only if a key chain is configured.

Cisco supports two modes of authentication on an interface on which RIP is enabled: plain-text authentication and message digest algorithm 5 (MD5) authentication. Plain-text authentication is the default authentication in every RIPv2 packet.

Note Do not use plain text authentication in RIP packets for security purposes, because the unencrypted authentication key is sent in every RIPv2 packet. Use plain-text authentication when security is not an issue; for example, you can use plain-text authentication to ensure that misconfigured hosts do not participate in routing.

RIP Routing Metric

The Routing Information Protocol (RIP) uses a single routing metric to measure the distance between the source and the destination network. Each hop in a path from the source to the destination is assigned a hop-count value, which is typically 1. When a device receives a routing update that contains a new or changed destination network entry, the device adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop. If an interface network is not specified in the routing table, it will not be advertised in any RIP update.

RIP Versions

The original version of Routing Information Protocol (RIP), is known as RIP Version 1 (RIPv1). The specification of the RIP, defined in RFC 1058, uses classful routing. Periodic routing updates do not support variable length subnet masks (VLSM) because periodic routing updates do not contain subnet information. All subnets in a network class must be of the same size. Because RIP, as per RFC 1058, does not support VLSM, it is not possible to have subnets of varying sizes inside the same network class. This limitation makes RIP vulnerable to attacks.

To rectify the deficiencies of the original RIP specification, RIP Version 2 (RIPv2), as described in RFC 2453, was developed. RIPv2 has the ability to carry subnet information; thus, it supports Classless Inter-Domain Routing (CIDR).

Exchange of Routing Information

Routing Information Protocol (RIP) is normally a broadcast protocol, and for RIP routing updates to reach nonbroadcast networks, you must configure the Cisco software to permit this exchange of routing information.

To control the set of interfaces with which you want to exchange routing updates, you can disable the sending of routing updates on specified interfaces by configuring the **passive-interface** router configuration command.

You can use an offset list to increase increasing incoming and outgoing metrics to routes learned via RIP. Optionally, you can limit the offset list with either an access list or an interface.

Routing protocols use several timers that determine variables such as the frequency of routing updates, the length of time before a route becomes invalid, and other parameters. You can adjust these timers to tune routing protocol performance to better suit your internetwork needs. You can make the following timer adjustments:

- The rate (time, in seconds, between updates) at which routing updates are sent
- The interval of time, in seconds, after which a route is declared invalid
- The interval, in seconds, during which routing information about better paths is suppressed
- The amount of time, in seconds, that must pass before a route is removed from the routing table
- The amount of time for which routing updates will be postponed

You can adjust the IP routing support in the Cisco software to enable faster convergence of various IP routing algorithms, and hence, cause quicker fallback to redundant devices. The total effect is to minimize disruptions to end users of the network in situations where quick recovery is essential

In addition, an address family can have timers that explicitly apply to that address family (or Virtual Routing and Forwarding [VRF] instance). The **timers-basic** command must be specified for an address family or the

system defaults for the **timers-basic** command are used regardless of the timer that is configured for RIP routing. The VRF does not inherit the timer values from the base RIP configuration. The VRF will always use the system default timers unless the timers are explicitly changed using the **timers-basic** command.

Neighbor Router Authentication

You can prevent your router from receiving fraudulent route updates by configuring neighbor router authentication. When configured, neighbor authentication occurs whenever routing updates are exchanged between neighbor routers. This authentication ensures that a router receives reliable routing information from a trusted source.

Without neighbor authentication, unauthorized or deliberately malicious routing updates could compromise the security of your network traffic. A security compromise could occur if an unfriendly party diverts or analyzes your network traffic. For example, an unauthorized router could send a fictitious routing update to convince your router to send traffic to an incorrect destination. This diverted traffic could be analyzed to learn confidential information about your organization or merely used to disrupt your organization's ability to effectively communicate using the network. Neighbor authentication prevents any such fraudulent route updates from being received by your router.

When neighbor authentication has been configured on a router, the router authenticates the source of each routing update packet that it receives. This is accomplished by the exchange of an authenticating key (sometimes referred to as a password) that is known to both the sending and the receiving router.

There are two types of neighbor authentication used: plain text authentication and Message Digest Algorithm Version 5 (MD5) authentication. Both forms work in the same way, with the exception that MD5 sends a "message digest" instead of the authenticating key itself. The message digest is created using the key and a message, but the key itself is not sent, preventing it from being read while it is being transmitted. Plain text authentication sends the authenticating key itself over the wire.

Note Note that plain text authentication is not recommended for use as part of your security strategy. Its primary use is to avoid accidental changes to the routing infrastructure. Using MD5 authentication, however, is a recommended security practice.

In plain text authentication, each participating neighbor router must share an authenticating key. This key is specified at each router during configuration. Multiple keys can be specified with some protocols; each key must then be identified by a key number.

In general, when a routing update is sent, the following authentication sequence occurs:

1. A router sends a routing update with a key and the corresponding key number to the neighbor router. In protocols that can have only one key, the key number is always zero. The receiving (neighbor) router checks the received key against the same key stored in its own memory.
2. If the two keys match, the receiving router accepts the routing update packet. If the two keys do not match, the routing update packet is rejected.

MD5 authentication works similarly to plain text authentication, except that the key is never sent over the wire. Instead, the router uses the MD5 algorithm to produce a "message digest" of the key (also called a "hash"). The message digest is then sent instead of the key itself. This ensures that nobody can eavesdrop on the line and learn keys during transmission.

Another form of neighbor router authentication is to configure key management using key chains. When you configure a key chain, you specify a series of keys with lifetimes, and the Cisco IOS software rotates through each of these keys. This decreases the likelihood that keys will be compromised.

How to Configure Routing Information Protocol

Enabling RIP and Configuring RIP Parameters

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | router rip Example: Device(config)# router rip | Enables a RIP routing process and enters router configuration mode. |
| Step 4 | network <i>ip-address</i> Example: Device(config-router)# network 10.1.1.0 | Associates a network with a RIP routing process. |
| Step 5 | neighbor <i>ip-address</i> Example: Device(config-router)# neighbor 10.1.1.2 | Defines a neighboring device with which to exchange routing information. |
| Step 6 | auto-summary Example: Device(config-router)# auto-summary | Restores the default behavior of automatic summarization of subnet routes into network-level routes. |
| Step 7 | offset-list [<i>access-list-number</i> <i>access-list-name</i>] {in out} <i>offset</i> [<i>interface-type interface-number</i>] Example: | (Optional) Applies an offset list to routing metrics. |

| | Command or Action | Purpose |
|----------------|---|---|
| | Device(config-router)# offset-list 98 in 1 Ethernet 1/0 | |
| Step 8 | timers basic <i>update invalid holddown flush</i> [<i>sleeptime</i>] Example: Device(config-router)# timers basic 1 2 3 4 | (Optional) Adjusts routing protocol timers. |
| Step 9 | maximum-paths <i>maximum</i> Example: Device(config-router)# maximum-paths 16 | Configures the maximum number of equal cost parallel routes that RIP will install into the routing table. |
| Step 10 | distance <i>admin-distance</i> [<i>prefix prefix-length</i> <i>prefix-mask</i>] Example: Device(config-router)# distance 85 192.168.10.0/24 | Defines the administrative distance assigned to routes discovered by RIP. |
| Step 11 | end Example: Device(config-router)# end | Exits router configuration mode and returns to privileged EXEC mode. |

Specifying a RIP Version and Enabling Authentication

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | router rip Example: Device(config)# router rip | Enters router configuration mode. |

| | Command or Action | Purpose |
|----------------|--|---|
| Step 4 | version {1 2} Example: Device(config-router)# version 2 | Enables the Cisco software to send only RIP Version 2 (RIPv2) packets. |
| Step 5 | exit Example: Device(config-router)# exit | Exits the router configuration mode and enters the global configuration mode. |
| Step 6 | interface <i>type number</i> Example: Device(config)# interface GigabitEthernet 0/0 | Specifies an interface and enters interface configuration mode. |
| Step 7 | ip rip send version [1] [2] Example: Device(config-if)# ip rip send version 2 | Configures an interface to send only RIPv2 packets. |
| Step 8 | ip rip receive version [1] [2] Example: Device(config-if)# ip rip receive version 2 | Configures an interface to accept only RIPv2 packets. |
| Step 9 | ip rip authentication key-chain <i>name-of-chain</i> Example: Device(config-if)# ip rip authentication key-chain chainname | Enables RIP authentication. |
| Step 10 | ip rip authentication mode {text md5} Example: Device(config-if)# ip rip authentication mode md5 | Configures the interface to use message digest algorithm 5 (MD5) authentication (or let it default to plain-text authentication). |
| Step 11 | end Example: Device(config-if)# end | Exits interface configuration mode and returns to privileged EXEC mode. |

Configuration Examples for Routing Information Protocol

Example: Enabling RIP and Configuring RIP Parameters

```

Device> enable
Device# configure terminal
Device(config)# router rip
Device(config-router)# network 10.1.1.0
Device(config-router)# neighbor 10.1.1.2
Device(config-router)# auto-summary
Device(config-router)# offset-list 98 in 1 GigabitEthernet 1/0
Device(config-router)# timers basic 1 2 3 4
Device(config-router)# maximum-paths 16
Device(config-router)# distance 85 192.168.10.0/24
Device(config-router)# end

```

Example: Specifying a RIP Version and Enabling Authentication

```

Device> enable
Device# configure terminal
Device(config)# router rip
Device(config-router)# version 2
Device(config-router)# exit
Device(config)# interface GigabitEthernet 0/0
Device(config-if)# ip rip send version 2
Device(config-if)# ip rip receive version 2
Device(config-if)# ip rip authentication key-chain chainname
Device(config-if)# ip rip authentication mode md5
Device(config-if)# end

```

Feature Information for RIP

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 89: Feature Information for RIP

| Feature Name | Releases | Feature Information |
|------------------------------------|-----------------------------|---|
| RIP (Routing Information Protocol) | Cisco IOS Release 15.2(5)E2 | RIP is a commonly used routing protocol in small to medium TCP/IP networks. RIP is a stable protocol that uses a distance-vector algorithm to calculate routes. |

CHAPTER 37

Open Shortest Path First (OSPF)

- [Information About OSPF, on page 733](#)
- [How to Configure OSPF, on page 736](#)
- [Monitoring OSPF, on page 746](#)
- [Configuration Examples for OSPF, on page 747](#)

Information About OSPF

OSPF is an Interior Gateway Protocol (IGP) designed expressly for IP networks, supporting IP subnetting and tagging of externally derived routing information. OSPF also allows packet authentication and uses IP multicast when sending and receiving packets. The Cisco implementation supports RFC 1253, OSPF management information base (MIB).

The Cisco implementation conforms to the OSPF Version 2 specifications with these key features:

- Definition of stub areas is supported.
- Routes learned through any IP routing protocol can be redistributed into another IP routing protocol. At the intradomain level, this means that OSPF can import routes learned through EIGRP and RIP. OSPF routes can also be exported into RIP.
- Plain text and MD5 authentication among neighboring routers within an area is supported.
- Configurable routing interface parameters include interface output cost, retransmission interval, interface transmit delay, router priority, router dead and hello intervals, and authentication key.
- Virtual links are supported.
- Not-so-stubby-areas (NSSAs) per RFC 1587 are supported.

OSPF typically requires coordination among many internal routers, area border routers (ABRs) connected to multiple areas, and autonomous system boundary routers (ASBRs). The minimum configuration would use all default parameter values, no authentication, and interfaces assigned to areas. If you customize your environment, you must ensure coordinated configuration of all routers.

OSPF for Routed Access

Note OSPF is supported in . OSPF for Routed Access supports only one OSPFv2 and one OSPFv3 instance with a combined total of 1000 dynamically learned routes. The image provides OSPF for routed access. However, these restrictions are not enforced in this release.

With the typical topology (hub and spoke) in a campus environment, where the wiring closets (spokes) are connected to the distribution switch (hub) that forwards all nonlocal traffic to the distribution layer, the wiring closet switch need not hold a complete routing table. A best practice design, where the distribution switch sends a default route to the wiring closet switch to reach interarea and external routes (OSPF stub or totally stub area configuration) should be used when OSPF for Routed Access is used in the wiring closet.

For more details, see the “High Availability Campus Network Design—Routed Access Layer using EIGRP or OSPF” document.

OSPF Area Parameters

You can optionally configure several OSPF area parameters. These parameters include authentication for password-based protection against unauthorized access to an area, stub areas, and not-so-stubby-areas (NSSAs). Stub areas are areas into which information on external routes is not sent. Instead, the area border router (ABR) generates a default external route into the stub area for destinations outside the autonomous system (AS). An NSSA does not flood all LSAs from the core into the area, but can import AS external routes within the area by redistribution.

Route summarization is the consolidation of advertised addresses into a single summary route to be advertised by other areas. If network numbers are contiguous, you can use the **area range** router configuration command to configure the ABR to advertise a summary route that covers all networks in the range.

Other OSPF Parameters

You can optionally configure other OSPF parameters in router configuration mode.

- **Route summarization:** When redistributing routes from other protocols. Each route is advertised individually in an external LSA. To help decrease the size of the OSPF link state database, you can use the **summary-address** router configuration command to advertise a single router for all the redistributed routes included in a specified network address and mask.
- **Virtual links:** In OSPF, all areas must be connected to a backbone area. You can establish a virtual link in case of a backbone-continuity break by configuring two Area Border Routers as endpoints of a virtual link. Configuration information includes the identity of the other virtual endpoint (the other ABR) and the nonbackbone link that the two routers have in common (the transit area). Virtual links cannot be configured through a stub area.
- **Default route:** When you specifically configure redistribution of routes into an OSPF routing domain, the route automatically becomes an autonomous system boundary router (ASBR). You can force the ASBR to generate a default route into the OSPF routing domain.
- **Domain Name Server (DNS) names for use in all OSPF **show** privileged EXEC command displays** makes it easier to identify a router than displaying it by router ID or neighbor ID.

- **Default Metrics:** OSPF calculates the OSPF metric for an interface according to the bandwidth of the interface. The metric is calculated as $ref-bw$ divided by bandwidth, where ref is 10 by default, and bandwidth (bw) is specified by the **bandwidth** interface configuration command. For multiple links with high bandwidth, you can specify a larger number to differentiate the cost on those links.
- **Administrative distance** is a rating of the trustworthiness of a routing information source, an integer between 0 and 255, with a higher value meaning a lower trust rating. An administrative distance of 255 means the routing information source cannot be trusted at all and should be ignored. OSPF uses three different administrative distances: routes within an area (interarea), routes to another area (interarea), and routes from another routing domain learned through redistribution (external). You can change any of the distance values.
- **Passive interfaces:** Because interfaces between two devices on an Ethernet represent only one network segment, to prevent OSPF from sending hello packets for the sending interface, you must configure the sending device to be a passive interface. Both devices can identify each other through the hello packet for the receiving interface.
- **Route calculation timers:** You can configure the delay time between when OSPF receives a topology change and when it starts the shortest path first (SPF) calculation and the hold time between two SPF calculations.
- **Log neighbor changes:** You can configure the router to send a syslog message when an OSPF neighbor state changes, providing a high-level view of changes in the router.

LSA Group Pacing

The OSPF LSA group pacing feature allows the router to group OSPF LSAs and pace the refreshing, check-summing, and aging functions for more efficient router use. This feature is enabled by default with a 4-minute default pacing interval, and you will not usually need to modify this parameter. The optimum group pacing interval is inversely proportional to the number of LSAs the router is refreshing, check-summing, and aging. For example, if you have approximately 10,000 LSAs in the database, decreasing the pacing interval would benefit you. If you have a very small database (40 to 100 LSAs), increasing the pacing interval to 10 to 20 minutes might benefit you slightly.

Loopback Interfaces

OSPF uses the highest IP address configured on the interfaces as its router ID. If this interface is down or removed, the OSPF process must recalculate a new router ID and resend all its routing information out its interfaces. If a loopback interface is configured with an IP address, OSPF uses this IP address as its router ID, even if other interfaces have higher IP addresses. Because loopback interfaces never fail, this provides greater stability. OSPF automatically prefers a loopback interface over other interfaces, and it chooses the highest IP address among all loopback interfaces.

How to Configure OSPF

Default OSPF Configuration

Table 90: Default OSPF Configuration

| Feature | Default Setting |
|-------------------------------|--|
| Interface parameters | Cost: Retransmit interval: 5 seconds. Transmit delay: 1 second. Priority: 1. Hello interval: 10 seconds. Dead interval: 4 times the hello interval. No authentication. No password specified. MD5 authentication disabled. |
| Area | Authentication type: 0 (no authentication). Default cost: 1. Range: Disabled. Stub: No stub area defined. NSSA: No NSSA area defined. |
| Auto cost | 100 Mb/s. |
| Default-information originate | Disabled. When enabled, the default metric setting is 10, and the external route type is Type 2. |
| Default metric | Built-in, automatic metric translation, as appropriate for each routing protocol. |
| Distance OSPF | dist1 (all routes within an area): 110. dist2 (all routes from one area to another): 110. dist3 (routes from other routing domains): 110. |
| OSPF database filter | Disabled. All outgoing link-state advertisements (LSAs) are flooded to the interface. |
| IP OSPF name lookup | Disabled. |
| Log adjacency changes | Enabled. |
| Neighbor | None specified. |
| Neighbor database filter | Disabled. All outgoing LSAs are flooded to the neighbor. |
| Network area | Disabled. |

| Feature | Default Setting |
|----------------------------------|---|
| Router ID | No OSPF routing process defined. |
| Summary address | Disabled. |
| Timers LSA group pacing | 240 seconds. |
| Timers shortest path first (spf) | spf delay: 5 seconds.; spf-holdtime: 10 seconds. |
| Virtual link | No area ID or router ID defined. Hello interval: 10 seconds. Retransmit interval: 5 seconds. Transmit delay: 1 second. Dead interval: 40 seconds. Authentication key: no key predefined. Message-digest key (MD5): no key predefined. |

Configuring Basic OSPF Parameters

To enable OSPF, create an OSPF routing process, specify the range of IP addresses to associate with the routing process, and assign area IDs to be associated with that range.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | router ospf <i>process-id</i> Example: Device(config)# <code>router ospf 15</code> | Enables OSPF routing, and enter router configuration mode. The process ID is an internally used identification parameter that is locally assigned and can be any positive integer. Each OSPF routing process has a unique value. Note OSPF for Routed Access supports only one OSPFv2 and one OSPFv3 instance with a maximum number of 1000 dynamically learned routes. |
| Step 3 | network <i>address wildcard-mask area area-id</i> Example: | Define an interface on which OSPF runs and the area ID for that interface. You can use the wildcard-mask to use a single command to |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device(config-router)# network 10.1.1.1 255.240.0.0 area 20 | define one or more multiple interfaces to be associated with a specific OSPF area. The area ID can be a decimal value or an IP address. |
| Step 4 | end Example: Device(config-router)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip protocols Example: Device# show ip protocols | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring OSPF Interfaces

You can use the **ip ospf** interface configuration commands to modify interface-specific OSPF parameters. You are not required to modify any of these parameters, but some interface parameters (hello interval, dead interval, and authentication key) must be consistent across all routers in an attached network. If you modify these parameters, be sure all routers in the network have compatible values.

Note The **ip ospf** interface configuration commands are all optional.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface <i>interface-id</i> Example: Device(config)# interface gigabitethernet 1/0/1 | Enters interface configuration mode, and specifies the Layer 3 interface to configure. |

| | Command or Action | Purpose |
|----------------|--|---|
| Step 3 | ip ospf cost <i>cost</i> Example: Device(config-if)# ip ospf cost 8 | (Optional) Explicitly specifies the cost of sending a packet on the interface. |
| Step 4 | ip ospf retransmit-interval <i>seconds</i> Example: Device(config-if)# ip ospf transmit-interval 10 | (Optional) Specifies the number of seconds between link state advertisement transmissions. The range is 1 to 65535 seconds. The default is 5 seconds. |
| Step 5 | ip ospf transmit-delay <i>seconds</i> Example: Device(config-if)# ip ospf transmit-delay 2 | (Optional) Sets the estimated number of seconds to wait before sending a link state update packet. The range is 1 to 65535 seconds. The default is 1 second. |
| Step 6 | ip ospf priority <i>number</i> Example: Device(config-if)# ip ospf priority 5 | (Optional) Sets priority to help find the OSPF designated router for a network. The range is from 0 to 255. The default is 1. |
| Step 7 | ip ospf hello-interval <i>seconds</i> Example: Device(config-if)# ip ospf hello-interval 12 | (Optional) Sets the number of seconds between hello packets sent on an OSPF interface. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 10 seconds. |
| Step 8 | ip ospf dead-interval <i>seconds</i> Example: Device(config-if)# ip ospf dead-interval 8 | (Optional) Sets the number of seconds after the last device hello packet was seen before its neighbors declare the OSPF router to be down. The value must be the same for all nodes on a network. The range is 1 to 65535 seconds. The default is 4 times the hello interval. |
| Step 9 | ip ospf authentication-key <i>key</i> Example: Device(config-if)# ip ospf authentication-key password | (Optional) Assign a password to be used by neighboring OSPF routers. The password can be any string of keyboard-entered characters up to 8 bytes in length. All neighboring routers on the same network must have the same password to exchange OSPF information. |
| Step 10 | ip ospf message-digest-key <i>keyid md5 key</i> Example: Device(config-if)# ip ospf message digest-key 16 md5 yourlpass | (Optional) Enables MDS authentication. <ul style="list-style-type: none"> • <i>keyid</i>—An identifier from 1 to 255. • <i>key</i>—An alphanumeric password of up to 16 bytes. |

| | Command or Action | Purpose |
|---------|--|---|
| Step 11 | ip ospf database-filter all out Example: <pre>Device(config-if)# ip ospf database-filter all out</pre> | (Optional) Block flooding of OSPF LSA packets to the interface. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. |
| Step 12 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 13 | show ip ospf interface [interface-name] Example: <pre>Device# show ip ospf interface</pre> | Displays OSPF-related interface information. |
| Step 14 | show ip ospf neighbor detail Example: <pre>Device# show ip ospf neighbor detail</pre> | Displays NSF awareness status of neighbor switch. The output matches one of these examples: <ul style="list-style-type: none"> • <i>Options is 0x52</i> <i>LLS Options is 0x1 (LR)</i> When both of these lines appear, the neighbor switch is NSF aware. • <i>Options is 0x42</i>—This means the neighbor switch is not NSF aware. |
| Step 15 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring OSPF Area Parameters

Before you begin

Note The OSPF **area** router configuration commands are all optional.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | router ospf <i>process-id</i> Example: Device(config)# router ospf 109 | Enables OSPF routing, and enter router configuration mode. |
| Step 3 | area <i>area-id</i> authentication Example: Device(config-router)# area 1 authentication | (Optional) Allow password-based protection against unauthorized access to the identified area. The identifier can be either a decimal value or an IP address. |
| Step 4 | area <i>area-id</i> authentication message-digest Example: Device(config-router)# area 1 authentication message-digest | (Optional) Enables MD5 authentication on the area. |
| Step 5 | area <i>area-id</i> stub [no-summary] Example: Device(config-router)# area 1 stub | (Optional) Define an area as a stub area. The no-summary keyword prevents an ABR from sending summary link advertisements into the stub area. |
| Step 6 | area <i>area-id</i> nssa [no-redistribution] [default-information-originate] [no-summary] Example: Device(config-router)# area 1 nssa default-information-originate | (Optional) Defines an area as a not-so-stubby-area. Every router within the same area must agree that the area is NSSA. Select one of these keywords: <ul style="list-style-type: none"> • no-redistribution—Select when the router is an NSSA ABR and you want the redistribute command to import routes into normal areas, but not into the NSSA. • default-information-originate—Select on an ABR to allow importing type 7 LSAs into the NSSA. • no-redistribution—Select to not send summary LSAs into the NSSA. |

| | Command or Action | Purpose |
|----------------|--|---|
| Step 7 | area <i>area-id</i> range <i>address mask</i> Example: <pre>Device(config-router)# area 1 range 255.240.0.0</pre> | (Optional) Specifies an address range for which a single route is advertised. Use this command only with area border routers. |
| Step 8 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 9 | show ip ospf [<i>process-id</i>] Example: <pre>Device# show ip ospf</pre> | Displays information about the OSPF routing process in general or for a specific process ID to verify configuration. |
| Step 10 | show ip ospf [<i>process-id</i> [<i>area-id</i>]] database Example: <pre>Device# show ip ospf database</pre> | Displays lists of information related to the OSPF database for a specific router. |
| Step 11 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring Other OSPF Parameters

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 2 | router ospf <i>process-id</i> Example: <pre>Device(config)# router ospf 10</pre> | Enables OSPF routing, and enter router configuration mode. |

| | Command or Action | Purpose |
|---------|---|--|
| Step 3 | summary-address <i>address mask</i> Example: <pre>Device(config)# summary-address 10.1.1.1 255.255.255.0</pre> | (Optional) Specifies an address and IP subnet mask for redistributed routes so that only one summary route is advertised. |
| Step 4 | area <i>area-id</i> virtual-link <i>router-id</i> [hello-interval <i>seconds</i>] [retransmit-interval <i>seconds</i>] [trans [[authentication-key <i>key</i>] message-digest-key <i>keyid md5 key</i>]] Example: <pre>Device(config)# area 2 virtual-link 192.168.255.1 hello-interval 5</pre> | (Optional) Establishes a virtual link and set its parameters. |
| Step 5 | default-information originate [always] [metric <i>metric-value</i>] [metric-type <i>type-value</i>] [route-map <i>map-name</i>] Example: <pre>Device(config)# default-information originate metric 100 metric-type 1</pre> | (Optional) Forces the ASBR to generate a default route into the OSPF routing domain. Parameters are all optional. |
| Step 6 | ip ospf name-lookup Example: <pre>Device(config)# ip ospf name-lookup</pre> | (Optional) Configures DNS name lookup. The default is disabled. |
| Step 7 | ip auto-cost reference-bandwidth <i>ref-bw</i> Example: <pre>Device(config)# ip auto-cost reference-bandwidth 5</pre> | (Optional) Specifies an address range for which a single route will be advertised. Use this command only with area border routers. |
| Step 8 | distance ospf [[inter-area <i>dist1</i>] [inter-area <i>dist2</i>] [external <i>dist3</i>] Example: <pre>Device(config)# distance ospf inter-area 150</pre> | (Optional) Changes the OSPF distance values. The default distance for each type of route is 110. The range is 1 to 255. |
| Step 9 | passive-interface <i>type number</i> Example: <pre>Device(config)# passive-interface gigabitethernet 1/0/6</pre> | (Optional) Suppresses the sending of hello packets through the specified interface. |
| Step 10 | timers throttle spf <i>spf-delay spf-holdtime</i> <i>spf-wait</i> | (Optional) Configures route calculation timers. |

| | Command or Action | Purpose |
|----------------|---|---|
| | Example: <pre>Device(config)# timers throttle spf 200 100 100</pre> | <ul style="list-style-type: none"> • <i>spf-delay</i>—Delay between receiving a change to SPF calculation. The range is from 1 to 600000 milliseconds. • <i>spf-holdtime</i>—Delay between first and second SPF calculation. The range is from 1 to 600000 in milliseconds. • <i>spf-wait</i>—Maximum wait time in milliseconds for SPF calculations. The range is from 1 to 600000 in milliseconds. |
| Step 11 | ospf log-adj-changes Example: <pre>Device(config)# ospf log-adj-changes</pre> | (Optional) Sends syslog message when a neighbor state changes. |
| Step 12 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 13 | show ip ospf [process-id [area-id]] database Example: <pre>Device# show ip ospf database</pre> | Displays lists of information related to the OSPF database for a specific router. |
| Step 14 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Changing LSA Group Pacing

Procedure

| | Command or Action | Purpose |
|---------------|---|-----------------------------------|
| Step 1 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 2 | router ospf <i>process-id</i> Example: Device(config)# router ospf 25 | Enables OSPF routing, and enter router configuration mode. |
| Step 3 | timers lsa-group-pacing <i>seconds</i> Example: Device(config-router)# timers lsa-group-pacing 15 | Changes the group pacing of LSAs. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring a Loopback Interface

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | interface loopback 0 Example: Device(config)# interface loopback 0 | Creates a loopback interface, and enter interface configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 3 | ip address address mask Example: Device(config-if)# ip address 10.1.1.5 255.255.240.0 | Assign an IP address to this interface. |
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show ip interface Example: Device# show ip interface | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring OSPF

You can display specific statistics such as the contents of IP routing tables, caches, and databases.

Table 91: Show IP OSPF Statistics Commands

| | |
|---|---|
| show ip ospf [process-id] | Displays general information about OSPF processes. |
| show ip ospf [process-id] database [router] [link-state-id] show ip ospf [process-id] database [router] [self-originate] show ip ospf [process-id] database [router] [adv-router [ip-address]] show ip ospf [process-id] database [network] [link-state-id] show ip ospf [process-id] database [summary] [link-state-id] show ip ospf [process-id] database [asbr-summary] [link-state-id] show ip ospf [process-id] database [external] [link-state-id] show ip ospf [process-id area-id] database [database-summary] | Displays lists of information about OSPF databases. |
| show ip ospf border-routes | Displays the internal OSPF routing table entries. |

| | |
|--|--------------------|
| <code>show ip ospf interface [interface-name]</code> | Displays OSPF-rela |
| <code>show ip ospf neighbor [interface-name] [neighbor-id] detail</code> | Displays OSPF inte |
| <code>show ip ospf virtual-links</code> | Displays OSPF-rela |

Configuration Examples for OSPF

Example: Configuring Basic OSPF Parameters

This example shows how to configure an OSPF routing process and assign it a process number of 109:

```
Device(config)# router ospf 109
Device(config-router)# network 131.108.0.0 255.255.255.0 area 24
```

CHAPTER 38

IPv6 Open Shortest Path First version 3

- [IPv6 Routing: OSPFv3, on page 749](#)

IPv6 Routing: OSPFv3

Open Shortest Path First version 3 (OSPFv3) is an IPv4 and IPv6 link-state routing protocol that supports IPv6 and IPv4 unicast address families (AFs).

Prerequisites for IPv6 Routing: OSPFv3

- Complete the OSPFv3 network strategy and planning for your IPv6 network. For example, you must decide whether multiple areas are required.
- Enable IPv6 unicast routing.
- Enable IPv6 on the interface.

Restrictions for IPv6 Routing: OSPFv3

When running a dual-stack IP network with OSPF version 2 for IPv4 and OSPFv3, be careful when changing the defaults for commands used to enable OSPFv3. Changing these defaults may affect your OSPFv3 network, possibly adversely.

Information About IPv6 Routing: OSPFv3

How OSPFv3 Works

OSPFv3 is a routing protocol for IPv4 and IPv6. It is a link-state protocol, as opposed to a distance-vector protocol. Think of a link as being an interface on a networking device. A link-state protocol makes its routing decisions based on the states of the links that connect source and destination machines. The state of a link is a description of that interface and its relationship to its neighboring networking devices. The interface information includes the IPv6 prefix of the interface, the network mask, the type of network it is connected to, the devices connected to that network, and so on. This information is propagated in various type of link-state advertisements (LSAs).

A device's collection of LSA data is stored in a link-state database. The contents of the database, when subjected to the Dijkstra algorithm, result in the creation of the OSPF routing table. The difference between the database and the routing table is that the database contains a complete collection of raw data; the routing table contains a list of shortest paths to known destinations via specific device interface ports.

OSPFv3, which is described in RFC 5340, supports IPv6 and IPv4 unicast AFs.

Comparison of OSPFv3 and OSPF Version 2

Much of OSPF version 3 is the same as in OSPF version 2. OSPFv3, which is described in RFC 5340, expands on OSPF version 2 to provide support for IPv6 routing prefixes and the larger size of IPv6 addresses.

In OSPFv3, a routing process does not need to be explicitly created. Enabling OSPFv3 on an interface will cause a routing process, and its associated configuration, to be created.

In OSPFv3, each interface must be enabled using commands in interface configuration mode. This feature is different from OSPF version 2, in which interfaces are indirectly enabled using the device configuration mode.

When using a nonbroadcast multiaccess (NBMA) interface in OSPFv3, you must manually configure the device with the list of neighbors. Neighboring devices are identified by their device ID.

In IPv6, you can configure many address prefixes on an interface. In OSPFv3, all address prefixes on an interface are included by default. You cannot select some address prefixes to be imported into OSPFv3; either all address prefixes on an interface are imported, or no address prefixes on an interface are imported.

Unlike OSPF version 2, multiple instances of OSPFv3 can be run on a link.

OSPF automatically prefers a loopback interface over any other kind, and it chooses the highest IP address among all loopback interfaces. If no loopback interfaces are present, the highest IP address in the device is chosen. You cannot tell OSPF to use any particular interface.

LSA Types for OSPFv3

The following list describes LSA types, each of which has a different purpose:

- Device LSAs (Type 1)—Describes the link state and costs of a device's links to the area. These LSAs are flooded within an area only. The LSA indicates if the device is an Area Border Router (ABR) or Autonomous System Boundary Router (ASBR), and if it is one end of a virtual link. Type 1 LSAs are also used to advertise stub networks. In OSPFv3, these LSAs have no address information and are network-protocol-independent. In OSPFv3, device interface information may be spread across multiple device LSAs. Receivers must concatenate all device LSAs originated by a given device when running the SPF calculation.
- Network LSAs (Type 2)—Describes the link-state and cost information for all devices attached to the network. This LSA is an aggregation of all the link-state and cost information in the network. Only a designated device tracks this information and can generate a network LSA. In OSPFv3, network LSAs have no address information and are network-protocol-independent.
- Interarea-prefix LSAs for ABRs (Type 3)—Advertises internal networks to devices in other areas (interarea routes). Type 3 LSAs may represent a single network or a set of networks summarized into one advertisement. Only ABRs generate summary LSAs. In OSPFv3, addresses for these LSAs are expressed as *prefix, prefix length* instead of *address, mask*. The default route is expressed as a prefix with length 0.
- Interarea-device LSAs for ASBRs (Type 4)—Advertises the location of an ASBR. Devices that are trying to reach an external network use these advertisements to determine the best path to the next hop. Type 4 LSAs are generated by ABRs on behalf of ASBRs.

- Autonomous system external LSAs (Type 5)—Redistributes routes from another autonomous system, usually from a different routing protocol into OSPFv3. In OSPFv3, addresses for these LSAs are expressed as *prefix, prefix length* instead of *address, mask*. The default route is expressed as a prefix with length 0.
- Link LSAs (Type 8)—Have local-link flooding scope and are never flooded beyond the link with which they are associated. Link LSAs provide the link-local address of the device to all other devices attached to the link, inform other devices attached to the link of a list of prefixes to associate with the link, and allow the device to assert a collection of Options bits to associate with the network LSA that will be originated for the link.
- Intra-Area-Prefix LSAs (Type 9)—A device can originate multiple intra-area-prefix LSAs for each device or transit network, each with a unique link-state ID. The link-state ID for each intra-area-prefix LSA describes its association to either the device LSA or the network LSA and contains prefixes for stub and transit networks.

An address prefix occurs in almost all newly defined LSAs. The prefix is represented by three fields: PrefixLength, PrefixOptions, and Address Prefix. In OSPFv3, addresses for these LSAs are expressed as *prefix, prefix length* instead of *address, mask*. The default route is expressed as a prefix with length 0. Type 3 and Type 9 LSAs carry all prefix (subnet) information that, in OSPFv2, is included in device LSAs and network LSAs. The Options field in certain LSAs (device LSAs, network LSAs, interarea-device LSAs, and link LSAs) has been expanded to 24 bits to provide support for OSPFv3.

In OSPFv3, the sole function of the link-state ID in interarea-prefix LSAs, interarea-device LSAs, and autonomous-system external LSAs is to identify individual pieces of the link-state database. All addresses or device IDs that are expressed by the link-state ID in OSPF version 2 are carried in the body of the LSA in OSPFv3.

The link-state ID in network LSAs and link LSAs is always the interface ID of the originating device on the link being described. For this reason, network LSAs and link LSAs are now the only LSAs whose size cannot be limited. A network LSA must list all devices connected to the link, and a link LSA must list all of the address prefixes of a device on the link.

NBMA in OSPFv3

On NBMA networks, the designated router (DR) or backup DR (BDR) performs the LSA flooding. On point-to-point networks, flooding simply goes out an interface directly to a neighbor.

Devices that share a common segment (Layer 2 link between two interfaces) become neighbors on that segment. OSPFv3 uses the Hello protocol, periodically sending hello packets out each interface. Devices become neighbors when they see themselves listed in the neighbor's hello packet. After two devices become neighbors, they may proceed to exchange and synchronize their databases, which creates an adjacency. Not all neighboring devices have an adjacency.

On point-to-point and point-to-multipoint networks, the software floods routing updates to immediate neighbors. There is no DR or BDR; all routing information is flooded to each networking device.

On broadcast or NBMA segments only, OSPFv3 minimizes the amount of information being exchanged on a segment by choosing one device to be a DR and one device to be a BDR. Thus, the devices on the segment have a central point of contact for information exchange. Instead of each device exchanging routing updates with every other device on the segment, each device exchanges information with the DR and BDR. The DR and BDR relay the information to the other devices.

The software looks at the priority of the devices on the segment to determine which devices will be the DR and BDR. The device with the highest priority is elected the DR. If there is a tie, then the device with the

higher device ID takes precedence. After the DR is elected, the BDR is elected the same way. A device with a device priority set to zero is ineligible to become the DR or BDR.

When using NBMA in OSPFv3, you cannot automatically detect neighbors. On an NBMA interface, you must configure your neighbors manually using interface configuration mode.

Load Balancing in OSPFv3

When a device learns multiple routes to a specific network via multiple routing processes (or routing protocols), it installs the route with the lowest administrative distance in the routing table. Sometimes the device must select a route from among many learned via the same routing process with the same administrative distance. In this case, the device chooses the path with the lowest cost (or metric) to the destination. Each routing process calculates its cost differently and the costs may need to be manipulated in order to achieve load balancing.

OSPFv3 performs load balancing automatically in the following way. If OSPFv3 finds that it can reach a destination through more than one interface and each path has the same cost, it installs each path in the routing table. The only restriction on the number of paths to the same destination is controlled by the **maximum-paths** command. The default maximum paths is 32, and the range is from 1 to 32.

Addresses Imported into OSPFv3

When importing the set of addresses specified on an interface on which OSPFv3 is running into OSPFv3, you cannot select specific addresses to be imported. Either all addresses are imported, or no addresses are imported.

OSPFv3 Customization

You can customize OSPFv3 for your network, but you likely will not need to do so. The defaults for OSPFv3 are set to meet the requirements of most customers and features. If you must change the defaults, refer to the IPv6 command reference to find the appropriate syntax.

Caution Be careful when changing the defaults. Changing defaults will affect your OSPFv3 network, possibly adversely.

OSPFv3 Cost Calculation

Because cost components can change rapidly, it might be necessary to reduce the volume of changes to reduce network-wide churn. The recommended values for S2, S3, and S4 in the second table below are based on network simulations that may reduce the rate of network changes. The recommended value for S1 is 0 to eliminate this variable from the route cost calculation.

The overall link cost is computed using the formula shown in the figure below.

Figure 77: Overall Link Cost Formula

$$\text{LinkCost} = \text{OC} + \text{BW} \left(\frac{\text{Throughput_weight}}{100} \right) + \text{Resources} \left(\frac{\text{Resources_weight}}{100} \right) + \text{Latency} \left(\frac{\text{Latency_weight}}{100} \right) + \text{L2_factor} \left(\frac{\text{L2_weight}}{100} \right)$$

$$\text{OC} = \left[\frac{\text{ospf_reference_bw}}{(\text{MDR})(1000)} \right]$$

$$\text{ospf_reference_bw} = 10^8$$

$$\text{BW} = \frac{(65535) \left(100 - \frac{\text{CDR}}{\text{MDR}} (100) \right)}{100}$$

$$\text{Resources} = \frac{(100 - \text{resources})^3 (65535)}{1000000}$$

$$\text{Latency} = \text{latency}$$

$$\text{L2_factor} = \frac{(100 - \text{RLQ})(65535)}{100}$$

231048

The table below defines the symbols used in the OSPFv3 cost calculation.

Table 92: OSPFv3 Cost Calculation Definitions

| Cost Component | Component Definition |
|----------------|---|
| OC | The default OSPFv3 cost. Calculated from reference bandwidth using reference_bw / (MDR*1000), where reference_bw=10^8. |
| A through D | Various radio-specific data-based formulas that produce results in the 0 through 64,000 range. |
| A | CDR- and MDR-related formula: $(2^{16} * (100 - (\text{CDR} * 100 / \text{MDR}))) / 100$ |
| B | Resources related formula: $((100 - \text{RESOURCES})^3 * 2^{16} / 10^6)$ |
| C | Latency as reported by the radio, already in the 0 through 64,000 range when reported (LATENCY). |
| D | RLF-related formula: $((100 - \text{RLF}) * 2^{16}) / 100$ |
| S1 through S4 | Scalar weighting factors input from the CLI. These scalars scale down the values as computed by A through D. The value of 0 disables and the value of 100 enables full 0 through 64,000 range for one component. |

Because each network might have unique characteristics that require different settings to optimize actual network performance, these are recommended values intended as a starting point for optimizing an OSPFv3 network. The table below lists the recommended value settings for OSPFv3 cost metrics.

Table 93: Recommended Value Settings for OSPFv3 Cost Metrics

| Setting | Metric Description | Default Value | Recommended Value |
|---------|-------------------------------------|---------------|-------------------|
| S1 | ipv6 ospf dynamic weight throughout | 100 | 0 |
| S2 | ipv6 ospf dynamic weight resources | 100 | 29 |
| S3 | ipv6 ospf dynamic weight latency | 100 | 29 |
| S4 | ipv6 ospf dynamic weight L2 factor | 100 | 29 |

The default path costs were calculated using this formula, as noted in the following list. If these values do not suit your network, you can use your own method of calculating path costs.

- 56-kbps serial link—Default cost is 1785.
- 64-kbps serial link—Default cost is 1562.
- T1 (1.544-Mbps serial link)—Default cost is 64.
- E1 (2.048-Mbps serial link)—Default cost is 48.
- 4-Mbps Token Ring—Default cost is 25.
- Ethernet—Default cost is 10.
- 16-Mbps Token Ring—Default cost is 6.
- FDDI—Default cost is 1.
- X25—Default cost is 5208.
- Asynchronous—Default cost is 10,000.
- ATM—Default cost is 1.

Force SPF in OSPFv3

When the **process** keyword is used with the **clear ipv6 ospf** command, the OSPFv3 database is cleared and repopulated, and then the SPF algorithm is performed. When the **force-spf** keyword is used with the **clear ipv6 ospf** command, the OSPFv3 database is not cleared before the SPF algorithm is performed.

How to Configure Load Balancing in OSPFv3

Configuring the OSPFv3 Device Process

Once you have completed step 3 and entered OSPFv3 router configuration mode, you can perform any of the subsequent steps in this task as needed to configure OSPFv3 Device configuration.

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Example: Device> enable | <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | router ospfv3 [process-id] Example: Device(config)# router ospfv3 1 | Enters router configuration mode for the IPv4 or IPv6 address family. |
| Step 4 | area area-ID [default-cost nssa stub] Example: Device(config-router)# area 1 | Configures the OSPFv3 area. |
| Step 5 | auto-cost reference-bandwidth Mbps Example: Device(config-router)# auto-cost reference-bandwidth 1000 | Controls the reference value OSPFv3 uses when calculating metrics for interfaces in an IPv4 OSPFv3 process. |
| Step 6 | default {area area-ID [range ipv6-prefix virtual-link router-id]} [default-information originate [always metric metric-type route-map] distance distribute-list prefix-list prefix-list-name {in out} [interface] maximum-paths paths redistribute protocol summary-prefix ipv6-prefix] Example: Device(config-router)# default area 1 | Returns an OSPFv3 parameter to its default value. |
| Step 7 | ignore lsa mospf Example: Device(config-router)# ignore lsa mospf | Suppresses the sending of syslog messages when the device receives LSA Type 6 multicast OSPFv3 packets, which are unsupported. |
| Step 8 | interface-id snmp-if-index Example: Device(config-router)# interface-id snmp-if-index | Configures OSPFv3 interfaces with Simple Network Management Protocol (SNMP) MIB-II interface Index (ifIndex) identification numbers in IPv4 and IPv6. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 9 | log-adjacency-changes [detail] Example: Device(config-router)# log-adjacency-changes | Configures the device to send a syslog message when an OSPFv3 neighbor goes up or down. |
| Step 10 | passive-interface [default <i>interface-type</i> <i>interface-number</i>] Example: Device(config-router)# passive-interface default | Suppresses sending routing updates on an interface when an IPv4 OSPFv3 process is used. |
| Step 11 | queue-depth {hello update} { <i>queue-size</i> unlimited} Example: Device(config-router)# queue-depth update 1500 | Configures the number of incoming packets that the IPv4 OSPFv3 process can keep in its queue. |
| Step 12 | router-id <i>router-id</i> Example: Device(config-router)# router-id 10.1.1.1 | Enter this command to use a fixed router ID. |

Configuring NBMA Interfaces in OSPFv3

You can customize OSPFv3 in your network to use NBMA interfaces. OSPFv3 cannot automatically detect neighbors over NBMA interfaces. On an NBMA interface, you must configure your neighbors manually using interface configuration mode.

Before you begin

Before you configure NBMA interfaces, you must perform the following tasks:

- Configure your network to be an NBMA network
- Identify each neighbor

Note

- You cannot automatically detect neighbors when using NBMA interfaces. You must manually configure your device to detect neighbors when using an NBMA interface.
- When the **ipv6 ospf neighbor** command is configured, the IPv6 address used must be the link-local address of the neighbor.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>type number</i> Example: | Specifies an interface type and number, and places the device in interface configuration mode. |
| Step 4 | ipv6 enable Example: Device (config-if)#ipv6 enable | Enables ipv6 on an interface. |
| Step 5 | ipv6 ospf neighbor <i>ipv6-address</i> [priority number] [poll-interval seconds] [cost number] [database-filter all out] Example: Device(config-if) ipv6 ospf neighbor FE80::A8BB:CCFF:FE00:C01 | Configures an OSPFv3 neighboring device. |

Forcing an SPF Calculation

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | clear ospfv3 [<i>process-id</i>] force-spf Example: Device# clear ospfv3 1 force-spf | Runs SPF calculations for an OSPFv3 process. • If the clear ospfv3 force-spf command is configured, it overwrites the clear ipv6 ospf configuration. • Once the clear ospfv3 force-spf command has been used, the clear ipv6 ospf command cannot be used. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | clear ospfv3 [<i>process-id</i>] process Example: Device# clear ospfv3 2 process | Resets an OSPFv3 process. <ul style="list-style-type: none"> • If the clear ospfv3 force-spf command is configured, it overwrites the clear ipv6 ospf configuration. • Once the clear ospfv3 force-spf command has been used, the clear ipv6 ospf command cannot be used. |
| Step 4 | clear ospfv3 [<i>process-id</i>] redistribution Example: Device# clear ospfv3 redistribution | Clears OSPFv3 route redistribution. <ul style="list-style-type: none"> • If the clear ospfv3 force-spf command is configured, it overwrites the clear ipv6 ospf configuration. • Once the clear ospfv3 force-spf command has been used, the clear ipv6 ospf command cannot be used. |
| Step 5 | clear ipv6 ospf [<i>process-id</i>] { process force-spf redistribution } Example: Device# clear ipv6 ospf force-spf | Clears the OSPFv3 state based on the OSPFv3 routing process ID, and forces the start of the SPF algorithm. <ul style="list-style-type: none"> • If the clear ospfv3 force-spf command is configured, it overwrites the clear ipv6 ospf configuration. • Once the clear ospfv3 force-spf command has been used, the clear ipv6 ospf command cannot be used. |

Verifying OSPFv3 Configuration and Operation

This task is optional, and the commands can be entered in any order, as needed.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show ospfv3 [<i>process-id</i>] [<i>address-family</i>] border-routers Example: | Displays the internal OSPFv3 routing table entries to an ABR and ASBR. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device# show ospfv3 border-routers | |
| Step 3 | <p>show ospfv3 [<i>process-id</i> [<i>area-id</i>]] [<i>address-family</i>] database [database-summary internal external [<i>ipv6-prefix</i>] [<i>link-state-id</i>] grace inter-area prefix [<i>ipv6-prefix</i> <i>link-state-id</i>] inter-area router [<i>destination-router-id</i> <i>link-state-id</i>] link [interface <i>interface-name</i> <i>link-state-id</i>] network [<i>link-state-id</i>] nssa-external [<i>ipv6-prefix</i>] [<i>link-state-id</i>] prefix [ref-lsa {router network} <i>link-state-id</i>] promiscuous router [<i>link-state-id</i>] unknown [{area as link} [<i>link-state-id</i>]] adv-router <i>router-id</i>] [self-originate]</p> <p>Example:</p> <pre>Device# show ospfv3 database</pre> | Displays lists of information related to the OSPFv3 database for a specific device. |
| Step 4 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] events [generic interface lsa neighbor reverse rib spf]</p> <p>Example:</p> <pre>Device# show ospfv3 events</pre> | Displays detailed information about OSPFv3 events. |
| Step 5 | <p>show ospfv3 [<i>process-id</i>] [<i>area-id</i>] [<i>address-family</i>] flood-list <i>interface-type</i> <i>interface-number</i></p> <p>Example:</p> <pre>Device# show ospfv3 flood-list</pre> | Displays a list of OSPFv3 LSAs waiting to be flooded over an interface. |
| Step 6 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] graceful-restart</p> <p>Example:</p> <pre>Device# show ospfv3 graceful-restart</pre> | Displays OSPFv3 graceful restart information. |
| Step 7 | <p>show ospfv3 [<i>process-id</i>] [<i>area-id</i>] [<i>address-family</i>] interface [<i>type number</i>] [brief]</p> <p>Example:</p> <pre>Device# show ospfv3 interface</pre> | Displays OSPFv3-related interface information. |

| | Command or Action | Purpose |
|----------------|--|---|
| Step 8 | <p>show ospfv3 [<i>process-id</i>] [<i>area-id</i>] [<i>address-family</i>] neighbor [<i>interface-type interface-number</i>] [<i>neighbor-id</i>] [detail]</p> <p>Example:</p> <pre>Device# show ospfv3 neighbor</pre> | Displays OSPFv3 neighbor information on a per-interface basis. |
| Step 9 | <p>show ospfv3 [<i>process-id</i>] [<i>area-id</i>] [<i>address-family</i>] request-list [<i>neighbor</i>] [<i>interface</i>] [<i>interface-neighbor</i>]</p> <p>Example:</p> <pre>Device# show ospfv3 request-list</pre> | Displays a list of all LSAs requested by a device. |
| Step 10 | <p>show ospfv3 [<i>process-id</i>] [<i>area-id</i>] [<i>address-family</i>] retransmission-list [<i>neighbor</i>] [<i>interface</i>] [<i>interface-neighbor</i>]</p> <p>Example:</p> <pre>Device# show ospfv3 retransmission-list</pre> | Displays a list of all LSAs waiting to be re-sent. |
| Step 11 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] statistic [detail]</p> <p>Example:</p> <pre>Device# show ospfv3 statistic</pre> | Displays OSPFv3 SPF calculation statistics. |
| Step 12 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] summary-prefix</p> <p>Example:</p> <pre>Device# show ospfv3 summary-prefix</pre> | Displays a list of all summary address redistribution information configured under an OSPFv3 process. |
| Step 13 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] timers rate-limit</p> <p>Example:</p> <pre>Device# show ospfv3 timers rate-limit</pre> | Displays all of the LSAs in the rate limit queue. |
| Step 14 | <p>show ospfv3 [<i>process-id</i>] [<i>address-family</i>] traffic [<i>interface-type interface-number</i>]</p> <p>Example:</p> <pre>Device# show ospfv3 traffic</pre> | Displays OSPFv3 traffic statistics. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 15 | show ospfv3 [<i>process-id</i>] [<i>address-family</i>] virtual-links Example: Device# show ospfv3 virtual-links | Displays parameters and the current state of OSPFv3 virtual links. |

Configuration Examples for Load Balancing in OSPFv3

Example: Configuring the OSPFv3 Device Process

```

Device# show ospfv3 database
      OSPFv3 Device with ID (172.16.4.4) (Process ID 1)
          Device Link States (Area 0)
ADV Device      Age      Seq#      Fragment ID  Link count  Bits
172.16.4.4      239      0x80000003  0            1            B
172.16.6.6      239      0x80000003  0            1            B
      Inter Area Prefix Link States (Area 0)
ADV Device      Age      Seq#      Prefix
172.16.4.4      249      0x80000001  FEC0:3344::/32
172.16.4.4      219      0x80000001  FEC0:3366::/32
172.16.6.6      247      0x80000001  FEC0:3366::/32
172.16.6.6      193      0x80000001  FEC0:3344::/32
172.16.6.6      82       0x80000001  FEC0::/32

172.16.6.6      252      0x80000002  0            0x2001      0

Device# show ospfv3 neighbor

OSPFv3 Device with ID (10.1.1.1) (Process ID 42)
Neighbor ID     Pri  State           Dead Time   Interface ID  Interface
10.4.4.4        1    FULL/ -         00:00:39   12            vm1
OSPFv3 Device with ID (10.2.1.1) (Process ID 100)
Neighbor ID     Pri  State           Dead Time   Interface ID  Interface
10.5.4.4        1    FULL/ -         00:00:35   12            vm1

```

Example: Configuring NBMA Interfaces

The following example shows how to configure an OSPFv3 neighboring device with the IPv6 address of FE80::A8BB:CCFF:FE00:C01.

```
ipv6 enable
```

```
ipv6 ospf neighbor FE80::A8BB:CCFF:FE00:C0
```

Example: Forcing SPF Configuration

The following example shows how to trigger SPF to redo the SPF and repopulate the routing tables:

```
clear ipv6 ospf force-spf
```

Feature Information for IPv6 Routing: OSPFv3

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

| Feature Name | Releases | Feature Information |
|----------------------|----------------------------|---|
| IPv6 Routing: OSPFv3 | Cisco IOS Release 15.2(6)E | OSPF version 3 for IPv6 expands on OSPF version 2 to provide support for IPv6 routing prefixes and the larger size of IPv6 addresses. |

CHAPTER 39

Configuring Policy-Based Routing (PBR)

- [Policy-Based Routing, on page 765](#)

Policy-Based Routing

Information About Policy-Based Routing

You can use policy-based routing (PBR) to configure a defined policy for traffic flows. By using PBR, you can have more control over routing by reducing the reliance on routes derived from routing protocols. PBR can specify and implement routing policies that allow or deny paths based on:

- Identity of a particular end system
- Application
- Protocol

You can use PBR to provide equal-access and source-sensitive routing, routing based on interactive versus batch traffic, or routing based on dedicated links. For example, you could transfer stock records to a corporate office on a high-bandwidth, high-cost link for a short time while transmitting routine application data such as e-mail over a low-bandwidth, low-cost link.

With PBR, you classify traffic using access control lists (ACLs) and then make traffic go through a different path. PBR is applied to incoming packets. All packets received on an interface with PBR enabled are passed through route maps. Based on the criteria defined in the route maps, packets are forwarded (routed) to the appropriate next hop.

- Route map statement marked as permit is processed as follows:
 - A match command can match on length or multiple ACLs. A route map statement can contain multiple match commands. Logical or algorithm function is performed across all the match commands to reach a permit or deny decision.

For example:

```
match length A B
match ip address acl1 acl2
match ip address acl3
```

A packet is permitted if it is permitted by match length A B or acl1 or acl2 or acl3

- If the decision reached is permit, then the action specified by the set command is applied on the packet .
- If the decision reached is deny, then the PBR action (specified in the set command) is not applied. Instead the processing logic moves forward to look at the next route-map statement in the sequence (the statement with the next higher sequence number). If no next statement exists, PBR processing terminates, and the packet is routed using the default IP routing table.
- For PBR, route-map statements marked as deny are not supported.

You can use standard IP ACLs to specify match criteria for a source address or extended IP ACLs to specify match criteria based on an application, a protocol type, or an end station. The process proceeds through the route map until a match is found. If no match is found, normal destination-based routing occurs. There is an implicit deny at the end of the list of match statements.

If match clauses are satisfied, you can use a set clause to specify the IP addresses identifying the next hop router in the path.

Policy-Based Routing Using Object Tracking

You can configure policy-based routing (PBR) to use object tracking to verify the most viable next-hop IP address to which to forward packets, using an Internet Control Message Protocol (ICMP) ping as the verification method.

PBR with Object Tracking is most suitable for devices that have multiple Ethernet connections as the next hop. Normally, Ethernet interfaces connect to DSL modems or cable modems, and do not detect a failure upstream, in the ISP broadband network. The Ethernet interface remains up, and any form of static routing points to that interface. PBR with object tracking allows you to back up two Ethernet interfaces, determine the interface that is available by sending ICMP pings to verify reachability, and then route traffic to that interface.

To verify the next-hop IP address for the device, PBR informs the object-tracking process that it is interested in tracking a certain object. The tracking process, in turn, informs PBR when the state of the object changes.

Note VRF is not supported with PBR using Object Tracking.

How to Configure PBR

- To use PBR, you must have the feature set enabled on the switch or active stack.
- Multicast traffic is not policy-routed. PBR applies to only to unicast traffic.
- You can enable PBR on a routed port or an SVI.
- The switch supports PBR based on match length.
- You can apply a policy route map to an EtherChannel port channel in Layer 3 mode, but you cannot apply a policy route map to a physical interface that is a member of the EtherChannel. If you try to do so, the command is rejected. When a policy route map is applied to a physical interface, that interface cannot become a member of an EtherChannel.

- You can define a maximum of 128 IP policy route maps on the switch or switch stack.
- You can define a maximum of 512 access control entries (ACEs) for PBR on the switch or switch stack.
- When configuring match criteria in a route map, follow these guidelines:
 - Do not match ACLs that permit packets destined for a local address. PBR would forward these packets, which could cause ping or Telnet failure or route protocol flapping.
- VRF and PBR are mutually exclusive on a switch interface. You cannot enable VRF when PBR is enabled on an interface. The reverse is also true, you cannot enable PBR when VRF is enabled on an interface.
- The number of hardware entries used by PBR depends on the route map itself, the ACLs used, and the order of the ACLs and route-map entries.
- PBR based on TOS, DSCP and IP Precedence are not supported.
- Set interface, set default next-hop and set default interface are not supported.
- **ip next-hop recursive** and **ip next-hop verify availability** features are not available and the next-hop should be directly connected.
- Policy-maps with no set actions are supported. Matching packets are routed normally.
- Policy-maps with no match clauses are supported. Set actions are applied to all packets.

By default, PBR is disabled on the switch. To enable PBR, you must create a route map that specifies the match criteria and the resulting action. Then, you must enable PBR for that route map on an interface. All packets arriving on the specified interface matching the match clauses are subject to PBR.

Packets that are generated by the switch, or local packets, are not normally policy-routed. When you globally enable local PBR on the switch, all packets that originate on the switch are subject to local PBR. Local PBR is disabled by default.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 2 | route-map <i>map-tag</i> [permit] [<i>sequence number</i>] Example: Device(config)# route-map pbr-map permit | Defines route maps that are used to control where packets are output, and enters route-map configuration mode. <ul style="list-style-type: none"> • <i>map-tag</i> – A meaningful name for the route map. The ip policy route-map interface configuration command uses this name to reference the route map. Multiple route-map statements with the same map tag define a single route map. • (Optional) permit – If permit is specified and the match criteria are met |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>for this route map, the route is policy routed as defined by the set actions.</p> <ul style="list-style-type: none"> • (Optional) <i>sequence number</i> — The sequence number shows the position of the route-map statement in the given route map. |
| Step 3 | <p>match ip address {<i>access-list-number</i> <i>access-list-name</i>} [<i>access-list-number</i> ...<i>access-list-name</i>]</p> <p>Example:</p> <pre>Device(config-route-map)# match ip address 110 140</pre> | <p>Matches the source and destination IP addresses that are permitted by one or more standard or extended access lists. ACLs can match on more than one source and destination IP address.</p> <p>If you do not specify a match command, the route map is applicable to all packets.</p> |
| Step 4 | <p>match length <i>min max</i></p> <p>Example:</p> <pre>Device(config-route-map)# match length 64 1500</pre> | Matches the length of the packet. |
| Step 5 | <p>set ip next-hop <i>ip-address</i> [...<i>ip-address</i>]</p> <p>Example:</p> <pre>Device(config-route-map)# set ip next-hop 10.1.6.2</pre> | Specifies the action to be taken on the packets that match the criteria. Sets next hop to which to route the packet (the next hop must be adjacent). |
| Step 6 | <p>set ip next-hop verify-availability [<i>next-hop-address sequence track object</i>]</p> <p>Example:</p> <pre>Device(config-route-map)# set ip next-hop verify-availability 95.1.1.2.1 track 100</pre> | <p>Configures the route map to verify the reachability of the tracked object.</p> <p>Note This command is not supported on IPv6 and VRF.</p> |
| Step 7 | <p>exit</p> <p>Example:</p> <pre>Device(config-route-map)# exit</pre> | Returns to global configuration mode. |
| Step 8 | <p>interface <i>interface-id</i></p> <p>Example:</p> <pre>Device(config)# interface gigabitethernet 1/0/1</pre> | Enters interface configuration mode, and specifies the interface to be configured. |
| Step 9 | <p>ip policy route-map <i>map-tag</i></p> <p>Example:</p> <pre>Device(config-if)# ip policy route-map pbr-map</pre> | <p>Enables PBR on a Layer 3 interface, and identify the route map to use. You can configure only one route map on an interface. However, you can have multiple route map entries with different sequence numbers. These entries are evaluated in the order of sequence</p> |

| | Command or Action | Purpose |
|----------------|---|--|
| | | number until the first match. If there is no match, packets are routed as usual. |
| Step 10 | ip route-cache policy Example: Device(config-if)# ip route-cache policy | (Optional) Enables fast-switching PBR. You must enable PBR before enabling fast-switching PBR. |
| Step 11 | exit Example: Device(config-if)# exit | Returns to global configuration mode. |
| Step 12 | ip local policy route-map <i>map-tag</i> Example: Device(config)# ip local policy route-map local-pbr | (Optional) Enables local PBR to perform policy-based routing on packets originating at the switch. This applies to packets generated by the switch, and not to incoming packets. |
| Step 13 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 14 | show route-map [<i>map-name</i>] Example: Device# show route-map | (Optional) Displays all the route maps configured or only the one specified to verify configuration. |
| Step 15 | show ip policy Example: Device# show ip policy | (Optional) Displays policy route maps attached to the interface. |
| Step 16 | show ip local policy Example: Device# show ip local policy | (Optional) Displays whether or not local policy routing is enabled and, if so, the route map being used. |

Verifying Next-Hop IP Using Object Tracking

To verify the next-hop IP address using PBR with object tracking, perform the following steps:

Procedure

| | Command or Action | Purpose |
|---------------|--|-----------------------------------|
| Step 1 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 2 | track <i>object-number</i> ip sla <i>entry-number</i> Example: Device(config)# track 100 ip sla 100 | Tracks the state of an IP SLA object. |
| Step 3 | ip sla <i>operation-number</i> Example: Device(config)# ip sla 100 | Starts a Cisco IOS IP Service Level Agreement (SLA) operation configuration, and enters IP SLA configuration mode. |
| Step 4 | icmp-echo <i>ip-address</i> source-ip <i>ip-address</i> Example: Device(config-ip-sla)# icmp-echo 172.19.255.253 source-ip 172.19.255.47 | Configures an IP SLA Internet Control Message Protocol(ICMP) echo probe operation, and enters Echo configuration mode. |
| Step 5 | frequency <i>seconds</i> Example: Device(config-ip-sla-echo)# frequency 2 | (Optional) Sets the rate, in seconds, at which a specified IP SLA operation is repeated. |
| Step 6 | threshold <i>milliseconds</i> Example: Device(config-ip-sla-echo)# threshold 1000 | (Optional) Sets the length of time, in ms, required for a rising threshold event to be declared. |
| Step 7 | timeout <i>milliseconds</i> Example: Device(config-ip-sla-echo)# timeout 1500 | (Optional) Sets the maximum time, in ms, required for the IP SLA operation to be completed. |
| Step 8 | ip sla schedule <i>operation-number</i> [life { forever <i>seconds</i> }] [start-time { <i>hh:mm:ss</i> <i>month day</i> <i>day month</i> }] pending <i>now</i> <i>after hh:mm:ss</i>] [ageout <i>seconds</i>] Example: Device(config)# ip sla schedule 100 life forever start-time now | Configures the scheduling parameters for a single Cisco IOS IP SLA operation. |
| Step 9 | route-map <i>map-tag</i> [permit deny] [<i>sequence-number</i>] Example: Device(config)# route-map alpha permit 10 | Specifies a route map and enters route-map configuration mode. |
| Step 10 | match ip address [<i>access-list-name</i>] Example: Device(config-route-map)# match ip address exlist | Distributes routes that have a destination IPv4 network number address that is permitted by a standard access list. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 11 | set ip next-hop verify-availability <i>[next-hop-address sequence track object]</i> Example: Device(config-route-map)# set ip next-hop verify-availability 95.1.1.2.1 track 100 | Configures the route map to verify the reachability of the tracked object. |

CHAPTER 40

Security Features Overview

- [Security Features Overview](#), on page 775

Security Features Overview

The switch supports a LAN base image or a LAN lite image with a reduced feature set, depending on switch hardware. The security features are as follows:

- IPv6 First Hop Security—A suite of security features to be applied at the first hop switch to protect against vulnerabilities inherent in IPv6 networks. These include, Binding Integrity Guard (Binding Table), Router Advertisement Guard (RA Guard), DHCP Guard, IPv6 Neighbor Discovery Inspection (ND Guard), and IPv6 Source Guard.

This feature is not supported on LanLite images on Catalyst 2960-X Series Switches.

- Web Authentication—Allows a supplicant (client) that does not support IEEE 802.1x functionality to be authenticated using a web browser.
- Local Web Authentication Banner—A custom banner or an image file displayed at a web authentication login screen.
- IEEE 802.1x Authentication with ACLs and the RADIUS Filter-Id Attribute
- Password-protected access (read-only and read-write access) to management interfaces (device manager, Network Assistant, and the CLI) for protection against unauthorized configuration changes
- Multilevel security for a choice of security level, notification, and resulting actions
- Static MAC addressing for ensuring security
- Protected port option for restricting the forwarding of traffic to designated ports on the same switch
- Port security option for limiting and identifying MAC addresses of the stations allowed to access the port
- VLAN aware port security option to shut down the VLAN on the port when a violation occurs, instead of shutting down the entire port.
- Port security aging to set the aging time for secure addresses on a port.
- Protocol storm protection to control the rate of incoming protocol traffic to a switch by dropping packets that exceed a specified ingress rate.

- BPDU guard for shutting down a Port Fast-configured port when an invalid configuration occurs.
- Standard and extended IP access control lists (ACLs) for defining inbound security policies on Layer 2 interfaces (port ACLs).
- Extended MAC access control lists for defining security policies in the inbound direction on Layer 2 interfaces.
- Source and destination MAC-based ACLs for filtering non-IP traffic.
- DHCP snooping to filter untrusted DHCP messages between untrusted hosts and DHCP servers.
- IP source guard to restrict traffic on nonrouted interfaces by filtering traffic based on the DHCP snooping database and IP source bindings.
- Dynamic ARP inspection to prevent malicious attacks on the switch by not relaying invalid ARP requests and responses to other ports in the same VLAN.

This feature is not supported on LanLite images on Catalyst 2960-X Series Switches.

- IEEE 802.1x port-based authentication to prevent unauthorized devices (clients) from gaining access to the network. These 802.1x features are supported:
 - Support for single-host, multi-host, multi-auth, and multi-domain-auth modes.
 - Multidomain authentication (MDA) to allow both a data device and a voice device, such as an IP phone (Cisco or non-Cisco), to independently authenticate on the same IEEE 802.1x-enabled switch port.
 - Dynamic voice virtual LAN (VLAN) for MDA to allow a dynamic voice VLAN on an MDA-enabled port.
 - VLAN assignment for restricting 802.1x-authenticated users to a specified VLAN.
 - Support for VLAN assignment on a port configured for multi-auth mode. The RADIUS server assigns a VLAN to the first host to authenticate on the port, and subsequent hosts use the same VLAN. Voice VLAN assignment is supported for one IP phone.
 - Port security for controlling access to 802.1x ports.
 - Voice VLAN to permit a Cisco IP Phone to access the voice VLAN regardless of the authorized or unauthorized state of the port.
 - IP phone detection enhancement to detect and recognize a Cisco IP phone.
 - Guest VLAN to provide limited services to non-802.1x-compliant users.
 - Restricted VLAN to provide limited services to users who are 802.1x compliant, but do not have the credentials to authenticate via the standard 802.1x processes.
 - 802.1x accounting to track network usage.
 - 802.1x with wake-on-LAN to allow dormant PCs to be powered on based on the receipt of a specific Ethernet frame.
 - 802.1x readiness check to determine the readiness of connected end hosts before configuring IEEE 802.1x on the switch.
 - Voice aware 802.1x security to apply traffic violation actions only on the VLAN on which a security violation occurs.

- MAC authentication bypass (MAB) to authorize clients based on the client MAC address.
- Network Admission Control (NAC) Layer 2 802.1x validation of the antivirus condition or posture of endpoint systems or clients before granting the devices network access.

Note NAC is not supported on LanLite images.

- Network Edge Access Topology (NEAT) with 802.1X switch supplicant, host authorization with CISP, and auto enablement to authenticate a switch outside a wiring closet as a supplicant to another switch.

Note NEAT is not supported on LanLite images.

- IEEE 802.1x with open access to allow a host to access the network before being authenticated.

Note This feature is not supported on LanLite images.

- IEEE 802.1x authentication with downloadable ACLs and redirect URLs to allow per-user ACL downloads from a Cisco Secure ACS server to an authenticated switch.
- Support for dynamic creation or attachment of an auth-default ACL on a port that has no configured static ACLs.

Note This feature is not supported on LanLite images.

- Flexible-authentication sequencing to configure the order of the authentication methods that a port tries when authenticating a new host.
- Multiple-user authentication to allow more than one host to authenticate on an 802.1x-enabled port.
- TACACS+, a proprietary feature for managing network security through a TACACS server for both IPv4 and IPv6.
- RADIUS for verifying the identity of, granting access to, and tracking the actions of remote users through authentication, authorization, and accounting (AAA) services for both IPv4 and IPv6.
- Enhancements to RADIUS, TACACS+, and SSH to function over IPv6.
- Secure Socket Layer (SSL) Version 3.0 support for the HTTP 1.1 server authentication, encryption, and message integrity and HTTP client authentication to allow secure HTTP communications (requires the cryptographic version of the software).
- IEEE 802.1x Authentication with ACLs and the RADIUS Filter-Id Attribute.
- Support for IP source guard on static hosts.

- RADIUS Change of Authorization (CoA) to change the attributes of a certain session after it is authenticated. When there is a change in policy for a user or user group in AAA, administrators can send the RADIUS CoA packets from the AAA server, such as Cisco Identity Services Engine, or Cisco Secure ACS to reinitialize authentication, and apply to the new policies.
- IEEE 802.1x User Distribution to allow deployments with multiple VLANs (for a group of users) to improve scalability of the network by load balancing users across different VLANs. Authorized users are assigned to the least populated VLAN in the group, assigned by RADIUS server.

Note This feature is not supported on LanLite images.

- Support for critical VLAN—multi-host/multi-auth enabled ports are placed in a critical VLAN in order to permit access to critical resources if AAA server becomes unreachable.

Note This feature is not supported on LanLite images.

- Support for Network Edge Access Topology (NEAT) to change the port host mode and to apply a standard port configuration on the authenticator switch port.
- VLAN-ID based MAC authentication to use the combined VLAN and MAC address information for user authentication to prevent network access from unauthorized VLANs.
- MAC move to allow hosts (including the hosts connected behind an IP phone) to move across ports within the same switch without any restrictions to enable mobility. With MAC move, the switch treats the reappearance of the same MAC address on another port in the same way as a completely new MAC address.
- Support for 3DES and AES with version 3 of the Simple Network Management Protocol (SNMPv3). This release adds support for the 168-bit Triple Data Encryption Standard (3DES) and the 128-bit, 192-bit, and 256-bit Advanced Encryption Standard (AES) encryption algorithms to SNMPv3.
- Support for Cisco TrustSec SXP protocol. This feature is not supported on LanLite images.

CHAPTER 41

Preventing Unauthorized Access

- [Preventing Unauthorized Access, on page 779](#)

Preventing Unauthorized Access

You can prevent unauthorized users from reconfiguring your switch and viewing configuration information. Typically, you want network administrators to have access to your switch while you restrict access to users who dial from outside the network through an asynchronous port, connect from outside the network through a serial port, or connect through a terminal or workstation from within the local network.

To prevent unauthorized access into your switch, you should configure one or more of these security features:

- At a minimum, you should configure passwords and privileges at each switch port. These passwords are locally stored on the switch. When users attempt to access the switch through a port or line, they must enter the password specified for the port or line before they can access the switch.
- For an additional layer of security, you can also configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.
- If you want to use username and password pairs, but you want to store them centrally on a server instead of locally, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information.
- You can also enable the login enhancements feature, which logs both failed and unsuccessful login attempts. Login enhancements can also be configured to block future login attempts after a set number of unsuccessful attempts are made. For more information, see the Cisco IOS Login Enhancements documentation.

CHAPTER 42

Controlling Switch Access with Passwords and Privilege Levels

- [Restrictions for Controlling Switch Access with Passwords and Privileges, on page 781](#)
- [Information About Passwords and Privilege Levels, on page 781](#)
- [How to Control Switch Access with Passwords and Privilege Levels, on page 784](#)
- [Monitoring Switch Access, on page 793](#)
- [Configuration Examples for Setting Passwords and Privilege Levels, on page 794](#)
- [Additional References, on page 794](#)

Restrictions for Controlling Switch Access with Passwords and Privileges

The following are the restrictions for controlling switch access with passwords and privileges:

- Disabling password recovery will not work if you have set the switch to boot up manually by using the **boot manual** global configuration command. This command produces the boot loader prompt (*switch:*) after the switch is power cycled.

Information About Passwords and Privilege Levels

Default Password and Privilege Level Configuration

A simple way of providing terminal access control in your network is to use passwords and assign privilege levels. Password protection restricts access to a network or network device. Privilege levels define what commands users can enter after they have logged into a network device.

This table shows the default password and privilege level configuration.

Table 96: Default Password and Privilege Levels

| Feature | Default Setting |
|--|--|
| Enable password and privilege level | No password is defined. The default is level 15 (privileged EXEC level). The password is not encrypted in the configuration file. |
| Enable secret password and privilege level | No password is defined. The default is level 15 (privileged EXEC level). The password is encrypted before it is written to the configuration file. |
| Line password | No password is defined. |

Additional Password Security

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a Trivial File Transfer Protocol (TFTP) server, you can use either the **enable password** or **enable secret** global configuration commands. Both commands accomplish the same thing; that is, you can establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify.

We recommend that you use the **enable secret** command because it uses an improved encryption algorithm.

If you configure the **enable secret** command, it takes precedence over the **enable password** command; the two commands cannot be in effect simultaneously.

If you enable password encryption, it applies to all passwords including username passwords, authentication key passwords, the privileged command password, and console and virtual terminal line passwords.

Password Recovery

By default, any end user with physical access to the switch can recover from a lost password by interrupting the boot process while the switch is powering on and then by entering a new password.

The password-recovery disable feature protects access to the switch password by disabling part of this functionality. When this feature is enabled, the end user can interrupt the boot process only by agreeing to set the system back to the default configuration. With password recovery disabled, you can still interrupt the boot process and change the password, but the configuration file (config.text) and the VLAN database file (vlan.dat) are deleted.

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

Terminal Line Telnet Configuration

When you power-up your switch for the first time, an automatic setup program runs to assign IP information and to create a default configuration for continued use. The setup program also prompts you to configure your switch for Telnet access through a password. If you did not configure this password during the setup program, you can configure it when you set a Telnet password for a terminal line.

Username and Password Pairs

You can configure username and password pairs, which are locally stored on the switch. These pairs are assigned to lines or ports and authenticate each user before that user can access the switch. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username and password pair.

Privilege Levels

Cisco devices use privilege levels to provide password security for different levels of switch operation. By default, the Cisco IOS software operates in two modes (privilege levels) of password security: user EXEC (Level 1) and privileged EXEC (Level 15). You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

Privilege Levels on Lines

Users can override the privilege level you set using the **privilege level** line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the **disable** command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

For example, if you want many users to have access to the **clear line** command, you can assign it level 2 security and distribute the level 2 password fairly widely. But if you want more restricted access to the **configure** command, you can assign it level 3 security and distribute that password to a more restricted group of users.

Command Privilege Levels

When you set a command to a privilege level, all commands whose syntax is a subset of that command are also set to that level. For example, if you set the **show ip traffic** command to level 15, the **show** commands and **show ip** commands are automatically set to privilege level 15 unless you set them individually to different levels.

How to Control Switch Access with Passwords and Privilege Levels

Setting or Changing a Static Enable Password

The enable password controls access to the privileged EXEC mode. Follow these steps to set or change a static enable password:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | enable password <i>password</i> Example: Device(config)# enable password secret321 | Defines a new password or changes an existing password for access to privileged EXEC mode. By default, no password is defined. For <i>password</i> , specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. It can contain the question mark (?) character if you precede the question mark with the key combination Ctrl-v when you create the password; for example, to create the password abc?123, do this: <ol style="list-style-type: none"> Enter abc. Enter Ctrl-v. Enter ?123. When the system prompts you to enter the enable password, you need not precede the question mark with the Ctrl-v; you can simply enter abc?123 at the password prompt. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 5 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Protecting Enable and Enable Secret Passwords with Encryption

Follow these steps to establish an encrypted password that users must enter to access privileged EXEC mode (the default) or any privilege level you specify:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | Use one of the following: <ul style="list-style-type: none"> • <code>enable password [level level] {password encryption-type encrypted-password}</code> • <code>enable secret [level level] {password encryption-type encrypted-password}</code> | <ul style="list-style-type: none"> • Defines a new password or changes an existing password for access to privileged EXEC mode. • Defines a secret password, which is saved using a nonreversible encryption method. <ul style="list-style-type: none"> • (Optional) For <i>level</i>, the range is from 0 to 15. Level 1 is normal user EXEC |

| | Command or Action | Purpose |
|---------------|--|--|
| | <p>Example:</p> <pre>Device(config)# enable password example102</pre> <p>OR</p> <pre>Device(config)# enable secret level 1 password secret123sample</pre> | <p>mode privileges. The default level is 15 (privileged EXEC mode privileges).</p> <ul style="list-style-type: none"> For <i>password</i>, specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined. (Optional) For <i>encryption-type</i>, only type 5, a Cisco proprietary encryption algorithm, is available. If you specify an encryption type, you must provide an encrypted password—an encrypted password that you copy from another switch configuration. <p>Note If you specify an encryption type and then enter a clear text password, you can not re-enter privileged EXEC mode. You cannot recover a lost encrypted password by any method.</p> |
| Step 4 | <p>service password-encryption</p> <p>Example:</p> <pre>Device(config)# service password-encryption</pre> | <p>(Optional) Encrypts the password when the password is defined or when the configuration is written.</p> <p>Encryption prevents the password from being readable in the configuration file.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | <p>copy running-config startup-config</p> <p>Example:</p> | (Optional) Saves your entries in the configuration file. |

| | Command or Action | Purpose |
|--|---|---------|
| | Device# <code>copy running-config startup-config</code> | |

Disabling Password Recovery

Follow these steps to disable password recovery to protect the security of your switch:

Before you begin

If you disable password recovery, we recommend that you keep a backup copy of the configuration file on a secure server in case the end user interrupts the boot process and sets the system back to default values. Do not keep a backup copy of the configuration file on the switch. If the switch is operating in VTP transparent mode, we recommend that you also keep a backup copy of the VLAN database file on a secure server. When the switch is returned to the default system configuration, you can download the saved files to the switch by using the Xmodem protocol.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> <code>enable</code> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | system disable password recovery switch { <i>all</i> <1-9>} Example: Device(config)# <code>system disable password recovery switch all</code> | Disables password recovery. <ul style="list-style-type: none"> • <i>all</i> - Sets the configuration on switches in stack. • <1-9> - Sets the configuration on the Switch Number selected. This setting is saved in an area of the flash memory that is accessible by the boot loader and the Cisco IOS image, but it is not part of the file system and is not accessible by any user. |
| Step 4 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |

What to do next

To remove **disable password recovery**, use the **no system disable password recovery switch all** global configuration command.

Setting a Telnet Password for a Terminal Line

Beginning in user EXEC mode, follow these steps to set a Telnet password for the connected terminal line:

Before you begin

- Attach a PC or workstation with emulation software to the switch console port, or attach a PC to the Ethernet management port.
- The default data characteristics of the console port are 9600, 8, 1, no parity. You might need to press the Return key several times to see the command-line prompt.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Note If a password is required for access to privileged EXEC mode, you will be prompted for it. Enters privileged EXEC mode. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line vty 0 15 Example: Device(config)# line vty 0 15 | Configures the number of Telnet sessions (lines), and enters line configuration mode. There are 16 possible sessions on a command-capable Device. The 0 and 15 mean that you are configuring all 16 possible Telnet sessions. |
| Step 4 | password <i>password</i> Example: Device(config-line)# password abcxyz543 | Sets a Telnet password for the line or lines. For <i>password</i> , specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined. |
| Step 5 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config-line)# end | |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring Username and Password Pairs

Follow these steps to configure username and password pairs:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | username name [privilege level] {password encryption-type password} Example: Device(config)# username adamsample privilege 1 password secret456 Device(config)# username 111111111111 mac attribute | Sets the username, privilege level, and password for each user. <ul style="list-style-type: none"> • For <i>name</i>, specify the user ID as one word or the MAC address. Spaces and quotation marks are not allowed. • You can configure a maximum of 12000 clients each, for both username and MAC filter. • (Optional) For <i>level</i>, specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged |

| | Command or Action | Purpose |
|---------------|--|---|
| | | <p>EXEC mode access. Level 1 gives user EXEC mode access.</p> <ul style="list-style-type: none"> For <i>encryption-type</i>, enter 0 to specify that an unencrypted password will follow. Enter 7 to specify that a hidden password will follow. For <i>password</i>, specify the password the user must enter to gain access to the Device. The password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command. |
| Step 4 | <p>Use one of the following:</p> <ul style="list-style-type: none"> line console 0 line vty 0 15 <p>Example:</p> <pre>Device(config)# line console 0</pre> <p>or</p> <pre>Device(config)# line vty 15</pre> | Enters line configuration mode, and configures the console port (line 0) or the VTY lines (line 0 to 15). |
| Step 5 | <p>login local</p> <p>Example:</p> <pre>Device(config-line)# login local</pre> | Enables local password checking at login time. Authentication is based on the username specified in Step 3. |
| Step 6 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 7 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 8 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Setting the Privilege Level for a Command

Follow these steps to set the privilege level for a command:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | privilege mode level level command Example: <pre>Device(config)# privilege exec level 14 configure</pre> | Sets the privilege level for a command. <ul style="list-style-type: none"> • For <i>mode</i>, enter configure for global configuration mode, exec for EXEC mode, interface for interface configuration mode, or line for line configuration mode. • For <i>level</i>, the range is from 0 to 15. Level 1 is for normal user EXEC mode privileges. Level 15 is the level of access permitted by the enable password. • For <i>command</i>, specify the command to which you want to restrict access. |
| Step 4 | enable password level level password Example: <pre>Device(config)# enable password level 14 SecretPswd14</pre> | Specifies the password to enable the privilege level. <ul style="list-style-type: none"> • For <i>level</i>, the range is from 0 to 15. Level 1 is for normal user EXEC mode privileges. • For <i>password</i>, specify a string from 1 to 25 alphanumeric characters. The string cannot start with a number, is case sensitive, and allows spaces but ignores leading spaces. By default, no password is defined. |
| Step 5 | end Example: | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config)# end | |
| Step 6 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Changing the Default Privilege Level for Lines

Follow these steps to change the default privilege level for the specified line:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line vty line Example: Device(config)# line vty 10 | Selects the virtual terminal line on which to restrict access. |
| Step 4 | privilege level level Example: Device(config)# privilege level 15 | Changes the default privilege level for the line. For <i>level</i> , the range is from 0 to 15. Level 1 is for normal user EXEC mode privileges. Level 15 is the level of access permitted by the enable password. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 6 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

What to do next

Users can override the privilege level you set using the **privilege level** line configuration command by logging in to the line and enabling a different privilege level. They can lower the privilege level by using the **disable** command. If users know the password to a higher privilege level, they can use that password to enable the higher privilege level. You might specify a high level or privilege level for your console line to restrict line usage.

Logging into and Exiting a Privilege Level

Beginning in user EXEC mode, follow these steps to log into a specified privilege level and exit a specified privilege level.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable level Example: Device> <code>enable 15</code> | Logs in to a specified privilege level. Following the example, Level 15 is privileged EXEC mode. For <i>level</i> , the range is 0 to 15. |
| Step 2 | disable level Example: Device# <code>disable 1</code> | Exits to a specified privilege level. Following the example, Level 1 is user EXEC mode. For <i>level</i> , the range is 0 to 15. |

Monitoring Switch Access

Table 97: Commands for Displaying DHCP Information

| | |
|-----------------------------|---|
| <code>show privilege</code> | Displays the privilege level configuration. |
|-----------------------------|---|

Configuration Examples for Setting Passwords and Privilege Levels

Example: Setting or Changing a Static Enable Password

This example shows how to change the enable password to *l1u2c3k4y5*. The password is not encrypted and provides access to level 15 (traditional privileged EXEC mode access):

```
Device(config)# enable password l1u2c3k4y5
```

Example: Protecting Enable and Enable Secret Passwords with Encryption

This example shows how to configure the encrypted password *\$1\$FaD0\$Xyti5Rkls3LoyxzS8* for privilege level 2:

```
Device(config)# enable secret level 2 5 $1$FaD0$Xyti5Rkls3LoyxzS8
```

Example: Setting a Telnet Password for a Terminal Line

This example shows how to set the Telnet password to *let45me67in89*:

```
Device(config)# line vty 10
Device(config-line)# password let45me67in89
```

Example: Setting the Privilege Level for a Command

This example shows how to set the **configure** command to privilege level 14 and define *SecretPswd14* as the password users must enter to use level 14 commands:

```
Device(config)# privilege exec level 14 configure
Device(config)# enable password level 14 SecretPswd14
```

CHAPTER 43

Configuring TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through authentication, authorization and accounting (AAA) and can be enabled only through AAA commands.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for TACACS+

The following are the prerequisites for set up and configuration of switch access with TACACS+ (must be performed in the order presented):

1. Configure the switches with the TACACS+ server addresses.
2. Set an authentication key.
3. Configure the key from Step 2 on the TACACS+ servers.
4. Enable authentication, authorization, and accounting (AAA).

5. Create a login authentication method list.
6. Apply the list to the terminal lines.
7. Create an authorization and accounting method list.

The following are the prerequisites for controlling switch access with TACACS+:

- You must have access to a configured TACACS+ server to configure TACACS+ features on your switch. Also, you must have access to TACACS+ services maintained in a database on a TACACS+ daemon typically running on a LINUX or Windows workstation.
- We recommend a redundant connection between a switch stack and the TACACS+ server. This is to help ensure that the TACACS+ server remains accessible in case one of the connected stack members is removed from the switch stack.
- You need a system running the TACACS+ daemon software to use TACACS+ on your switch.
- To use TACACS+, it must be enabled.
- Authorization must be enabled on the switch to be used.
- Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.
- To use any of the AAA commands listed in this section or elsewhere, you must first enable AAA with the **aaa new-model** command.
- At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting.
- The method list defines the types of authentication to be performed and the sequence in which they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list (which, by coincidence, is named *default*). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.
- Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.
- Use the local database if authentication was not performed by using TACACS+.

Restrictions for TACACS+

TACACS+ can be enabled only through AAA commands.

Information About TACACS+

TACACS+ and Switch Access

This section describes TACACS+. TACACS+ provides detailed accounting information and flexible administrative control over the authentication and authorization processes. It is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

TACACS+ Overview

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers.

Figure 78: Typical TACACS+ Network Configuration

TACACS+, administered through the AAA security services, can provide these services:

- **Authentication**—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.

The authentication facility can conduct a dialog with the user (for example, after a username and password are provided, to challenge a user with several questions, such as home address, mother's maiden name,

service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company's password aging policy.

- **Authorization**—Provides fine-grained control over user capabilities for the duration of the user's session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user can execute with the TACACS+ authorization feature.
- **Accounting**—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the switch and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between the switch and the TACACS+ daemon are encrypted.

TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a switch using TACACS+, this process occurs:

1. When the connection is established, the switch contacts the TACACS+ daemon to obtain a username prompt to show to the user. The user enters a username, and the switch then contacts the TACACS+ daemon to obtain a password prompt. The switch displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

TACACS+ allows a dialog between the daemon and the user until the daemon receives enough information to authenticate the user. The daemon prompts for a username and password combination, but can include other items, such as the user's mother's maiden name.

2. The switch eventually receives one of these responses from the TACACS+ daemon:
 - **ACCEPT**—The user is authenticated and service can begin. If the switch is configured to require authorization, authorization begins at this time.
 - **REJECT**—The user is not authenticated. The user can be denied access or is prompted to retry the login sequence, depending on the TACACS+ daemon.
 - **ERROR**—An error occurred at some time during authentication with the daemon or in the network connection between the daemon and the switch. If an ERROR response is received, the switch typically tries to use an alternative method for authenticating the user.
 - **CONTINUE**—The user is prompted for additional authentication information.

After authentication, the user undergoes an additional authorization phase if authorization has been enabled on the switch. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

3. If TACACS+ authorization is required, the TACACS+ daemon is again contacted, and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the response contains data in the form of attributes that direct the EXEC or NETWORK session for that user and the services that the user can access:
 - Telnet, Secure Shell (SSH), rlogin, or privileged EXEC services

- Connection parameters, including the host or client IP address, access list, and user timeouts

Method List

A method list defines the sequence and methods to be used to authenticate, to authorize, or to keep accounts on a user. You can use method lists to designate one or more security protocols to be used, thus ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users; if that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.

If a method list is configured under VTY lines, the corresponding method list must be added to AAA. The following example shows how to configure a method list under a VTY line:

```
Device# configure terminal
Device(config)# line vty 0 4
Device(config)# authorization commands 15 auth1
```

The following example shows how to configure a method list in AAA:

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization commands 15 auth1 group tacacs+
```

If no method list is configured under VTY lines, the default method list must be added to AAA. The following example shows a VTY configuration without a method list:

```
Device# configure terminal
Device(config)# line vty 0 4
```

The following example shows how to configure the default method list:

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization commands 15 default group tacacs+
```

TACACS AV Pairs

The network access server implements TACACS+ authorization and accounting functions by transmitting and receiving TACACS+ attribute-value (AV) pairs for each user session.

TACACS Authentication and Authorization AV Pairs

The following table lists and describes the supported TACACS+ authentication and authorization AV pairs and specifies the Cisco IOS release in which they are implemented.

Table 98: Supported TACACS+ Authentication and Authorization AV Pairs

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|-----------|---|------|------|------|------|------|------|------|
| acl=x | ASCII number representing a connection access list. Used only when service=shell. | yes | yes | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|----------------------|--|------|------|------|------|------|------|------|
| addr=x | A network address. Used with service=slip, service=ppp, and protocol=ip. Contains the IP address that the remote host should use when connecting via SLIP or PPP/IP. For example, addr=10.2.3.4. | yes | yes | yes | yes | yes | yes | yes |
| addr-pool=x | Specifies the name of a local pool from which to get the address of the remote host. Used with service=ppp and protocol=ip. Note that addr-pool works in conjunction with local pooling. It specifies the name of a local pool (which must be preconfigured on the network access server). Use the ip-local pool command to declare local pools. For example: ip address-pool local ip local pool boo 10.0.0.1 10.0.0.10 ip local pool moo 10.0.0.1 10.0.0.20 You can then use TACACS+ to return addr-pool=boo or addr-pool=moo to indicate the address pool from which you want to get this remote node's address. | yes | yes | yes | yes | yes | yes | yes |
| autocmd=x | Specifies an autocommand to be executed at EXEC startup (for example, autocmd=telnet example.com). Used only with service=shell. | yes | yes | yes | yes | yes | yes | yes |
| callback- dialstring | Sets the telephone number for a callback (for example: callback-dialstring= 408-555-1212). Value is NULL, or a dial-string. A NULL value indicates that the service might choose to get the dial string through other means. Used with service=arap, service=slip, service=ppp, service=shell. Not valid for ISDN. | no | yes | yes | yes | yes | yes | yes |
| callback-line | The number of a TTY line to use for callback (for example: callback-line=4). Used with service=arap, service=slip, service=ppp, service=shell. Not valid for ISDN. | no | yes | yes | yes | yes | yes | yes |
| callback-rotary | The number of a rotary group (between 0 and 100 inclusive) to use for callback (for example: callback-rotary=34). Used with service=arap, service=slip, service=ppp, service=shell. Not valid for ISDN. | no | yes | yes | yes | yes | yes | yes |
| cmd-arg=x | An argument to a shell (EXEC) command. This indicates an argument for the shell command that is to be run. Multiple cmd-arg attributes can be specified, and they are order dependent. Note This TACACS+ AV pair cannot be used with RADIUS attribute 26. | yes | yes | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|----------------------|---|------|------|------|------|------|------|------|
| cmd=x | A shell (EXEC) command. This indicates the command name for a shell command that is to be run. This attribute must be specified if service equals "shell." A NULL value indicates that the shell itself is being referred to. Note This TACACS+ AV pair cannot be used with RADIUS attribute 26. | yes | yes | yes | yes | yes | yes | yes |
| data-service | Used with the service=outbound and protocol=ip. | no | no | no | no | no | yes | yes |
| dial-number | Defines the number to dial. Used with the service=outbound and protocol=ip. | no | no | no | no | no | yes | yes |
| dns-servers= | Identifies a DNS server (primary or secondary) that can be requested by Microsoft PPP clients from the network access server during IPCP negotiation. To be used with service=ppp and protocol=ip. The IP address identifying each DNS server is entered in dotted decimal format. | no | no | no | yes | yes | yes | yes |
| force-56 | Determines whether the network access server uses only the 56 K portion of a channel, even when all 64 K appear to be available. To turn on this attribute, use the "true" value (force-56=true). Any other value is treated as false. Used with the service=outbound and protocol=ip. | no | no | no | no | no | yes | yes |
| gw-password | Specifies the password for the home gateway during the L2F tunnel authentication. Used with service=ppp and protocol=vpdn. | no | no | yes | yes | yes | yes | yes |
| idletime=x | Sets a value, in minutes, after which an idle session is terminated. A value of zero indicates no timeout. | no | yes | yes | yes | yes | yes | yes |
| inacl#<n> | ASCII access list identifier for an input access list to be installed and applied to an interface for the duration of the current connection. Used with service=ppp and protocol=ip, and service=ppp and protocol=ipx. Per-user access lists do not currently work with ISDN interfaces. | no | no | no | yes | yes | yes | yes |
| inacl=x | ASCII identifier for an interface input access list. Used with service=ppp and protocol=ip. Per-user access lists do not currently work with ISDN interfaces. | yes | yes | yes | yes | yes | yes | yes |
| interface-config#<n> | Specifies user-specific AAA interface configuration information with Virtual Profiles. The information that follows the equal sign (=) can be any Cisco IOS interface configuration command. Multiple instances of the attributes are allowed, but each instance must have a unique number. Used with service=ppp and protocol=lcp. Note This attribute replaces the "interface-config=" attribute. | no | no | no | yes | yes | yes | yes |
| ip-addresses | Space-separated list of possible IP addresses that can be used for the end-point of a tunnel. Used with service=ppp and protocol=vpdn. | no | no | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|---------------------------|---|------|------|------|------|------|------|------|
| l2tp-busy-disconnect | If a vpdn-group on an LNS uses a virtual-template that is configured to be pre-cloned, this attribute will control the disposition of a new L2TP session that finds no pre-cloned interface to which to connect. If the attribute is true (the default), the session will be disconnected by the LNS. Otherwise, a new interface will be cloned from the virtual-template. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-cm-local-window-size | Specifies the maximum receive window size for L2TP control messages. This value is advertised to the peer during tunnel establishment. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-drop-out-of-order | Respects sequence numbers on data packets by dropping those that are received out of order. This does not ensure that sequence numbers will be sent on data packets, just how to handle them if they are received. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-hello- interval | Specifies the number of seconds for the hello keepalive interval. Hello packets are sent when no data has been sent on a tunnel for the number of seconds configured here. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-hidden-avp | When enabled, sensitive AVPs in L2TP control messages are scrambled or hidden. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-nosession-timeout | Specifies the number of seconds that a tunnel will stay active with no sessions before timing out and shutting down. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-tos-reflect | Copies the IP ToS field from the IP header of each payload packet to the IP header of the tunnel packet for packets entering the tunnel at the LNS. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-tunnel- authen | If this attribute is set, it performs L2TP tunnel authentication. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-tunnel-password | Shared secret used for L2TP tunnel authentication and AVP hiding. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |
| l2tp-udp- checksum | This is an authorization attribute and defines whether L2TP should perform UDP checksums for data packets. Valid values are “yes” and “no.” The default is no. Used with service=ppp and protocol=vpdn. | no | no | no | no | no | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|--------------------|---|------|------|------|------|------|------|------|
| link- compression= | Defines whether to turn on or turn off “stac” compression over a PPP link. Used with service=ppp. Link compression is defined as a numeric value as follows: <ul style="list-style-type: none"> • 0: None • 1: Stac • 2: Stac-Draft-9 • 3: MS-Stac | no | no | no | yes | yes | yes | yes |
| load-threshold=<n> | Sets the load threshold for the caller at which additional links are either added to or deleted from the multilink bundle. If the load goes above the specified value, additional links are added. If the load goes below the specified value, links are deleted. Used with service=ppp and protocol=multilink. The range for <n> is from 1 to 255. | no | no | no | yes | yes | yes | yes |
| map-class | Allows the user profile to reference information configured in a map class of the same name on the network access server that dials out. Used with the service=outbound and protocol=ip. | no | no | no | no | no | yes | yes |
| max-links=<n> | Restricts the number of links that a user can have in a multilink bundle. Used with service=ppp and protocol=multilink. The range for <n> is from 1 to 255. | no | no | no | yes | yes | yes | yes |
| min-links | Sets the minimum number of links for MLP. Used with service=ppp and protocol=multilink, protocol=vpdn. | no | no | no | no | no | yes | yes |
| nas-password | Specifies the password for the network access server during the L2F tunnel authentication. Used with service=ppp and protocol=vpdn. | no | no | yes | yes | yes | yes | yes |
| nocallback-verify | Indicates that no callback verification is required. The only valid value for this parameter is 1 (for example, nocallback-verify=1). Used with service=arap, service=slip, service=ppp, service=shell. There is no authentication on callback. Not valid for ISDN. | no | yes | yes | yes | yes | yes | yes |
| noescape=x | Prevents user from using an escape character. Used with service=shell. Can be either true or false (for example, noescape=true). | yes | yes | yes | yes | yes | yes | yes |
| nohangup=x | Used with service=shell. Specifies the nohangup option, which means that after an EXEC shell is terminated, the user is presented with another login (username) prompt. Can be either true or false (for example, nohangup=false). | yes | yes | yes | yes | yes | yes | yes |
| old-prompts | Allows providers to make the prompts in TACACS+ appear identical to those of earlier systems (TACACS and Extended TACACS). This allows administrators to upgrade from TACACS or Extended TACACS to TACACS+ transparently to users. | yes | yes | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|-------------------------|---|----------------------|------|------|------|------|------|------|
| outacl#<n> | ASCII access list identifier for an interface output access list to be installed and applied to an interface for the duration of the current condition. Used with service=ppp and protocol=ip, and service service=ppp and protocol=ipx. Per-user access lists do not currently work with ISDN interfaces. | no | no | no | yes | yes | yes | yes |
| outacl=x | ASCII identifier for an interface output access list. Used with service=ppp and protocol=ip, and service service=ppp and protocol=ipx. Contains an IP output access list for SLIP or PPP/IP (for example, outacl=4). The access list itself must be preconfigured on the router. Per-user access lists do not currently work with ISDN interfaces. | yes (PPP/IP only) | yes | yes | yes | yes | yes | yes |
| pool-def#<n> | Defines IP address pools on the network access server. Used with service=ppp and protocol=ip. | no | no | no | yes | yes | yes | yes |
| pool-timeout= | Defines (in conjunction with pool-def) IP address pools on the network access server. During IPCP address negotiation, if an IP pool name is specified for a user (see the addr-pool attribute), a check is made to see if the named pool is defined on the network access server. If it is, the pool is consulted for an IP address. Used with service=ppp and protocol=ip. | no | no | yes | yes | yes | yes | yes |
| port-type | Indicates the type of physical port the network access server is using to authenticate the user. Physical ports are indicated by a numeric value as follows: <ul style="list-style-type: none"> • 0: Asynchronous • 1: Synchronous • 2: ISDN-Synchronous • 3: ISDN-Asynchronous (V.120) • 4: ISDN- Asynchronous (V.110) • 5: Virtual Used with service=any and protocol=aaa. | no | no | no | no | no | yes | yes |
| ppp-vj-slot-compression | Instructs the Cisco router not to use slot compression when sending VJ-compressed packets over a PPP link. | no | no | no | yes | yes | yes | yes |
| priv-lvl=x | Privilege level to be assigned for the EXEC. Used with service=shell. Privilege levels range from 0 to 15, with 15 being the highest. | yes | yes | yes | yes | yes | yes | yes |
| protocol=x | A protocol that is a subset of a service. An example would be any PPP NCP. Currently known values are lcp , ip , ipx , atalk , vines , lat , xremote , tn3270 , telnet , rlogin , pad , vpdn , osicp , deccp , ccp , cdp , bridging , xns , nbf , bap , multilink , and unknown . | yes | yes | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|------------------|---|------|------|------|------|------|------|------|
| proxyacl#<n> | Allows users to configure the downloadable user profiles (dynamic ACLs) by using the authentication proxy feature so that users can have the configured authorization to permit traffic going through the configured interfaces. Used with the service=shell and protocol=exec. | no | no | no | no | no | yes | yes |
| route | Specifies a route to be applied to an interface. Used with service=slip, service=ppp, and protocol=ip. During network authorization, the route attribute can be used to specify a per-user static route, to be installed by TACACS+ as follows: route="dst_address mask [gateway]" This indicates a temporary static route that is to be applied. The <i>dst_address</i> , <i>mask</i> , and <i>gateway</i> are expected to be in the usual dotted-decimal notation, with the same meanings as in the familiar ip route configuration command on a network access server. If <i>gateway</i> is omitted, the peer's address is the gateway. The route is expunged when the connection terminates. | no | yes | yes | yes | yes | yes | yes |
| route#<n> | Like the route AV pair, this specifies a route to be applied to an interface, but these routes are numbered, allowing multiple routes to be applied. Used with service=ppp and protocol=ip, and service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |
| routing=x | Specifies whether routing information is to be propagated to and accepted from this interface. Used with service=slip, service=ppp, and protocol=ip. Equivalent in function to the /routing flag in SLIP and PPP commands. Can either be true or false (for example, routing=true). | yes | yes | yes | yes | yes | yes | yes |
| rte-fltr-in#<n> | Specifies an input access list definition to be installed and applied to routing updates on the current interface for the duration of the current connection. Used with service=ppp and protocol=ip, and with service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |
| rte-fltr-out#<n> | Specifies an output access list definition to be installed and applied to routing updates on the current interface for the duration of the current connection. Used with service=ppp and protocol=ip, and with service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |
| sap#<n> | Specifies static Service Advertising Protocol (SAP) entries to be installed for the duration of a connection. Used with service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |
| sap-fltr-in#<n> | Specifies an input SAP filter access list definition to be installed and applied on the current interface for the duration of the current connection. Used with service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|------------------|---|------|------|------|------|------|------|------|
| sap-fltr-out#<n> | Specifies an output SAP filter access list definition to be installed and applied on the current interface for the duration of the current connection. Used with service=ppp and protocol=ipx. | no | no | no | yes | yes | yes | yes |
| send-auth | Defines the protocol to use (PAP or CHAP) for username-password authentication following CLID authentication. Used with service=any and protocol=aaa. | no | no | no | no | no | yes | yes |
| send-secret | Specifies the password that the NAS needs to respond to a chap/pap request from the remote end of a connection on an outgoing call. Used with service=ppp and protocol=ip. | no | no | no | no | no | yes | yes |
| service=x | The primary service. Specifying a service attribute indicates that this is a request for authorization or accounting of that service. Current values are slip , ppp , arap , shell , tty-daemon , connection , and system . This attribute must always be included. | yes | yes | yes | yes | yes | yes | yes |
| source-ip=x | Used as the source IP address of all VPDN packets generated as part of a VPDN tunnel. This is equivalent to the Cisco vpdn outgoing global configuration command. | no | no | yes | yes | yes | yes | yes |
| spi | Carries the authentication information needed by the home agent to authenticate a mobile node during registration. The information is in the same syntax as the ip mobile secure host <addr> configuration command. Basically it contains the rest of the configuration command that follows that string, verbatim. It provides the Security Parameter Index (SPI), key, authentication algorithm, authentication mode, and replay protection timestamp range. Used with the service=mobileip and protocol=ip. | no | no | no | no | no | yes | yes |
| timeout=x | The number of minutes before an EXEC or ARA session disconnects (for example, timeout=60). A value of zero indicates no timeout. Used with service=arap. | yes | yes | yes | yes | yes | yes | yes |
| tunnel-id | Specifies the username that will be used to authenticate the tunnel over which the individual user MID will be projected. This is analogous to the <i>remote name</i> in the vpdn outgoing command. Used with service=ppp and protocol=vpdn. | no | no | yes | yes | yes | yes | yes |
| wins-servers= | Identifies a Windows NT server that can be requested by Microsoft PPP clients from the network access server during IPCP negotiation. To be used with service=ppp and protocol=ip. The IP address identifying each Windows NT server is entered in dotted decimal format. | no | no | no | yes | yes | yes | yes |
| zonelist=x | A numeric zonelist value. Used with service=arap. Specifies an AppleTalk zonelist for ARA (for example, zonelist=5). | yes | yes | yes | yes | yes | yes | yes |

See Configuring TACACS+ module for the documents used to configure TACACS+, and TACACS+ authentication and authorization.

TACACS Accounting AV Pairs

The following table lists and describes the supported TACACS+ accounting AV pairs and specifies the Cisco IOS release in which they are implemented.

Table 99: Supported TACACS+ Accounting AV Pairs

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|-----------------------|--|------|------|------|------|------|------|------|
| Abort-Cause | If the fax session is terminated, indicates the system component that signaled the termination. Examples of system components that could trigger a termination are FAP (Fax Application Process), TIFF (the TIFF reader or the TIFF writer), fax-mail client, fax-mail server, ESMTP client, or ESMTP server. | no | no | no | no | no | yes | yes |
| bytes_in | The number of input bytes transferred during this connection. | yes | yes | yes | yes | yes | yes | yes |
| bytes_out | The number of output bytes transferred during this connection. | yes | yes | yes | yes | yes | yes | yes |
| Call-Type | Describes the type of fax activity: fax receive or fax send. | no | no | no | no | no | yes | yes |
| cmd | The command the user executed. | yes | yes | yes | yes | yes | yes | yes |
| data-rate | This AV pair has been renamed. See nas-rx-speed. | | | | | | | |
| disc-cause | Specifies the reason a connection was taken off-line. The Disconnect-Cause attribute is sent in accounting-stop records. This attribute also causes stop records to be generated without first generating start records if disconnection occurs before authentication is performed. Refer to the following table (Disconnect Cause Extensions) for a list of Disconnect-Cause values and their meanings. | no | no | no | yes | yes | yes | yes |
| disc-cause-ext | Extends the disc-cause attribute to support vendor-specific reasons why a connection was taken off-line. | no | no | no | yes | yes | yes | yes |
| elapsed_time | The elapsed time in seconds for the action. Useful when the device does not keep real time. | yes | yes | yes | yes | yes | yes | yes |
| Email-Server-Address | Indicates the IP address of the e-mail server handling the on-ramp fax-mail message. | no | no | no | no | no | yes | yes |
| Email-Server-Ack-Flag | Indicates that the on-ramp gateway has received a positive acknowledgment from the e-mail server accepting the fax-mail message. | no | no | no | no | no | yes | yes |
| event | Information included in the accounting packet that describes a state change in the router. Events described are accounting starting and accounting stopping. | yes | yes | yes | yes | yes | yes | yes |
| Fax-Account-Id-Origin | Indicates the account ID origin as defined by system administrator for the mmpoip aaa receive-id or the mmpoip aaa send-id command. | no | no | no | no | no | yes | yes |
| Fax-Auth-Status | Indicates whether or not authentication for this fax session was successful. Possible values for this field are success, failed, bypassed, or unknown. | no | no | no | no | no | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|------------------------|--|------|------|------|------|------|------|------|
| Fax-Connect-Speed | Indicates the modem speed at which this fax-mail was initially transmitted or received. Possible values are 1200, 4800, 9600, and 14400. | no | no | no | no | no | yes | yes |
| Fax-Coverpage-Flag | Indicates whether or not a cover page was generated by the off-ramp gateway for this fax session. True indicates that a cover page was generated; false means that a cover page was not generated. | no | no | no | no | no | yes | yes |
| Fax-Dsn-Address | Indicates the address to which DSNs will be sent. | no | no | no | no | no | yes | yes |
| Fax-Dsn-Flag | Indicates whether or not DSN has been enabled. True indicates that DSN has been enabled; false means that DSN has not been enabled. | no | no | no | no | no | yes | yes |
| Fax-Mdn-Address | Indicates the address to which MDNs will be sent. | no | no | no | no | no | yes | yes |
| Fax-Mdn-Flag | Indicates whether or not message delivery notification (MDN) has been enabled. True indicates that MDN had been enabled; false means that MDN had not been enabled. | no | no | no | no | no | yes | yes |
| Fax-Modem-Time | Indicates the amount of time in seconds the modem sent fax data (x) and the amount of time in seconds of the total fax session (y), which includes both fax-mail and PSTN time, in the form x/y. For example, 10/15 means that the transfer time took 10 seconds, and the total fax session took 15 seconds. | no | no | no | no | no | yes | yes |
| Fax-Msg-Id= | Indicates a unique fax message identification number assigned by Store and Forward Fax. | no | no | no | no | no | yes | yes |
| Fax-Pages | Indicates the number of pages transmitted or received during this fax session. This page count includes cover pages. | no | no | no | no | no | yes | yes |
| Fax-Process-Abort-Flag | Indicates that the fax session was terminated or successful. True means that the session was terminated; false means that the session was successful. | no | no | no | no | no | yes | yes |
| Fax-Recipient-Count | Indicates the number of recipients for this fax transmission. Until e-mail servers support Session mode, the number should be 1. | no | no | no | no | no | yes | yes |
| Gateway-Id | Indicates the name of the gateway that processed the fax session. The name appears in the following format: hostname.domain-name | no | no | no | no | no | yes | yes |
| mlp-links-max | Gives the count of links which are known to have been in a given multilink session at the time the accounting record is generated. | no | no | no | yes | yes | yes | yes |
| mlp-sess-id | Reports the identification number of the multilink bundle when the session closes. This attribute applies to sessions that are part of a multilink bundle. This attribute is sent in authentication-response packets. | no | no | no | yes | yes | yes | yes |
| nas-rx-speed | Specifies the average number of bits per second over the course of the connection's lifetime. This attribute is sent in accounting-stop records. | no | no | no | yes | yes | yes | yes |
| nas-tx-speed | Reports the transmit speed negotiated by the two modems. | no | no | no | yes | yes | yes | yes |
| paks_in | The number of input packets transferred during this connection. | yes | yes | yes | yes | yes | yes | yes |

| Attribute | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 |
|------------------|---|------|------|------|------|------|------|------|
| paks_out | The number of output packets transferred during this connection. | yes | yes | yes | yes | yes | yes | yes |
| port | The port the user was logged in to. | yes | yes | yes | yes | yes | yes | yes |
| Port-Used | Indicates the slot/port number of the Cisco AS5300 used to either transmit or receive this fax-mail. | no | no | no | no | no | yes | yes |
| pre-bytes-in | Records the number of input bytes before authentication. This attribute is sent in accounting-stop records. | no | no | no | yes | yes | yes | yes |
| pre-bytes-out | Records the number of output bytes before authentication. This attribute is sent in accounting-stop records. | no | no | no | yes | yes | yes | yes |
| pre-paks-in | Records the number of input packets before authentication. This attribute is sent in accounting-stop records. | no | no | no | yes | yes | yes | yes |
| pre-paks-out | Records the number of output packets before authentication. The Pre-Output-Packets attribute is sent in accounting-stop records. | no | no | no | yes | yes | yes | yes |
| pre-session-time | Specifies the length of time, in seconds, from when a call first connects to when it completes authentication. | no | no | no | yes | yes | yes | yes |
| priv_level | The privilege level associated with the action. | yes | yes | yes | yes | yes | yes | yes |
| protocol | The protocol associated with the action. | yes | yes | yes | yes | yes | yes | yes |
| reason | Information included in the accounting packet that describes the event that caused a system change. Events described are system reload, system shutdown, or when accounting is reconfigured (turned on or off). | yes | yes | yes | yes | yes | yes | yes |
| service | The service the user used. | yes | yes | yes | yes | yes | yes | yes |
| start_time | The time the action started (in seconds since the epoch, 12:00 a.m. Jan 1 1970). The clock must be configured to receive this information. | yes | yes | yes | yes | yes | yes | yes |
| stop_time | The time the action stopped (in seconds since the epoch.) The clock must be configured to receive this information. | yes | yes | yes | yes | yes | yes | yes |
| task_id | Start and stop records for the same event must have matching (unique) task_id numbers. | yes | yes | yes | yes | yes | yes | yes |
| timezone | The time zone abbreviation for all timestamps included in this packet. | yes | yes | yes | yes | yes | yes | yes |
| xmit-rate | This AV pair has been renamed. See nas-tx-speed. | | | | | | | |

The following table lists the cause codes and descriptions for the Disconnect Cause Extended (disc-cause-ext) attribute.

Table 100: Disconnect Cause Extensions

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|---------------------------|---|------|------|------|------|------|------|------|------|
| 1000 - No Reason | No reason for the disconnect. | no | no | no | no | yes | yes | yes | yes |
| 1001 - No Disconnect | The event was not a disconnect. | no | no | no | no | yes | yes | yes | yes |
| 1002 - Unknown | The reason for the disconnect is unknown. This code can appear when the remote connection goes down. | no | no | no | no | yes | yes | yes | yes |
| 1003 - Call Disconnect | The call has disconnected. | no | no | no | no | yes | yes | yes | yes |
| 1004 - CLID Auth Fail | Calling line ID (CLID) authentication has failed. | no | no | no | no | yes | yes | yes | yes |
| 1009 - No Modem Available | The modem is not available. | no | no | no | no | yes | yes | yes | yes |
| 1010 - No Carrier | The modem never detected data carrier detect (DCD). This code can appear if a disconnect occurs during the initial modem connection. | no | no | no | no | yes | yes | yes | yes |
| 1011 - Lost Carrier | The modem detected DCD but became inactive. This code can appear if a disconnect occurs during the initial modem connection. | no | no | no | no | yes | yes | yes | yes |
| 1012 - No Modem Results | The result codes could not be parsed. This code can appear if a disconnect occurs during the initial modem connection. | no | no | no | no | yes | yes | yes | yes |
| 1020 - TS User Exit | The user exited normally from the terminal server. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1021 - Idle Timeout | The user exited from the terminal server because the idle timer expired. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1022 - TS Exit Telnet | The user exited normally from a Telnet session. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1023 - TS No IP Addr | The user could not switch to Serial Line Internet Protocol (SLIP) or PPP because the remote host had no IP address or because the dynamic pool could not assign one. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1024 - TS TCP Raw Exit | The user exited normally from a raw TCP session. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|------------------------------|--|------|------|------|------|------|------|------|------|
| 1025 - TS Bad Password | The login process ended because the user failed to enter a correct password after three attempts. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1026 - TS No TCP Raw | The raw TCP option is not enabled. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1027 - TS CNTL-C | The login process ended because the user typed Ctrl-C. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1028 - TS Session End | The terminal server session has ended. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1029 - TS Close Vconn | The user closed the virtual connection. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1030 - TS End Vconn | The virtual connection has ended. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1031 - TS Rlogin Exit | The user exited normally from an Rlogin session. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1032 - TS Rlogin Opt Invalid | The user selected an invalid Rlogin option. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1033 - TS Insuff Resources | The access server has insufficient resources for the terminal server session. This code is related to immediate Telnet and raw TCP disconnects during a terminal server session. | no | no | no | no | yes | yes | yes | yes |
| 1040 - PPP LCP Timeout | PPP link control protocol (LCP) negotiation timed out while waiting for a response from a peer. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1041 - PPP LCP Fail | There was a failure to converge on PPP LCP negotiations. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1042 - PPP Pap Fail | PPP Password Authentication Protocol (PAP) authentication failed. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1043 - PPP CHAP Fail | PPP Challenge Handshake Authentication Protocol (CHAP) authentication failed. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1044 - PPP Remote Fail | Authentication failed from the remote server. This code concerns PPP sessions. | no | no | no | no | yes | yes | yes | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|-------------------------------|---|------|------|------|------|------|------|------|------|
| 1045 - PPP Receive Term | The peer sent a PPP termination request. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| PPP LCP Close (1046) | LCP got a close request from the upper layer while LCP was in an open state. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1047 - PPP No NCP | LCP closed because no NCPs were open. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1048 - PPP MP Error | LCP closed because it could not determine to which Multilink PPP bundle that it should add the user. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1049 - PPP Max Channels | LCP closed because the access server could not add any more channels to an MP session. This code concerns PPP connections. | no | no | no | no | yes | yes | yes | yes |
| 1050 - TS Tables Full | The raw TCP or Telnet internal session tables are full. This code relates to immediate Telnet and raw TCP disconnects and contains more specific information than the Telnet and TCP codes listed earlier in this table. | no | no | no | no | yes | yes | yes | yes |
| 1051 - TS Resource Full | Internal resources are full. This code relates to immediate Telnet and raw TCP disconnects and contains more specific information than the Telnet and TCP codes listed earlier in this table. | no | no | no | no | yes | yes | yes | yes |
| 1052 - TS Invalid IP Addr | The IP address for the Telnet host is invalid. This code relates to immediate Telnet and raw TCP disconnects and contains more specific information than the Telnet and TCP codes listed earlier in this table. | no | no | no | no | yes | yes | yes | yes |
| 1053 - TS Bad Hostname | The access server could not resolve the host name. This code relates to immediate Telnet and raw TCP disconnects and contains more specific information than the Telnet and TCP codes listed earlier in this table. | no | no | no | no | yes | yes | yes | yes |
| 1054 - TS Bad Port | The access server detected a bad or missing port number. This code relates to immediate Telnet and raw TCP disconnects and contains more specific information than the Telnet and TCP codes listed earlier in this table. | no | no | no | no | yes | yes | yes | yes |
| 1060 - TCP Reset | The host reset the TCP connection. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1061 - TCP Connection Refused | The host refused the TCP connection. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|-----------------------------------|--|------|------|------|------|------|------|------|------|
| 1062 - TCP Timeout | The TCP connection timed out. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1063 - TCP Foreign Host Close | A foreign host closed the TCP connection. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1064 - TCP Net Unreachable | The TCP network was unreachable. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1065 - TCP Host Unreachable | The TCP host was unreachable. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1066 - TCP Net Admin Unreachable | The TCP network was administratively unreachable. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1067 - TCP Host Admin Unreachable | The TCP host was administratively unreachable. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1068 - TCP Port Unreachable | The TCP port was unreachable. The TCP stack can return this disconnect code during an immediate Telnet or raw TCP session. | no | no | no | no | yes | yes | yes | yes |
| 1100 - Session Timeout | The session timed out because there was no activity on a PPP link. This code applies to all session types. | no | no | no | no | yes | yes | yes | yes |
| 1101 - Security Fail | The session failed for security reasons. This code applies to all session types. | no | no | no | no | yes | yes | yes | yes |
| 1102 - Callback | The session ended for callback. This code applies to all session types. | no | no | no | no | yes | yes | yes | yes |
| 1120 - Unsupported | One end refused the call because the protocol was disabled or unsupported. This code applies to all session types. | no | no | no | no | yes | yes | yes | yes |
| 1150 - Radius Disc | The RADIUS server requested the disconnect. | no | no | no | no | yes | yes | yes | yes |
| 1151 - Local Admin Disc | The local administrator has disconnected. | no | no | no | no | yes | yes | yes | yes |
| 1152 - SNMP Disc | Simple Network Management Protocol (SNMP) has disconnected. | no | no | no | no | yes | yes | yes | yes |
| 1160 - V110 Retries | The allowed retries for V110 synchronization have been exceeded. | no | no | no | no | yes | yes | yes | yes |
| 1170 - PPP Auth Timeout | Authentication timeout. This code applies to PPP sessions. | no | no | no | no | yes | yes | yes | yes |
| 1180 - Local Hangup | The call disconnected as the result of a local hangup. | no | no | no | no | yes | yes | yes | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|-------------------------------------|--|------|------|------|------|------|------|------|------|
| 1185 - Remote Hangup | The call disconnected because the remote end hung up. | no | no | no | no | yes | yes | yes | yes |
| 1190 - T1 Quiesced | The call disconnected because the T1 line that carried it was quiesced. | no | no | no | no | yes | yes | yes | yes |
| 1195 - Call Duration | The call disconnected because the call duration exceeded the maximum amount of time allowed by the Max Call Mins or Max DS0 Mins parameter on the access server. | no | no | no | no | yes | yes | yes | yes |
| 1600 - VPDN User Disconnect | The user disconnected. This value applies to virtual private dial-up network (VPDN) sessions. | no | no | no | no | no | no | yes | yes |
| 1601 - VPDN Carrier Loss | Carrier loss has occurred. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1602 - VPDN No Resources | There are no resources. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1603 - VPDN Bad Control Packet | The control packet is invalid. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1604 - VPDN Admin Disconnect | The administrator disconnected. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1605 - VPDN Tunnel Down/Setup Fail | The tunnel is down or the setup failed. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1606 - VPDN Local PPP Disconnect | There was a local PPP disconnect. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1607 - VPDN Softshut/Session Limit | New sessions cannot be established on the VPN tunnel. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1608 - VPDN Call Redirected | The call was redirected. This code applies to VPDN sessions. | no | no | no | no | no | no | yes | yes |
| 1801 - Q850 Unassigned Number | The number has not been assigned. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1802 - Q850 No Route | The equipment that is sending this code has received a request to route the call through a particular transit network that it does not recognize. The equipment that is sending this code does not recognize the transit network because either the transit network does not exist or because that particular transit network, while it does exist, does not serve the equipment that is sending this code. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1803 - Q850 No Route To Destination | The called party cannot be reached because the network through which the call has been routed does not serve the destination that is desired. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|--------------------------------------|---|------|------|------|------|------|------|------|------|
| 1806 - Q850 Channel Unacceptable | The channel that has been most recently identified is not acceptable to the sending entity for use in this call. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1816 - Q850 Normal Clearing | The call is being cleared because one of the users who is involved in the call has requested that the call be cleared. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1817 - Q850 User Busy | The called party is unable to accept another call because the user-busy condition has been encountered. This code may be generated by the called user or by the network. In the case of the user, the user equipment is compatible with the call. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1818 - Q850 No User Responding | Used when a called party does not respond to a call-establishment message with either an alerting or connect indication within the prescribed period of time that was allocated. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1819 - Q850 No User Answer | The called party has been alerted but does not respond with a connect indication within a prescribed period of time. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1821 - Q850 Call Rejected | The equipment that is sending this code does not wish to accept this call although it could have accepted the call because the equipment that is sending this code is neither busy nor incompatible. This code may also be generated by the network, indicating that the call was cleared due to a supplementary service constraint. The diagnostic field may contain additional information about the supplementary service and reason for rejection. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1822 - Q850 Number Changed | The number that is indicated for the called party is no longer assigned. The new called party number may optionally be included in the diagnostic field. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1827 - Q850 Destination Out of Order | The destination that was indicated by the user cannot be reached because the interface to the destination is not functioning correctly. The term "not functioning correctly" indicates that a signaling message was unable to be delivered to the remote party. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1828 - Q850 Invalid Number Format | The called party cannot be reached because the called party number is not in a valid format or is not complete. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|---|---|------|------|------|------|------|------|------|------|
| 1829 - Q850 Facility Rejected | This code is returned when a supplementary service that was requested by the user cannot be provided by the network. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1830 - Q850 Responding to Status Enquiry | This code is included in the STATUS message when the reason for generating the STATUS message was the prior receipt of a STATUS ENQUIRY message. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1831 - Q850 Unspecified Cause | No other code applies. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1834 - Q850 No Circuit Available | No circuit or channel is available to handle the call. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1838 - Q850 Network Out of Order | The network is not functioning correctly and the condition is likely to last a relatively long period of time. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1841 - Q850 Temporary Failure | The network is not functioning correctly and the condition is not likely to last a long period of time. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1842 - Q850 Network Congestion | The network is congested. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1843 - Q850 Access Info Discarded | This code indicates that the network could not deliver access information to the remote user as requested. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1844 - Q850 Requested Channel Not Available | This code is returned when the circuit or channel that is indicated by the requesting entity cannot be provided by the other side of the interface. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1845 - Q850 Call Pre-empted | The call was preempted. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1847 - Q850 Resource Unavailable | This code is used to report a resource-unavailable event only when no other code in the resource-unavailable class applies. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1850 - Q850 Facility Not Subscribed | Not a subscribed facility. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |
| 1852 - Q850 Outgoing Call Barred | Although the calling party is a member of the closed user group for the outgoing closed user group call, outgoing calls are not allowed for this member. This code applies to ISDN or modem calls that came in over ISDN. | no | no | no | no | no | no | no | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|---|--|------|------|------|------|------|------|------|------|
| Q850 Incoming Call Barred (1854) | Although the called party is a member of the closed user group for the incoming closed user group call, incoming calls are not allowed to this member. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1858 - Q850 Bearer Capability Not Available | The user has requested a bearer capability that is implemented by the equipment that generated this code but that is not available at this time. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1863 - Q850 Service Not Available | The code is used to report a service- or option-not-available event only when no other code in the service- or option-not-available class applies. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1865 - Q850 Bearer Capability Not Implemented | The equipment that is sending this code does not support the bearer capability that was requested. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1866 - Q850 Channel Not Implemented | The equipment that is sending this code does not support the channel type that was requested. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1869 - Q850 Facility Not Implemented | The supplementary service requested by the user cannot be provided by the network. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1881 - Q850 Invalid Call Reference | The equipment that is sending this code has received a message having a call reference that is not currently in use on the user-network interface. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1882 - Q850 Channel Does Not Exist | The channel most recently identified is not acceptable to the sending entity for use in this call. This code applies to ISDN or modem calls that have come in over ISDN. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1888 - Q850 Incompatible Destination | The equipment that is sending this code has received a request to establish a call that has low-layer compatibility or other compatibility attributes that cannot be accommodated. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1896 - Q850 Mandatory Info Element Is Missing | The equipment that is sending this code has received a message that is missing an information element that must be present in the message before that message can be processed. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |

| Cause Codes | Description | 11.0 | 11.1 | 11.2 | 11.3 | 12.0 | 12.1 | 12.2 | 12.3 |
|---|---|------|------|------|------|------|------|------|------|
| 1897 - Q850 Non Existent Message Type | The equipment that is sending this code has received a message with a message type that it does not recognize either because this is a message that is not defined or that is defined but not implemented by the equipment that is sending this code. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1898 - Q850 Invalid Message | This code is used to report an invalid message when no other code in the invalid message class applies. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1899 - Q850 Bad Info Element | The information element not recognized. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1900 - Q850 Invalid Element Contents | The equipment that is sending this code has received an information element that it has implemented; however, one or more fields in the information element are coded in such a way that has not been implemented by the equipment that is sending this code. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1901 - Q850 Wrong Message for State | The message that was received is incompatible with the call state. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1902 - Q850 Recovery on Timer Expiration | A procedure has been initiated by the expiration of a timer in association with error-handling procedures. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1903 - Q850 Info Element Error | The equipment that is sending this code has received a message that includes information elements or parameters that are not recognized because the information element identifiers or parameter names are not defined or are defined but not implemented by the equipment that is sending this code. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1911 - Q850 Protocol Error | This code is used to report a protocol error event only when no other code in the protocol error class applies. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |
| 1927 - Q850 Unspecified Internetworking Event | There has been an error when interworking with a network that does not provide codes for actions that it takes. This code applies to ISDN or modem calls that have come in over ISDN. | no | no | no | no | no | no | no | yes |

Configuring AAA Server Group Selection Based on DNIS

Cisco software allows you to authenticate users to a particular AAA server group based on the Dialed Number Identification Service (DNIS) number of the session. Any phone line (a regular home phone or a commercial

T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco devices with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different TACACS+ server groups for different customers (that is, different TACACS+ servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally--AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per interface--AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping--You can use DNIS to specify an AAA server to supply AAA services.

Because AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS--If you configure the network access server to use DNIS to identify which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface--If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally--If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the lowest precedence.

Note Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the remote security servers associated with each AAA server group. See *Identifying the TACACS Server Host* and *Configuring AAA Server Groups* for more information.

To configure the device to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

Procedure

| | Command or Action | Purpose |
|---------------|-----------------------------------|--|
| Step 1 | Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 3 | Device (config)# aaa dnis map enable | Enables DNIS mapping. |
| Step 4 | Router(config)# aaa dnis map <i>dnis-number</i> authentication ppp group <i>server-group-name</i> | Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication. |
| Step 5 | Router(config)# aaa dnis map <i>dnis-number</i> accounting network [none start-stop stop-only] group <i>server-group-name</i> | Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for accounting. |

TACACS+ Configuration Options

You can configure the switch to use a single server or AAA server groups to group existing server hosts for authentication. You can group servers to select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list and contains the list of IP addresses of the selected server hosts.

TACACS+ Login Authentication

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

TACACS+ Authorization for Privileged EXEC Access and Network Services

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

TACACS+ Authentication

After you have identified the TACACS+ daemon and defined an associated TACACS+ encryption key, you must define method lists for TACACS+ authentication. Because TACACS+ authentication is operated via AAA, you need to issue the **aaa authentication** command, specifying TACACS+ as the authentication method.

TACACS+ Authorization

AAA authorization enables you to set parameters that restrict a user's access to the network. Authorization via TACACS+ may be applied to commands, network connections, and EXEC sessions. Because TACACS+

authorization is facilitated through AAA, you must issue the **aaa authorization** command, specifying TACACS+ as the authorization method.

TACACS+ Accounting

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.

Default TACACS+ Configuration

TACACS+ and AAA are disabled by default.

To prevent a lapse in security, you cannot configure TACACS+ through a network management application. When enabled, TACACS+ can authenticate users accessing the switch through the CLI.

Note Although TACACS+ configuration is performed through the CLI, the TACACS+ server authenticates HTTP connections that have been configured with a privilege level of 15.

Per VRF for TACACS Servers

The Per VRF for TACACS+ Servers feature allows per virtual routing and forwarding (VRF) AAA to be configured on TACACS+ servers. TACACS+ server access is required to configure this feature.

How to Configure TACACS+

Identifying the TACACS+ Server Host and Setting the Authentication Key

Follow these steps to identify the TACACS+ server host and set the authentication key:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# <code>configure terminal</code> | |
| Step 3 | <p>tacacs-server host <i>hostname</i></p> <p>Example:</p> <pre>Device(config)# tacacs-server host yourserver</pre> | <p>Identifies the IP host or hosts maintaining a TACACS+ server. Enter this command multiple times to create a list of preferred hosts. The software searches for hosts in the order in which you specify them.</p> <p>For <i>hostname</i>, specify the name or IP address of the host.</p> |
| Step 4 | <p>aaa new-model</p> <p>Example:</p> <pre>Device(config)# aaa new-model</pre> | Enables AAA. |
| Step 5 | <p>aaa group server tacacs+ <i>group-name</i></p> <p>Example:</p> <pre>Device(config)# aaa group server tacacs+ your_server_group</pre> | <p>(Optional) Defines the AAA server-group with a group name.</p> <p>This command puts the Device in a server group subconfiguration mode.</p> |
| Step 6 | <p>server <i>ip-address</i></p> <p>Example:</p> <pre>Device(config)# server 10.1.2.3</pre> | <p>(Optional) Associates a particular TACACS+ server with the defined server group. Repeat this step for each TACACS+ server in the AAA server group.</p> <p>Each server in the group must be previously defined in Step 3.</p> |
| Step 7 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 9 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring TACACS+ Login Authentication

Follow these steps to configure TACACS+ login authentication:

Before you begin

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports.

Note To secure the for HTTP access by using AAA methods, you must configure the with the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the for HTTP access by using AAA methods.

For more information about the **ip http authentication** command, see the *Cisco IOS Security Command Reference, Release 12.4*.

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa new-model Example: Device(config)# aaa new-model | Enables AAA. |
| Step 4 | aaa authentication login {default list-name} method1 [method2...] Example: Device(config)# aaa authentication login default tacacs+ local | Creates a login authentication method list. <ul style="list-style-type: none"> • To create a default list that is used when a named list is <i>not</i> specified in the login authentication command, use the default keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all ports. • For <i>list-name</i>, specify a character string to name the list you are creating. |

| | Command or Action | Purpose |
|---------------|--|--|
| | | <ul style="list-style-type: none"> For <i>method1...</i>, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. <p>Select one of these methods:</p> <ul style="list-style-type: none"> <i>enable</i>—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the enable password global configuration command. <i>group tacacs+</i>—Uses TACACS+ authentication. Before you can use this authentication method, you must configure the TACACS+ server. <i>line</i> —Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the password password line configuration command. <i>local</i>—Use the local username database for authentication. You must enter username information in the database. Use the username password global configuration command. <i>local-case</i>—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username name password global configuration command. <i>none</i>—Do not use any authentication for login. |
| Step 5 | line [console tty vty] <i>line-number</i> [<i>ending-line-number</i>] Example: <pre>Device(config)# line 2 4</pre> | Enters line configuration mode, and configures the lines to which you want to apply the authentication list. |
| Step 6 | login authentication { default <i>list-name</i> } Example: | Applies the authentication list to a line or set of lines. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device (config-line)# login authentication default | <ul style="list-style-type: none"> If you specify default, use the default list created with the aaa authentication login command. For <i>list-name</i>, specify the list created with the aaa authentication login command. |
| Step 7 | end Example: Device (config-line)# end | Returns to privileged EXEC mode. |
| Step 8 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 9 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services

You can use the **aaa authorization** global configuration command with the **tacacs+** keyword to set parameters that restrict a user's network access to privileged EXEC mode.

Note Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Follow these steps to specify TACACS+ authorization for privileged EXEC access and network services:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | aaa authorization network tacacs+ Example: Device(config)# <code>aaa authorization network tacacs+</code> | Configures the switch for user TACACS+ authorization for all network-related service requests. |
| Step 4 | aaa authorization exec tacacs+ Example: Device(config)# <code>aaa authorization exec tacacs+</code> | Configures the switch for user TACACS+ authorization if the user has privileged EXEC access. The exec keyword might return user profile information (such as autocommand information). |
| Step 5 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Starting TACACS+ Accounting

Follow these steps to start TACACS+ Accounting:

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Example: Device> enable | <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa accounting network start-stop tacacs+ Example: Device(config)# aaa accounting network start-stop tacacs+ | Enables TACACS+ accounting for all network-related service requests. |
| Step 4 | aaa accounting exec start-stop tacacs+ Example: Device(config)# aaa accounting exec start-stop tacacs+ | Enables TACACS+ accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

What to do next

To establish a session with a router if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Establishing a Session with a Router if the AAA Server is Unreachable

To establishing a session with a router if the AAA server is unreachable, use the **aaa accounting system guarantee-first** command. It guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Establishing a Session with a Router if the AAA Server is Unreachable

The **aaa accounting system guarantee-first** command guarantees system accounting as the first record, which is the default condition. In some situations, users might be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than 3 minutes.

To establish a console or Telnet session with the router if the AAA server is unreachable when the router reloads, use the **no aaa accounting system guarantee-first** command.

Configuring Per VRF on a TACACS Server

The initial steps in this procedure are used to configure AAA and a server group, create a VRF routing table, and configure an interface. Steps 10 through 13 are used to configure the per VRF on a TACACS+ server feature:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | ip vrf vrf-name Example: Device(config)# ip vrf cisco | Configures a VRF table and enters VRF configuration mode. |
| Step 4 | rd route-distinguisher Example: | Creates routing and forwarding tables for a VRF instance. |

| | Command or Action | Purpose |
|----------------|---|--|
| | Device(config-vrf)# rd 100:1 | |
| Step 5 | exit Example: Device(config-vrf)# exit | Exits VRF configuration mode. |
| Step 6 | interface <i>interface-name</i> Example: Device(config)# interface Loopback0 | Configures an interface and enters interface configuration mode. |
| Step 7 | ip vrf forwarding <i>vrf-name</i> Example: Device(config-if)# ip vrf forwarding cisco | Configures a VRF for the interface. |
| Step 8 | ip address <i>ip-address mask [secondary]</i> Example: Device(config-if)# ip address 10.0.0.2 255.0.0.0 | Sets a primary or secondary IP address for an interface. |
| Step 9 | exit Example: Device(config-if)# exit | Exits interface configuration mode. |
| Step 10 | aaa group server tacacs+ <i>group-name</i> Example: Device(config)# aaa group server tacacs+ tacacs1 | Groups different TACACS+ server hosts into distinct lists and distinct methods and enters server-group configuration mode. |
| Step 11 | server-private <i>{ip-address name}</i> [nat] [single-connection] [port <i>port-number</i>] [timeout <i>seconds</i>] [key [0 7] <i>string</i>] Example: Device(config-sg-tacacs+)# server-private 10.1.1.1 port 19 key cisco | Configures the IP address of the private TACACS+ server for the group server. |
| Step 12 | ip vrf forwarding <i>vrf-name</i> Example: | Configures the VRF reference of a AAA TACACS+ server group. |

| | Command or Action | Purpose |
|----------------|---|--|
| | Device(config-sg-tacacs)# ip vrf forwarding cisco | |
| Step 13 | ip tacacs source-interface <i>subinterface-name</i> Example: Device(config-sg-tacacs)# ip tacacs source-interface Loopback0 | Uses the IP address of a specified interface for all outgoing TACACS+ packets. |
| Step 14 | exit Example: Device(config-sg-tacacs)# exit | Exits server-group configuration mode. |

Verifying Per VRF for TACACS Servers

To verify the per VRF TACACS+ configuration, perform the following steps:

Note The **debug** commands may be used in any order.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | debug tacacs authentication Example: Device# debug tacacs authentication | Displays information about AAA/TACACS+ authentication. |
| Step 3 | debug tacacs authorization Example: Device# debug tacacs authorization | Displays information about AAA/TACACS+ authorization. |
| Step 4 | debug tacacs accounting Example: Device# debug tacacs accounting | Displays information about accountable events as they occur. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 5 | debug tacacs packets Example: Device# debug tacacs packets | Displays information about TACACS+ packets. |

Monitoring TACACS+

Table 101: Commands for Displaying TACACS+ Information

| Command | Purpose |
|-------------|-------------------------------------|
| show tacacs | Displays TACACS+ server statistics. |

Configuration Examples for TACACS+

Example: TACACS Authorization

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure network authorization via TACACS+:

```

aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa authorization network default group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
  
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **aaa authorization** command configures network authorization via TACACS+. Unlike authentication lists, this authorization list always applies to all incoming network connections made to the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

Example: TACACS Accounting

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure accounting via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa accounting network default stop-only group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **aaa accounting** command configures network accounting via TACACS+. In this example, accounting records describing the session that just terminated will be sent to the TACACS+ daemon whenever a network connection terminates.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

Example: TACACS Authentication

The following example shows how to configure TACACS+ as the security protocol for PPP authentication:

```
aaa new-model
aaa authentication ppp test group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap pap test
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the test method list to this line.

The following example shows how to configure TACACS+ as the security protocol for PPP authentication, but instead of the “test” method list, the “default” method list is used.

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa new-model
aaa authentication ppp MIS-access if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication pap MIS-access
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “MIS-access,” to be used on serial interfaces running PPP. The method list, “MIS-access,” means that PPP authentication is applied to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows the configuration for a TACACS+ daemon with an IP address of 10.2.3.4 and an encryption key of “apple”:

```
aaa new-model
aaa authentication login default group tacacs+ local
tacacs-server host 10.2.3.4
tacacs-server key apple
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines the default method list. Incoming ASCII logins on all interfaces (by default) will use TACACS+ for authentication. If no TACACS+ server responds, then the network access server will use the information contained in the local username database for authentication.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.2.3.4. The **tacacs-server key** command defines the shared encryption key to be “apple.”

Example: Configuring Per VRF for TACACS Servers

The following output example shows that the group server **tacacs1** is configured for per VRF AAA services:

```
aaa group server tacacs+ tacacs1
  server-private 10.1.1.1 port 19 key cisco
  ip vrf forwarding cisco
  ip tacacs source-interface Loopback0
ip vrf cisco
  rd 100:1
interface Loopback0
  ip address 10.0.0.2 255.0.0.0
  ip vrf forwarding cisco
```

CHAPTER 44

Configuring RADIUS

The RADIUS security system is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco devices and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

- [Prerequisites for Configuring RADIUS, on page 839](#)
- [Restrictions for Configuring RADIUS, on page 840](#)
- [Information about RADIUS, on page 840](#)
- [How to Configure RADIUS, on page 860](#)
- [Configuration Examples for RADIUS, on page 874](#)
- [Additional References for RADIUS, on page 877](#)
- [Feature Information for RADIUS, on page 878](#)

Prerequisites for Configuring RADIUS

This section lists the prerequisites for controlling Device access with RADIUS.

General:

- RADIUS and Authentication, Authorization, and Accounting (AAA) must be enabled to use any of the configuration commands in this chapter.
- RADIUS is facilitated through AAA and can be enabled only through AAA commands.
- Use the **aaa new-model** global configuration command to enable AAA.
- Use the **aaa authentication** global configuration command to define method lists for RADIUS authentication.
- Use **line** and **interface** commands to enable the defined method lists to be used.
- At a minimum, you must identify the host or hosts that run the RADIUS server software and define the method lists for RADIUS authentication. You can optionally define method lists for RADIUS authorization and accounting.
- You should have access to and should configure a RADIUS server before configuring RADIUS features on your Device.
- The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (Cisco Secure Access Control Server Version 3.0), Livingston, Merit, Microsoft, or another software provider. For more information, see the RADIUS server documentation.

- To use the Change-of-Authorization (CoA) interface, a session must already exist on the switch. CoA can be used to identify a session and enforce a disconnect request. The update affects only the specified session.

For RADIUS operation:

- Users must first successfully complete RADIUS authentication before proceeding to RADIUS authorization, if it is enabled.

Restrictions for Configuring RADIUS

This topic covers restrictions for controlling Device access with RADIUS.

General:

- To prevent a lapse in security, you cannot configure RADIUS through a network management application.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support AppleTalk Remote Access (ARA), NetBIOS Frame Control Protocol (NBFCP), NetWare Asynchronous Services Interface (NASI), or X.25 PAD connections.
- Switch-to-switch or router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one device to a non-Cisco device if the non-Cisco device requires authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

Information about RADIUS

RADIUS and Switch Access

This section describes how to enable and configure RADIUS. RADIUS provides detailed accounting information and flexible administrative control over the authentication and authorization processes.

RADIUS Overview

RADIUS is a distributed client/server system that secures networks against unauthorized access. RADIUS clients run on supported Cisco routers and switches. Clients send authentication requests to a central RADIUS server, which contains all user authentication and network service access information.

Use RADIUS in these network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.

- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a *smart card* access control system. In one case, RADIUS has been used with Enigma's security cards to validate users and to grant access to network resources.
- Networks already using RADIUS. You can add a Cisco Device containing a RADIUS client to the network. This might be the first step when you make a transition to a TACACS+ server. See Figure 2: Transitioning from RADIUS to TACACS+ Services below.
- Network in which the user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to the network through a protocol such as IEEE 802.1x. For more information about this protocol, see Chapter 11, "Configuring IEEE 802.1x Port-Based Authentication."
- Networks that require resource accounting. You can use RADIUS accounting independently of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, showing the amount of resources (such as time, packets, bytes, and so forth) used during the session. An Internet service provider might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.

Figure 79: Transitioning from RADIUS to TACACS+ Services

RADIUS Operation

When a user attempts to log in and authenticate to a Device that is access controlled by a RADIUS server, these events occur:

1. The user is prompted to enter a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.
3. The user receives one of the following responses from the RADIUS server:
 - ACCEPT—The user is authenticated.
 - REJECT—The user is either not authenticated and is prompted to re-enter the username and password, or access is denied.
 - CHALLENGE—A challenge requires additional data from the user.
 - CHALLENGE PASSWORD—A response requests the user to select a new password.

The ACCEPT or REJECT response is bundled with additional data that is used for privileged EXEC or network authorization. The additional data included with the ACCEPT or REJECT packets includes these items:

- Telnet, SSH, rlogin, or privileged EXEC services
- Connection parameters, including the host or client IP address, access list, and user timeouts

Default RADIUS Configuration

RADIUS and AAA are disabled by default.

To prevent a lapse in security, you cannot configure RADIUS through a network management application. When enabled, RADIUS can authenticate users accessing the switch through the CLI.

RADIUS Server Host

Switch-to-RADIUS-server communication involves several components:

- Hostname or IP address
- Authentication destination port
- Accounting destination port
- Key string
- Timeout period
- Retransmission value

You identify RADIUS security servers by their hostname or IP address, hostname and specific UDP port numbers, or their IP address and specific UDP port numbers. The combination of the IP address and the UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address.

If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as a fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the %RADIUS-4-RADIUS_DEAD message appears, and then the switch tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order that they are configured.)

A RADIUS server and the switch use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the switch.

The timeout, retransmission, and encryption key values can be configured globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings.

RADIUS Login Authentication

To configure AAA authentication, you define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication to be performed and the sequence in which

they are performed; it must be applied to a specific port before any of the defined authentication methods are performed. The only exception is the default method list. The default method list is automatically applied to all ports except those that have a named method list explicitly defined.

A method list describes the sequence and authentication methods to be queried to authenticate a user. You can designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

AAA Server Groups

You can configure the switch to use AAA server groups to group existing server hosts for authentication. You select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list, which lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server if each entry has a unique identifier (the combination of the IP address and UDP port number), allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. This unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If you configure two different host entries on the same RADIUS server for the same service, (for example, accounting), the second configured host entry acts as a fail-over backup to the first one. If the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

AAA Authorization

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user's profile, which is in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

RADIUS Accounting

The AAA accounting feature tracks the services that users are using and the amount of network resources that they are consuming. When you enable AAA accounting, the switch reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. You can then analyze the data for network management, client billing, or auditing.

Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the switch and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option by using

the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named *cisco-avpair*. The value is a string with this format:

```
protocol : attribute sep value *
```

Protocol is a value of the Cisco protocol attribute for a particular type of authorization. *Attribute* and *value* are an appropriate attributevalue (AV) pair defined in the Cisco TACACS+ specification, and *sep* is = for mandatory attributes and is * for optional attributes. The full set of features available for TACACS+ authorization can then be used for RADIUS.

For example, the following AV pair causes Cisco's "multiple named IP address pools" feature to be activated during IP authorization (during PPP's Internet Protocol Control Protocol (IPCP) address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

If you insert an "*", the AV pair "ip:addr-pool=first" becomes optional. Note that any AV pair can be made optional:

```
cisco-avpair= "ip:addr-pool*first"
```

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, see RFC 2138, "Remote Authentication Dial-In User Service (RADIUS)."

Attribute 26 contains the following three elements:

- Type
- Length
- String (also known as data)
 - Vendor-Id
 - Vendor-Type
 - Vendor-Length
 - Vendor-Data

The figure below shows the packet format for a VSA encapsulated "behind" attribute 26.

Figure 80: VSA Encapsulated Behind Attribute 26

81325

Note It is up to the vendor to specify the format of their VSA. The Attribute-Specific field (also known as Vendor-Data) is dependent on the vendor's definition of that attribute.

The table below describes significant fields listed in the Vendor-Specific RADIUS IETF Attributes table (second table below), which lists supported vendor-specific RADIUS attributes (IETF attribute 26).

Table 102: Vendor-Specific Attributes Table Field Descriptions

| Field | Description |
|-------------------------------|--|
| Number | All attributes listed in the following table are extensions of IETF attribute 26. |
| Vendor-Specific Command Codes | A defined code used to identify a particular vendor. Code 9 defines Cisco VSAs, 311 defines Microsoft VSAs, and 529 defines Ascend VSAs. |
| Sub-Type Number | The attribute ID number. This number is much like the ID numbers of IETF attributes, except it is a "second layer" ID number encapsulated behind attribute 26. |
| Attribute | The ASCII string name of the attribute. |
| Description | Description of the attribute. |

Table 103: Vendor-Specific RADIUS IETF Attributes

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------------------|------------------------------|-----------------|------------------|--|
| MS-CHAP Attributes | | | | |
| 26 | 311 | 1 | MSCHAP-Response | Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier. (RFC 2548) |
| 26 | 311 | 11 | MSCHAP-Challenge | Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets. (RFC 2548) |
| VPDN Attributes | | | | |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------|------------------------------|-----------------|---------------------------|--|
| 26 | 9 | 1 | l2tp-cm-local-window-size | Specifies the maximum receive window size for L2TP control messages. This value is advertised to the peer during tunnel establishment. |
| 26 | 9 | 1 | l2tp-drop-out-of-order | Respects sequence numbers on data packets by dropping those that are received out of order. This does not ensure that sequence numbers will be sent on data packets, just how to handle them if they are received. |
| 26 | 9 | 1 | l2tp-hello-interval | Specifies the number of seconds for the hello keepalive interval. Hello packets are sent when no data has been sent on a tunnel for the number of seconds configured here. |
| 26 | 9 | 1 | l2tp-hidden-avp | When enabled, sensitive AVPs in L2TP control messages are scrambled or hidden. |
| 26 | 9 | 1 | l2tp-nosession-timeout | Specifies the number of seconds that a tunnel will stay active with no sessions before timing out and shutting down. |
| 26 | 9 | 1 | tunnel-tos-reflect | Copies the IP ToS field from the IP header of each payload packet to the IP header of the tunnel packet for packets entering the tunnel at the LNS. |
| 26 | 9 | 1 | l2tp-tunnel-authen | If this attribute is set, it performs L2TP tunnel authentication. |
| 26 | 9 | 1 | l2tp-tunnel-password | Shared secret used for L2TP tunnel authentication and AVP hiding. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|----------------------------------|------------------------------|-----------------|-----------------------|--|
| 26 | 9 | 1 | l2tp-udp-checksum | This is an authorization attribute and defines whether L2TP should perform UDP checksums for data packets. Valid values are “yes” and “no.” The default is no. |
| Store and Forward Fax Attributes | | | | |
| 26 | 9 | 3 | Fax-Account-Id-Origin | Indicates the account ID origin as defined by system administrator for the mmoip aaa receive-id or the mmoip aaa send-id commands. |
| 26 | 9 | 4 | Fax-Msg-Id= | Indicates a unique fax message identification number assigned by Store and Forward Fax. |
| 26 | 9 | 5 | Fax-Pages | Indicates the number of pages transmitted or received during this fax session. This page count includes cover pages. |
| 26 | 9 | 6 | Fax-Coverpage-Flag | Indicates whether or not a cover page was generated by the off-ramp gateway for this fax session. True indicates that a cover page was generated; false means that a cover page was not generated. |
| 26 | 9 | 7 | Fax-Modem-Time | Indicates the amount of time in seconds the modem sent fax data (x) and the amount of time in seconds of the total fax session (y), which includes both fax-mail and PSTN time, in the form x/y. For example, 10/15 means that the transfer time took 10 seconds, and the total fax session took 15 seconds. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------|------------------------------|-----------------|------------------------|---|
| 26 | 9 | 8 | Fax-Connect-Speed | Indicates the modem speed at which this fax-mail was initially transmitted or received. Possible values are 1200, 4800, 9600, and 14400. |
| 26 | 9 | 9 | Fax-Recipient-Count | Indicates the number of recipients for this fax transmission. Until e-mail servers support Session mode, the number should be 1. |
| 26 | 9 | 10 | Fax-Process-Abort-Flag | Indicates that the fax session was cancelled or successful. True means that the session was cancelled; false means that the session was successful. |
| 26 | 9 | 11 | Fax-Dsn-Address | Indicates the address to which DSNs will be sent. |
| 26 | 9 | 12 | Fax-Dsn-Flag | Indicates whether or not DSN has been enabled. True indicates that DSN has been enabled; false means that DSN has not been enabled. |
| 26 | 9 | 13 | Fax-Mdn-Address | Indicates the address to which MDNs will be sent. |
| 26 | 9 | 14 | Fax-Mdn-Flag | Indicates whether or not message delivery notification (MDN) has been enabled. True indicates that MDN had been enabled; false means that MDN had not been enabled. |
| 26 | 9 | 15 | Fax-Auth-Status | Indicates whether or not authentication for this fax session was successful. Possible values for this field are success, failed, bypassed, or unknown. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|-----------------|------------------------------|-----------------|---|---|
| 26 | 9 | 16 | Email-Server-Address | Indicates the IP address of the e-mail server handling the on-ramp fax-mail message. |
| 26 | 9 | 17 | Email-Server-Ack-Flag | Indicates that the on-ramp gateway has received a positive acknowledgment from the e-mail server accepting the fax-mail message. |
| 26 | 9 | 18 | Gateway-Id | Indicates the name of the gateway that processed the fax session. The name appears in the following format: hostname.domain-name. |
| 26 | 9 | 19 | Call-Type | Describes the type of fax activity: fax receive or fax send. |
| 26 | 9 | 20 | Port-Used | Indicates the slot/port number of the Cisco AS5300 used to either transmit or receive this fax-mail. |
| 26 | 9 | 21 | Abort-Cause | If the fax session cancels, indicates the system component that signaled the cancel operation. Examples of system components that could trigger a cancel operation are FAP (Fax Application Process), TIFF (the TIFF reader or the TIFF writer), fax-mail client, fax-mail server, ESMTP client, or ESMTP server. |
| H323 Attributes | | | | |
| 26 | 9 | 23 | Remote-Gateway-ID (h323-remote-address) | Indicates the IP address of the remote gateway. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------------------------------|------------------------------|-----------------|---|---|
| 26 | 9 | 24 | Connection-ID (h323-conf-id) | Identifies the conference ID. |
| 26 | 9 | 25 | Setup-Time (h323-setup-time) | Indicates the setup time for this connection in Coordinated Universal Time (UTC) formerly known as Greenwich Mean Time (GMT) and Zulu time. |
| 26 | 9 | 26 | Call-Origin (h323-call-origin) | Indicates the origin of the call relative to the gateway. Possible values are originating and terminating (answer). |
| 26 | 9 | 27 | Call-Type (h323-call-type) | Indicates call leg type. Possible values are telephony and VoIP . |
| 26 | 9 | 28 | Connect-Time (h323-connect-time) | Indicates the connection time for this call leg in UTC. |
| 26 | 9 | 29 | Disconnect-Time (h323-disconnect-time) | Indicates the time this call leg was disconnected in UTC. |
| 26 | 9 | 30 | Disconnect-Cause (h323-disconnect-cause) | Specifies the reason a connection was taken offline per Q.931 specification. |
| 26 | 9 | 31 | Voice-Quality (h323-voice-quality) | Specifies the impairment factor (ICPIF) affecting voice quality for a call. |
| 26 | 9 | 33 | Gateway-ID (h323-gw-id) | Indicates the name of the underlying gateway. |
| Large Scale Dialout Attributes | | | | |
| 26 | 9 | 1 | callback-dialstring | Defines a dialing string to be used for callback. |
| 26 | 9 | 1 | data-service | No description available. |
| 26 | 9 | 1 | dial-number | Defines the number to dial. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|---------------|-------------------------------------|------------------------|------------------|--|
| 26 | 9 | 1 | force-56 | Determines whether the network access server uses only the 56 K portion of a channel, even when all 64 K appear to be available. |
| 26 | 9 | 1 | map-class | Allows the user profile to reference information configured in a map class of the same name on the network access server that dials out. |
| 26 | 9 | 1 | send-auth | Defines the protocol to use (PAP or CHAP) for username-password authentication following CLID authentication. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------|------------------------------|-----------------|-----------|---|
| 26 | 9 | 1 | send-name | <p>PPP name authentication. To apply for PAP, do not configure the ppp pap sent-name password command on the interface. For PAP, “preauth:send-name” and “preauth:send-secret” will be used as the PAP username and PAP password for outbound authentication. For CHAP, “preauth:send-name” will be used not only for outbound authentication, but also for inbound authentication. For a CHAP inbound case, the NAS will use the name defined in “preauth:send-name” in the challenge packet to the caller box.</p> <p>Note The send-name attribute has changed over time: Initially, it performed the functions now provided by both the send-name and remote-name attributes. Because the remote-name attribute has been added, the send-name attribute is restricted to its current behavior.</p> |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------------------------|------------------------------|-----------------|-------------|---|
| 26 | 9 | 1 | send-secret | PPP password authentication. The vendor-specific attributes (VSAs) "preauth:send-name" and "preauth:send-secret" will be used as the PAP username and PAP password for outbound authentication. For a CHAP outbound case, both "preauth:send-name" and "preauth:send-secret" will be used in the response packet. |
| 26 | 9 | 1 | remote-name | Provides the name of the remote host for use in large-scale dial-out. Dialer checks that the large-scale dial-out remote name matches the authenticated name, to protect against accidental user RADIUS misconfiguration. (For example, dialing a valid phone number but connecting to the wrong device.) |
| Miscellaneous Attributes | | | | |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------|------------------------------|-----------------|----------------|--|
| 26 | 9 | 2 | Cisco-NAS-Port | <p>Specifies additional vendor specific attribute (VSA) information for NAS-Port accounting. To specify additional NAS-Port information in the form an Attribute-Value Pair (AVPair) string, use the radius-server vsa send global configuration command.</p> <p>Note This VSA is typically used in Accounting, but may also be used in Authentication (Access-Request) packets.</p> |
| 26 | 9 | 1 | min-links | Sets the minimum number of links for MLP. |
| 26 | 9 | 1 | proxyacl#<n> | Allows users to configure the downloadable user profiles (dynamic ACLs) by using the authentication proxy feature so that users can have the configured authorization to permit traffic going through the configured interfaces. |

| Number | Vendor-Specific Company Code | Sub-Type Number | Attribute | Description |
|--------|------------------------------|-----------------|-----------|---|
| 26 | 9 | 1 | spi | Carries the authentication information needed by the home agent to authenticate a mobile node during registration. The information is in the same syntax as the ip mobile secure host <addr> configuration command. Basically it contains the rest of the configuration command that follows that string, verbatim. It provides the Security Parameter Index (SPI), key, authentication algorithm, authentication mode, and replay protection timestamp range. |

RADIUS Disconnect-Cause Attribute Values

Disconnect-cause attribute values specify the reason a connection was taken offline. The attribute values are sent in Accounting request packets. These values are sent at the end of a session, even if the session fails to be authenticated. If the session is not authenticated, the attribute can cause stop records to be generated without first generating start records.

The table below lists the cause codes, values, and descriptions for the Disconnect-Cause (195) attribute.

Note The Disconnect-Cause is incremented by 1000 when it is used in RADIUS AVPairs; for example, disc-cause 4 becomes 1004.

Table 104: Disconnect-Cause Attribute Values

| Cause Code | Value | Description |
|------------|-----------------------------|--|
| 0 | No-Reason | No reason is given for the disconnect. |
| 1 | No-Disconnect | The event was not disconnected. |
| 2 | Unknown | Reason unknown. |
| 3 | Call-Disconnect | The call has been disconnected. |
| 4 | CLID-Authentication-Failure | Failure to authenticate number of the calling-party. |

| Cause Code | Value | Description |
|------------|----------------------------|---|
| 9 | No-Modem-Available | A modem is not available to connect the call. |
| 10 | No-Carrier | No carrier detected. Note Codes 10, 11, and 12 can be sent if there is a disconnection during initial modem connection. |
| 11 | Lost-Carrier | Loss of carrier. |
| 12 | No-Detected-Result-Codes | Failure to detect modem result codes. |
| 20 | User-Ends-Session | User terminates a session. Note Codes 20, 22, 23, 24, 25, 26, 27, and 28 apply to EXEC sessions. |
| 21 | Idle-Timeout | Timeout waiting for user input. Codes 21, 100, 101, 102, and 120 apply to all session types. |
| 22 | Exit-Telnet-Session | Disconnect due to exiting Telnet session. |
| 23 | No-Remote-IP-Addr | Could not switch to SLIP/PPP; the remote end has no IP address. |
| 24 | Exit-Raw-TCP | Disconnect due to exiting raw TCP. |
| 25 | Password-Fail | Bad passwords. |
| 26 | Raw-TCP-Disabled | Raw TCP disabled. |
| 27 | Control-C-Detected | Control-C detected. |
| 28 | EXEC-Process-Destroyed | EXEC process destroyed. |
| 29 | Close-Virtual-Connection | User closes a virtual connection. |
| 30 | End-Virtual-Connection | Virtual connection has ended. |
| 31 | Exit-Rlogin | User exits Rlogin. |
| 32 | Invalid-Rlogin-Option | Invalid Rlogin option selected. |
| 33 | Insufficient-Resources | Insufficient resources. |
| 40 | Timeout-PPP-LCP | PPP LCP negotiation timed out. Note Codes 40 through 49 apply to PPP sessions. |
| 41 | Failed-PPP-LCP-Negotiation | PPP LCP negotiation failed. |
| 42 | Failed-PPP-PAP-Auth-Fail | PPP PAP authentication failed. |
| 43 | Failed-PPP-CHAP-Auth | PPP CHAP authentication failed. |
| 44 | Failed-PPP-Remote-Auth | PPP remote authentication failed. |

| Cause Code | Value | Description |
|------------|-------------------------------|--|
| 45 | PPP-Remote-Terminate | PPP received a Terminate Request from remote end. |
| 46 | PPP-Closed-Event | Upper layer requested that the session be closed. |
| 47 | NCP-Closed-PPP | PPP session closed because there were no NCPs open. |
| 48 | MP-Error-PPP | PPP session closed because of an MP error. |
| 49 | PPP-Maximum-Channels | PPP session closed because maximum channels were reached. |
| 50 | Tables-Full | Disconnect due to full terminal server tables. |
| 51 | Resources-Full | Disconnect due to full internal resources. |
| 52 | Invalid-IP-Address | IP address is not valid for Telnet host. |
| 53 | Bad-Hostname | Hostname cannot be validated. |
| 54 | Bad-Port | Port number is invalid or missing. |
| 60 | Reset-TCP | TCP connection has been reset. Note Codes 60 through 67 apply to Telnet or raw TCP sessions. |
| 61 | TCP-Connection-Refused | TCP connection has been refused by the host. |
| 62 | Timeout-TCP | TCP connection has timed out. |
| 63 | Foreign-Host-Close-TCP | TCP connection has been closed. |
| 64 | TCP-Network-Unreachable | TCP network is unreachable. |
| 65 | TCP-Host-Unreachable | TCP host is unreachable. |
| 66 | TCP-Network-Admin Unreachable | TCP network is unreachable for administrative reasons. |
| 67 | TCP-Port-Unreachable | TCP port is unreachable. |
| 100 | Session-Timeout | Session timed out. |
| 101 | Session-Failed-Security | Session failed for security reasons. |
| 102 | Session-End-Callback | Session terminated due to callback. |
| 120 | Invalid-Protocol | Call refused because the detected protocol is disabled. |
| 150 | RADIUS-Disconnect | Disconnected by RADIUS request. |
| 151 | Local-Admin-Disconnect | Administrative disconnect. |
| 152 | SNMP-Disconnect | Disconnected by SNMP request. |
| 160 | V110-Retries | Allowed V.110 retries have been exceeded. |
| 170 | PPP-Authentication-Timeout | PPP authentication timed out. |

| Cause Code | Value | Description |
|------------|------------------------|---|
| 180 | Local-Hangup | Disconnected by local hangup. |
| 185 | Remote-Hangup | Disconnected by remote end hangup. |
| 190 | T1-Quiesced | Disconnected because T1 line was quiesced. |
| 195 | Call-Duration | Disconnected because the maximum duration of the call was exceeded. |
| 600 | VPN-User-Disconnect | Call disconnected by client (through PPP). Code is sent if the LNS receives a PPP terminate request from the client. |
| 601 | VPN-Carrier-Loss | Loss of carrier. This can be the result of a physical line going dead. Code is sent when a client is unable to dial out using a dialer. |
| 602 | VPN-No-Resources | No resources available to handle the call. Code is sent when the client is unable to allocate memory (running low on memory). |
| 603 | VPN-Bad-Control-Packet | Bad L2TP or L2F control packets. This code is sent when an invalid control packet, such as missing mandatory Attribute-Value pairs (AVP), from the peer is received. When using L2TP, the code will be sent after six retransmits; when using L2F, the number of retransmits is user configurable. Note VPN-Tunnel-Shut will be sent if there are active sessions in the tunnel. |
| 604 | VPN-Admin-Disconnect | Administrative disconnect. This can be the result of a VPN soft shutdown, which is when a client reaches maximum session limit or exceeds maximum hopcount. Code is sent when a tunnel is brought down by issuing the clear vpdn tunnel command. |
| 605 | VPN-Tunnel-Shut | Tunnel teardown or tunnel setup has failed. Code is sent when there are active sessions in a tunnel and the tunnel goes down. Note This code is not sent when tunnel authentication fails. |
| 606 | VPN-Local-Disconnect | Call is disconnected by LNS PPP module. Code is sent when the LNS sends a PPP terminate request to the client. It indicates a normal PPP disconnection initiated by the LNS. |
| 607 | VPN-Session-Limit | VPN soft shutdown is enabled. Code is sent when a call has been refused due to any of the soft shutdown restrictions previously mentioned. |
| 608 | VPN-Call-Redirect | VPN call redirect is enabled. |

RADIUS Progress Codes

The RADIUS Progress Codes feature adds additional progress codes to RADIUS attribute 196 (Ascend-Connect-Progress), which indicates a connection state before a call is disconnected through progress codes.

Attribute 196 is sent in network, exec, and resource accounting “start” and “stop” records. This attribute can facilitate call failure debugging because each progress code identifies accounting information relevant to the connection state of a call. The attribute is activated by default; when an accounting “start” or “stop” accounting record is requested, authentication, authorization, and accounting (AAA) adds attribute 196 into the record as part of the standard attribute list. Attribute 196 is valuable because the progress codes, which are sent in accounting “start” and “stop” records, facilitate the debugging of call failures.

Note In accounting “start” records, attribute 196 does not have a value.

Table 105: Newly Supported Progress Codes for Attribute 196

| Code | Description |
|------|---|
| 10 | Modem allocation and negotiation is complete; the call is up. |
| 30 | The modem is up. |
| 33 | The modem is waiting for result codes. |
| 41 | The max TNT is establishing the TCP connection by setting up a TCP clear call. |
| 60 | Link control protocol (LCP) is the open state with PPP and IP Control Protocol (IPCP) negotiation; the LAN session is up. |
| 65 | PPP negotiation occurs and, initially, the LCP negotiation occurs; LCP is in the open state. |
| 67 | After PPP negotiation with LCP in the open state occurs, IPCP negotiation begins. |

Note Progress codes 33, 30, and 67 are generated and seen through debugs on the NAS; all other codes are generated and seen through debugs and the accounting record on the RADIUS server.

Vendor-Proprietary RADIUS Server Communication

Although an IETF draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the switch and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-proprietary or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the switch. You specify the RADIUS host and secret text string by using the **radius server** global configuration commands.

Enhanced Test Command

The Enhanced Test Command feature allows a named user profile to be created with calling line ID (CLID) or dialed number identification service (DNIS) attribute values. The CLID or DNIS attribute values can be associated with the RADIUS record that is sent with the user profile so that the RADIUS server can access CLID or DNIS attribute information for all incoming calls.

How to Configure RADIUS

Identifying the RADIUS Server Host

To apply these settings globally to all RADIUS servers communicating with the Device, use the three unique global configuration commands: **radius-server timeout**, **radius-server retransmit**, and **radius-server key**.

You can configure the Device to use AAA server groups to group existing server hosts for authentication. For more information, see Related Topics below.

You also need to configure some settings on the RADIUS server. These settings include the IP address of the Device and the key string to be shared by both the server and the Device. For more information, see the RADIUS server documentation.

Follow these steps to configure per-server RADIUS server communication.

Before you begin

If you configure both global and per-server functions (timeout, retransmission, and key commands) on the device, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands. For information on configuring these settings on all RADIUS servers, see Related Topics below.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | radius server <i>name</i> Example: | Specifies the name of the RADIUS server configuration for Protected Access Credential (PAC) provisioning and enters RADIUS server configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device (config) # radius server ISE | The device also supports RADIUS for IPv6. |
| Step 4 | <p>address {ipv4 ipv6} <i>ip address</i> {auth-port <i>port number</i> acct-port <i>port number</i>}</p> <p>Example:</p> <pre>Device (config-radius-server) # address ipv4 10.1.1.1 auth-port 1645 acct-port 1646</pre> | <p>(Optional) Specifies the RADIUS server parameters.</p> <p>For auth-port <i>port-number</i>, specify the UDP destination port for authentication requests. The default is 1645. The range is 0 to 65536.</p> <p>For acct-port <i>port-number</i>, specify the UDP destination port for authentication requests. The default is 1646.</p> |
| Step 5 | <p>key string</p> <p>Example:</p> <pre>Device (config-radius-server) # key cisco123</pre> | <p>(Optional) For key string, specify the authentication and encryption key used between the Device and the RADIUS daemon running on the RADIUS server.</p> <p>Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius server command. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.</p> |
| Step 6 | <p>retransmit value</p> <p>Example:</p> <pre>Device (config-radius-server) # retransmit 10</pre> | <p>(Optional) Specifies the number of times a RADIUS request is resent when the server is not responding or responding slowly. The range is 1 to 100. This setting overrides the radius-server retransmit global configuration command setting.</p> |
| Step 7 | <p>timeout seconds</p> <p>Example:</p> <pre>Device (config-radius-server) # timeout 60</pre> | <p>(Optional) Specifies the time interval that the Device waits for the RADIUS server to reply before sending a request again. The range is 1 to 1000. This setting overrides the radius-server timeout global configuration command setting.</p> |
| Step 8 | <p>end</p> <p>Example:</p> <pre>Device (config) # end</pre> | Returns to privileged EXEC mode. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 9 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 10 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

Configuring Settings for All RADIUS Servers

Beginning in privileged EXEC mode, follow these steps to configure settings for all RADIUS servers:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 2 | radius-server key <i>string</i> Example: Device(config)# <code>radius-server key your_server_key</code> Device(config)# <code>key your_server_key</code> | Specifies the shared secret text string used between the switch and all RADIUS servers. Note The key is a text string that must match the encryption key used on the RADIUS server. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key. |
| Step 3 | radius-server retransmit <i>retries</i> Example: Device(config)# <code>radius-server retransmit 5</code> | Specifies the number of times the switch sends each RADIUS request to the server before giving up. The default is 3; the range 1 to 1000. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 4 | radius-server timeout <i>seconds</i> Example: Device(config)# radius-server timeout 3 | Specifies the number of seconds a switch waits for a reply to a RADIUS request before resending the request. The default is 5 seconds; the range is 1 to 1000. |
| Step 5 | radius-server deadtime <i>minutes</i> Example: Device(config)# radius-server deadtime 0 | When a RADIUS server is not responding to authentication requests, this command specifies a time to stop the request on that server. This avoids the wait for the request to timeout before trying the next configured server. The default is 0; the range is 1 to 1440 minutes. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring RADIUS Login Authentication

Follow these steps to configure RADIUS login authentication:

Before you begin

To secure the device for HTTP access by using AAA methods, you must configure the device with the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the device for HTTP access by using AAA methods.

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|---|
| | <p>Example:</p> <pre>Device> enable</pre> | <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | <p>aaa new-model</p> <p>Example:</p> <pre>Device(config)# aaa new-model</pre> | Enables AAA. |
| Step 4 | <p>aaa authentication login {default list-name} method1 [method2...]</p> <p>Example:</p> <pre>Device(config)# aaa authentication login default local</pre> | <p>Creates a login authentication method list.</p> <ul style="list-style-type: none"> • To create a default list that is used when a named list is <i>not</i> specified in the login authentication command, use the default keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all ports. • For <i>list-name</i>, specify a character string to name the list you are creating. • For <i>method1...</i>, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. <p>Select one of these methods:</p> <ul style="list-style-type: none"> • <i>enable</i>—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the enable password global configuration command. • <i>group radius</i>—Use RADIUS authentication. Before you can use this authentication method, you must configure the RADIUS server. • <i>line</i>—Use the line password for authentication. Before you can use this authentication method, you must |

| | Command or Action | Purpose |
|---------------|---|---|
| | | <p>define a line password. Use the password <i>password</i> line configuration command.</p> <ul style="list-style-type: none"> • <i>local</i>—Use the local username database for authentication. You must enter username information in the database. Use the username <i>name</i> password global configuration command. • <i>local-case</i>—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username <i>password</i> global configuration command. • <i>none</i>—Do not use any authentication for login. |
| Step 5 | <p>line [console tty vty] <i>line-number</i> [<i>ending-line-number</i>]</p> <p>Example:</p> <pre>Device(config)# line 1 4</pre> | Enters line configuration mode, and configure the lines to which you want to apply the authentication list. |
| Step 6 | <p>login authentication {default <i>list-name</i>}</p> <p>Example:</p> <pre>Device(config)# login authentication default</pre> | <p>Applies the authentication list to a line or set of lines.</p> <ul style="list-style-type: none"> • If you specify default, use the default list created with the aaa authentication login command. • For <i>list-name</i>, specify the list created with the aaa authentication login command. |
| Step 7 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 8 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 9 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Defining AAA Server Groups

You use the **server** group server configuration command to associate a particular server with a defined group server. You can either identify the server by its IP address or identify multiple host instances or entries by using the optional **auth-port** and **acct-port** keywords.

Follow these steps to define AAA server groups:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | radius server name Example: <pre>Device(config)# radius server ISE</pre> | Specifies the name of the RADIUS server configuration for Protected Access Credential (PAC) provisioning and enters RADIUS server configuration mode. The device also supports RADIUS for IPv6. |
| Step 4 | address {ipv4 ipv6} {ip-address hostname} auth-port port-number acct-port port-number Example: <pre>Device(config-radius-server)# address ipv4 10.1.1.1 auth-port 1645 acct-port 1646</pre> | Configures the IPv4 address for the RADIUS server accounting and authentication parameters. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | key string Example: <pre>Device(config-radius-server) # key cisco123</pre> | Specifies the authentication and encryption key for all RADIUS communications between the device and the RADIUS server. |
| Step 6 | end Example: <pre>Device(config-radius-server) # end</pre> | Exits RADIUS server configuration mode and returns to privileged EXEC mode. |
| Step 7 | show running-config Example: <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring RADIUS Authorization for User Privileged Access and Network Services

Note Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

Follow these steps to configure RADIUS authorization for user privileged access and network services:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|--|
| Step 2 | configure terminal Example: Device# <code>configure terminal</code> | Enters global configuration mode. |
| Step 3 | aaa authorization network radius Example: Device(config)# <code>aaa authorization network radius</code> | Configures the device for user RADIUS authorization for all network-related service requests. |
| Step 4 | aaa authorization exec radius Example: Device(config)# <code>aaa authorization exec radius</code> | Configures the device for user RADIUS authorization if the user has privileged EXEC access. The exec keyword might return user profile information (such as autocommand information). |
| Step 5 | end Example: Device(config)# <code>end</code> | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# <code>show running-config</code> | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# <code>copy running-config startup-config</code> | (Optional) Saves your entries in the configuration file. |

What to do next

You can use the **aaa authorization** global configuration command with the **radius** keyword to set parameters that restrict a user's network access to privileged EXEC mode.

The **aaa authorization exec radius local** command sets these authorization parameters:

- Use RADIUS for privileged EXEC access authorization if authentication was performed by using RADIUS.
- Use the local database if authentication was not performed by using RADIUS.

Starting RADIUS Accounting

Follow these steps to start RADIUS accounting:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa accounting network start-stop radius Example: Device(config)# aaa accounting network start-stop radius | Enables RADIUS accounting for all network-related service requests. |
| Step 4 | aaa accounting exec start-stop radius Example: Device(config)# aaa accounting exec start-stop radius | Enables RADIUS accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 6 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 7 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Verifying Attribute 196

No configuration is required to configure RADIUS Progress Codes. To verify attribute 196 in accounting “start” and “stop” records, perform the following steps.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | debug aaa accounting Example: Device# debug aaa accounting | Displays information on accountable events as they occur. |
| Step 3 | show radius statistics Example: Device# debug aaa authorization | Displays the RADIUS statistics for accounting and authentication packets. |

Configuring the Device to Use Vendor-Specific RADIUS Attributes

Follow these steps to configure the device to use vendor-specific RADIUS attributes:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | radius-server vsa send [accounting authentication] Example: Device(config)# radius-server vsa send | Enables the device to recognize and use VSAs as defined by RADIUS IETF attribute 26. <ul style="list-style-type: none"> • (Optional) Use the accounting keyword to limit the set of recognized |

| | Command or Action | Purpose |
|---------------|---|---|
| | <code>accounting</code> | <p>vendor-specific attributes to only accounting attributes.</p> <ul style="list-style-type: none"> • (Optional) Use the authentication keyword to limit the set of recognized vendor-specific attributes to only authentication attributes. <p>If you enter this command without keywords, both accounting and authentication vendor-specific attributes are used.</p> |
| Step 4 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 5 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 6 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring the Device for Vendor-Proprietary RADIUS Server Communication

Follow these steps to configure the device to use vendor-proprietary RADIUS server communication:

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>configure terminal</p> <p>Example:</p> | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Device# <code>configure terminal</code> | |
| Step 3 | <p>radius-server host <i>{hostname ip-address}</i> non-standard</p> <p>Example:</p> <pre>Device(config)# radius-server host 172.20.30.15 non-standard</pre> | Specifies the IP address or hostname of the remote RADIUS server host and identifies that it is using a vendor-proprietary implementation of RADIUS. |
| Step 4 | <p>radius-server key <i>string</i></p> <p>Example:</p> <pre>Device(config)# radius-server key rad124</pre> | <p>Specifies the shared secret text string used between the device and the vendor-proprietary RADIUS server. The device and the RADIUS server use this text string to encrypt passwords and exchange responses.</p> <p>Note The key is a text string that must match the encryption key used on the RADIUS server. Leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks are part of the key.</p> |
| Step 5 | <p>end</p> <p>Example:</p> <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |
| Step 6 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 7 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Configuring a User Profile and Associating it with the RADIUS Record

This section describes how to create a named user profile with CLID or DNIS attribute values and associate it with the RADIUS record.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa user profile <i>profile-name</i> Example: Device(config)# aaa user profile profilename1 | Creates a user profile. |
| Step 4 | aaa attribute {dnis clid} Example: Device# configure terminal | Adds DNIS or CLID attribute values to the user profile and enters AAA-user configuration mode. |
| Step 5 | exit | Exit Global Configuration mode. |
| Step 6 | test aaa group { <i>group-name</i> radius} <i>username password new-code</i> [profile <i>profile-name</i>] Example: Device# test aaa group radius secret new-code profile profilename1 | Associates a DNIS or CLID named user profile with the record sent to the RADIUS server. Note The <i>profile-name</i> must match the profile-name specified in the aaa user profile command. |

Verifying the Enhanced Test Command Configuration

To verify the Enhanced Test Command configuration, use the following commands in privileged EXEC mode:

| Command | Purpose |
|-----------------------------|--|
| Device# debug radius | Displays information associated with RADIUS. |

| Command | Purpose |
|---|---|
| <pre>Device# more system:running-config</pre> | Displays the contents of the current running configuration file. (Note that the more system:running-config command has replaced the show running-config command.) |

Configuration Examples for RADIUS

Examples: Identifying the RADIUS Server Host

This example shows how to configure one RADIUS server to be used for authentication and another to be used for accounting:

```
Device(config)# radius-server host 172.29.36.49 auth-port 1612 key rad1
Device(config)# radius-server host 172.20.36.50 acct-port 1618 key rad2
```

This example shows how to configure *host1* as the RADIUS server and to use the default ports for both authentication and accounting:

```
Device(config)# radius-server host host1
```

Example: Using Two Different RADIUS Group Servers

In this example, the switch is configured to recognize two different RADIUS group servers (*group1* and *group2*). Group1 has two different host entries on the same RADIUS server configured for the same services. The second host entry acts as a fail-over backup to the first entry.

```
Device(config)# radius-server host 172.20.0.1 auth-port 1000 acct-port 1001
Device(config)# radius-server host 172.10.0.1 auth-port 1645 acct-port 1646
Device(config)# aaa new-model
Device(config)# aaa group server radius group1
Device(config-sg-radius)# server 172.20.0.1 auth-port 1000 acct-port 1001
Device(config-sg-radius)# exit
Device(config)# aaa group server radius group2
Device(config-sg-radius)# server 172.20.0.1 auth-port 2000 acct-port 2001
Device(config-sg-radius)# exit
```

Examples: AAA Server Groups

The following example shows how to create server group *radgroup1* with three different RADIUS server members, each using the default authentication port (1645) and accounting port (1646):

```
aaa group server radius radgroup1
  server 172.16.1.11
  server 172.17.1.21
  server 172.18.1.31
```

The following example shows how to create server group radgroup2 with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

```
aaa group server radius radgroup2
server 172.16.1.1 auth-port 1000 acct-port 1001
server 172.16.1.1 auth-port 2000 acct-port 2001
server 172.16.1.1 auth-port 3000 acct-port 3001
```

Troubleshooting Tips for RADIUS Progress Codes

The following example is a sample debug output from the **debug ppp negotiation** command. This debug output is used to verify that accounting “stop” records have been generated and that attribute 196 (Ascend-Connect-Progress) has a value of 65.

```
Tue Aug 7 06:21:03 2001
NAS-IP-Address = 10.0.58.62
NAS-Port = 20018
Vendor-Specific = ""
NAS-Port-Type = ISDN
User-Name = "peer_16a"
Called-Station-Id = "5213124"
Calling-Station-Id = "5212175"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed-User
Acct-Session-Id = "00000014"
Framed-Protocol = PPP
Framed-IP-Address = 172.16.0.2
Acct-Input-Octets = 3180
Acct-Output-Octets = 3186
Acct-Input-Packets = 40
Acct-Output-Packets = 40
Ascend-Connect-Pr = 65
Acct-Session-Time = 49
Acct-Delay-Time = 0
Timestamp = 997190463
Request-Authenticator = Unverified
```

Examples: Configuring the Switch to Use Vendor-Specific RADIUS Attributes

For example, this AV pair activates Cisco’s *multiple named ip address pools* feature during IP authorization (during PPP IPCP address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

This example shows how to provide a user logging in from a switch with immediate access to privileged EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

This example shows how to specify an authorized VLAN in the RADIUS server database:

```
cisco-avpair= "tunnel-type (#64)=VLAN (13) "
cisco-avpair= "tunnel-medium-type (#65)=802 media (6) "
```

```
cisco-avpair= "tunnel-private-group-id(#81)=vlanid"
```

This example shows how to apply an input ACL in ASCII format to an interface for the duration of this connection:

```
cisco-avpair= "ip:inacl#1=deny ip 10.10.10.10 0.0.255.255 20.20.20.20 255.255.0.0"
cisco-avpair= "ip:inacl#2=deny ip 10.10.10.10 0.0.255.255 any"
cisco-avpair= "mac:inacl#3=deny any any decnet-iv"
```

This example shows how to apply an output ACL in ASCII format to an interface for the duration of this connection:

```
cisco-avpair= "ip:outacl#2=deny ip 10.10.10.10 0.0.255.255 any"
```

Example: Configuring the Switch for Vendor-Proprietary RADIUS Server Communication

This example shows how to specify a vendor-proprietary RADIUS host and to use a secret key of *rad124* between the switch and the server:

```
Device(config)# radius-server host 172.20.30.15 nonstandard
Device(config)# radius-server key rad124
```

Example: User Profile Associated With the test aaa group Command

The following example shows how to configure the `dnis = dnisvalue` user profile “*prfl1*” and associate it with a **test aaa group** command. In this example, the **debug radius** command has been enabled and the output follows the configuration.

```
aaa user profile prfl1
  aaa attribute dnis
  aaa attribute dnis dnisvalue
  no aaa attribute clid
! Attribute not found.
  aaa attribute clid clidvalue
  no aaa attribute clid
  exit
!
! Associate the dnis user profile with the test aaa group command.
test aaa group radius user1 pass new-code profile prfl1
!
!
! debug radius output, which shows that the dnis value has been passed to the radius !
server.

| Cisco IOS Release 15.0(2)EX | This feature was introduced. |
| Cisco IOS 15.2(1)E | The RADIUS Progress Codes feature adds additional progress codes to RADIUS attribute 196 (Ascend-Connect-Progress), which indicates a connection state before a call is disconnected through progress codes. |
| Cisco IOS 15.2(1)E | <p>The Enhanced Test Command feature allows a named user profile to be created with calling line ID (CLID) or Dialed Number Identification Service (DNIS) attribute values. The CLID or DNIS attribute values can be associated with the RADIUS record that is sent with the user profile so that the RADIUS server can access CLID or DNIS attribute information for all incoming calls.</p> <p>The following commands were introduced or modified: aaa attribute, aaa user profile, and test aaa group</p> |

CHAPTER 45

RADIUS Server Load Balancing

The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across RADIUS servers in a server group. These servers can share the AAA transaction load and thereby respond faster to incoming requests.

This module describes the RADIUS Server Load Balancing feature.

- [Finding Feature Information, on page 879](#)
- [Prerequisites for RADIUS Server Load Balancing, on page 879](#)
- [Restrictions for RADIUS Server Load Balancing, on page 880](#)
- [Information About RADIUS Server Load Balancing, on page 880](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for RADIUS Server Load Balancing

- Authentication, authorization, and accounting (AAA) must be configured on the RADIUS server.
- AAA RADIUS server groups must be configured.
- RADIUS must be configured for functions such as authentication, accounting, or static route download.

Restrictions for RADIUS Server Load Balancing

- Incoming RADIUS requests, such as Packet of Disconnect (POD) requests, are not supported.
- Load balancing is not supported on proxy RADIUS servers and for private server groups.

Information About RADIUS Server Load Balancing

RADIUS Server Load Balancing Overview

Load balancing distributes batches of transactions to RADIUS servers within a server group. Load balancing assigns each batch of transactions to the server with the lowest number of outstanding transactions in its queue. The process of assigning a batch of transactions is as follows:

1. The first transaction is received for a new batch.
2. All server transaction queues are checked.
3. The server with the lowest number of outstanding transactions is identified.
4. The identified server is assigned the next batch of transactions.

The batch size is a user-configured parameter. Changes in the batch size may impact CPU load and network throughput. As batch size increases, CPU load decreases and network throughput increases. However, if a large batch size is used, all available server resources may not be fully utilized. As batch size decreases, CPU load increases and network throughput decreases.

Note There is no set number for large or small batch sizes. A batch with more than 50 transactions is considered large and a batch with fewer than 25 transactions is considered small.

Note If a server group contains ten or more servers, we recommend that you set a high batch size to reduce CPU load.

Transaction Load Balancing Across RADIUS Server Groups

You can configure load balancing either per-named RADIUS server group or for the global RADIUS server group. The load balancing server group must be referred to as “radius” in the authentication, authorization, and accounting (AAA) method lists. All public servers that are part of the RADIUS server group are then load balanced.

You can configure authentication and accounting to use the same RADIUS server or different servers. In some cases, the same server can be used for preauthentication, authentication, or accounting transactions for a session. The preferred server, which is an internal setting and is set as the default, informs AAA to use the same server for the start and stop record for a session regardless of the server cost. When using the preferred

server setting, ensure that the server that is used for the initial transaction (for example, authentication), the preferred server, is part of any other server group that is used for a subsequent transaction (for example, accounting).

The preferred server is not used if one of the following criteria is true:

- The **load-balance method least-outstanding ignore-preferred-server** command is used.
- The preferred server is dead.
- The preferred server is in quarantine.
- The want server flag has been set, overriding the preferred server setting.

The want server flag, an internal setting, is used when the same server must be used for all stages of a multistage transaction regardless of the server cost. If the want server is not available, the transaction fails.

You can use the **load-balance method least-outstanding ignore-preferred-server** command if you have either of the following configurations:

- Dedicated authentication server and a separate dedicated accounting server
- Network where you can track all call record statistics and call record details, including start and stop records and records that are stored on separate servers

If you have a configuration where authentication servers are a superset of accounting servers, the preferred server is not used.

RADIUS Server Status and Automated Testing

The RADIUS Server Load Balancing feature considers the server status when assigning batches. Transaction batches are sent only to live servers. We recommend that you test the status of all RADIUS load-balanced servers, including low usage servers (for example, backup servers).

Transactions are not sent to a server that is marked dead. A server is marked dead until its timer expires, at which time it moves to quarantine state. A server is in quarantine until it is verified alive by the RADIUS automated tester functionality.

To determine if a server is alive and available to process transactions, the RADIUS automated tester sends a request periodically to the server for a test user ID. If the server returns an Access-Reject message, the server is alive; otherwise the server is either dead or quarantined.

A transaction sent to an unresponsive server is failed over to the next available server before the unresponsive server is marked dead. We recommend that you use the retry reorder mode for failed transactions.

When using the RADIUS automated tester, verify that the authentication, authorization, and accounting (AAA) servers are responding to the test packets that are sent by the network access server (NAS). If the servers are not configured correctly, packets may be dropped and the server erroneously marked dead.

Caution

We recommend that you use a test user that is not defined on the RADIUS server for the RADIUS server automated testing to protect against security issues that may arise if the test user is not correctly configured.

Note Use the **test aaa group** command to check load-balancing transactions.

How to Configure RADIUS Server Load Balancing

Enabling Load Balancing for a Named RADIUS Server Group

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | radius-server host {hostname ip-address} [test username name] [auth-port number] [ignore-auth-port] [acct-port number] [ignore-acct-port] [idle-time seconds] Example: Device(config)# radius-server host 192.0.2.1 test username test1 idle-time 1 | Enables RADIUS automated testing. |
| Step 4 | aaa group server radius group-name Example: Device(config)# aaa group server radius rad-sg | Enters server group configuration mode. |
| Step 5 | load-balance method least-outstanding [batch-size number] [ignore-preferred-server] Example: Device(config-sg)# load-balance method least-outstanding batch-size 30 | Enables the least-outstanding load balancing for a named server group. |
| Step 6 | end Example: Device(config-sg)# end | Exits server group configuration mode and enters privileged EXEC mode. |

Enabling Load Balancing for a Global RADIUS Server Group

The global RADIUS server group is referred to as “radius” in the authentication, authorization, and accounting (AAA) method lists.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | radius-server host {hostname ip-address} [test username name] [auth-port number] [ignore-auth-port] [acct-port number] [ignore-acct-port] [idle-time seconds] Example: Device(config)# radius-server host 192.0.2.1 test username test1 idle-time 1 | Enables RADIUS automated testing. |
| Step 4 | radius-server load-balance method least-outstanding [batch-size number] [ignore-preferred-server] Example: Device(config)# radius-server load-balance method least-outstanding | Enables the least-outstanding load balancing for the global RADIUS server group and enters server group configuration mode. <ul style="list-style-type: none">• The default batch size is 25. The batch size range is from 1 to 2147483647. |
| Step 5 | load-balance method least-outstanding [batch-size number] [ignore-preferred-server] Example: Device(config-sg)# load-balance method least-outstanding batch-size 5 | Enables least-outstanding load balancing for a global named server group. |
| Step 6 | end Example: Device(config-sg)# end | Exits server group configuration mode and enters privileged EXEC mode. |

Troubleshooting RADIUS Server Load Balancing

After configuring the RADIUS Server Load Balancing feature, you can monitor the idle timer, dead timer, and load balancing server selection or verify the server status by using a manual test command.

Procedure

Step 1 Use the **debug aaa test** command to determine when an idle timer or dead timer has expired, when test packets are sent, the status of the server, or to verify the server state.

The idle timer is used to check the server status and is updated with or without any incoming requests. Monitoring the idle timer helps to determine if there are nonresponsive servers and to keep the RADIUS server status updated to efficiently utilize available resources. For instance, an updated idle timer would help ensure that incoming requests are sent to servers that are alive.

The dead timer is used either to determine that a server is dead or to update a dead server's status appropriately.

Monitoring server selection helps to determine how often the server selection changes. Server selection is effective in analyzing if there are any bottlenecks, a large number of queued requests, or if only specific servers are processing incoming requests.

The following sample output from the **debug aaa test** command shows when the idle timer expired:

Example:

```
Device# debug aaa test

Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) quarantined.
Jul 16 00:07:01: AAA/SG/TEST: Sending test request(s) to server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Sending 1 Access-Requests, 1 Accounting-Requests in current
batch.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Access-Request.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Accounting-Request.
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Necessary responses received from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) marked ALIVE. Idle timer set
for 60 sec(s).
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) removed from quarantine.
```

Step 2 Use the **debug aaa sg-server selection** command to determine the server that is selected for load balancing.

The following sample output from the **debug aaa sg-server selection** command shows five access requests being sent to a server group with a batch size of three:

Example:

```
Device# debug aaa sg-server selection

Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [1] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: No more transactions in batch. Obtaining a new server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining a new least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[0] load: 3
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[1] load: 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[2] load: 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Selected Server[1] with load 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing server.
```

Step 3 Use the **test aaa group** command to manually verify the RADIUS load-balanced server status.

The following sample output shows the response from a load-balanced RADIUS server that is alive when the username “test” does not match a user profile. The server is verified alive when it issues an Access-Reject response to an authentication, authorization, and accounting (AAA) packet generated using the **test aaa group** command.

Example:

```
Device# test aaa group SG1 test lab new-code

00:06:07: RADIUS/ENCODE(00000000):Orig. component type = INVALID
00:06:07: RADIUS/ENCODE(00000000): dropping service type, "radius-server attribute 6

00:06:07: RADIUS(00000000): Received from id 1645/1
00:06:07: RADIUS/DECODE: Reply-Message fragments, 22, total 22 bytes
```

Configuration Examples for RADIUS Server Load Balancing

Example: Enabling Load Balancing for a Named RADIUS Server Group

The following examples show load balancing enabled for a named RADIUS server group. These examples are shown in three parts: the current configuration of the RADIUS command output, debug output, and authentication, authorization, and accounting (AAA) server status information.

The following sample output shows the relevant RADIUS configuration:

```
Device# show running-config
.
.
.
aaa group server radius server-group1
 server 192.0.2.238 auth-port 2095 acct-port 2096
 server 192.0.2.238 auth-port 2015 acct-port 2016
 load-balance method least-outstanding batch-size 5
!
aaa authentication ppp default group server-group1
aaa accounting network default start-stop group server-group1
.
.
.
```

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The **aaa group server radius** command shows the configuration of a server group with two member servers.

- The **load-balance** command enables load balancing for global RADIUS server groups with the batch size specified.
- The **aaa authentication ppp** command authenticates all PPP users using RADIUS.
- The **aaa accounting** command enables sending of all accounting requests to the AAA server when the client is authenticated and then disconnected using the **start-stop** keyword.

The show debug sample output below shows the selection of the preferred server and the processing of requests for the preceding configuration:

```
Device# show debug

*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT(0000002C):No preferred server available.
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:Obtaining least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:No more transactions in batch. Obtaining a new
server.
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:Obtaining a new least loaded server.
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:Server[0] load:0
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:Server[1] load:0
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:Selected Server[0] with load 0
*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT:[5] transactions remaining in batch.

```

Example: Enabling Load Balancing for a Global RADIUS Server Group

The following examples show how to enable load balancing for global RADIUS server groups. These examples are shown in three parts: the current configuration of the RADIUS command output, debug output, and authentication, authorization, and accounting (AAA) server status information. You can use delimiting characters to display relevant parts of the configuration.

The following example shows the relevant RADIUS configuration:

```
Device# show running-config | include radius

aaa authentication ppp default group radius
aaa accounting network default start-stop group radius
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 key cisco
radius-server load-balance method least-outstanding batch-size 5
```

Lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The **aaa authentication ppp** command authenticates all PPP users using RADIUS.

- The **aaa accounting** command enables the sending of all accounting requests to an AAA server when the client is authenticated and then disconnected through use of the **start-stop** keyword.
- The **radius-server host** command defines the IP address of the RADIUS server host with the authorization and accounting ports specified and the authentication and encryption keys identified.
- The **radius-server load-balance** command enables load balancing for global RADIUS server groups with the batch size specified.

The **show debug** sample output below shows the selection of the preferred server and the processing of requests for the configuration:

```
Device# show debug

General OS:
  AAA server group server selection debugging is on
#
<sending 10 pppoe requests>
Device#

server.
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT:Obtaining a new least loaded server.
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT:Server[1] load:0
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT:Server[0] load:5
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT:Selected Server[1] with load 0
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT:[5] transactions remaining in batch.
```

```
*Feb 28 13:40:32.199:AAA/SG/SERVER_SELECT(00000019):Server (192.0.2.238:2015,2016) now being
used as preferred server.
```

The following sample output from the **show aaa servers** command shows the AAA server status for the global RADIUS server group configuration:

The sample output shows the status of two RADIUS servers. Both servers are up and successfully processed in the last 2 minutes:

- Five out of six authentication requests
- Five out of five accounting requests

```
Device# show aaa servers

RADIUS:id 4, priority 1, host 192.0.2.238, auth-port 2095, acct-port 2096
  State:current UP, duration 3175s, previous duration 0s
  Dead:total time 0s, count 0
  Quarantined:No
  Authen:request 6, timeouts 1
    Response:unexpected 1, server error 0, incorrect 0, time 1841ms
    Transaction:success 5, failure 0
  Author:request 0, timeouts 0
    Response:unexpected 0, server error 0, incorrect 0, time 0ms
    Transaction:success 0, failure 0
  Account:request 5, timeouts 0
    Response:unexpected 0, server error 0, incorrect 0, time 3303ms
    Transaction:success 5, failure 0
  Elapsed time since counters last cleared:2m
RADIUS:id 5, priority 2, host 192.0.2.238, auth-port 2015, acct-port 2016
  State:current UP, duration 3175s, previous duration 0s
  Dead:total time 0s, count 0

    Transaction:success 0, failure 0
  Account:request 5, timeouts 0
    Response:unexpected 0, server error 0, incorrect 0, time 3247ms
    Transaction:success 5, failure 0
  Elapsed time since counters last cleared:2m
```

Example: Monitoring Idle Timer

The following example shows idle timer and related server state for load balancing enabled for a named RADIUS server group. The current configuration of the RADIUS command output and debug command output are also displayed.

The following sample output shows the relevant RADIUS configuration:

```
Device# show running-config | include radius

aaa group server radius server-group1
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 test username junk1 idle-time
 1 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 test username junk1 idle-time
 1 key cisco
radius-server load-balance method least-outstanding batch-size 5
```

The lines in the current configuration of the preceding RADIUS command output are defined as follows:

- The **aaa group server radius** command shows the configuration of a server group.
- The **radius-server host** command defines the IP address of the RADIUS server host with authorization and accounting ports specified and the authentication and encryption key identified.
- The **radius-server load-balance** command enables load balancing for the RADIUS server with the batch size specified.

The **show debug** sample output below shows test requests being sent to servers. The response to the test request sent to the server is received, the server is removed from quarantine as appropriate, the server is marked alive, and then the idle timer is reset.

```
Device# show debug
*Feb 28 13:52:20.835:AAA/SG/TEST:Server (192.0.2.238:2015,2016) quarantined.
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending test request(s) to server (192.0.2.238:2015,2016)
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending 1 Access-Requests, 1 Accounting-Requests in current
  batch.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Access-Request.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Accounting-Request.
*Feb 28 13:52:21.087:AAA/SG/TEST:Obtained Test response from server (192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Obtained Test response from server (192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Necessary responses received from server
  (192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) marked ALIVE. Idle timer
  set for 60 secs(s).
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) removed from quarantine.
.
.
.
```

Example: Configuring the Preferred Server with the Same Authentication and Authorization Server

The following example shows an authentication server group and an authorization server group that use the same servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
```

When a preferred server is selected for a session, all transactions for that session will continue to use the original preferred server. The servers 209.165.200.225 and 209.165.200.226 are load balanced based on sessions rather than transactions.

Example: Configuring the Preferred Server with Different Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
```

```
server 209.165.200.226 key radkey2
aaa group server radius accounting-group
server 209.165.201.1 key radkey3
server 209.165.201.2 key radkey4
```

The authentication server group and the accounting server group do not share any common servers. A preferred server is never found for accounting transactions; therefore, authentication and accounting servers are load-balanced based on transactions. Start and stop records are sent to the same server for a session.

Example: Configuring the Preferred Server with Overlapping Authentication and Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an accounting server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
server 209.165.200.225 key radkey1
server 209.165.200.226 key radkey2
server 209.165.201.1 key radkey3
aaa group server radius accounting-group
server 209.165.201.1 key radkey3
server 209.165.201.2 key radkey4
```

If all servers have equal transaction processing capability, one-third of all authentication transactions are directed toward the server 209.165.201.1. Therefore, one-third of all accounting transactions are also directed toward the server 209.165.201.1. The remaining two-third of accounting transactions are load balanced equally between servers 209.165.201.1 and 209.165.201.2. The server 209.165.201.1 receives fewer authentication transactions because the server 209.165.201.1 has outstanding accounting transactions.

Example: Configuring the Preferred Server with Authentication Servers As a Subset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
server 209.165.200.225 key radkey1
server 209.165.200.226 key radkey2
aaa group server radius accounting-group
server 209.165.200.225 key radkey1
server 209.165.200.226 key radkey2
server 209.165.201.1 key radkey3
```

One-half of all authentication transactions are sent to the server 209.165.200.225 and the other half to the server 209.165.200.226. Servers 209.165.200.225 and 209.165.200.226 are preferred servers for authentication and accounting transaction. Therefore, there is an equal distribution of authentication and accounting transactions across servers 209.165.200.225 and 209.165.200.226. The server 209.165.201.1 is relatively unused.

Example: Configuring the Preferred Server with Authentication Servers As a Superset of Authorization Servers

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an authorization server group that uses servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
  server 209.165.201.1 key radkey3
aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
```

Initially, one-third of authentication transactions are assigned to each server in the authorization server group. As accounting transactions are generated for more sessions, accounting transactions are sent to servers 209.165.200.225 and 209.165.200.226 because the preferred server flag is on. As servers 209.165.200.225 and 209.165.200.226 begin to process more transactions, authentication transactions will start to be sent to server 209.165.201.1. Transaction requests authenticated by server 209.165.201.1 do not have any preferred server setting and are split between servers 209.165.200.225 and 209.165.200.226, which negates the use of the preferred server flag. This configuration should be used cautiously.

| Feature Name | Releases | Feature Information |
|------------------------------|--------------------|--|
| RADIUS Server Load Balancing | Cisco IOS 15.2(1)E | <p>The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across servers in a server group. These servers can share the AAA transaction load and thereby respond faster to incoming requests.</p> <p>The following commands were introduced or modified: debug aaa sg-server selection, debug aaa test, load-balance (server-group), radius-server host, radius-server load-balance, and test aaa group.</p> |

CHAPTER 46

RADIUS Change of Authorization Support

The RADIUS Change of Authorization (CoA) provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated

Identity-Based Networking Services supports RADIUS change of authorization (CoA) commands for session query, reauthentication, and termination, port bounce and port shutdown, and service template activation and deactivation.

Information About RADIUS Change-of-Authorization

RADIUS Change of Authorization

The RADIUS Change of Authorization (CoA) provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated. When a policy changes for a user or user group in AAA, administrators can send RADIUS CoA packets from the AAA server such as a Cisco Secure Access Control Server (ACS) to reinitialize authentication and apply the new policy. This section provides an overview of the RADIUS interface including available primitives and how they are used during a CoA.

- Session Reauthentication
- Stacking Guidelines for Session Termination

A standard RADIUS interface is typically used in a pulled model where the request originates from a network attached device and the response come from the queried servers. Catalyst support the RADIUS CoA extensions defined in RFC 5176 that are typically used in a pushed model and allow for the dynamic reconfiguring of sessions from external AAA or policy servers.

The supports these per-session CoA requests:

- Session reauthentication
- Session termination
- Session termination with port shutdown
- Session termination with port bounce

This feature is integrated with Cisco Secure Access Control Server (ACS) 5.1.

The RADIUS interface is enabled by default on Catalyst . However, some basic configuration is required for the following attributes:

- Security and Password—refer to the “Preventing Unauthorized Access to Your Switch” section in this guide.
- Accounting—refer to the “Starting RADIUS Accounting” section in the Configuring Switch-Based Authentication chapter in this guide.

Cisco IOS software supports the RADIUS CoA extensions defined in RFC 5176 that are typically used in a push model to allow the dynamic reconfiguring of sessions from external AAA or policy servers. Per-session CoA requests are supported for session identification, session termination, host reauthentication, port shutdown, and port bounce. This model comprises one request (CoA-Request) and two possible response codes:

- CoA acknowledgement (ACK) [CoA-ACK]
- CoA nonacknowledgement (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a AAA or policy server) and directed to the device that acts as a listener.

The table below shows the RADIUS CoA commands and vendor-specific attributes (VSAs) supported by Identity-Based Networking Services. All CoA commands must include the session identifier between the device and the CoA client.

Table 107: RADIUS CoA Commands Supported by Identity-Based Networking Services

| CoA Command | Cisco VSA |
|--------------------|--|
| Activate service | Cisco:Avpair=“subscriber:command=activate-service” Cisco:Avpair=“subscriber:service-name=<service-name>” Cisco:Avpair=“subscriber:precedence=<precedence-number>” Cisco:Avpair=“subscriber:activation-mode=replace-all” |
| Deactivate service | Cisco:Avpair=“subscriber:command=deactivate-service” Cisco:Avpair=“subscriber:service-name=<service-name>” |
| Bounce host port | Cisco:Avpair=“subscriber:command=bounce-host-port” |
| Disable host port | Cisco:Avpair=“subscriber:command=disable-host-port” |
| Session query | Cisco:Avpair=“subscriber:command=session-query” |

| CoA Command | Cisco VSA |
|------------------------|--|
| Session reauthenticate | Cisco:Avpair="subscriber:command=reauthenticate" Cisco:Avpair="subscriber:reauthenticate-type=last" or Cisco:Avpair="subscriber:reauthenticate-type=rerun" |
| Session terminate | This is a standard disconnect request and does not require a VSA. |
| Interface template | Cisco:AVpair="interface-template-name=<interfacetemplate>" |

Change-of-Authorization Requests

Change of Authorization (CoA) requests, as described in RFC 5176, are used in a push model to allow for session identification, host reauthentication, and session termination. The model is comprised of one request (CoA-Request) and two possible response codes:

- CoA acknowledgment (ACK) [CoA-ACK]
- CoA non-acknowledgment (NAK) [CoA-NAK]

The request is initiated from a CoA client (typically a RADIUS or policy server) and directed to the switch that acts as a listener.

RFC 5176 Compliance

The Disconnect Request message, which is also referred to as Packet of Disconnect (POD), is supported by the switch for session termination.

This table shows the IETF attributes are supported for this feature.

Table 108: Supported IETF Attributes

| Attribute Number | Attribute Name |
|------------------|-----------------------|
| 24 | State |
| 31 | Calling-Station-ID |
| 44 | Acct-Session-ID |
| 80 | Message-Authenticator |
| 101 | Error-Cause |

This table shows the possible values for the Error-Cause attribute.

Table 109: Error-Cause Values

| Value | Explanation |
|-------|----------------------------------|
| 201 | Residual Session Context Removed |

| Value | Explanation |
|-------|--|
| 202 | Invalid EAP Packet (Ignored) |
| 401 | Unsupported Attribute |
| 402 | Missing Attribute |
| 403 | NAS Identification Mismatch |
| 404 | Invalid Request |
| 405 | Unsupported Service |
| 406 | Unsupported Extension |
| 407 | Invalid Attribute Value |
| 501 | Administratively Prohibited |
| 502 | Request Not Routable (Proxy) |
| 503 | Session Context Not Found |
| 504 | Session Context Not Removable |
| 505 | Other Proxy Processing Error |
| 506 | Resources Unavailable |
| 507 | Request Initiated |
| 508 | Multiple Session Selection Unsupported |

Preconditions

To use the CoA interface, a session must already exist on the switch. CoA can be used to identify a session and enforce a disconnect request. The update affects only the specified session.

CoA Request Response Code

The CoA Request response code can be used to convey a command to the switch.

The packet format for a CoA Request Response code as defined in RFC 5176 consists of the following fields: Code, Identifier, Length, Authenticator, and Attributes in the Type:Length:Value (TLV) format. The Attributes field is used to carry Cisco vendor-specific attributes (VSAs).

Session Identification

For disconnect and CoA requests targeted at a particular session, the switch locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)

- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31 which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

Unless all session identification attributes included in the CoA message match the session, the switch returns a Disconnect-NAK or CoA-NAK with the “Invalid Attribute Value” error-code attribute.

If more than one session identification attribute is included in the message, all the attributes must match the session or the switch returns a Disconnect- negative acknowledgment (NAK) or CoA-NAK with the error code “Invalid Attribute Value.”

The packet format for a CoA Request code as defined in RFC 5176 consists of the fields: Code, Identifier, Length, Authenticator, and Attributes in Type:Length:Value (TLV) format.

The attributes field is used to carry Cisco vendor-specific attributes (VSAs).

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code “Invalid Attribute Value” if any of the above session identification attributes are included in the message.

Session Identification

For disconnect and CoA requests targeted at a particular session, the device locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31, which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address

- Plain IP Address (IETF attribute #8)

If more than one session identification attribute is included in the message, all of the attributes must match the session or the device returns a Disconnect-NAK or CoA-NAK with the error code “Invalid Attribute Value.”

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code “Invalid Attribute Value” if any of the above session identification attributes are included in the message.

CoA ACK Response Code

If the authorization state is changed successfully, a positive acknowledgment (ACK) is sent. The attributes returned within CoA ACK will vary based on the CoA Request and are discussed in individual CoA Commands.

CoA NAK Response Code

A negative acknowledgment (NAK) indicates a failure to change the authorization state and can include attributes that indicate the reason for the failure. Use **show** commands to verify a successful CoA.

Session Reauthentication

The AAA server typically generates a session reauthentication request when a host with an unknown identity or posture joins the network and is associated with a restricted access authorization profile (such as a guest VLAN). A reauthentication request allows the host to be placed in the appropriate authorization group when its credentials are known.

To initiate session authentication, the AAA server sends a standard CoA-Request message which contains a Cisco VSA in this form: *Cisco:Avpair=“subscriber:command=reauthenticate”* and one or more session identification attributes.

The current session state determines the switch response to the message. If the session is currently authenticated by IEEE 802.1x, the switch responds by sending an EAPoL (Extensible Authentication Protocol over Lan) -RequestId message to the server.

If the session is currently authenticated by MAC authentication bypass (MAB), the switch sends an access-request to the server, passing the same identity attributes used for the initial successful authentication.

If session authentication is in progress when the switch receives the command, the switch terminates the process, and restarts the authentication sequence, starting with the method configured to be attempted first.

If the session is not yet authorized, or is authorized via guest VLAN, or critical VLAN, or similar policies, the reauthentication message restarts the access control methods, beginning with the method configured to be attempted first. The current authorization of the session is maintained until the reauthentication leads to a different authorization result.

Session Reauthentication in a Switch Stack

When a switch stack receives a session reauthentication message:

- It checkpoints the need for a re-authentication before returning an acknowledgment (ACK).
- It initiates reauthentication for the appropriate session.

- If authentication completes with either success or failure, the signal that triggered the reauthentication is removed from the stack's member switch.
- If the stack's active switch fails before authentication completes, reauthentication is initiated after active switch changeover based on the original command (which is subsequently removed).
- If the active switch fails before sending an ACK, the new active switch treats the re-transmitted command as a new command.

Session Termination

There are three types of CoA requests that can trigger session termination. A CoA Disconnect-Request terminates the session, without disabling the host port. This command causes re-initialization of the authenticator state machine for the specified host, but does not restrict that host access to the network.

To restrict a host's access to the network, use a CoA Request with the Cisco:Avpair="subscriber:command=disable-host-port" VSA. This command is useful when a host is known to be causing problems on the network, and you need to immediately block network access for the host. When you want to restore network access on the port, re-enable it using a non-RADIUS mechanism.

When a device with no supplicant, such as a printer, needs to acquire a new IP address (for example, after a VLAN change), terminate the session on the host port with port-bounce (temporarily disable and then re-enable the port).

CoA Activate Service Command

The CoA activate service command can be used to activate a service template on a session. The AAA server sends the request in a standard CoA-Request message using the following VSAs:

```
Cisco:Avpair="subscriber:command=activate-service"
```

```
Cisco:Avpair="subscriber:service-name=<service-name>"
```

```
Cisco:Avpair="subscriber:precedence=<precedence-number>"
```

```
Cisco:Avpair="subscriber:activation-mode=replace-all"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the *Session Identification* section below. If the device cannot locate a session, it returns a CoA-NAK message with the "Session Context Not Found" error-code attribute. If the device locates a session, it initiates an activate template operation for the hosting port and a CoA-ACK is returned. If activating the template fails, a CoA-NAK message is returned with the Error-Code attribute set to the appropriate message.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation is complete, the operation is restarted on the new active device.

Session Identification

For disconnect and CoA requests targeted at a particular session, the device locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)

- Calling-Station-Id (IETF attribute #31, which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

If more than one session identification attribute is included in the message, all of the attributes must match the session or the device returns a Disconnect-NAK or CoA-NAK with the error code “Invalid Attribute Value.”

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code “Invalid Attribute Value” if any of the above session identification attributes are included in the message.

CoA Deactivate Service Command

The CoA deactivate service command can be used to deactivate a service template on a session. The AAA server sends the request in a standard CoA-Request message using the following VSAs:

```
Cisco:Avpair="subscriber:command=deactivate-service"
```

```
Cisco:Avpair="subscriber:service-name=<service-name>"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the *Session Identification* section below. If the device cannot locate a session, it returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the device locates a session, it initiates a deactivate template operation for the hosting port and a CoA-ACK is returned. If deactivating the template fails, a CoA-NAK message is returned with the Error-Code attribute set to the appropriate message.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation is complete, the operation is restarted on the new active device.

Session Identification

For disconnect and CoA requests targeted at a particular session, the device locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31, which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

If more than one session identification attribute is included in the message, all of the attributes must match the session or the device returns a Disconnect-NAK or CoA-NAK with the error code “Invalid Attribute Value.”

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code “Invalid Attribute Value” if any of the above session identification attributes are included in the message.

CoA Request: Disable Host Port

The RADIUS server CoA disable port command administratively shuts down the authentication port that is hosting a session, resulting in session termination. This command is useful when a host is known to cause problems on the network and network access needs to be immediately blocked for the host. To restore network access on the port, reenable it using a non-RADIUS mechanism. This command is carried in a standard CoA-Request message that has this new vendor-specific attribute (VSA):

```
Cisco:Avpair="subscriber:command=disable-host-port"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the “Session Identification” section. If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port and returns a CoA-ACK message.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is restarted on the new active switch.

Note A Disconnect-Request failure following command re-sending could be the result of either a successful session termination before change-over (if the Disconnect-ACK was not sent) or a session termination by other means (for example, a link failure) that occurred after the original command was issued and before the standby switch became active.

CoA Request: Bounce-Port

A RADIUS server CoA bounce port sent from a RADIUS server can cause a link flap on an authentication port, which triggers DHCP renegotiation from one or more hosts connected to this port. This incident can occur when there is a VLAN change and the endpoint is a device (such as a printer) that does not have a mechanism to detect a change on this authentication port. The CoA bounce port is carried in a standard CoA-Request message that contains the following VSA:

```
Cisco:Avpair="subscriber:command=bounce-host-port"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes. If the session cannot be located, the switch returns a CoA-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the switch disables the hosting port for a period of 10 seconds, re-enables it (port-bounce), and returns a CoA-ACK.

If the switch fails before returning a CoA-ACK to the client, the process is repeated on the new active switch when the request is re-sent from the client. If the switch fails after returning a CoA-ACK message to the client but before the operation has completed, the operation is re-started on the new active switch.

CoA Session Query Command

The CoA session query command requests service information about a subscriber session. The AAA server sends the request in a standard CoA-Request message containing the following VSA:

```
Cisco:Avpair="subscriber:command=session-query"
```

Because this command is session-oriented, it must be accompanied by one or more of the session identification attributes described in the *Session Identification* section below. If the device cannot locate a session, it returns a CoA-NAK message with the "Session Context Not Found" error-code attribute. If the device locates a session, it performs a session query operation on the session and returns a CoA-ACK message.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation is complete, the operation is restarted on the new active device.

Session Identification

For disconnect and CoA requests targeted at a particular session, the device locates the session based on one or more of the following attributes:

- Acct-Session-Id (IETF attribute #44)
- Audit-Session-Id (Cisco VSA)
- Calling-Station-Id (IETF attribute #31, which contains the host MAC address)
- IPv6 Attributes, which can be one of the following:
 - Framed-IPv6-Prefix (IETF attribute #97) and Framed-Interface-Id (IETF attribute #96), which together create a full IPv6 address per RFC 3162
 - Framed-IPv6-Address
- Plain IP Address (IETF attribute #8)

If more than one session identification attribute is included in the message, all of the attributes must match the session or the device returns a Disconnect-NAK or CoA-NAK with the error code "Invalid Attribute Value."

For CoA requests targeted at a particular enforcement policy, the device returns a CoA-NAK with the error code "Invalid Attribute Value" if any of the above session identification attributes are included in the message.

CoA Session Reauthenticate Command

To initiate session authentication, the AAA server sends a standard CoA-Request message containing the following VSAs:

```
Cisco:Avpair="subscriber:command=reauthenticate"
```

```
Cisco:Avpair="subscriber:reauthenticate-type=<last | rerun>"
```

"reauthenticate-type" defines whether the CoA reauthentication request uses the authentication method that last succeeded on the session or whether the authentication process is completely rerun.

The following rules apply:

- "subscriber:command=reauthenticate" must be present to trigger a reauthentication.

- If “subscriber:reauthenticate-type” is not specified, the default behavior is to rerun the last successful authentication method for the session. If the method reauthenticates successfully, all old authorization data is replaced with the new reauthenticated authorization data.
- “subscriber:reauthenticate-type” is valid only when included with “subscriber:command=reauthenticate.” If it is included in another CoA command, the VSA will be silently ignored.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is resent from the client. If the device fails after returning a CoA-ACK message to the client but before the operation is complete, the operation is restarted on the new active device.

CoA Session Terminate Command

A CoA Disconnect-Request command terminates a session without disabling the host port. This command causes reinitialization of the authenticator state machine for the specified host, but does not restrict the host’s access to the network. If the session cannot be located, the device returns a Disconnect-NAK message with the “Session Context Not Found” error-code attribute. If the session is located, the device terminates the session. After the session has been completely removed, the device returns a Disconnect-ACK.

If the device fails before returning a CoA-ACK to the client, the process is repeated on the new active device when the request is re-sent from the client.

To restrict a host’s access to the network, use a CoA Request with the Cisco:Avpair=“subscriber:command=disable-host-port” VSA. This command is useful when a host is known to cause problems on the network and network access needs to be immediately blocked for the host. When you want to restore network access on the port, reenable it using a non-RADIUS mechanism.

Stacking Guidelines for Session Termination

No special handling is required for CoA Disconnect-Request messages in a switch stack.

Stacking Guidelines for CoA-Request Bounce-Port

Because the **bounce-port** command is targeted at a session, not a port, if the session is not found, the command cannot be executed.

When the Auth Manager command handler on the active switch receives a valid **bounce-port** command, it checkpoints the following information before returning a CoA-ACK message:

- the need for a port-bounce
- the port-id (found in the local session context)

The switch initiates a port-bounce (disables the port for 10 seconds, then re-enables it).

If the port-bounce is successful, the signal that triggered the port-bounce is removed from the standby switch.

If the active switch fails before the port-bounce completes, a port-bounce is initiated after an active switch changeover based on the original command (which is subsequently removed).

If the active switch fails before sending a CoA-ACK message, the new active switch treats the re-sent command as a new command.

Stacking Guidelines for CoA-Request Disable-Port

Because the **disable-port** command is targeted at a session, not a port, if the session is not found, the command cannot be executed.

When the Auth Manager command handler on the active switch receives a valid **disable-port** command, it verifies this information before returning a CoA-ACK message:

- the need for a port-disable
- the port-id (found in the local session context)

The switch attempts to disable the port.

If the port-disable operation is successful, the signal that triggered the port-disable is removed from the standby switch.

If the active switch fails before the port-disable operation completes, the port is disabled after an active switch changeover based on the original command (which is subsequently removed).

If the active switch fails before sending a CoA-ACK message, the new active switch treats the re-sent command as a new command.

How to Configure RADIUS Change-of-Authorization

Configuring CoA on the Device

Follow these steps to configure CoA on a device. This procedure is required.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa new-model Example: Device(config)# aaa new-model | Enables AAA. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 4 | aaa server radius dynamic-author Example: Device(config)# aaa server radius dynamic-author | Configures the device as an authentication, authorization, and accounting (AAA) server to facilitate interaction with an external policy server. |
| Step 5 | client {ip-address name} [vrf vrfname] [server-key string] | Enters dynamic authorization local server configuration mode and specifies a RADIUS client from which a device will accept CoA and disconnect requests. |
| Step 6 | server-key [0 7] string Example: Device(config-sg-radius)# server-key your_server_key | Configures the RADIUS key to be shared between a device and RADIUS clients. |
| Step 7 | port port-number Example: Device(config-sg-radius)# port 25 | Specifies the port on which a device listens for RADIUS requests from configured RADIUS clients. |
| Step 8 | auth-type {any all session-key} Example: Device(config-sg-radius)# auth-type any | Specifies the type of authorization the device uses for RADIUS clients. The client must match all the configured attributes for authorization. |
| Step 9 | ignore session-key | (Optional) Configures the device to ignore the session-key. For more information about the ignore command, see the <i>Cisco IOS Intelligent Services Gateway Command Reference</i> on Cisco.com. |
| Step 10 | ignore server-key Example: Device(config-sg-radius)# ignore server-key | (Optional) Configures the device to ignore the server-key. For more information about the ignore command, see the <i>Cisco IOS Intelligent Services Gateway Command Reference</i> on Cisco.com. |
| Step 11 | authentication command bounce-port ignore Example: | (Optional) Configures the device to ignore a CoA request to temporarily disable the port hosting a session. The purpose of temporarily |

| | Command or Action | Purpose |
|----------------|---|--|
| | Device (config-sg-radius) # authentication command bounce-port ignore | disabling the port is to trigger a DHCP renegotiation from the host when a VLAN change occurs and there is no supplicant on the endpoint to detect the change. |
| Step 12 | authentication command disable-port ignore Example: Device (config-sg-radius) # authentication command disable-port ignore | (Optional) Configures the device to ignore a nonstandard command requesting that the port hosting a session be administratively shut down. Shutting down the port results in termination of the session. Use standard CLI or SNMP commands to re-enable the port. |
| Step 13 | end Example: Device (config-sg-radius) # end | Returns to privileged EXEC mode. |
| Step 14 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 15 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Monitoring and Troubleshooting CoA Functionality

The following Cisco IOS commands can be used to monitor and troubleshoot CoA functionality on the switch:

- **debug radius**
- **debug aaa coa**
- **debug aaa pod**
- **debug aaa subsystem**
- **debug cmdhd [detail | error | events]**
- **show aaa attributes protocol radius**

Feature Information for RADIUS Change-of-Authorization Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 110: Feature Information for RADIUS Change-of-Authorization Support

| Feature Name | Releases | Feature Information |
|-----------------------------------|----------------------------|--|
| RADIUS Change-of-Authorization | Cisco IOS Release 15.2(1)E | <p>Supports CoA requests for initiating the following:</p> <ul style="list-style-type: none">• Activating and deactivating service templates on sessions• Port bounce• Port shutdown• Querying a session• Reauthenticating a session• Terminating a session <p>These VSAs are sent in a standard CoA-Request message from a AAA server.</p> |

CHAPTER 47

Configuring Kerberos

Kerberos is a secret-key network authentication protocol, developed at the Massachusetts Institute of Technology (MIT), that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources. Kerberos, like other secret-key systems, is based on the concept of a trusted third party that performs secure verification of users and services. In the Kerberos protocol, this trusted third party is called the key distribution center (KDC).

- [How to Configure Kerberos, on page 916](#)
- [Configuration Examples for Kerberos, on page 922](#)
- [Additional References, on page 932](#)
- [Feature Information for Kerberos, on page 933](#)

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Controlling Switch Access with Kerberos

The following are the prerequisites for controlling switch access with Kerberos.

- So that remote users can authenticate to network services, you must configure the hosts and the KDC in the Kerberos realm to communicate and mutually authenticate users and network services. To do this, you must identify them to each other. You add entries for the hosts to the Kerberos database on the KDC and add KEYTAB files generated by the KDC to all hosts in the Kerberos realm. You also create entries for the users in the KDC database.

- A Kerberos server can be a switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

When you add or create entries for the hosts and users, follow these guidelines:

- The Kerberos principal name *must* be in all lowercase characters.
- The Kerberos instance name *must* be in all lowercase characters.
- The Kerberos realm name *must* be in all uppercase characters.

Information About Kerberos

Kerberos and Switch Access

This section describes how to enable and configure the Kerberos security system, which authenticates requests for network resources by using a trusted third party.

Note In the Kerberos configuration examples, the trusted third party can be any switch that supports Kerberos, that is configured as a network security server, and that can authenticate users by using the Kerberos protocol.

Kerberos Overview

Kerberos is a secret-key network authentication protocol, which was developed at the Massachusetts Institute of Technology (MIT). It uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication and authenticates requests for network resources. Kerberos uses the concept of a trusted third party to perform secure verification of users and services. This trusted third party is called the *key distribution center* (KDC).

Kerberos verifies that users are who they claim to be and the network services that they use are what the services claim to be. To do this, a KDC or trusted Kerberos server issues tickets to users. These tickets, which have a limited life span, are stored in user credential caches. The Kerberos server uses the tickets instead of user names and passwords to authenticate users and network services.

Note A Kerberos server can be any switch that is configured as a network security server and that can authenticate users by using the Kerberos protocol.

The Kerberos credential scheme uses a process called *single logon*. This process authenticates a user once and then allows secure authentication (without encrypting another password) wherever that user credential is accepted.

This software release supports Kerberos 5, which allows organizations that are already using Kerberos 5 to use the same Kerberos authentication database on the KDC that they are already using on their other network hosts (such as UNIX servers and PCs).

Kerberos supports these network services:

- Telnet
- rlogin
- rsh

This table lists the common Kerberos-related terms and definitions.

Table 111: Kerberos Terms

| Term | Definition |
|------------------|---|
| Authentication | A process by which a user or service identifies itself to another service. For example, a client can authenticate to a switch or a switch can authenticate to another switch. |
| Authorization | A means by which the switch identifies what privileges the user has in a network or on the switch and what actions the user can perform. |
| Credential | A general term that refers to authentication tickets, such as TGTs ⁸ and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of re-entering a username and password. Credentials have a default life span of eight hours. |
| Instance | An authorization level label for Kerberos principals. Most Kerberos principals are of the form <i>user@REALM</i> (for example, <i>smith@EXAMPLE.COM</i>). A Kerberos principal with a Kerberos instance has the form <i>user/instance@REALM</i> (for example, <i>smith/admin@EXAMPLE.COM</i>). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. The server of each network service might implement and enforce the authorization mappings of Kerberos instances but is not required to do so. Note The Kerberos principal and instance names <i>must</i> be in all lowercase characters. Note The Kerberos realm name <i>must</i> be in all uppercase characters. |
| KDC ⁹ | Key distribution center that consists of a Kerberos server and database program that is running on a network host. |
| Kerberized | A term that describes applications and services that have been modified to support the Kerberos credential infrastructure. |
| Kerberos realm | A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service. Note The Kerberos realm name <i>must</i> be in all uppercase characters. |
| Kerberos server | A daemon that is running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services. |

| Term | Definition |
|----------------------|--|
| KEYTAB ¹⁰ | A password that a network service shares with the KDC. In Kerberos 5 and later Kerberos versions, the network service authenticates an encrypted service credential by using the KEYTAB to decrypt it. In Kerberos versions earlier than Kerberos 5, KEYTAB is referred to as SRVTAB ¹¹ . |
| Principal | Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server. Note The Kerberos principal name <i>must</i> be in all lowercase characters. |
| Service credential | A credential for a network service. When issued from the KDC, this credential is encrypted with the password shared by the network service and the KDC. The password is also shared with the user TGT. |
| SRVTAB | A password that a network service shares with the KDC. In Kerberos 5 or later Kerberos versions, SRVTAB is referred to as KEYTAB. |
| TGT | Ticket granting ticket that is a credential that the KDC issues to authenticated users. When users receive a TGT, they can authenticate to network services within the Kerberos realm represented by the KDC. |

⁸ ticket granting ticket

⁹ key distribution center

¹⁰ key table

¹¹ server table

Kerberos Operation

A Kerberos server can be a switch that is configured as a network security server and that can authenticate remote users by using the Kerberos protocol. Although you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

Kerberos Operation

A Kerberos server can be a device that is configured as a network security server and that can authenticate remote users by using the Kerberos protocol. Although you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

To authenticate to network services by using a device as a Kerberos server, remote users must follow these steps:

Authenticating to a Boundary Switch

This section describes the first layer of security through which a remote user must pass. The user must first authenticate to the boundary switch. This process then occurs:

1. The user opens an un-Kerberized Telnet connection to the boundary switch.

2. The switch prompts the user for a username and password.
3. The switch requests a TGT from the KDC for this user.
4. The KDC sends an encrypted TGT that includes the user identity to the switch.
5. The switch attempts to decrypt the TGT by using the password that the user entered.
 - If the decryption is successful, the user is authenticated to the switch.
 - If the decryption is not successful, the user repeats Step 2 either by re-entering the username and password (noting if Caps Lock or Num Lock is on or off) or by entering a different username and password.

A remote user who initiates a un-Kerberized Telnet session and authenticates to a boundary switch is inside the firewall, but the user must still authenticate directly to the KDC before getting access to the network services. The user must authenticate to the KDC because the TGT that the KDC issues is stored on the switch and cannot be used for additional authentication until the user logs on to the switch.

Obtaining a TGT from a KDC

This section describes the second layer of security through which a remote user must pass. The user must now authenticate to a key distribution center (KDC) and obtain a ticket granting ticket (TGT) from the KDC to access network services.

When a remote user authenticates to a boundary device, that user technically becomes part of the network; that is, the network is extended to include the remote user and the user's machine or network. To gain access to network services, however, the remote user must obtain a TGT from the KDC. The following process describes how remote users authenticate to the KDC:

1. The remote user, at a workstation on a remote site, launches the KINIT program (part of the client software provided with the Kerberos protocol).
2. The KINIT program finds the identity of the user and requests a TGT from the KDC.
3. The KDC creates a TGT, which contains the identity of the user, the identity of the KDC, and the expiration time of the TGT.
4. Using the user's password as a key, the KDC encrypts the TGT and sends the TGT to the workstation.
5. When the KINIT program receives the encrypted TGT, it prompts the user for a password (this is the password that is defined for the user in the KDC).
6. If the KINIT program can decrypt the TGT with the password the user enters, the user is authenticated to the KDC, and the KINIT program stores the TGT in the user's credential cache.

At this point, the user has a TGT and can communicate securely with the KDC. In turn, the TGT allows the user to authenticate to other network services.

Authenticating to Network Services

This section describes the third layer of security through which a remote user must pass. The user with a ticket granting ticket (TGT) must now authenticate to the network services in a Kerberos realm.

The following process describes how a remote user with a TGT authenticates to network services within a given Kerberos realm. Assume the user is on a remote workstation (Host A) and wants to log in to Host B.

1. The user on Host A initiates a Kerberized application (such as Telnet) to Host B.
2. The Kerberized application builds a service credential request and sends it to the KDC. The service credential request includes (among other things) the user's identity and the identity of the desired network service. The TGT is used to encrypt the service credential request.
3. The KDC tries to decrypt the service credential request with the TGT it issued to the user on Host A. If the KDC can decrypt the packet, it is assured that the authenticated user on Host A sent the request.
4. The KDC notes the network service identity in the service credential request.
5. The KDC builds a service credential for the appropriate network service on Host B on behalf of the user on Host A. The service credential contains the client's identity and the desired network service's identity.
6. The KDC then encrypts the service credential twice. It first encrypts the credential with the SRVTAB that it shares with the network service identified in the credential. It then encrypts the resulting packet with the TGT of the user (who, in this case, is on Host A).
7. The KDC sends the twice-encrypted credential to Host A.
8. Host A attempts to decrypt the service credential with the user's TGT. If Host A can decrypt the service credential, it is assured the credential came from the real KDC.
9. Host A sends the service credential to the desired network service. Note that the credential is still encrypted with the SRVTAB shared by the KDC and the network service.
10. The network service attempts to decrypt the service credential using its SRVTAB.
11. If the network service can decrypt the credential, it is assured the credential was in fact issued from the KDC. Note that the network service trusts anything it can decrypt from the KDC, even if it receives it indirectly from a user. This is because the user first authenticated with the KDC.

At this point, the user is authenticated to the network service on Host B. This process is repeated each time a user wants to access a network service in the Kerberos realm.

How to Configure Kerberos

To set up a Kerberos-authenticated server-client system, follow these steps:

- Configure the KDC by using Kerberos commands.
- Configure the switch to use the Kerberos protocol.

Configuring the KDC Using Kerberos Commands

After a host is configured to function as the KDC in the Kerberos realm, entries must be made to the KDC database (and to modify existing database information) for all principals in the realm. Principals can be network services on devices and hosts or principals can be users.

Note All Kerberos command examples are based on Kerberos 5 Beta 5 of the original MIT implementation. Later versions use a slightly different interface.

Adding Users to the KDC Database

Follow these steps to add users to the KDC and create privileged instances for those users:

Procedure

Step 1 Use the **su** command to become root on the host running the KDC.

Step 2 Use the **kdb5_edit** program to configure the commands in the next steps.

Note The Kerberos realm name in the following steps must be in uppercase characters.

Step 3 Use the **ank** (add new key) command in privileged EXEC mode to add a user to the KDC. This command prompts for a password that the user must enter to authenticate the router. For example:

Example:

```
Device # ank username@REALM
```

Step 4 Use the **ank** command to add a privileged instance of a user. For example:

```
Device # ank username/instance@REALM
```

Example

The following example adds the user *loki* to the Kerberos realm COMPANY.COM:

```
ank loki@COMPANY.COM
```

Privileged instances can be created to allow network administrators to connect to the router at the enable level so that a clear text password is not used to avoid compromising security and to enter enabled modes. See the [Enabling Kerberos Instance Mapping, on page 922](#) for more information on mapping Kerberos instances to various Cisco IOS privilege levels.

Creating and Extracting a SRVTAB on the KDC

All devices authenticated through Kerberos must have a SRVTAB that contains the password or randomly generated key for the service principal key that was entered into the KDC database. A service principal key must be shared with the host running that service. To do this, the SRVTAB entry must be saved (extracted) to a file and copied to the device and all hosts in the Kerberos realm.

Follow these steps to make a SRVTAB entry and extract this SRVTAB to a file on the KDC in privileged EXEC mode:

Procedure

Step 1 Use the **ark** (add random key) command to add a network service supported by a host or device to the KDC. For example:

Example:

```
Device# ark
SERVICE/HOSTNAME@REALM
```

Step 2 Use the **kdb5_edit** command **xst** to write an SRVTAB entry to a file. For example:

Example:

```
Device# xst
device-name host
```

Step 3 Use the **quit** command to exit the **kdb5_edit** program.

Example

The following example shows how to add a Kerberized authentication service for a device called *device1* to the Kerberos realm COMPANY.COM:

```
ark host/device1.company.com@COMPANY.COM
```

The following example shows how to write an entry for all network services on all Kerberized hosts that use this KDC for authentication to a file:

```
xst device1.company.com@COMPANY.COM host
```

Configuring the Device to Use the Kerberos Protocol

Defining a Kerberos Realm

For a device to authenticate a user defined in the Kerberos database, it must know the host name or IP address of the host running the KDC, the name of the Kerberos realm and, optionally, be able to map the host name or Domain Name System (DNS) domain to the Kerberos realm.

To configure the device to authenticate to a specified KDC in a specified Kerberos realm, use the following commands in global configuration mode. Note that DNS domain names must begin with a leading dot (.):

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | Device(config)# kerberos local-realm <i>kerberos-realm</i> | Defines the default realm for the device. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 2 | Device(config)# kerberos server <i>kerberos-realm {hostname ip-address } [port-number]</i> | Specifies to the device which KDC to use in a given Kerberos realm and, optionally, the port number that the KDC is monitoring. (The default is 88.) |
| Step 3 | Device(config)# kerberos realm <i>{dns-domain host } kerberos-realm</i> | (Optional) Maps a host name or DNS domain to a Kerberos realm. |

What to do next

Note Because the machine running the KDC and all Kerberized hosts must interact within a 5-minute window or authentication fails, all Kerberized machines, and especially the KDC, should be running the Network Time Protocol (NTP).

The **kerberos local-realm**, **kerberos realm**, and **kerberos server** commands are equivalent to the UNIX `krb.conf` file. The table below identifies mappings from the Cisco IOS configuration commands to a Kerberos 5 configuration file (`krb5.conf`).

Table 112: Kerberos 5 Configuration File and Commands

| krb5.conf File | Cisco IOS Configuration Command |
|--|--|
| [libdefaults] default_realm = DOMAIN.COM | (in configuration mode) kerberos local-realm DOMAIN.COM |
| [domain_realm] .domain.com = DOMAIN.COM domain.com = DOMAIN.COM | (in configuration mode) kerberos realm .domain.com DOMAIN.COM kerberos realm domain.com DOMAIN.COM |
| [realms] kdc = DOMAIN.PIL.COM:750 admin_server = DOMAIN.PIL.COM default_domain = DOMAIN.COM | (in configuration mode) kerberos server DOMAIN.COM 172.65.44.2 (172.65.44.2 is the example IP address for DOMAIN.PIL.COM) |

Copying SRVTAB Files

To make it possible for remote users to authenticate to the device using Kerberos credentials, the device must share a secret key with the KDC. To do this, you must give the device a copy of the SRVTAB you extracted on the KDC.

The most secure method to copy an SRVTAB file to the hosts in your Kerberos realm is to copy it onto physical media and go to each host in turn and manually copy the files onto the system. To copy an SRVTAB file to the device, which does not have a physical media drive, it must be transferred over the network using TFTP.

To remotely copy an SRVTAB file to the device from the KDC, use the **kerberos srvtab remote** command in global configuration mode:

```
Device(config)# kerberos srvtab remote {hostname | ip-address } {filename }
```

When you copy the SRVTAB file from the device to the KDC, the **kerberos srvtab remote** command parses the information in this file and stores it in the running configuration of the device, in the **kerberos srvtab entry** format. To ensure that the SRVTAB is available (does not need to be acquired from the KDC) when you reboot the device, use the **write memory** configuration command to write your running configuration (which contains the parsed SRVTAB file) to NVRAM.

Specifying Kerberos Authentication

See the Configuring Authentication feature module for more information on configuring authentication on the device **aaa authentication** command is used to specify Kerberos as the authentication method.

Enabling Credentials Forwarding

With Kerberos configured thus far, a user authenticated to a Kerberized device has a TGT and can use it to authenticate to a host on the network. However, if the user tries to list credentials after authenticating to a host, the output will show no Kerberos credentials present.

You can optionally configure the device to forward users' TGTs with them as they authenticate from the device to Kerberized remote hosts on the network when using Kerberized Telnet, rcp, rsh, and rlogin (with the appropriate flags).

To force all clients to forward users' credentials as they connect to other hosts in the Kerberos realm, use the following command in global configuration mode:

| Command | Purpose |
|---|---|
| Device(config)# kerberos credentials forward | Forces all clients to forward user credentials upon successful Kerberos authentication. |

With credentials forwarding enabled, users' TGTs are automatically forwarded to the next host they authenticate to. In this way, users can connect to multiple hosts in the Kerberos realm without running the KINIT program each time to get a new TGT.

Opening a Telnet Session to a Device

To use Kerberos to authenticate users opening a Telnet session to the device from within the network, use the following command in global configuration mode:

| Command | Purpose |
|---|--|
| Device(config)# aaa authentication login {default list-name } krb5_telnet | Sets login authentication to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the device. |

Although Telnet sessions to the device are authenticated, users must still enter a clear text password if they want to enter enable mode. The **kerberos instance map** command, discussed in a later section, allows them to authenticate to the device at a predefined privilege level.

Establishing an Encrypted Kerberized Telnet Session

Another way for users to open a secure Telnet session is to use Encrypted Kerberized Telnet. With Encrypted Kerberized Telnet, users are authenticated by their Kerberos credentials before a Telnet session is established. The Telnet session is encrypted using 56-bit Data Encryption Standard (DES) encryption with 64-bit Cipher Feedback (CFB). Because data sent or received is encrypted, not clear text, the integrity of the dialed device or access server can be more easily controlled.

Note This feature is available only if you have the 56-bit encryption image. 56-bit DES encryption is subject to U.S. Government export control regulations.

To establish an encrypted Kerberized Telnet session from a device to a remote host, use either of the following commands in EXEC command mode:

| Command | Purpose |
|--|--|
| <pre>Device(config)# connect host [<i>port</i>] /encrypt kerberos or Device(config)# telnet host [<i>port</i>] /encrypt kerberos</pre> | Establishes an encrypted Telnet session. |

When a user opens a Telnet session from a device to a remote host, the device and remote host negotiate to authenticate the user using Kerberos credentials. If this authentication is successful, the device and remote host then negotiate whether or not to use encryption. If this negotiation is successful, both inbound and outbound traffic is encrypted using 56-bit DES encryption with 64-bit CFB.

When a user dials in from a remote host to a device configured for Kerberos authentication, the host and device will attempt to negotiate whether or not to use encryption for the Telnet session. If this negotiation is successful, the device will encrypt all outbound data during the Telnet session.

If encryption is not successfully negotiated, the session will be terminated and the user will receive a message stating that the encrypted Telnet session was not successfully established.

Enabling Mandatory Kerberos Authentication

As an added layer of security, you can optionally configure the device so that, after remote users authenticate to it, these users can authenticate to other services on the network only with Kerberized Telnet, rlogin, rsh, and rcp. If you do not make Kerberos authentication mandatory and Kerberos authentication fails, the application attempts to authenticate users using the default method of authentication for that network service; for example, Telnet and rlogin prompt for a password, and rsh attempts to authenticate using the local rhost file.

To make Kerberos authentication mandatory, use the following command in global configuration mode:

| Command | Purpose |
|--|--|
| Device (config)# kerberos clients mandatory | Sets Telnet, rlogin, rsh, and rcp to fail if they cannot negotiate the Kerberos protocol with the remote server. |

Enabling Kerberos Instance Mapping

You can create administrative instances of users in the KDC database. The **kerberos instance map** command allows you to map those instances to Cisco IOS privilege levels so that users can open secure Telnet sessions to the device at a predefined privilege level, obviating the need to enter a clear text password to enter enable mode.

To map a Kerberos instance to a Cisco IOS privilege level, use the following command in global configuration mode:

| Command | Purpose |
|--|--|
| Device (config)# kerberos instance map <i>instance</i> <i>privilege-level</i> | Maps a Kerberos instance to a Cisco IOS privilege level. |

If there is a Kerberos instance for user *loki* in the KDC database (for example, *loki/admin*), user *loki* can now open a Telnet session to the device as *loki/admin* and authenticate automatically at privilege level 15, assuming instance “admin” is mapped to privilege level 15.

Cisco IOS commands can be set to various privilege levels using the **privilege level** command.

After you map a Kerberos instance to a Cisco IOS privilege level, you must configure the device to check for Kerberos instances each time a user logs in. To run authorization to determine if a user is allowed to run an EXEC shell based on a mapped Kerberos instance, use the **aaa authorization** command with the **krb5-instance** keyword. For more information, refer to the chapter “Configuring Authorization.”

Monitoring the Kerberos Configuration

To display the Kerberos configuration, use the following commands:

- **show running-config**
- **show kerberos creds**: Lists the credentials in a current user’s credentials cache.
- **clear kerberos creds**: Destroys all credentials in a current user’s credentials cache, including those forwarded.

Configuration Examples for Kerberos

Example: Defining a Kerberos Realm

To define CISCO.COM as the default Kerberos realm, use the following command:

```
kerberos local-realm CISCO.COM
```

To tell the device that the CISCO.COM KDC is running on host 10.2.3.4 at port number 170, use the following Kerberos command:

```
kerberos server CISCO.COM 10.2.3.4 170
```

To map the DNS domain cisco.com to the Kerberos realm CISCO.COM, use the following command:

```
kerberos realm.cisco.com CISCO.COM
```

Example: Copying a SRVTAB File

To copy over the SRVTAB file on a host named host123.cisco.com for a device named device1.cisco.com, the command would look like this:

```
kerberos srvtab remote host123.cisco.com device1.cisco.com-new-srvtab
```

Example: Configuring Kerberos

This section provides a typical non-Kerberos device configuration and shows output for this configuration from the **write term** command, then builds on this configuration by adding optional Kerberos functionality. Output for each configuration is presented for comparison against the previous configuration.

This example shows how to use the `kdb5_edit` program to perform the following configuration tasks:

- Adding user chet to the Kerberos database
- Adding a privileged Kerberos instance of user chet (chet/admin) to the Kerberos database
- Adding a restricted instance of chet (chet/restricted) to the Kerberos database
- Adding workstation chet-ss20.cisco.com
- Adding device chet-2500.cisco.com to the Kerberos database
- Adding workstation chet-ss20.cisco.com to the Kerberos database
- Extracting SRVTABs for the device and workstations
- Listing the contents of the KDC database (with the **ldb** command)

Note In this sample configuration, host chet-ss20 is also the KDC:

```
chet-ss20# sbin/kdb5_edit
kdb5_edit: ank chet
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/admin
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/restricted
Enter password:
Re-enter password for verification:
kdb5_edit: ank host/chet-ss20.cisco.com
```

```

kdb5_edit: ark host/chet-2500.cisco.com
kdb5_edit: xst chet-ss20.cisco.com host
'host/chet-ss20.cisco.com@CISCO.COM' added to keytab 'WRFILE:chet-ss20.cisco.com-new-srvtab'
kdb5_edit: xst chet-2500.cisco.com host
'host/chet-2500.cisco.com@CISCO.COM' added to keytab 'WRFILE:chet-2500.cisco.com-new-srvtab'
kdb5_edit: ldb
entry: host/chet-2500.cisco.com@CISCO.COM
entry: chet/restricted@CISCO.COM
entry: chet@CISCO.COM
entry: K/M@CISCO.COM
entry: host/chet-ss20.cisco.com@CISCO.COM
entry: krbtgt/CISCO.COM@CISCO.COM
entry: chet/admin@CISCO.COM
kdb5_edit: q
chet-ss20#

```

The following example shows output from a **write term** command, which displays the configuration of device chet-2500. This is a typical configuration with no Kerberos authentication.

```

chet-2500# write term

The following example shows how to enable user authentication on the device via the Kerberos database. To enable user authentication via the Kerberos database, you would perform the following tasks:

- Entering configuration mode
- Defining the Kerberos local realm
- Identifying the machine hosting the KDC
- Enabling credentials forwarding
- Specifying Kerberos as the method of authentication for login
- Exiting configuration mode (CTL-Z)
- Writing the new configuration to the terminal

```

chet-2500# configure term
Enter configuration commands, one per line. End with CNTL/Z.
chet-2500(config)# kerberos local-realm CISCO.COM
chet-2500(config)# kerberos server CISCO.COM chet-ss20
Translating "chet-ss20"...domain server (192.168.0.0) [OK]
chet-2500(config)# kerberos credentials forward

```

```

chet-2500(config)# aaa authentication login default krb5
chet-2500(config)#
chet-2500#
%SYS-5-CONFIG_I: Configured from console by console
chet-2500# write term

```

Compare the following configuration with the previous one. In particular, look at the lines beginning with the words “aaa,” “username,” and “kerberos” (lines 10 through 20) in this new configuration.

```

With the device configured thus far, user chet can log in to the device with a username and password and automatically obtain a TGT, as illustrated in the next example. With possession of a credential, user chet successfully authenticates to host chet-ss20 without entering a username/password.

```

chet-ss20% telnet chet-2500

```

The following example shows how to authenticate to the device using Kerberos credentials. To authenticate using Kerberos credentials, you would perform the following tasks:

- Entering configuration mode
- Remotely copying over the SRVTAB file from the KDC

- Setting authentication at login to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the device
- Writing the configuration to the terminal

Note that the new configuration contains a **kerberos srvtab entry** line. This line is created by the **kerberos srvtab remotecommand**.

```

chet-2500# configure term
Enter configuration commands, one per line. End with CNTL/Z.

CHAPTER 48

Configuring Accounting

The AAA Accounting feature allows the services that users are accessing and the amount of network resources that users are consuming to be tracked. When AAA Accounting is enabled, the network access server reports user activity to the TACACS+ or RADIUS security server (depending on which security method is implemented) in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, and auditing.

- [Prerequisites for Configuring Accounting, on page 935](#)
- [Restrictions for Configuring Accounting, on page 935](#)
- [Information About Configuring Accounting, on page 936](#)
- [How to Configure Accounting, on page 949](#)
- [Configuration Examples for Accounting, on page 957](#)
- [Additional References for Configuring Accounting, on page 961](#)
- [Feature Information for Configuring Accounting, on page 962](#)

Prerequisites for Configuring Accounting

The following tasks must be performed before configuring accounting using named method lists:

- Enable AAA on the network access server by using the **aaa new-model** command in global configuration mode.
- Define the characteristics of the RADIUS or TACACS+ security server if RADIUS or TACACS+ authorization is issued. For more information about configuring the Cisco network access server to communicate with the RADIUS security server, see the Configuring RADIUS module. For more information about configuring the Cisco network access server to communicate with the TACACS+ security server, see the Configuring TACACS+ module.

Restrictions for Configuring Accounting

- Accounting information can be sent simultaneously to a maximum of only four AAA servers.
- For Service Selection Gateway (SSG) systems, the **aaa accounting network broadcast** command broadcasts only **start-stop** accounting records. If interim accounting records are configured using the

ssg accounting interval command, the interim accounting records are sent only to the configured default RADIUS server.

Information About Configuring Accounting

Named Method Lists for Accounting

Similar to authentication and authorization method lists, method lists for accounting define the way accounting is performed and the sequence in which these methods are performed.

Named accounting method lists allow particular security protocol to be designated and used on specific lines or interfaces for accounting services. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is simply a named list describing the accounting methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists allow one or more security protocols to be designated and used for accounting, thus ensuring a backup system for accounting in case the initial method fails. Cisco IOS software uses the first method listed to support accounting; if that method fails to respond, the Cisco IOS software selects the next accounting method listed in the method list. This process continues until there is successful communication with a listed accounting method, or all methods defined are exhausted.

Note The Cisco IOS software attempts accounting with the next listed accounting method only when there is no response from the previous method. If accounting fails at any point in this cycle--meaning that the security server responds by denying the user access--the accounting process stops and no other accounting methods are attempted.

Accounting method lists are specific to the type of accounting being requested. AAA supports seven different types of accounting:

- **Network** --Provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.
- **EXEC** --Provides information about user EXEC terminal sessions of the network access server.
- **Commands** --Provides information about the EXEC mode commands that a user issues. Command accounting generates accounting records for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **Connection** --Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.
- **System** --Provides information about system-level events.
- **Resource** --Provides “start” and “stop” records for calls that have passed user authentication, and provides “stop” records for calls that fail to authenticate.
- **VRRS** --Provides information about Virtual Router Redundancy Service (VRRS).

Note System accounting does not use named accounting lists; only the default list for system accounting can be defined.

Once again, when a named method list is created, a particular list of accounting methods for the indicated accounting type are defined.

Accounting method lists must be applied to specific lines or interfaces before any of the defined methods are performed. The only exception is the default method list (which is named “default”). If the **aaa accounting** command for a particular accounting type is issued without specifying a named method list, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined (A defined method list overrides the default method list). If no default method list is defined, then no accounting takes place.

This section includes the following subsections:

Method Lists and Server Groups

A server group is a way to group existing LDAP, RADIUS, or TACACS+ server hosts for use in method lists. The figure below shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Using server groups, a subset of the configured server hosts can be specified and use them for a particular service. For example, server groups allows R1 and R2 to be defined as separate server groups, and T1 and T2 as separate server groups. This allows either R1 and T1 to be specified in the method list or R2 and T2 in the method list, which provides more flexibility in the way that RADIUS and TACACS+ resources are assigned.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service--for example, authorization--the second host entry configured acts as fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order they are configured.)

AAA Accounting Methods

The Cisco IOS software supports the following two methods for accounting:

- **TACACS+--**The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.
- **RADIUS--**The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.

Note With CSCuc32663, passwords and accounting logs are masked before being sent to the TACACS+ or RADIUS security servers. Use the **aaa accounting commands visible-keys** command to send unmasked information to the TACACS+ or RADIUS security servers.

Accounting Record Types

For minimal accounting, use the **stop-only** keyword, which instructs the specified method (**RADIUS** or **TACACS+**) to send a stop record accounting notice at the end of the requested user process. For more accounting information, use the **start-stop** keyword to send a start accounting notice at the beginning of the requested event and a stop accounting notice at the end of the event. To stop all accounting activities on this line or interface, use the **none** keyword.

AAA Accounting Methods

The Cisco IOS software supports the following two methods for accounting:

- **TACACS+**--The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.
- **RADIUS**--The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting AV pairs and is stored on the security server.

Note With CSCuc32663, passwords and accounting logs are masked before being sent to the TACACS+ or RADIUS security servers. Use the **aaa accounting commands visible-keys** command to send unmasked information to the TACACS+ or RADIUS security servers.

AAA Accounting Types

Network Accounting

Network accounting provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through an EXEC session:

```
Wed Jun 27 04:44:45 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 5
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "562"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "0000000D"
```

```

Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:45:00 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000E"
Framed-IP-Address = "10.1.1.2"
Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:47:46 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000E"
Framed-IP-Address = "10.1.1.2"
Framed-Protocol = PPP
Acct-Input-Octets = 3075
Acct-Output-Octets = 167
Acct-Input-Packets = 39
Acct-Output-Packets = 9
Acct-Session-Time = 171
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:48:45 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "408"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "0000000D"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who first started an EXEC session:

```

Wed Jun 27 04:00:35 2001 172.16.25.15  username1  tty4  562/4327528  starttask_id=28
      service=shell
Wed Jun 27 04:00:46 2001 172.16.25.15  username1  tty4  562/4327528  starttask_id=30
      addr=10.1.1.1  service=ppp
Wed Jun 27 04:00:49 2001 172.16.25.15  username1  tty4  408/4327528  update
task_id=30  addr=10.1.1.1  service=ppp  protocol=ip  addr=10.1.1.1
Wed Jun 27 04:01:31 2001 172.16.25.15  username1  tty4  562/4327528  stoptask_id=30
      addr=10.1.1.1  service=ppp  protocol=ip  addr=10.1.1.1  bytes_in=2844

```

```

bytes_out=1682 paks_in=36 paks_out=24 elapsed_time=51
Wed Jun 27 04:01:32 2001 172.16.25.15 username1 tty4 562/4327528 stoptask_id=28
service=shell elapsed_time=57

```

Note The precise format of accounting packets records may vary depending on the security server daemon.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:30:52 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

```

Wed Jun 27 04:36:49 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Framed-IP-Address = "10.1.1.1"
Acct-Input-Octets = 8630
Acct-Output-Octets = 5722
Acct-Input-Packets = 94
Acct-Output-Packets = 64
Acct-Session-Time = 357
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:02:19 2001 172.16.25.15 username1 Async5 562/4327528 starttask_id=35
service=ppp
Wed Jun 27 04:02:25 2001 172.16.25.15 username1 Async5 562/4327528 update
task_id=35 service=ppp protocol=ip addr=10.1.1.2
Wed Jun 27 04:05:03 2001 172.16.25.15 username1 Async5 562/4327528 stoptask_id=35
service=ppp protocol=ip addr=10.1.1.2 bytes_in=3366 bytes_out=2149
paks_in=42 paks_out=28 elapsed_time=164

```

EXEC Accounting

EXEC accounting provides information about user EXEC terminal sessions (user shells) on the network access server, including username, date, start and stop times, the access server IP address, and (for dial-in users) the telephone number the call originated from.

The following example shows the information contained in a RADIUS EXEC accounting record for a dial-in user:

```
Wed Jun 27 04:26:23 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 1
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "5622329483"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000006"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
Wed Jun 27 04:27:25 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 1
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "5622329483"
  Acct-Status-Type = Stop
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000006"
  Acct-Session-Time = 62
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ EXEC accounting record for a dial-in user:

```
Wed Jun 27 03:46:21 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=2      service=shell
Wed Jun 27 04:08:55 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=2      service=shell      elapsed_time=1354
```

The following example shows the information contained in a RADIUS EXEC accounting record for a Telnet user:

```
Wed Jun 27 04:48:32 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 26
  User-Name = "username1"
  Caller-ID = "10.68.202.158"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000010"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

```

Wed Jun 27 04:48:46 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 26
  User-Name = "username1"
  Caller-ID = "10.68.202.158"
  Acct-Status-Type = Stop
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "00000010"
  Acct-Session-Time = 14
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ EXEC accounting record for a Telnet user:

```

Wed Jun 27 04:06:53 2001      172.16.25.15      username1      tty26      10.68.202.158
starttask_id=41      service=shell
Wed Jun 27 04:07:02 2001      172.16.25.15      username1      tty26      10.68.202.158
stoptask_id=41      service=shell      elapsed_time=9

```

Command Accounting

Command accounting provides information about the EXEC shell commands for a specified privilege level that are being executed on a network access server. Each command accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the user who executed it.

The following example shows the information contained in a TACACS+ command accounting record for privilege level 1:

```

Wed Jun 27 03:46:47 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=3      service=shell      priv-lvl=1      cmd=show version <cr>
Wed Jun 27 03:46:58 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=4      service=shell      priv-lvl=1      cmd=show interfaces Ethernet 0
<cr>
Wed Jun 27 03:47:03 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=5      service=shell      priv-lvl=1      cmd=show ip route <cr>

```

The following example shows the information contained in a TACACS+ command accounting record for privilege level 15:

```

Wed Jun 27 03:47:17 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=6      service=shell      priv-lvl=15      cmd=configure terminal <cr>
Wed Jun 27 03:47:21 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=7      service=shell      priv-lvl=15      cmd=interface Serial 0 <cr>
Wed Jun 27 03:47:29 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=8      service=shell      priv-lvl=15      cmd=ip address 10.1.1.1 255.255.255.0
<cr>

```

Note The Cisco implementation of RADIUS does not support command accounting.

Connection Accounting

Connection accounting provides information about all outbound connections made from the network access server such as Telnet, LAT, TN3270, PAD, and rlogin.

The following example shows the information contained in a RADIUS connection accounting record for an outbound Telnet connection:

```
Wed Jun 27 04:28:00 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 2
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "5622329477"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Login
  Acct-Session-Id = "00000008"
  Login-Service = Telnet
  Login-IP-Host = "10.68.202.158"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

```
Wed Jun 27 04:28:39 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 2
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "5622329477"
  Acct-Status-Type = Stop
  Acct-Authentic = RADIUS
  Service-Type = Login
  Acct-Session-Id = "00000008"
  Login-Service = Telnet
  Login-IP-Host = "10.68.202.158"
  Acct-Input-Octets = 10774
  Acct-Output-Octets = 112
  Acct-Input-Packets = 91
  Acct-Output-Packets = 99
  Acct-Session-Time = 39
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound Telnet connection:

```
Wed Jun 27 03:47:43 2001      172.16.25.15      username1  tty3      5622329430/4327528
start  task_id=10      service=connection      protocol=telnet  addr=10.68.202.158  cmd=telnet
      username1-sun
Wed Jun 27 03:48:38 2001      172.16.25.15      username1  tty3      5622329430/4327528
stop   task_id=10      service=connection      protocol=telnet  addr=10.68.202.158  cmd=telnet
      username1-sun      bytes_in=4467  bytes_out=96  paks_in=61      paks_out=72  elapsed_time=55
```

The following example shows the information contained in a RADIUS connection accounting record for an outbound rlogin connection:

```
Wed Jun 27 04:29:48 2001
  NAS-IP-Address = "172.16.25.15"
```

```

NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:30:09 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Input-Octets = 18686
Acct-Output-Octets = 86
Acct-Input-Packets = 90
Acct-Output-Packets = 68
Acct-Session-Time = 22
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound rlogin connection:

```

Wed Jun 27 03:48:46 2001      172.16.25.15      username1  tty3      5622329430/4327528
start  task_id=12      service=connection  protocol=rlogin  addr=10.68.202.158  cmd=rlogin
username1-sun /user username1
Wed Jun 27 03:51:37 2001      172.16.25.15      username1  tty3      5622329430/4327528
stop   task_id=12      service=connection  protocol=rlogin  addr=10.68.202.158  cmd=rlogin
username1-sun /user username1 bytes_in=659926 bytes_out=138 paks_in=2378 paks_
out=1251      elapsed_time=171

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound LAT connection:

```

Wed Jun 27 03:53:06 2001      172.16.25.15      username1  tty3      5622329430/4327528
start  task_id=18      service=connection  protocol=lat      addr=VAX          cmd=lat
VAX
Wed Jun 27 03:54:15 2001      172.16.25.15      username1  tty3      5622329430/4327528
stop   task_id=18      service=connection  protocol=lat      addr=VAX          cmd=lat
VAX bytes_in=0      bytes_out=0      paks_in=0      paks_out=0      elapsed_time=6

```

System Accounting

System accounting provides information about all system-level events (for example, when the system reboots or when accounting is turned on or off).

The following accounting record shows a typical TACACS+ system accounting record server indicating that AAA Accounting has been turned off:

```
Wed Jun 27 03:55:32 2001      172.16.25.15      unknown unknown unknown start   task_id=25
service=system event=sys_acct reason=reconfigure
```

Note The precise format of accounting packets records may vary depending on the TACACS+ daemon.

The following accounting record shows a TACACS+ system accounting record indicating that AAA Accounting has been turned on:

```
Wed Jun 27 03:55:22 2001      172.16.25.15      unknown unknown unknown stop    task_id=23
service=system event=sys_acct reason=reconfigure
```

Additional tasks for measuring system resources are covered in the Cisco IOS software configuration guides. For example, IP accounting tasks are described in the Configuring IP Services chapter in the *CiscoIOS Application Services Configuration Guide*.

Resource Accounting

The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. The additional feature of generating “stop” records for calls that fail to authenticate as part of user authentication is also supported. Such records are necessary for users employing accounting records to manage and monitor their networks.

This section includes the following subsections:

AAA Resource Failure Stop Accounting

Before AAA resource failure stop accounting, there was no method of providing accounting records for calls that failed to reach the user authentication stage of a call setup sequence. Such records are necessary for users employing accounting records to manage and monitor their networks and their wholesale customers.

This functionality generates a “stop” accounting record for any calls that do not reach user authentication; “stop” records are generated from the moment of call setup. All calls that pass user authentication behave as they did before; that is, no additional accounting records are seen.

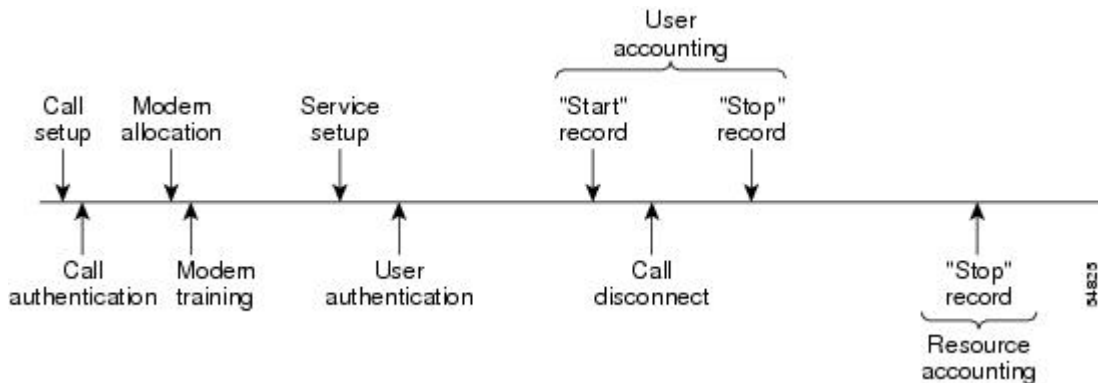

The figure below illustrates a call setup sequence with normal call flow (no disconnect) and without AAA resource failure stop accounting enabled.

Figure 81: Modem Dial-In Call Setup Sequence With Normal Flow and Without Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with normal call flow (no disconnect) and with AAA resource failure stop accounting enabled.

Figure 82: Modem Dial-In Call Setup Sequence With Normal Flow and With Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with call disconnect occurring before user authentication and with AAA resource failure stop accounting enabled.

Figure 83: Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and With Resource Failure Stop Accounting Enabled

The figure below illustrates a call setup sequence with call disconnect occurring before user authentication and without AAA resource failure stop accounting enabled.

Figure 84: Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and Without Resource Failure Stop Accounting Enabled

AAA Resource Accounting for Start-Stop Records

AAA resource accounting for start-stop records supports the ability to send a “start” record at each call setup, followed by a corresponding “stop” record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

With this feature, a call setup and call disconnect “start-stop” accounting record tracks the progress of the resource connection to the device. A separate user authentication “start-stop” accounting record tracks the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

The figure below illustrates a call setup sequence with AAA resource start-stop accounting enabled.

Figure 85: Modem Dial-In Call Setup Sequence With Resource Start-Stop Accounting Enabled

VRRS Accounting

Virtual Router Redundancy Service (VRRS) provides a multiclient information abstraction and management service between a First Hop Redundancy Protocol (FHRP) and a registered client. The VRRS multiclient service provides a consistent interface with FHRP protocols by abstracting over several FHRPs and providing an idealized view of their state. VRRS manages data updates, allowing interested clients to register in one place and receive updates for named FHRP groups or all registered FHRP groups.

Virtual Router Redundancy Protocol (VRRP) is an FHRP that acts as a server that pushes FHRP status information out to all registered VRRS clients. Clients obtain status on essential information provided by the FHRP, including current and previous redundancy states, active and inactive L3 and L2 addresses, and, in some cases, information about other redundant gateways in the network. Clients can use this information to provide stateless and stateful redundancy information to clients and protocols.

VRRS Accounting Plug-in

The VRRS Accounting plug-in provides a configurable AAA method list mechanism that provides updates to a RADIUS server when a VRRS group transitions its state. The VRRS accounting plug-in is an extension of existing AAA system accounting messages. The VRRS Accounting plug-in provides accounting-on and accounting-off messages and an additional Vendor-Specific Attribute (VSA) that sends the configured VRRS name in RADIUS accounting messages. The VRRS name is configured using the **vrrp name** command in interface configuration mode.

The VRRS Accounting plug-in provides a configurable AAA method list mechanism that provides updates to a RADIUS server when a VRRS group transitions its state.

The VRRS accounting plug-in is an extension of existing AAA system accounting messages. The VRRS Accounting plug-in provides accounting-on and accounting-off messages and an additional Vendor-Specific Attribute (VSA) that sends the configured VRRS name in RADIUS accounting messages. The VRRS name is configured using the **vrrp name** command in interface configuration mode. The VRRS Accounting plug-in sends an accounting-on message to RADIUS when a VRRS group transitions to the active state, and it sends an accounting-off message when a VRRS group transitions from the active state.

The following RADIUS attributes are included in VRRS accounting messages by default:

- Attribute 4, NAS-IP-Address
- Attribute 26, Cisco VSA Type 1, VRRS Name
- Attribute 40, Acct-Status-Type
- Attribute 41, Acct-Delay-Time
- Attribute 44, Acct-Session-Id

Accounting messages for a VRRS transitioning out of active state are sent after all PPPoE accounting stop messages for sessions that are part of that VRRS.

AAA Accounting Enhancements

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

AAA Session MIB

The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using Simple Network Management Protocol (SNMP). The data of the client is presented so that it correlates directly to the AAA Accounting information reported by either the RADIUS or the TACACS+ server. AAA session MIB provides the following information:

- Statistics for each AAA function (when used in conjunction with the **show radius statistics** command)
- Status of servers providing AAA functions
- Identities of external AAA servers
- Real-time information (such as idle times), providing additional criteria for use by SNMP networks for assessing whether or not to terminate an active call

Note This command is supported only on Cisco AS5300 and Cisco AS5800 universal access server platforms.

The table below shows the SNMP user-end data objects that can be used to monitor and terminate authenticated client connections with the AAA session MIB feature.

Table 113: SNMP End-User Data Objects

| | |
|-----------|---|
| SessionId | The session identification used by the AAA Accounting protocol (same value as reported by RADIUS attribute 44 (Acct-Session-ID)). |
| UserId | The user login ID or zero-length string if a login is unavailable. |
| IpAddr | The IP address of the session or 0.0.0.0 if an IP address is not applicable or unavailable. |
| IdleTime | The elapsed time in seconds that the session has been idle. |

| | |
|------------|---|
| Disconnect | The session termination object used to disconnect the given client. |
| CallId | The entry index corresponding to this accounting session that the Call Tracker record stored. |

The table below describes the AAA summary information provided by the AAA session MIB feature using SNMP on a per-system basis.

Table 114: SNMP AAA Session Summary

| | |
|--------------------------|--|
| ActiveTableEntries | Number of sessions currently active. |
| ActiveTableHighWaterMark | Maximum number of sessions present at once since last system reinstallation. |
| TotalSessions | Total number of sessions since last system reinstallation. |
| DisconnectedSessions | Total number of sessions that have been disconnected using since last system reinstallation. |

Accounting Attribute-Value Pairs

The network access server monitors the accounting functions defined in either TACACS+ AV pairs or RADIUS attributes, depending on which security method is implemented.

How to Configure Accounting

Configuring AAA Accounting Using Named Method Lists

To configure AAA Accounting using named method lists, perform the following steps:

Note System accounting does not use named method lists. For system accounting, define only the default method list.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | aaa accounting {system network exec connection commands <i>level</i> } {default <i>list-name</i> } {start-stop stop-only none} [<i>method1</i> [<i>method2...</i>]] Example: Device(config)# aaa accounting system default start-stop | Creates an accounting method list and enables accounting. The argument <i>list-name</i> is a character string used to name the created list. |
| Step 4 | Do one of the following: <ul style="list-style-type: none"> • line [aux console tty vty] <i>line-number</i> [<i>ending-line-number</i>] • interface <i>interface-type interface-number</i> Example: Device(config)# line aux line1 | Enters the line configuration mode for the lines to which the accounting method list is applied. or Enters the interface configuration mode for the interfaces to which the accounting method list is applied. |
| Step 5 | Do one of the following: <ul style="list-style-type: none"> • accounting {arap commands <i>level</i> connection exec} {default <i>list-name</i>} • ppp accounting {default <i>list-name</i>} Example: Device(config-line)# accounting arap default | Applies the accounting method list to a line or set of lines. or Applies the accounting method list to an interface or set of interfaces. |
| Step 6 | Device(config-line)# end Example: Device(config-line)# end | (Optional) Exits line configuration mode and returns to global configuration mode. |

Configuring RADIUS System Accounting

Perform this task to configure RADIUS system accounting on the global RADIUS server:

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# configure terminal | |
| Step 3 | aaa new-model Example: Device(config)# aaa new-model | Enables AAA network security services. |
| Step 4 | radius-server accounting system host-config Example: Device(config)# radius-server accounting system host-config | Enables the device to send a system accounting record for the addition and deletion of a RADIUS server. |
| Step 5 | aaa group server radius <i>server-name</i> Example: Device(config)# aaa group server radius radgroup1 | Adds the RADIUS server and enters server-group configuration mode. <ul style="list-style-type: none"> • The <i>server-name</i> argument specifies the RADIUS server group name. |
| Step 6 | server-private {<i>host-name</i> <i>ip-address</i>} key {[0 <i>server-key</i> 7 <i>server-key</i>] <i>server-key</i>} Example: Device(config-sg-radius)# server-private 172.16.1.11 key cisco | Enters the hostname or IP address of the RADIUS server and hidden server key. <ul style="list-style-type: none"> • (Optional) 0 with the <i>server-key</i> argument specifies that an unencrypted (cleartext) hidden server key follows. • (Optional) 7 with the <i>server-key</i> argument specifies that an encrypted hidden server key follows. • The <i>server-key</i> argument specifies the hidden server key. If the <i>server-key</i> argument is configured without the 0 or 7 preceding it, it is unencrypted. <p>Note Once the server-private command is configured, RADIUS system accounting is enabled.</p> |
| Step 7 | accounting system host-config Example: Device(config-sg-radius)# accounting system host-config | Enables the generation of system accounting records for private server hosts when they are added or deleted. |
| Step 8 | end Example: Device(config-sg-radius)# end | Exits server-group configuration mode and returns to privileged EXEC mode. |

Suppressing Generation of Accounting Records for Null Username Sessions

When AAA Accounting is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. An example of this is users who come in on lines where the **aaa authentication login method-list none** command is applied. To prevent accounting records from being generated for sessions that do not have usernames associated with them, use the following command in global configuration mode:

| Command | Purpose |
|--|---|
| Device(config)# aaa accounting suppress null-username | Prevents accounting records from being generated for users whose username string is NULL. |

Generating Interim Accounting Records

To enable periodic interim accounting records to be sent to the accounting server, use the following command in global configuration mode:

| Command | Purpose |
|--|--|
| Device(config)# aaa accounting update [newinfo] [periodic] <i>number</i> | Enables periodic interim accounting records to be sent to the accounting server. |

When the **aaa accounting update** command is activated, the Cisco IOS software issues interim accounting records for all users on the system. If the keyword **newinfo** is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.

When used with the keyword **periodic**, interim accounting records are sent periodically as defined by the *number* argument. The interim accounting record contains all of the accounting information recorded for that user up to the time the interim accounting record is sent.

Caution Using the **aaa accounting update periodic** command can cause heavy congestion when many users are logged in to the network.

Generating Accounting Records for Failed Login or Session

When AAA Accounting is activated, the Cisco IOS software does not generate accounting records for system users who fail login authentication, or who succeed in login authentication but fail PPP negotiation for some reason.

To specify that accounting stop records be generated for users who fail to authenticate at login or during session negotiation, use the following command in global configuration mode:

| Command | Purpose |
|---|---|
| Device(config)# aaa accounting send stop-record authentication failure | Generates “stop” records for users who fail to authenticate at login or during session negotiation using PPP. |
| Device(config)# aaa accounting send stop-record always | Sends authentication, authorization, and accounting (AAA) stop records regardless of whether a start record was sent earlier. |

Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records

For PPP users who start EXEC terminal sessions, you can specify the NETWORK records to be generated before EXEC-stop records. In cases such as billing customers for specific services, it can be desirable to keep network start and stop records together, essentially “nesting” them within the framework of the EXEC start and stop messages. For example, a user dialing in using PPP can create the following records: EXEC-start, NETWORK-start, EXEC-stop, NETWORK-stop. By nesting the accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

To nest accounting records for user sessions, use the following command in global configuration mode:

| Command | Purpose |
|--|-----------------------------------|
| Device(config)# aaa accounting nested | Nests network accounting records. |

Configuring AAA Resource Failure Stop Accounting

To enable resource failure stop accounting, use the following command in global configuration mode:

| Command | Purpose |
|--|---|
| Device(config)# aaa accounting resource method-list stop-failure group server-group | Generates a “stop” record for any calls that do not reach user authentication. Note Before configuring this feature, the tasks described in the Prerequisites for Configuring Accounting, on page 935 section must be performed, and SNMP must be enabled on the network access server. |

Configuring AAA Resource Accounting for Start-Stop Records

To enable full resource accounting for start-stop records, use the following command in global configuration mode:

| Command | Purpose |
|---|---|
| <pre>Device(config)# aaa accounting resource method-list start-stop group server-group</pre> | <p>Supports the ability to send a “start” record at each call setup, followed with a corresponding “stop” record at the call disconnect.</p> <p>Note Before configuring this feature, the tasks described in the Prerequisites for Configuring Accounting, on page 935 section must be performed, and SNMP must be enabled on the network access server.</p> |

Configuring AAA Broadcast Accounting

To configure AAA broadcast accounting, use the **aaa accounting** command in global configuration mode:

| Command | Purpose |
|--|---|
| <pre>Device(config)# aaa accounting {system network exec connection commands level} {default <i>list-name</i>} {start-stop stop-only none} [broadcast] <i>method1</i> [<i>method2...</i>]</pre> | <p>Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.</p> |

Configuring Per-DNIS AAA Broadcast Accounting

To configure AAA broadcast accounting per DNIS, use the **aaa dnis map accounting network** command in global configuration mode:

| Command | Purpose |
|--|---|
| <pre>Device(config)# aaa dnis map <i>dnis-number</i> accounting network [start-stop stop-only none] [broadcast] <i>method1</i> [<i>method2...</i>]</pre> | <p>Allows per-DNIS accounting configuration. This command has precedence over the global aaa accounting command.</p> <p>Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.</p> |

Configuring AAA Session MIB

The following tasks must be performed before configuring the AAA session MIB feature:

- Configure SNMP.
- Configure AAA.
- Define the RADIUS or TACACS+ server characteristics.

Note Overusing SNMP can affect the overall system performance; therefore, normal network management performance must be considered when this feature is used.

To configure AAA session MIB, use the following command in global configuration mode

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | Device (config)# aaa session-mib disconnect | Monitors and terminates authenticated client connections using SNMP. To terminate the call, the disconnect keyword must be used. |

Configuring VRRS Accounting

Perform the following task to configure Virtual Router Redundancy Service (VRRS) to send AAA Accounting messages to the AAA server:

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa accounting vrrs {default list-name} start-stop method1 [method2...] Example: Device(config)# aaa accounting vrrs default start-stop | Enables AAA accounting for VRRS. |
| Step 4 | aaa attribute list list-name Example: Device(config)# aaa attribute list list1 | Defines a AAA attribute list locally on a device, and enters attribute list configuration mode. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 5 | attribute type name value [service service] [protocol protocol][mandatory][tag tag-value] Example: Device(config-attr-list)# attribute type example 1 | Defines an attribute type that is to be added to an attribute list locally on a device. |
| Step 6 | exit Example: Device(config-attr-list)# exit | Exits attribute list configuration mode and returns to global configuration mode. |
| Step 7 | vrrs vrrs-group-name Example: Device(config)# vrrs vrrs1 | (Optional) Defines a VRRP group and configures parameters for the VRRS group, and enters VRRS configuration mode. |
| Step 8 | accounting delay seconds Example: Device(config-vrrs)# accounting delay 10 | (Optional) Specifies the delay time for sending accounting-off messages to the VRRS. |
| Step 9 | accounting method {default accounting-method-list} Example: Device(config-vrrs)# accounting method default | (Optional) Enables VRRS accounting for a VRRP group. |
| Step 10 | end Example: Device(config-vrrs)# end | Exits VRRS configuration mode and returns to privileged EXEC mode. |

Establishing a Session with a Device if the AAA Server is Unreachable

To establish a console or telnet session with a device if the AAA server is unreachable, use the following command in global configuration mode:

| Command | Purpose |
|---|--|
| Device(config)# no aaa accounting system guarantee-first | The aaa accounting system guarantee-first command guarantees system accounting as the first record, which is the default condition. In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes. To resolve this problem, the no aaa accounting system guarantee-first command can be used. |

Note Entering the **no aaa accounting system guarantee-first** command is not the only condition by which the console or telnet session can be started. For example, if the privileged EXEC session is being authenticated by TACACS and the TACACS server is not reachable, then the session cannot start.

Monitoring Accounting

No specific **show** command exists for either RADIUS or TACACS+ accounting. To obtain accounting records displaying information about users currently logged in, use the following command in privileged EXEC mode:

| Command | Purpose |
|--------------------------------|--|
| Device# show accounting | Allows display of the active accountable events on the network and helps collect information in the event of a data loss on the accounting server. |

Troubleshooting Accounting

To troubleshoot accounting information, use the following command in privileged EXEC mode:

| Command | Purpose |
|-------------------------------------|---|
| Device# debug aaa accounting | Displays information on accountable events as they occur. |

Configuration Examples for Accounting

Example Configuring Named Method List

The following example shows how to configure a Cisco AS5200 (enabled for AAA and communication with a RADIUS security server) in order for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database is queried for authentication and authorization information, and accounting services are handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
```

```

aaa authorization network blue1 group radius local
aaa accounting network red1 start-stop group radius group tacacs+
username root password ALongPassword
tacacs-server host 172.31.255.0
tacacs-server key goaway
radius-server host 172.16.2.7
radius-server key myRaDiUSpassWoRd
interface group-async 1
  group-range 1 16
  encapsulation ppp
  ppp authentication chap dialins
  ppp authorization blue1
  ppp accounting red1
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem dialin

```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines a method list “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins”, which specifies that first RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.
- The **aaa authorization network blue1 group radius local** command defines the network authorization method list named “blue1”, which specifies that RADIUS authorization is used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization is performed.
- The **aaa accounting network red1 start-stop group radius group tacacs+** command defines the network accounting method list named red1, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) are used on serial lines using PPP. If the RADIUS server fails to respond, accounting services are handled by a TACACS+ server.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **tacacs-server host** command defines the name of the TACACS+ server host.
- The **tacacs-server key** command defines the shared secret text string between the network access server and the TACACS+ server host.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.

- The **ppp authorization blue1** command applies the blue1 network authorization method list to the specified interfaces.
- The **ppp accounting red1** command applies the red1 network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the admins method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

The **show accounting** command yields the following output for the preceding configuration:

```
Active Accounted actions on tty1, User username2 Priv 1
Task ID 5, Network Accounting record, 00:00:52 Elapsed
task_id=5 service=ppp protocol=ip address=10.0.0.98
```

The table below describes the fields contained in the preceding output.

Table 115: show accounting Field Descriptions

| Field | Description |
|-----------------------------|---|
| Active Accounted actions on | Terminal line or interface name user with which the user logged in. |
| User | User's ID. |
| Priv | User's privilege level. |
| Task ID | Unique identifier for each accounting session. |
| Accounting record | Type of accounting session. |
| Elapsed | Length of time (hh:mm:ss) for this session type. |
| attribute=value | AV pairs associated with this accounting session. |

Example Configuring AAA Resource Accounting

The following example shows how to configure the resource failure stop accounting and resource accounting for start-stop records functions:

```
!Enable AAA on your network access server.
aaa new-model
!Enable authentication at login and list the AOL string name to use for login authentication.
aaa authentication login AOL group radius local
!Enable authentication for ppp and list the default method to use for PPP authentication.
```

```

aaa authentication ppp default group radius local
!Enable authorization for all exec sessions and list the AOL string name to use for
authorization.
aaa authorization exec AOL group radius if-authenticated
!Enable authorization for all network-related service requests and list the default method
to use for all network-related authorizations.
aaa authorization network default group radius if-authenticated
!Enable accounting for all exec sessions and list the default method to use for all start-stop
accounting services.
aaa accounting exec default start-stop group radius
!Enable accounting for all network-related service requests and list the default method to
use for all start-stop accounting services.
aaa accounting network default start-stop group radius
!Enable failure stop accounting.
aaa accounting resource default stop-failure group radius
!Enable resource accounting for start-stop records.
aaa accounting resource default start-stop group radius

```

Example Configuring AAA Broadcast Accounting

The following example shows how to turn on broadcast accounting using the global **aaa accounting** command:

```

aaa group server radius isp
  server 10.0.0.1
  server 10.0.0.2
aaa group server tacacs+ isp_customer
  server 172.0.0.1
aaa accounting network default start-stop broadcast group isp group isp_customer
radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key1
tacacs-server host 172.0.0.1 key key2

```

The **broadcast** keyword causes “start” and “stop” accounting records for network connections to be sent simultaneously to server 10.0.0.1 in the group **isp** and to server 172.0.0.1 in the group **isp_customer**. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group **isp_customer**.

Example Configuring Per-DNIS AAA Broadcast Accounting

The following example shows how to turn on per DNIS broadcast accounting using the global **aaa dnis map accounting network** command:

```

aaa group server radius isp
  server 10.0.0.1
  server 10.0.0.2
aaa group server tacacs+ isp_customer
  server 172.0.0.1
aaa dnis map enable
aaa dnis map 7777 accounting network start-stop broadcast group isp group isp_customer
radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key_1
tacacs-server host 172.0.0.1 key key_2

```

The **broadcast** keyword causes “start” and “stop” accounting records for network connection calls having DNIS number **7777** to be sent simultaneously to server 10.0.0.1 in the group **isp** and to server 172.0.0.1 in

the group `isp_customer`. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group `isp_customer`.

Example AAA Session MIB

The following example shows how to set up the AAA session MIB feature to disconnect authenticated client connections for PPP users:

```
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting network default start-stop group radius
aaa session-mib disconnect
```

Example Configuring VRRS Accounting

The following example shows how to configure VRRS to send AAA Accounting messages to the AAA server:

```
Router# configure terminal
Router(config)# aaa accounting vrrs vrrp-mlist-1 start-stop group radius
Router(config)# aaa attribute list vrrp-1-attr
Router(config-attr-list)# attribute type account-delay 10
Router(config-attr-list)# exit
Router(config)# vrrs vrrp-group-1
Router(config-vrrs)# accounting delay 10
Router(config-vrrs)# accounting method vrrp-mlist-1
Router(config-vrrs)# exit
```

Feature Information for Configuring Accounting

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 116: Feature Information for Configuring Accounting

| Feature Name | Releases | Feature Information |
|--|--------------------|--|
| AAA Broadcast Accounting | Cisco IOS 15.2(1)E | AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. |
| AAA Resource Accounting for Start-Stop Records | Cisco IOS 15.2(1)E | AAA resource accounting for start-stop records supports the ability to send a “start” record at each call setup, followed by a corresponding “stop” record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records. |

| Feature Name | Releases | Feature Information |
|---|--------------------|--|
| AAA Session MIB | Cisco IOS 15.2(1)E | The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using SNMP. The data of the client is presented so that it correlates directly to the AAA Accounting information reported by either the RADIUS or the TACACS+ server. |
| AAA: IPv6 Accounting Delay Enhancements | Cisco IOS 15.2(1)E | VRRS provides a multiclient information abstraction and management service between a First Hop Redundancy Protocol (FHRP) and a registered client. |

Configuring Local Authentication and Authorization

- [How to Configure Local Authentication and Authorization, on page 965](#)
- [Monitoring Local Authentication and Authorization, on page 967](#)
- [Additional References, on page 967](#)
- [Feature Information for Local Authentication and Authorization, on page 968](#)

How to Configure Local Authentication and Authorization

Configuring the Switch for Local Authentication and Authorization

You can configure AAA to operate without a server by setting the switch to implement AAA in local mode. The switch then handles authentication and authorization. No accounting is available in this configuration.

Note To secure the switch for HTTP access by using AAA methods, you must configure the switch with the **ip http authentication aaa** global configuration command. Configuring AAA authentication does not secure the switch for HTTP access by using AAA methods.

Follow these steps to configure AAA to operate without a server by setting the switch to implement AAA in local mode:

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | aaa new-model Example: <pre>Device (config)# aaa new-model</pre> | Enables AAA. |
| Step 4 | aaa authentication login default local Example: <pre>Device (config)# aaa authentication login default local</pre> | Sets the login authentication to use the local username database. The default keyword applies the local user database authentication to all ports. |
| Step 5 | aaa authorization exec default local Example: <pre>Device (config)# aaa authorization exec default local</pre> | Configures user AAA authorization, check the local database, and allow the user to run an EXEC shell. |
| Step 6 | aaa authorization network default local Example: <pre>Device (config)# aaa authorization network default local</pre> | Configures user AAA authorization for all network-related service requests. |
| Step 7 | username name [privilege level] {password encryption-type password} Example: <pre>Device (config)# username your_user_name privilege 1 password 7 secret567</pre> | <p>Enters the local database, and establishes a username-based authentication system.</p> <p>Repeat this command for each user.</p> <ul style="list-style-type: none"> • For <i>name</i>, specify the user ID as one word. Spaces and quotation marks are not allowed. • (Optional) For <i>level</i>, specify the privilege level the user has after gaining access. The range is 0 to 15. Level 15 gives privileged EXEC mode access. Level 0 gives user EXEC mode access. • For <i>encryption-type</i>, enter 0 to specify that an unencrypted password follows. |

| | Command or Action | Purpose |
|----------------|---|--|
| | | <p>Enter 7 to specify that a hidden password follows.</p> <ul style="list-style-type: none"> For <i>password</i>, specify the password the user must enter to gain access to the switch. The password must be from 1 to 25 characters, can contain embedded spaces, and must be the last option specified in the username command. |
| Step 8 | <p>end</p> <p>Example:</p> <pre>Device (config) # end</pre> | Returns to privileged EXEC mode. |
| Step 9 | <p>show running-config</p> <p>Example:</p> <pre>Device# show running-config</pre> | Verifies your entries. |
| Step 10 | <p>copy running-config startup-config</p> <p>Example:</p> <pre>Device# copy running-config startup-config</pre> | (Optional) Saves your entries in the configuration file. |

Monitoring Local Authentication and Authorization

To display Local Authentication and Authorization configuration, use the **show running-config** privileged EXEC command.

CHAPTER 50

MAC Authentication Bypass

The MAC Authentication Bypass feature is a MAC-address-based authentication mechanism that allows clients in a network to integrate with the Cisco Identity Based Networking Services (IBNS) and Network Admission Control (NAC) strategy using the client MAC address. The MAC Authentication Bypass feature is applicable to the following network environments:

- Network environments in which a supplicant code is not available for a given client platform.
- Network environments in which the end client configuration is not under administrative control, that is, the IEEE 802.1X requests are not supported on these networks.
- [Prerequisites for Configuring MAC Authentication Bypass, on page 969](#)
- [Information About MAC Authentication Bypass, on page 970](#)
- [How to Configure MAC Authentication Bypass, on page 971](#)
- [Configuration Examples for MAC Authentication Bypass, on page 976](#)
- [Additional References for MAC Authentication Bypass, on page 976](#)
- [Feature Information for MAC Authentication Bypass, on page 977](#)

Prerequisites for Configuring MAC Authentication Bypass

IEEE 802.1x—Port-Based Network Access Control

You should understand the concepts of port-based network access control and have an understanding of how to configure port-based network access control on your Cisco platform.

RADIUS and ACLs

You should understand the concepts of the RADIUS protocol and have an understanding of how to create and apply access control lists (ACLs). For more information, see the documentation for your Cisco platform and the *Securing User Services Configuration Guide Library*.

The device must have a RADIUS configuration and be connected to the Cisco secure access control server (ACS). For more information, see the *User Guide for Secure ACS Appliance 3.2*.

Information About MAC Authentication Bypass

Overview of the Cisco IOS Auth Manager

The capabilities of devices connecting to a given network can be different, thus requiring that the network support different authentication methods and authorization policies. The Cisco IOS Auth Manager handles network authentication requests and enforces authorization policies regardless of authentication method. The Auth Manager maintains operational data for all port-based network connection attempts, authentications, authorizations, and disconnections and, as such, serves as a session manager.

The possible states for Auth Manager sessions are as follows:

- **Idle**—In the idle state, the authentication session has been initialized, but no methods have yet been run. This is an intermediate state.
- **Running**—A method is currently running. This is an intermediate state.
- **Authc Success**—The authentication method has run successfully. This is an intermediate state.
- **Authc Failed**—The authentication method has failed. This is an intermediate state.
- **Authz Success**—All features have been successfully applied for this session. This is a terminal state.
- **Authz Failed**—At least one feature has failed to be applied for this session. This is a terminal state.
- **No methods**—There were no results for this session. This is a terminal state.

Overview of the Configurable MAB Username and Password

A MAC Authentication Bypass (MAB) operation involves authentication using RADIUS Access-Request packets with both the username and password attributes. By default, the username and the password values are the same and contain the MAC address. The Configurable MAB Username and Password feature enables you to configure both the username and the password attributes in the following scenarios:

- To enable MAB for an existing large database that uses formatted username attributes, the username format in the client MAC needs to be configured. Use the **mab request format attribute 1** command to configure the username format.
- Some databases do not accept authentication if the username and password values are the same. In such instances, the password needs to be configured to ensure that the password is different from the username. Use the **mab request format attribute 2** command to configure the password.

The Configurable MAB Username and Password feature allows interoperability between the Cisco IOS Authentication Manager and the existing MAC databases and RADIUS servers. The password is a global password and hence is the same for all MAB authentications and interfaces. This password is also synchronized across all supervisor devices to achieve high availability.

If the password is not provided or configured, the password uses the same value as the username. The table below describes the formatting of the username and the password:

| MAC Address | Username Format (Group Size, Separator) | Username | Password Configured | Password Created |
|--------------|---|---|---------------------|---|
| 08002b8619de | (1, :) (1, -) (1, .) | 0:8:0:0:2:b:8:6:1:9:d:e 0-8-0-0-2-b-8-6-1-9-d-e 0.8.0.0.2.b.8.6.1.9.d.e | None | 0:8:0:0:2:b:8:6:1:9:d:e 0-8-0-0-2-b-8-6-1-9-d-e 0.8.0.0.2.b.8.6.1.9.d.e |
| 08002b8619de | (1, :) (1, -) (1, .) | 0:8:0:0:2:b:8:6:1:9:d:e 0-8-0-0-2-b-8-6-1-9-d-e 0.8.0.0.2.b.8.6.1.9.d.e | Password | Password |
| 08002b8619de | (2, :) (2, -) (2, .) | 08:00:2b:86:19:de 08-00-2b-86-19-de 08.00.2b.86.19.de | None | 08:00:2b:86:19:de 08-00-2b-86-19-de 08.00.2b.86.19.de |
| 08002b8619de | (2, :) (2, -) (2, .) | 08:00:2b:86:19:de 08-00-2b-86-19-de 08.00.2b.86.19.de | Password | Password |
| 08002b8619de | (4, :) (4, -) (4, .) | 0800:2b86:19de 0800-2b86-19de 0800.2b86.19de | None | 0800:2b86:19de 0800-2b86-19de 0800.2b86.19de |

| 08002b8619de | (12, <not applicable>) | 08002b8619de | None | 08002b8619de |
| 08002b8619de | (12, <not applicable>) | 08002b8619de | Password | Password |

How to Configure MAC Authentication Bypass

Enabling MAC Authentication Bypass

Perform this task to enable the MAC Authentication Bypass feature on an 802.1X port.

Procedure

| | Command or Action | Purpose |
|--------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Example: Device> enable | <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>type slot / port</i> Example: Device(config)# interface Gigabitethernet 1/2/1 | Enters interface configuration mode. |
| Step 4 | mab Example: Device(config-if)# mab | Enables MAB. |
| Step 5 | end Example: Device(config-if)# end | Returns to privileged EXEC mode. |
| Step 6 | show authentication sessions interface <i>type slot / port details</i> Example: Device# show authentication session interface Gigabitethernet 1/2/1 details | Displays the interface configuration and the authenticator instances on the interface. |

Enabling Reauthentication on a Port

By default, ports are not automatically reauthenticated. You can enable automatic reauthentication and specify how often reauthentication attempts are made.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|----------------|---|--|
| | Device# configure terminal | |
| Step 3 | interface <i>type slot / port</i> Example: Device(config)# interface Gigabitethernet 1/2/1 | Enters interface configuration mode. |
| Step 4 | switchport Example: Device(config-if)# switchport | Places interface in Layer 2 switched mode. |
| Step 5 | switchport mode access Example: Device(config-if)# switchport mode access | Sets the interface type as a nontrunking, nontagged single VLAN Layer 2 interface. |
| Step 6 | authentication port-control auto Example: Device(config-if)# authentication port-control auto | Configures the authorization state of the port. |
| Step 7 | mab [eap] Example: Device(config-if)# mab | Enables MAB. |
| Step 8 | authentication periodic Example: Device(config-if)# authentication periodic | Enables reauthentication. |
| Step 9 | authentication timer reauthenticate <i>{seconds server}</i> Example: Device(config-if)# authentication timer reauthenticate 900 | Configures the time, in seconds, between reauthentication attempts. |
| Step 10 | end Example: Device(config-if)# end | Exits interface configuration mode and returns to privileged EXEC mode. |

Specifying the Security Violation Mode

When there is a security violation on a port, the port can be shut down or traffic can be restricted. By default, the port is shut down. You can configure the period of time for which the port is shut down.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | interface <i>type slot / port</i> Example: Device(config)# interface Gigabitethernet 1/2/1 | Enters interface configuration mode. |
| Step 4 | switchport Example: Device(config-if)# switchport | Places interface in Layer 2 switched mode. |
| Step 5 | switchport mode access Example: Device(config-if)# switchport mode access | Sets the interface type as a nontrunking, nontagged single VLAN Layer 2 interface. |
| Step 6 | authentication port-control auto Example: Device(config-if)# authentication port-control auto | Configures the authorization state of the port. |
| Step 7 | mab [eap] Example: Device(config-if)# mab | Enables MAB. |
| Step 8 | authentication violation {restrict shutdown} Example: | Configures the action to be taken when a security violation occurs on the port. |

| | Command or Action | Purpose |
|----------------|---|---|
| | Device(config-if)# authentication violation shutdown | |
| Step 9 | authentication timer restart <i>seconds</i> Example: Device(config-if)# authentication timer restart 30 | Configures the period of time, in seconds, after which an attempt is made to authenticate an unauthorized port. |
| Step 10 | end Example: Device(config-if)# end | Exits interface configuration mode and returns to privileged EXEC mode. |

Enabling Configurable MAB Username and Password

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | mab request format attribute 1 groupsize {1 2 4 12} separator {- : .} [lowercase uppercase] Example: Device(config)# mab request format attribute 1 groupsize 2 separator : | Configures the username format for MAB requests. |
| Step 4 | mab request format attribute 2 [0 7] <i>password</i> Example: Device(config)# mab request format attribute 2 password1 | Configures a global password for all MAB requests. |
| Step 5 | end Example: Device(config)# end | Returns to privileged EXEC mode. |

Configuration Examples for MAC Authentication Bypass

Example: MAC Authentication Bypass Configuration

In the following example, the **mab** command has been configured to enable the MAC Authorization Bypass (MAB) feature on the specified interface. The optional **show authentication sessions** command has been enabled to display the interface configuration and the authentication instances on the interface.

```
Device> enable
Device# configure terminal
Device(config)# interface GigabitEthernet2/1
Device(config-if)# mab
Device(config-if)# end
Device# show authentication sessions interface GigabitEthernet2/1 details
```

Example: Enabling Configurable MAB Username and Password

The following example shows how to configure the username format and password for MAC Authentication Bypass (MAB). In this example, the username format is configured as a group of 12 hexadecimal digits with no separator and the global password as **password1**.

```
Device> enable
Device# configure terminal
Device(config)# mab request format attribute 1 groupsize 2 separator :
Device(config)# mab request format attribute 2 password1
Device(config)# end
```

Feature Information for MAC Authentication Bypass

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 117: Feature Information for MAC Authentication Bypass

| Feature Name | Releases | Feature Information |
|--|---|---|
| MAC Authentication Bypass (MAB) | Cisco IOS XE 3.2SE Cisco IOS XE 3.3SE Cisco IOS XE 3.5E Cisco IOS 15.2(1)E | The MAC Authentication Bypass feature is a MAC-address-based authentication mechanism that allows clients in a network to integrate with the Cisco IBNS and NAC strategy using the client MAC address. The following commands were introduced or modified: dot1x mac-auth-bypass , show dot1x interface . |
| Configurable MAB Username and Password | Cisco IOS 15.2(1)E | The Configurable MAB Username and Password feature enables you to configure MAC Authentication Bypass (MAB) username format and password to allow interoperability between the Cisco IOS Authentication Manager and existing MAC databases and RADIUS servers. The following commands were introduced or modified: mab request format attribute 1 , mab request format attribute 2 . |

CHAPTER 51

Password Strength and Management for Common Criteria

The Password Strength and Management for Common Criteria feature is used to specify password policies and security mechanisms for storing, retrieving, and providing rules to specify user passwords.

For local users, the user profile and the password information with the key parameters are stored on the Cisco device, and this profile is used for local authentication of users. The user can be an administrator (terminal access) or a network user (for example, PPP users being authenticated for network access).

For remote users, where the user profile information is stored in a remote server, a third-party authentication, authorization, and accounting (AAA) server may be used for providing AAA services, both for administrative and network access.

- [Information About Password Strength and Management for Common Criteria, on page 979](#)
- [How to Configure Password Strength and Management for Common Criteria, on page 981](#)
- [Configuration Examples for Password Strength and Management for Common Criteria, on page 984](#)
- [Additional References for Password Strength and Management for Common Criteria, on page 984](#)
- [Feature Information for Password Strength and Management for Common Criteria, on page 985](#)

Restrictions for Password Strength and Management for Common Criteria

Only four concurrent users can log on to the system by using vty at any moment.

Information About Password Strength and Management for Common Criteria

Password Composition Policy

The password composition policy allows you to create passwords of any combination of upper and lowercase characters, numbers, and special characters that include “!”, “@”, “#”, “\$”, “%”, “^”, “&”, “*”, “(”, and “)”.

Password Length Policy

The administrator has the flexibility to set the password's minimum and maximum length. The recommended minimum password length is 8 characters. The administrator can specify both the minimum (1) and the maximum (64) length for the password.

Password Lifetime Policy

The security administrator can provide a configurable option for a password to have a maximum lifetime. If the lifetime parameter is not configured, the configured password will never expire. The maximum lifetime can be configured by providing the configurable value in years, months, days, hours, minutes, and seconds. The lifetime configuration will survive across reloads as it is a part of the configuration, but every time the system reboots, the password creation time will be updated to the new time. For example, if a password is configured with a lifetime of one month and on the 29th day, the system reboots, then the password will be valid for one month after the system reboots.

Password Expiry Policy

If the user attempts to log on and if the user's password credentials have expired, then the following happens:

1. The user is prompted to set the new password after successfully entering the expired password.
2. When the user enters the new password, the password is validated against the password security policy.
3. If the new password matches the password security policy, then the AAA database is updated, and the user is authenticated with the new password.
4. If the new password does not match the password security policy, then the user is prompted again for the password. From AAA perspective, there is no restriction on the number of retries. The number of retries for password prompt in case of unsuccessful authentication is controlled by the respective terminal access interactive module. For example, for telnet, after three unsuccessful attempts, the session will be terminated.

If the password's lifetime is not configured for a user and the user has already logged on and if the security administrator configures the lifetime for that user, then the lifetime will be set in the database. When the same user is authenticated the next time, the system will check for password expiry. The password expiry is checked only during the authentication phase.

If the user has been already authenticated and logged on to the system and if the password expires, then no action will be taken. The user will be prompted to change the password only during the next authentication for the same user.

Password Change Policy

The new password must contain a minimum of 4 character changes from the previous password. A password change can be triggered by the following scenarios:

- The security administrator wants to change the password.
- The user is trying to get authenticated using a profile, and the password for that profile has expired.

When the security administrator changes the password security policy and the existing profile does not meet the password security policy rules, no action will be taken if the user has already logged on to the system.

The user will be prompted to change the password only when the user tries to get authenticated using the profile that does not meet the password security restriction.

When the user changes the password, the lifetime parameters set by the security administrator for the old profile will be the lifetime parameters for the new password.

For noninteractive clients such as dot1x, when the password expires, appropriate error messages will be sent to the clients, and the clients must contact the security administrator to renew the password.

User Reauthentication Policy

Users are reauthenticated when they change their passwords.

When users change their passwords on expiry, they will be authenticated against the new password. In such cases, the actual authentication happens based on the previous credentials, and the new password is updated in the database.

Note Users can change their passwords only when they are logging on and after the expiry of the old password; however, a security administrator can change the user's password at any time.

Support for Framed (Noninteractive) Session

When a client such as dot1x uses the local database for authentication, the Password Strength and Management for Common Criteria feature will be applicable; however, upon password expiry, clients will not be able to change the password. An appropriate failure message will be sent to such clients, and the user must request the security administrator to change the password.

How to Configure Password Strength and Management for Common Criteria

Configuring the Password Security Policy

Perform this task to create a password security policy and to apply the policy to a specific user profile.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|----------------|--|--|
| | Device# configure terminal | |
| Step 3 | aaa new-model Example: Device(config)# aaa new-model | Enables AAA globally. |
| Step 4 | aaa common-criteria policy <i>policy-name</i> Example: Device(config)# aaa common-criteria policy policy1 | Creates the AAA security password policy and enters common criteria configuration policy mode. |
| Step 5 | char-changes <i>number</i> Example: Device(config-cc-policy)# char-changes 4 | (Optional) Specifies the number of changed characters between old and new passwords. |
| Step 6 | max-length <i>number</i> Example: Device(config-cc-policy)# max-length 25 | (Optional) Specifies the maximum length of the password. |
| Step 7 | min-length <i>number</i> Example: Device(config-cc-policy)# min-length 8 | (Optional) Specifies the minimum length of the password. |
| Step 8 | numeric-count <i>number</i> Example: Device(config-cc-policy)# numeric-count 4 | (Optional) Specifies the number of numeric characters in the password. |
| Step 9 | special-case <i>number</i> Example: Device(config-cc-policy)# special-case 3 | (Optional) Specifies the number of special characters in the password. |
| Step 10 | exit Example: Device(config-cc-policy)# exit | (Optional) Exits common criteria configuration policy mode and returns to global configuration mode. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 11 | username <i>username</i> common-criteria-policy <i>policy-name</i> password <i>password</i> Example: <pre>Device(config)# username user1 common-criteria-policy policy1 password password1</pre> | (Optional) Applies a specific policy and password to a user profile. |
| Step 12 | end Example: <pre>Device(config)# end</pre> | Returns to privileged EXEC mode. |

Verifying the Common Criteria Policy

Perform this task to verify all the common criteria security policies.

Procedure

Step 1

enable

Enables privileged EXEC mode.

Example:

```
Device> enable
```

Step 2

show aaa common-criteria policy name *policy-name*

Displays the password security policy information for a specific policy.

Example:

```
Device# show aaa common-criteria policy name policy1

Policy name: policy1
Minimum length: 1
Maximum length: 64
Upper Count: 20
Lower Count: 20
Numeric Count: 5
Special Count: 2
Number of character changes 4
Valid forever. User tied to this policy will not expire.
```

Step 3

show aaa common-criteria policy all

Displays password security policy information for all the configured policies.

Example:

```
Device# show aaa common-criteria policy all
=====
Policy name: policy1
Minimum length: 1
```

```

Maximum length: 64
Upper Count: 20
Lower Count: 20
Numeric Count: 5
Special Count: 2
Number of character changes 4
Valid forever. User tied to this policy will not expire.
=====
Policy name: policy2
Minimum length: 1
Maximum length: 34
Upper Count: 10
Lower Count: 5
Numeric Count: 4
Special Count: 2
Number of character changes 2
Valid forever. User tied to this policy will not expire.
=====

```

Configuration Examples for Password Strength and Management for Common Criteria

Example: Password Strength and Management for Common Criteria

The following example shows how to create a common criteria security policy and apply the specific policy to a user profile:

```

Device> enable
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa common-criteria policy policy1
Device(config-cc-policy)# char-changes 4
Device(config-cc-policy)# max-length 20
Device(config-cc-policy)# min-length 6
Device(config-cc-policy)# numeric-count 2
Device(config-cc-policy)# special-case 2
Device(config-cc-policy)# exit
Device(config)# username user1 common-criteria-policy policy1 password password1
Device(config)# end

```

| Feature Name | Releases | Feature Information |
|--|---|--|
| Password Strength and Management for Common Criteria | Cisco IOS 15.0(2)SE Cisco IOS 15.2(1)E | <p>The Password Strength and Management for Common Criteria feature is used to specify password policies and security mechanisms for storing, retrieving, and providing rules to specify user passwords.</p> <p>The following commands were introduced or modified: aaa common-criteria policy, debug aaa common-criteria, and show aaa common-criteria policy.</p> |

CHAPTER 52

AAA-SERVER-MIB Set Operation

The AAA-SERVER-MIB Set Operation feature allows the authentication, authorization, and accounting (AAA) server configuration to be extended or expanded by using the CISCO-AAA-SERVER-MIB to create and add new AAA servers, modify the “KEY” under the CISCO-AAA-SERVER-MIB, and delete the AAA server configuration.

- [Prerequisites for AAA-SERVER-MIB Set Operation, on page 987](#)
- [Restrictions for AAA-SERVER-MIB Set Operation, on page 987](#)
- [Information About AAA-SERVER-MIB Set Operation, on page 987](#)
- [How to Configure AAA-SERVER-MIB Set Operation, on page 988](#)
- [Configuration Examples for AAA-SERVER-MIB Set Operation, on page 989](#)
- [Additional References for AAA-SERVER-MIB Set Operation, on page 991](#)
- [Feature Information for AAA-SERVER-MIB Set Operation, on page 991](#)

Prerequisites for AAA-SERVER-MIB Set Operation

AAA must have been enabled on the router, that is, the `aaa new-model` command must have been configured. If this configuration has not been accomplished, the set operation fails.

Restrictions for AAA-SERVER-MIB Set Operation

Currently, the CISCO SNMP set operation is supported only for the RADIUS protocol. Therefore, only RADIUS servers in global configuration mode can be added, modified, or deleted.

Information About AAA-SERVER-MIB Set Operation

CISCO-AAA-SERVER-MIB

The CISCO-AAA-SERVER-MIB provides that statistics reflect both the state of the AAA server operation with the server itself and of AAA communications with external servers. The CISCO-AAA-SERVER-MIB provides the following information:

- Statistics for each AAA operation

- Status of servers that are providing AAA functions
- Identities of external AAA servers

CISCO-AAA-SERVER-MIB Set Operation

With the SET operation, you can do the following:

- Create or add a new AAA server.
- Modify the KEY under the CISCO-AAA-SERVER-MIB. This “secret key” is used for secure connectivity to the AAA server, which is present with the network access server (NAS) and the AAA server.
- Delete the AAA server configuration.

How to Configure AAA-SERVER-MIB Set Operation

Configuring AAA-SERVER-MIB Set Operations

No special configuration is required for this feature. The Simple Network Management Protocol (SNMP) framework can be used to manage MIBs. See the Additional References section for a reference to configuring SNMP.

Verifying SNMP Values

SNMP values can be verified by performing the following steps.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show running-config include radius-server host Example: Device# show running-config include radius-server host | Displays all the RADIUS servers that are configured in the global configuration mode. |
| Step 3 | show aaa servers Example: Device# show aaa servers | Displays information about the number of requests sent to and received from authentication, authorization, and accounting (AAA) servers. |

Configuration Examples for AAA-SERVER-MIB Set Operation

RADIUS Server Configuration and Server Statistics Example

The following sample output shows the RADIUS server configuration and server statistics before and after the set operation.

Before the Set Operation

```
Device# show running-config | include radius-server host

! The following line is for server 1.
radius-server host 172.19.192.238 auth-port 2095 acct-port 2096 key cisco2
! The following line is for server 2.
radius-server host 172.19.192.238 auth-port 1645 acct-port 1646
```

Server Statistics

```
Device# show aaa servers

RADIUS: id 2, priority 1, host 172.19.192.238, auth-port 2095, acct-port 2096
State: current UP, duration 25s, previous duration 0s
  Dead: total time 0s, count 7
Authen: request 8, timeouts 8
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 2
Author: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Account: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Elapsed time since counters last cleared: 5m
RADIUS: id 3, priority 2, host 172.19.192.238, auth-port 1645, acct-port 1646
State: current UP, duration 5s, previous duration 0s
  Dead: total time 0s, count 2
Authen: request 8, timeouts 8
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 4
Author: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Account: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Elapsed time since counters last cleared: 3m
```

SNMP Get Operation to Check the Configuration and Statistics of the RADIUS Servers

```
aaa-server5:/users/smetri> getmany 10.0.1.42 casConfigTable
casAddress.2.2 = 172.19.192.238
casAddress.2.3 = 172.19.192.238
casAuthenPort.2.2 = 2095
casAuthenPort.2.3 = 1645
casAcctPort.2.2 = 2096
```

```

casAcctPort.2.3 = 1646
casKey.2.2 =
casKey.2.3 =
! The following line shows priority for server 1.
casPriority.2.2 = 1
! The following line shows priority for server 2.
casPriority.2.3 = 2
casConfigRowStatus.2.2 = active(1)
casConfigRowStatus.2.3 = active(1)
aaa-server5:/users/smetri>

```

SNMP Set Operation

The key of the existing RADIUS server is being changed. The index “1” is being used. That index acts as a wildcard for addition, deletion, or modification of any entries.

```

Change the key for server 1:=>
aaa-server5:/users/smetri> setany -v2c 10.0.1.42 public casAddress.2.1 -a 172.19.192.238
casAuthenPort.2.1 -i 2095 casAcctPort.2.1 -i 2096 casKey.2.1 -o king
casAddress.2.1 = 172.19.192.238
casAuthenPort.2.1 = 2095
casAcctPort.2.1 = 2096
casKey.2.1 = king
aaa-server5:/users/smetri>

```

After the Set Operation

After the above SNMP set operation, the configurations on the device change. The following output shows the output after the set operation.

```
Device# show running-config | include radius-server host
```

```

radius-server host 172.19.192.238 auth-port 1645 acct-port 1646
! The following line shows a change in the key value to "king."
radius-server host 172.19.192.238 auth-port 2095 acct-port 2096 key king

```

```
Device# show aaa servers
```

```

RADIUS: id 3, priority 1, host 172.19.192.238, auth-port 1645, acct-port 1646
State: current UP, duration 189s, previous duration 0s
  Dead: total time 0s, count 2
Authen: request 8, timeouts 8

Table 119: Feature Information for AAA-SERVER-MIB Set Operation

| Feature Name | Releases | Feature Information |
|------------------------------|--------------------|---|
| AAA-SERVER-MIB Set Operation | Cisco IOS 15.2(1)E | <p>The AAA-SERVER-MIB Set Operation feature allows the authentication, authorization, and accounting (AAA) server configuration to be extended or expanded by using the CISCO-AAA-SERVER-MIB to create and add new AAA servers, modify the “KEY” under the CISCO-AAA-SERVER-MIB, and delete the AAA server configuration.</p> <p>The following commands were introduced or modified: show aaa servers, show running-config, show running-config vrf.</p> |

CHAPTER 53

Configuring Secure Shell

The Secure Shell (SSH) feature is an application and a protocol that provides a secure replacement to the Berkeley r-tools. The protocol secures sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley rexec and rsh tools. Two versions of SSH are available: SSH Version 1 and SSH Version 2.

- [Prerequisites for Configuring Secure Shell, on page 993](#)
- [Restrictions for Configuring Secure Shell, on page 994](#)
- [Information About Configuring Secure Shell, on page 994](#)
- [How to Configure Secure Shell, on page 997](#)
- [Configuration Examples for Secure Shell, on page 1007](#)
- [Additional References for Secure Shell, on page 1009](#)
- [Feature Information for Configuring Secure Shell, on page 1009](#)

Prerequisites for Configuring Secure Shell

The following are the prerequisites for configuring the switch for secure shell (SSH):

- For SSH to work, the switch needs an Rivest, Shamir, and Adleman (RSA) public/private key pair. This is the same with Secure Copy Protocol (SCP), which relies on SSH for its secure transport.
- Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.
- Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.
- SCP relies on SSH for security.
- SCP requires that authentication, authorization, and accounting (AAA) authorization be configured so the router can determine whether the user has the correct privilege level.
- A user must have appropriate authorization to use SCP.
- A user who has appropriate authorization can use SCP to copy any file in the Cisco IOS File System (IFS) to and from a switch by using the **copy** command. An authorized administrator can also do this from a workstation.
- The Secure Shell (SSH) server requires an IPsec (Data Encryption Standard [DES] or 3DES) encryption software image; the SSH client requires an IPsec (DES or 3DES) encryption software image.)

- Configure a hostname and host domain for your device by using the **hostname** and **ip domain-name** commands in global configuration mode.

Restrictions for Configuring Secure Shell

The following are restrictions for configuring the Device for secure shell.

- The switch supports Rivest, Shamir, and Adelman (RSA) authentication.
- SSH supports only the execution-shell application.
- The SSH server and the SSH client are supported only on Data Encryption Standard (DES) (56-bit) and 3DES (168-bit) data encryption software. In DES software images, DES is the only encryption algorithm available. In 3DES software images, both DES and 3DES encryption algorithms are available.
- The Device supports the Advanced Encryption Standard (AES) encryption algorithm with a 128-bit key, 192-bit key, or 256-bit key. However, symmetric cipher AES to encrypt the keys is not supported.
- When using SCP, you cannot enter the password into the **copy** command. You must enter the password when prompted.
- The login banner is not supported in Secure Shell Version 1. It is supported in Secure Shell Version 2.
- The **-l** keyword and **userid** : {number} {ip-address} delimiter and arguments are mandatory when configuring the alternative method of Reverse SSH for console access.

Information About Configuring Secure Shell

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2).

SSH and Switch Access

Secure Shell (SSH) is a protocol that provides a secure, remote connection to a device. SSH provides more security for remote connections than Telnet does by providing strong encryption when a device is authenticated. This software release supports SSH Version 1 (SSHv1) and SSH Version 2 (SSHv2).

SSH functions the same in IPv6 as in IPv4. For IPv6, SSH supports IPv6 addresses and enables secure, encrypted connections with remote IPv6 nodes over an IPv6 transport.

SSH Servers, Integrated Clients, and Supported Versions

The Secure Shell (SSH) Integrated Client feature is an application that runs over the SSH protocol to provide device authentication and encryption. The SSH client enables a Cisco device to make a secure, encrypted connection to another Cisco device or to any other device running the SSH server. This connection provides functionality similar to that of an outbound Telnet connection except that the connection is encrypted. With authentication and encryption, the SSH client allows for secure communication over an unsecured network.

The SSH server and SSH integrated client are applications that run on the switch. The SSH server works with the SSH client supported in this release and with non-Cisco SSH clients. The SSH client works with publicly and commercially available SSH servers. The SSH client supports the ciphers of Data Encryption Standard (DES), 3DES, and password authentication.

The switch supports an SSHv1 or an SSHv2 server.

The switch supports an SSHv1 client.

Note The SSH client functionality is available only when the SSH server is enabled.

User authentication is performed like that in the Telnet session to the device. SSH also supports the following user authentication methods:

- TACACS+
- RADIUS
- Local authentication and authorization

RSA Authentication Support

Rivest, Shamir, and Adleman (RSA) authentication available in Secure Shell (SSH) clients is not supported on the SSH server for Cisco software by default.

SSL Configuration Guidelines

When SSL is used in a switch cluster, the SSL session terminates at the cluster commander. Cluster member switches must run standard HTTP.

Before you configure a CA trustpoint, you should ensure that the system clock is set. If the clock is not set, the certificate is rejected due to an incorrect date.

In a switch stack, the SSL session terminates at the active switch.

Secure Copy Protocol Overview

The Secure Copy Protocol (SCP) feature provides a secure and authenticated method for copying switch configurations or switch image files. SCP relies on Secure Shell (SSH), an application and a protocol that provides a secure replacement for the Berkeley r-tools.

For SSH to work, the switch needs an RSA public/private key pair. This is the same with SCP, which relies on SSH for its secure transport.

Because SSH also relies on AAA authentication, and SCP relies further on AAA authorization, correct configuration is necessary.

- Before enabling SCP, you must correctly configure SSH, authentication, and authorization on the switch.
- Because SCP relies on SSH for its secure transport, the router must have an Rivest, Shamir, and Adelman (RSA) key pair.

Note When using SCP, you cannot enter the password into the copy command. You must enter the password when prompted.

Secure Copy Protocol

Isn't Secure Copy Protocol related closely enough to SSH that it could be used in this book? I have moved all of the item in this topic to prerequisites or restrictions.

The Secure Copy Protocol (SCP) feature provides a secure and authenticated method for copying device configurations or switch image files. The behavior of SCP is similar to that of remote copy (rcp), which comes from the Berkeley r-tools suite, except that SCP relies on SSH for security. SCP also requires that authentication, authorization, and accounting (AAA) authorization be configured so the device can determine whether the user has the correct privilege level. To configure the Secure Copy feature, you should understand the SCP concepts.

How Secure Copy Works

The behavior of Secure Copy (SCP) is similar to that of remote copy (RCP), which comes from the Berkeley r-tools suite (Berkeley university's own set of networking applications), except that SCP relies on Secure Shell (SSH) for security. In addition, SCP requires that authentication, authorization, and accounting (AAA) authorization be configured so that the device can determine whether the user has the correct privilege level.

SCP allows a user only with a privilege level of 15 to copy any file that exists in the Cisco IOS File System (IFS) to and from a device by using the **copy** command. An authorized administrator may also perform this action from a workstation.

Note Enable the SCP option while using the pscp.exe file with the Cisco software.

Reverse Telnet

Reverse telnet allows you to telnet to a certain port range and connect to terminal or auxiliary lines. Reverse telnet has often been used to connect a Cisco device that has many terminal lines to the consoles of other Cisco devices. Telnet makes it easy to reach the device console from anywhere simply by telnet to the terminal server on a specific line. This telnet approach can be used to configure a device even if all network connectivity to that device is disconnected. Reverse telnet also allows modems that are attached to Cisco devices to be used for dial-out (usually with a rotary device).

Reverse SSH

Reverse telnet can be accomplished using SSH. Unlike reverse telnet, SSH provides for secure connections. The Reverse SSH Enhancements feature provides you with a simplified method of configuring SSH. Using this feature, you no longer have to configure a separate line for every terminal or auxiliary line on which you want to enable SSH. The previous method of configuring reverse SSH limited the number of ports that can be accessed to 100. The Reverse SSH Enhancements feature removes the port number limitation.

How to Configure Secure Shell

Setting Up the Device to Run SSH

Follow these steps to set up your Device to run SSH:

Before you begin

Configure user authentication for local or remote access. This step is required. For more information, see Related Topics below.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | hostname <i>hostname</i> Example: Device(config)# hostname <i>your_hostname</i> | Configures a hostname and IP domain name for your Device. Note Follow this procedure only if you are configuring the Device as an SSH server. |
| Step 4 | ip domain-name <i>domain_name</i> Example: Device(config)# ip domain-name <i>your_domain</i> | Configures a host domain for your Device. |
| Step 5 | crypto key generate rsa Example: Device(config)# crypto key generate rsa | Enables the SSH server for local and remote authentication on the Device and generates an RSA key pair. Generating an RSA key pair for the Device automatically enables SSH. We recommend that a minimum modulus size of 1024 bits. |

| | Command or Action | Purpose |
|---------------|---|---|
| | | When you generate RSA keys, you are prompted to enter a modulus length. A longer modulus length might be more secure, but it takes longer to generate and to use. Note Follow this procedure only if you are configuring the Device as an SSH server. |
| Step 6 | end Example: Device(config)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Configuring the SSH Server

Follow these steps to configure the SSH server:

Note This procedure is only required if you are configuring the Device as an SSH server.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device# <code>configure terminal</code> | |
| Step 3 | <p>ip ssh version [1 2]</p> <p>Example:</p> <pre>Device(config)# ip ssh version 1</pre> | <p>(Optional) Configures the Device to run SSH Version 1 or SSH Version 2.</p> <ul style="list-style-type: none"> • 1—Configure the Device to run SSH Version 1. • 2—Configure the Device to run SSH Version 2. <p>If you do not enter this command or do not specify a keyword, the SSH server selects the latest SSH version supported by the SSH client. For example, if the SSH client supports SSHv1 and SSHv2, the SSH server selects SSHv2.</p> |
| Step 4 | <p>ip ssh {time-out <i>seconds</i> authentication-retries <i>number</i>}</p> <p>Example:</p> <pre>Device(config)# ip ssh time-out 90 OR Device(config)# ip ssh authentication-retries 2</pre> | <p>Configures the SSH control parameters:</p> <ul style="list-style-type: none"> • time-out <i>seconds</i>: Specify the time-out value in seconds; the default is 120 seconds. The range is 0 to 120 seconds. This parameter applies to the SSH negotiation phase. After the connection is established, the Device uses the default time-out values of the CLI-based sessions. • authentication-retries <i>number</i>: Specify the number of times that a client can re-authenticate to the server. The default is 3; the range is 0 to 5. <p>By default, up to five simultaneous, encrypted SSH connections for multiple CLI-based sessions over the network are available (session 0 to session 4). After the execution shell starts, the CLI-based session time-out value returns to the default of 10 minutes.</p> <p>Repeat this step when configuring both parameters.</p> |
| Step 5 | <p>Use one or both of the following:</p> <ul style="list-style-type: none"> • <code>line vtyline_number[ending_line_number]</code> • transport input ssh <p>Example:</p> <pre>Device(config)# line vty 1 10</pre> | <p>(Optional) Configures the virtual terminal line settings.</p> <ul style="list-style-type: none"> • Enters line configuration mode to configure the virtual terminal line settings. For <i>line_number</i> and <i>ending_line_number</i>, specify a pair of lines. The range is 0 to 15. |

| | Command or Action | Purpose |
|---------------|---|---|
| | or Device(config-line)# transport input ssh | <ul style="list-style-type: none"> Specifies that the Device prevent non-SSH Telnet connections. This limits the router to only SSH connections. |
| Step 6 | end Example: Device(config-line)# end | Returns to privileged EXEC mode. |
| Step 7 | show running-config Example: Device# show running-config | Verifies your entries. |
| Step 8 | copy running-config startup-config Example: Device# copy running-config startup-config | (Optional) Saves your entries in the configuration file. |

Invoking an SSH Client

Perform this task to invoke the Secure Shell (SSH) client. The SSH client runs in user EXEC mode and has no specific configuration tasks.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | ssh -l username -vrf vrf-name ip-address Example: Device# ssh -l user1 -vrf vrf1 192.0.2.1 | Invokes the SSH client to connect to an IP host or address in the specified virtual routing and forwarding (VRF) instance. |

Troubleshooting Tips

- If your Secure Shell (SSH) configuration commands are rejected as illegal commands, you have not successfully generated an Rivest, Shamir, and Adleman (RSA) key pair for your device. Make sure that

you have specified a hostname and domain. Then use the **crypto key generate rsa** command to generate an RSA key pair and enable the SSH server.

- When configuring the RSA key pair, you might encounter the following error messages:
 - No hostname specified.
You must configure a hostname for the device using the **hostname** global configuration command.
 - No domain specified.
You must configure a host domain for the device using the **ip domain-name** global configuration command.
- The number of allowable SSH connections is limited to the maximum number of vtys configured for the device. Each SSH connection uses a vty resource.
- SSH uses either local security or the security protocol that is configured through AAA on your device for user authentication. When configuring Authentication, Authorization, and Accounting (AAA), you must ensure that AAA is disabled on the console for user authentication. AAA authorization is disabled on the console by default. If AAA authorization is enabled on the console, disable it by configuring the **no aaa authorization console** command during the AAA configuration stage.

Configuring Reverse SSH for Console Access

To configure reverse SSH console access on the SSH server, perform the following steps.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line line-number ending-line-number Example: Device# line 1 3 | Identifies a line for configuration and enters line configuration mode. |
| Step 4 | no exec Example: Device(config-line)# no exec | Disables EXEC processing on a line. |

| | Command or Action | Purpose |
|---------------|---|---|
| Step 5 | login authentication <i>listname</i> Example: Device(config-line)# login authentication default | Defines a login authentication mechanism for the lines. Note The authentication method must use a username and password. |
| Step 6 | transport input ssh Example: Device(config-line)# transport input ssh | Defines which protocols to use to connect to a specific line of the device. <ul style="list-style-type: none"> • The ssh keyword must be used for the Reverse SSH Enhancements feature. |
| Step 7 | exit Example: Device(config-line)# exit | Exits line configuration mode. |
| Step 8 | exit Example: Device(config)# exit | Exits global configuration mode. |
| Step 9 | ssh -l <i>userid</i> : { <i>number</i> } { <i>ip-address</i> } Example: Device# ssh -l lab:1 router.example.com | Specifies the user ID to use when logging in on the remote networking device that is running the SSH server. <ul style="list-style-type: none"> • <i>userid</i> --User ID. • : --Signifies that a port number and terminal IP address will follow the <i>userid</i> argument. • <i>number</i> --Terminal or auxiliary line number. • <i>ip-address</i> --Terminal server IP address. Note The <i>userid</i> argument and :rotary { <i>number</i> } { <i>ip-address</i> } delimiter and arguments are mandatory when configuring the alternative method of Reverse SSH for modem access. |

Configuring Reverse SSH for Modem Access

In this configuration, reverse SSH is being configured on a modem used for dial-out lines. To get any of the dial-out modems, you can use any SSH client and start a SSH session as shown (in Step 10) to get to the next available modem from the rotary device.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | line <i>line-number ending-line-number</i> Example: Device# line 1 200 | Identifies a line for configuration and enters line configuration mode. |
| Step 4 | no exec Example: Device(config-line)# no exec | Disables EXEC processing on a line. |
| Step 5 | login authentication <i>listname</i> Example: Device(config-line)# login authentication default | Defines a login authentication mechanism for the lines. Note The authentication method must use a username and password. |
| Step 6 | rotary <i>group</i> Example: Device(config-line)# rotary 1 | Defines a group of lines consisting of one or more virtual terminal lines or one auxiliary port line. |
| Step 7 | transport input ssh Example: Device(config-line)# transport input ssh | Defines which protocols to use to connect to a specific line of the device. <ul style="list-style-type: none"> • The ssh keyword must be used for the Reverse SSH Enhancements feature. |
| Step 8 | exit Example: Device(config-line)# exit | Exits line configuration mode. |
| Step 9 | exit Example: Device(config)# exit | Exits global configuration mode. |

| | Command or Action | Purpose |
|----------------|--|--|
| Step 10 | <p>ssh -l <i>userid</i> :rotary {<i>number</i>} {<i>ip-address</i>}</p> <p>Example:</p> <pre>Device# ssh -l lab:rotary1 router.example.com</pre> | <p>Specifies the user ID to use when logging in on the remote networking device that is running the SSH server.</p> <ul style="list-style-type: none"> • <i>userid</i> --User ID. • : --Signifies that a port number and terminal IP address will follow the <i>userid</i> argument. • <i>number</i> --Terminal or auxiliary line number. • <i>ip-address</i> --Terminal server IP address. <p>Note The <i>userid</i> argument and :rotary {<i>number</i>} {<i>ip-address</i>} delimiter and arguments are mandatory when configuring the alternative method of Reverse SSH for modem access.</p> |

Troubleshooting Reverse SSH on the Client

To troubleshoot the reverse SSH configuration on the client (remote device), perform the following steps.

Procedure

| | Command or Action | Purpose |
|---------------|---|---|
| Step 1 | <p>enable</p> <p>Example:</p> <pre>Device> enable</pre> | <p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | <p>debug ip ssh client</p> <p>Example:</p> <pre>Device# debug ip ssh client</pre> | <p>Displays debugging messages for the SSH client.</p> |

Troubleshooting Reverse SSH on the Server

To troubleshoot the reverse SSH configuration on the terminal server, perform the following steps. The steps may be configured in any order or independent of one another.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | debug ip ssh Example: Device# debug ip ssh | Displays debugging messages for the SSH server. |
| Step 3 | show ssh Example: Device# show ssh | Displays the status of the SSH server connections. |
| Step 4 | show line Example: Device# show line | Displays parameters of a terminal line. |

Monitoring the SSH Configuration and Status

This table displays the SSH server configuration and status.

Table 120: Commands for Displaying the SSH Server Configuration and Status

| Command | Purpose |
|--------------------|---|
| show ip ssh | Shows the version and configuration information for the SSH server. |
| show ssh | Shows the status of the SSH server. |

Configuring Secure Copy

To configure a Cisco device for Secure Copy (SCP) server-side functionality, perform the following steps.

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |

| | Command or Action | Purpose |
|---------------|--|---|
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | aaa new-model Example: <pre>Device(config)# aaa new-model</pre> | Sets AAA authentication at login. |
| Step 4 | aaa authentication login {default list-name} method1 [method2...] Example: <pre>Device(config)# aaa authentication login default group tacacs+</pre> | Enables the AAA access control system. |
| Step 5 | aaa authorization {network exec commands level reverse-access configuration} {default list-name} [method1 [method2...]] Example: <pre>Device(config)# aaa authorization exec default group tacacs+</pre> | Sets parameters that restrict user access to a network. Note The exec keyword runs authorization to determine if the user is allowed to run an EXEC shell; therefore, you must use the exec keyword when you configure SCP. |
| Step 6 | username name [privilege level] password encryption-type encrypted-password Example: <pre>Device(config)# username superuser privilege 2 password 0 superpassword</pre> | Establishes a username-based authentication system. Note You may omit this step if a network-based authentication mechanism, such as TACACS+ or RADIUS, has been configured. |
| Step 7 | ip scp server enable Example: <pre>Device(config)# ip scp server enable</pre> | Enables SCP server-side functionality. |
| Step 8 | exit Example: <pre>Device(config)# exit</pre> | Exits global configuration mode and returns to privileged EXEC mode. |
| Step 9 | show running-config Example: | (Optional) Displays the SCP server-side functionality. |

| | Command or Action | Purpose |
|----------------|--|---|
| | Device# show running-config | |
| Step 10 | debug ip scp Example: Device# debug ip scp | (Optional) Troubleshoots SCP authentication problems. |

Configuration Examples for Secure Shell

Example: Secure Copy Configuration Using Local Authentication

The following example shows how to configure the server-side functionality of Secure Copy (SCP). This example uses a locally defined username and password.

```
! AAA authentication and authorization must be configured properly in order for SCP to work.
aaa new-model
aaa authentication login default local
aaa authorization exec default local
username user1 privilege 15 password 0 lab
! SSH must be configured and functioning properly.
ip scp server enable
```

Example: SCP Server-Side Configuration Using Network-Based Authentication

The following example shows how to configure the server-side functionality of SCP using a network-based authentication mechanism:

```
! AAA authentication and authorization must be configured properly for SCP to work.
aaa new-model
aaa authentication login default group tacacs+
aaa authorization exec default group tacacs+
! SSH must be configured and functioning properly.
ip ssh time-out 120
ip ssh authentication-retries 3
ip scp server enable
```

Example Reverse SSH Console Access

The following configuration example shows that reverse SSH has been configured for console access for terminal lines 1 through 3:

Terminal Server Configuration

```
line 1 3
  no exec
  login authentication default
  transport input ssh
```

Client Configuration

The following commands configured on the SSH client will form the reverse SSH session with lines 1, 2, and 3, respectively:

```
ssh -l lab:1 router.example.com
ssh -l lab:2 router.example.com
ssh -l lab:3 router.example.com
```

Example Reverse SSH Modem Access

The following configuration example shows that dial-out lines 1 through 200 have been grouped under rotary group 1 for modem access:

```
line 1 200
  no exec
  login authentication default
  rotary 1
  transport input ssh
  exit
```

The following command shows that reverse SSH will connect to the first free line in the rotary group:

```
ssh -l lab:rotary1 router.example.com
```

Example: Monitoring the SSH Configuration and Status

To verify that the Secure Shell (SSH) server is enabled and to display the version and configuration data for your SSH connection, use the **show ip ssh** command. The following example shows that SSH is enabled:

```
Device# show ip ssh

SSH Enabled - version 1.5
Authentication timeout: 120 secs; Authentication retries: 3
```

The following example shows that SSH is disabled:

```
Device# show ip ssh

%SSH has not been enabled
```

To verify the status of your SSH server connections, use the **show ssh** command. The following example shows the SSH server connections on the device when SSH is enabled:

```
Device# show ssh

Connection      Version      Encryption State Username
 0 1.5 3DES Session Started guest
```

The following example shows that SSH is disabled:

```
Device# show ssh

%No SSH server connections running.
```

Feature Information for Configuring Secure Shell

| Release | Feature Information |
|-----------------------------|--|
| Cisco IOS Release 15.0(2)EX | This feature was introduced. |
| Cisco IOS Release 15.2(5)E | <p>Note Starting with Cisco IOS Release 15.2(5)E, Secure Shell Version 1 (SSHv1) is deprecated.</p> |
| Cisco IOS 15.2(1)E | <p>The Reverse SSH Enhancements feature, which is supported for SSH Version 1 and 2, provides an alternative way to configure reverse Secure Shell (SSH) so that separate lines do not need to be configured for every terminal or auxiliary line on which SSH must be enabled. This feature also eliminates the rotary-group limitation.</p> <p>This feature was supported on CAT4500-X, CAT4500E-SUP6E, CAT4500E-SUP6L-E, CAT4500E-SUP7E, CAT4500E-SUP7L-E.</p> <p>The following command was introduced: ssh.</p> |

CHAPTER 54

Secure Shell Version 2 Support

The Secure Shell Version 2 Support feature allows you to configure Secure Shell (SSH) Version 2. (SSH Version 1 support was implemented in an earlier Cisco software release.) SSH runs on top of a reliable transport layer and provides strong authentication and encryption capabilities. The only reliable transport that is defined for SSH is TCP. SSH provides a means to securely access and securely execute commands on another computer over a network. The Secure Copy Protocol (SCP) feature that is provided with SSH allows for the secure transfer of files.

- [How to Configure Secure Shell Version 2 Support, on page 1014](#)
- [Configuration Examples for Secure Shell Version 2 Support, on page 1027](#)
- [Additional References for Secure Shell Version 2 Support, on page 1032](#)
- [Feature Information for Secure Shell Version 2 Support, on page 1033](#)

Information About Secure Shell Version 2 Support

Secure Shell Version 2

The Secure Shell Version 2 Support feature allows you to configure SSH Version 2.

The configuration for the SSH Version 2 server is similar to the configuration for SSH Version 1. The **ip ssh version** command defines the SSH version to be configured. If you do not configure this command, SSH by default runs in compatibility mode; that is, both SSH Version 1 and SSH Version 2 connections are honored.

Note SSH Version 1 is a protocol that has never been defined in a standard. If you do not want your device to fall back to the undefined protocol (Version 1), you should use the **ip ssh version** command and specify Version 2.

The **ip ssh rsa keypair-name** command enables an SSH connection using the Rivest, Shamir, and Adleman (RSA) keys that you have configured. Previously, SSH was linked to the first RSA keys that were generated (that is, SSH was enabled when the first RSA key pair was generated). This behavior still exists, but by using the **ip ssh rsa keypair-name** command, you can overcome this behavior. If you configure the **ip ssh rsa keypair-name** command with a key pair name, SSH is enabled if the key pair exists or SSH will be enabled if the key pair is generated later. If you use this command to enable SSH, you are not forced to configure a hostname and a domain name, which was required in SSH Version 1 of the Cisco software.

Note The login banner is supported in SSH Version 2, but it is not supported in Secure Shell Version 1.

Secure Shell Version 2 Enhancements

The SSH Version 2 Enhancements feature includes a number of additional capabilities such as supporting Virtual Routing and Forwarding (VRF)-Aware SSH, SSH debug enhancements, and Diffie-Hellman (DH) group exchange support.

Note The VRF-Aware SSH feature is supported depending on your release.

The Cisco SSH implementation has traditionally used 768-bit modulus, but with an increasing need for higher key sizes to accommodate DH Group 14 (2048 bits) and Group 16 (4096 bits) cryptographic applications, a message exchange between the client and the server to establish the favored DH group becomes necessary. The **ip ssh dh min size** command configures the modulus size on the SSH server. In addition to this, the **ssh** command was extended to add VRF awareness to the SSH client-side functionality through which the VRF instance name in the client is provided with the IP address to look up the correct routing table and establish a connection.

Debugging was enhanced by modifying SSH debug commands. The **debug ip ssh** command was extended to simplify the debugging process. Before the simplification of the debugging process, this command printed all debug messages related to SSH regardless of what was specifically required. The behavior still exists, but if you configure the **debug ip ssh** command with a keyword, messages are limited to information specified by the keyword.

Secure Shell Version 2 Enhancements for RSA Keys

Cisco SSH Version 2 supports keyboard-interactive and password-based authentication methods. The SSH Version 2 Enhancements for RSA Keys feature also supports RSA-based public key authentication for the client and the server.

User authentication—RSA-based user authentication uses a private/public key pair associated with each user for authentication. The user must generate a private/public key pair on the client and configure a public key on the Cisco SSH server to complete the authentication.

An SSH user trying to establish credentials provides an encrypted signature using the private key. The signature and the user's public key are sent to the SSH server for authentication. The SSH server computes a hash over the public key provided by the user. The hash is used to determine if the server has a matching entry. If a match is found, an RSA-based message verification is performed using the public key. Hence, the user is authenticated or denied access based on the encrypted signature.

Server authentication—While establishing an SSH session, the Cisco SSH client authenticates the SSH server by using the server host keys available during the key exchange phase. SSH server keys are used to identify the SSH server. These keys are created at the time of enabling SSH and must be configured on the client.

For server authentication, the Cisco SSH client must assign a host key for each server. When the client tries to establish an SSH session with a server, the client receives the signature of the server as part of the key exchange message. If the strict host key checking flag is enabled on the client, the client checks if it has the host key entry corresponding to the server. If a match is found, the client tries to validate the signature by

using the server host key. If the server is successfully authenticated, the session establishment continues; otherwise, it is terminated and displays a “Server Authentication Failed” message.

Note Storing public keys on a server uses memory; therefore, the number of public keys configurable on an SSH server is restricted to ten users, with a maximum of two public keys per user.

Note RSA-based user authentication is supported by the Cisco server, but Cisco clients cannot propose public key as an authentication method. If the Cisco server receives a request from an open SSH client for RSA-based authentication, the server accepts the authentication request.

Note For server authentication, configure the RSA public key of the server manually and configure the **ip ssh stricthostkeycheck** command on the Cisco SSH client.

SNMP Trap Generation

Depending on your release, Simple Network Management Protocol (SNMP) traps are generated automatically when an SSH session terminates if the traps have been enabled and SNMP debugging has been enabled. For information about enabling SNMP traps, see the “Configuring SNMP Support” module in the *SNMP Configuration Guide*.

Note When you configure the **snmp-server host** command, the IP address must be the address of the PC that has the SSH (telnet) client and that has IP connectivity to the SSH server.

You must also enable SNMP debugging using the **debug snmp packet** command to display the traps. The trap information includes information such as the number of bytes sent and the protocol that was used for the SSH session.

The following example shows that an SNMP trap is set. The trap notification is generated automatically when the SSH session terminates. In the example, a.b.c.d is the IP address of the SSH client.

```
snmp-server
snmp-server host a.b.c.d public tty
```

The following is sample output from the **debug snmp packet** command. The output provides SNMP trap information for an SSH session.

```
Switch# debug snmp packet

SNMP packet debugging is on
Device1# ssh -l lab 10.0.0.2
Password:

Switch# exit
```

```
[Connection to 10.0.0.2 closed by foreign host]

SSH Keyboard Interactive Authentication

The SSH Keyboard Interactive Authentication feature, also known as Generic Message Authentication for SSH, is a method that can be used to implement different types of authentication mechanisms. Basically, any currently supported authentication method that requires only user input can be performed with this feature. The feature is automatically enabled.

The following methods are supported:

- Password
- SecurID and hardware tokens printing a number or a string in response to a challenge sent by the server
- Pluggable Authentication Module (PAM)
- S/KEY (and other One-Time-Pads)

How to Configure Secure Shell Version 2 Support

Configuring a Device for SSH Version 2 Using a Hostname and Domain Name

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | hostname <i>name</i> Example: | Configures a hostname for your device. |

| | Command or Action | Purpose |
|---------------|---|--|
| | Device(config)# hostname cisco7200 | |
| Step 4 | ip domain-name <i>name</i> Example: cisco7200(config)# ip domain-name example.com | Configures a domain name for your device. |
| Step 5 | crypto key generate rsa Example: cisco7200(config)# crypto key generate rsa | Enables the SSH server for local and remote authentication. |
| Step 6 | ip ssh [time-out <i>seconds</i> authentication-retries <i>integer</i>] Example: cisco7200(config)# ip ssh time-out 120 | (Optional) Configures SSH control variables on your device. |
| Step 7 | ip ssh version [1 2] Example: cisco7200(config)# ip ssh version 1 | (Optional) Specifies the version of SSH to be run on your device. |
| Step 8 | exit Example: cisco7200(config)# exit | Exits global configuration mode and enters privileged EXEC mode. <ul style="list-style-type: none"> • Use no hostname command to return to the default host. |

Configuring a Device for SSH Version 2 Using RSA Key Pairs

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| Step 3 | ip ssh rsa keypair-name <i>keypair-name</i> Example: Device(config)# ip ssh rsa keypair-name sshkeys | Specifies the RSA key pair to be used for SSH. Note A Cisco device can have many RSA key pairs. |
| Step 4 | crypto key generate rsa usage-keys label <i>key-label modulus modulus-size</i> Example: Device(config)# crypto key generate rsa usage-keys label sshkeys modulus 768 | Enables the SSH server for local and remote authentication on the device. <ul style="list-style-type: none"> For SSH Version 2, the modulus size must be at least 768 bits. Note To delete the RSA key pair, use the crypto key zeroize rsa command. When you delete the RSA key pair, you automatically disable the SSH server. |
| Step 5 | ip ssh [time-out seconds authentication-retries integer] Example: Device(config)# ip ssh time-out 12 | Configures SSH control variables on your device. |
| Step 6 | ip ssh version 2 Example: Device(config)# ip ssh version 2 | Specifies the version of SSH to be run on the device. |
| Step 7 | exit Example: Device(config)# exit | Exits global configuration mode and enters privileged EXEC mode. |

Configuring the Cisco SSH Server to Perform RSA-Based User Authentication

Procedure

| | Command or Action | Purpose |
|---------------|--|---|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: | Enters global configuration mode. |

| | Command or Action | Purpose |
|---------------|---|---|
| | Device# configure terminal | |
| Step 3 | hostname <i>name</i> Example: Device(config)# hostname host1 | Specifies the hostname. |
| Step 4 | ip domain-name <i>name</i> Example: host1(config)# ip domain-name name1 | Defines a default domain name that the Cisco software uses to complete unqualified hostnames. |
| Step 5 | crypto key generate rsa Example: host1(config)# crypto key generate rsa | Generates RSA key pairs. |
| Step 6 | ip ssh pubkey-chain Example: host1(config)# ip ssh pubkey-chain | Configures SSH-RSA keys for user and server authentication on the SSH server and enters public-key configuration mode. <ul style="list-style-type: none"> The user authentication is successful if the RSA public key stored on the server is verified with the public or the private key pair stored on the client. |
| Step 7 | username <i>username</i> Example: host1(conf-ssh-pubkey)# username user1 | Configures the SSH username and enters public-key user configuration mode. |
| Step 8 | key-string Example: host1(conf-ssh-pubkey-user)# key-string | Specifies the RSA public key of the remote peer and enters public-key data configuration mode. <p>Note You can obtain the public key value from an open SSH client; that is, from the .ssh/id_rsa.pub file.</p> |
| Step 9 | key-hash <i>key-type key-name</i> Example: host1(conf-ssh-pubkey-data)# key-hash ssh-rsa key1 | (Optional) Specifies the SSH key type and version. <ul style="list-style-type: none"> The key type must be ssh-rsa for the configuration of private public key pairs. This step is optional only if the key-string command is configured. |

| | Command or Action | Purpose |
|----------------|--|---|
| | | <ul style="list-style-type: none"> You must configure either the key-string command or the key-hash command. <p>Note You can use a hashing software to compute the hash of the public key string, or you can also copy the hash value from another Cisco device. Entering the public key data using the key-string command is the preferred way to enter the public key data for the first time.</p> |
| Step 10 | end Example: <pre>host1(conf-ssh-pubkey-data)# end</pre> | Exits public-key data configuration mode and returns to privileged EXEC mode. <ul style="list-style-type: none"> Use no hostname command to return to the default host. |

Configuring the Cisco IOS SSH Client to Perform RSA-Based Server Authentication

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: <pre>Device> enable</pre> | Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted. |
| Step 2 | configure terminal Example: <pre>Device# configure terminal</pre> | Enters global configuration mode. |
| Step 3 | hostname <i>name</i> Example: <pre>Device(config)# hostname host1</pre> | Specifies the hostname. |
| Step 4 | ip domain-name <i>name</i> Example: <pre>host1(config)# ip domain-name name1</pre> | Defines a default domain name that the Cisco software uses to complete unqualified hostnames. |

| | Command or Action | Purpose |
|----------------|---|--|
| Step 5 | crypto key generate rsa Example: <pre>host1(config)# crypto key generate rsa</pre> | Generates RSA key pairs. |
| Step 6 | ip ssh pubkey-chain Example: <pre>host1(config)# ip ssh pubkey-chain</pre> | Configures SSH-RSA keys for user and server authentication on the SSH server and enters public-key configuration mode. |
| Step 7 | server server-name Example: <pre>host1(conf-ssh-pubkey)# server server1</pre> | Enables the SSH server for public-key authentication on the device and enters public-key server configuration mode. |
| Step 8 | key-string Example: <pre>host1(conf-ssh-pubkey-server)# key-string</pre> | Specifies the RSA public-key of the remote peer and enters public key data configuration mode. Note You can obtain the public key value from an open SSH client; that is, from the <code>.ssh/id_rsa.pub</code> file. |
| Step 9 | exit Example: <pre>host1(conf-ssh-pubkey-data)# exit</pre> | Exits public-key data configuration mode and enters public-key server configuration mode. |
| Step 10 | key-hash key-type key-name Example: <pre>host1(conf-ssh-pubkey-server)# key-hash ssh-rsa key1</pre> | (Optional) Specifies the SSH key type and version. <ul style="list-style-type: none"> • The key type must be <code>ssh-rsa</code> for the configuration of private/public key pairs. • This step is optional only if the key-string command is configured. • You must configure either the key-string command or the key-hash command. Note You can use a hashing software to compute the hash of the public key string, or you can copy the hash value from another Cisco device. Entering the public key data using the key-string command is the preferred way to enter the public key data for the first time. |

| | Command or Action | Purpose |
|----------------|---|---|
| Step 11 | end Example: host1(conf-ssh-pubkey-server)# end | Exits public-key server configuration mode and returns to privileged EXEC mode. |
| Step 12 | configure terminal Example: host1# configure terminal | Enters global configuration mode. |
| Step 13 | ip ssh stricthostkeycheck Example: host1(config)# ip ssh stricthostkeycheck | Ensures that server authentication takes place. <ul style="list-style-type: none"> • The connection is terminated in case of a failure. • Use no hostname command to return to the default host. |

Starting an Encrypted Session with a Remote Device

Note The device with which you want to connect must support a Secure Shell (SSH) server that has an encryption algorithm that is supported in Cisco software. Also, you need not enable your device. SSH can be run in disabled mode.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | ssh [-v {1 2} -c {aes128-ctr aes192-ctr aes256-ctr aes128-cbc 3des aes192-cbc aes256-cbc} -l user-id -l user-id:vrf-name number ip-address ip-address -l user-id:rotary number ip-address -m {hmac-md5-128 hmac-md5-96 hmac-sha1-160 hmac-sha1-96} -o numberofpasswordprompts n -p port-num] {ip-addr hostname} [command -vrf] Example: Device# ssh -v 2 -c aes256-ctr -m hmac-sha1-96 -l user2 10.76.82.24 | Starts an encrypted session with a remote networking device. |

Enabling Secure Copy Protocol on the SSH Server

Note The following task configures the server-side functionality for SCP. This task shows a typical configuration that allows the device to securely copy files from a remote workstation.

Procedure

| | Command or Action | Purpose |
|---------------|---|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. • Enter your password if prompted. |
| Step 2 | configure terminal Example: Device# configure terminal | Enters global configuration mode. |
| Step 3 | aaa new-model Example: Device(config)# aaa new-model | Enables the AAA access control model. |
| Step 4 | aaa authentication login default local Example: Device(config)# aaa authentication login default local | Sets AAA authentication at login to use the local username database for authentication. |
| Step 5 | aaa authorization exec defaultlocal Example: Device(config)# aaa authorization exec default local | Sets the parameters that restrict user access to a network, runs the authorization to determine if the user ID is allowed to run an EXEC shell, and specifies that the system must use the local database for authorization. |
| Step 6 | username name privilege privilege-level password password Example: Device(config)# username samplename privilege 15 password password1 | Establishes a username-based authentication system, and specifies the username, privilege level, and an unencrypted password. Note The minimum value for the <i>privilege-level</i> argument is 15. A privilege level of less than 15 results in the connection closing. |
| Step 7 | ip ssh time-out seconds Example: | Sets the time interval (in seconds) that the device waits for the SSH client to respond. |

| | Command or Action | Purpose |
|----------------|---|--|
| | Device(config)# ip ssh time-out 120 | |
| Step 8 | ip ssh authentication-retries <i>integer</i> Example: Device(config)# ip ssh authentication-retries 3 | Sets the number of authentication attempts after which the interface is reset. |
| Step 9 | ip scpserverenable Example: Device(config)# ip scp server enable | Enables the device to securely copy files from a remote workstation. |
| Step 10 | exit Example: Device(config)# exit | Exits global configuration mode and returns to privileged EXEC mode. |
| Step 11 | debug ip scp Example: Device# debug ip scp | (Optional) Provides diagnostic information about SCP authentication problems. |

Verifying the Status of the Secure Shell Connection

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show ssh Example: Device# show ssh | Displays the status of SSH server connections. |
| Step 3 | exit Example: Device# exit | Exits privileged EXEC mode and returns to user EXEC mode. |

Examples

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for Version 1 and Version 2 connections:

```
-----
Device# show ssh

Connection      Version Encryption      State      Username
0               1.5      3DES              Session started  lab
Connection Version Mode Encryption Hmac      State
Username
1               2.0      IN aes128-cbc hmac-md5   Session started  lab
1               2.0      OUT aes128-cbc hmac-md5   Session started  lab
-----
```

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for a Version 2 connection with no Version 1 connection:

```
-----
Device# show ssh

Connection Version Mode Encryption Hmac      State
Username
1               2.0      IN aes128-cbc hmac-md5   Session started  lab
1               2.0      OUT aes128-cbc hmac-md5   Session started  lab
%No SSHv1 server connections running.
-----
```

The following sample output from the **show ssh** command displays status of various SSH Version 1 and Version 2 connections for a Version 1 connection with no Version 2 connection:

```
-----
Device# show ssh

Connection      Version Encryption      State      Username
0               1.5      3DES              Session started  lab
%No SSHv2 server connections running.
-----
```

Verifying the Secure Shell Status

Procedure

| | Command or Action | Purpose |
|---------------|--|--|
| Step 1 | enable Example: Device> enable | Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | show ip ssh Example: | Displays the version and configuration data for SSH. |

| | Command or Action | Purpose |
|---------------|--|---|
| | Device# show ip ssh | |
| Step 3 | exit Example: Device# exit | Exits privileged EXEC mode and returns to user EXEC mode. |

Examples

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for Version 1 and Version 2 connections:

```
-----
Device# show ip ssh

SSH Enabled - version 1.99
Authentication timeout: 120 secs; Authentication retries: 3
-----
```

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for a Version 2 connection with no Version 1 connection:

```
-----
Device# show ip ssh

SSH Enabled - version 2.0
Authentication timeout: 120 secs; Authentication retries: 3
-----
```

The following sample output from the **show ip ssh** command displays the version of SSH that is enabled, the authentication timeout values, and the number of authentication retries for a Version 1 connection with no Version 2 connection:

```
-----
Device# show ip ssh

3d06h: %SYS-5-CONFIG_I: Configured from console by console
SSH Enabled - version 1.5
Authentication timeout: 120 secs; Authentication retries: 3
-----
```

Monitoring and Maintaining Secure Shell Version 2

Procedure

| | Command or Action | Purpose |
|---------------|-------------------|-------------------------------|
| Step 1 | enable | Enables privileged EXEC mode. |

| | Command or Action | Purpose |
|---------------|--|--|
| | Example: Device> enable | <ul style="list-style-type: none"> • Enter your password if prompted. |
| Step 2 | debug ip ssh Example: Device# debug ip ssh | Enables debugging of SSH. |
| Step 3 | debug snmp packet Example: Device# debug snmp packet | Enables debugging of every SNMP packet sent or received by the device. |

Example

The following sample output from the **debug ip ssh** command shows the connection is an SSH Version 2 connection:

```
Device# debug ip ssh

00:33:55: SSH1: starting SSH control process

```

Configuration Examples for Secure Shell Version 2 Support

Example: Configuring Secure Shell Version 2

```
Device# configure terminal
Device(config)# ip ssh version 2
```

Example: Starting an Encrypted Session with a Remote Device

```
Device# ssh -v 2 -c aes256-cbc -m hmac-sha1-160 -l shaship 10.76.82.24
```

Example: Configuring Server-Side SCP

The following example shows how to configure the server-side functionality for SCP. This example also configures AAA authentication and authorization on the device. This example uses a locally defined username and password.

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication login default local
Device(config)# aaa authorization exec default local
Device(config)# username samplename privilege 15 password password1
Device(config)# ip ssh time-out 120
Device(config)# ip ssh authentication-retries 3
Device(config)# ip scp server enable
```

Example: Setting an SNMP Trap

The following example shows that an SNMP trap is set. The trap notification is generated automatically when the SSH session terminates. In the example, a.b.c.d is the IP address of the SSH client.

```
snmp-server
snmp-server host a.b.c.d public tty
```

The following is sample output from the **debug snmp packet** command. The output provides SNMP trap information for an SSH session.

```
Device1# debug snmp packet

SNMP packet debugging is on
Device1# ssh -l lab 10.0.0.2
Password:

Device2# exit

[Connection to 10.0.0.2 closed by foreign host]
Device1#
